The chroman-like chalcone Xanthohumol C, originally found in hops, was demonstrated to be a potent neuroregenerative and neuroprotective natural product and therefore constitutes a strong candidate for further pharmaceutical research. The bottleneck for experiments is the low water solubility of this chalcone. Consequently, we developed and validated a suitable formulation enabling administration. Cyclodextrins were used as water-soluble and nontoxic complexing agents, and the complex of Xanthohumol C and 2-hydroxypropyl--cyclodextrin was characterized using HPLC, HPLC-MS, NMR, and differential scanning calorimetry. The water solubility of Xanthohumol C increases with increasing concentrations of cyclodextrin. Using 50 mM 2-hydroxypropyl--cyclodextrin, solubility was increased 650-fold. Furthermore, bioactivity of Xanthohumol C in free and complexed form did not significantly differ, suggesting the release of Xanthohumol C from 2-hydroxypropyl--cyclodextrin. Finally, a small-scaled experiment in a rat model showed that after i.p. administration of the complex, Xanthohumol C can be detected in serum, the brain, and the cerebrospinal fluid at 1 and 6 h post-administration. Mean (± SD) Xanthohumol C serum concentrations after 1, 6, and 12 h were determined as 463.5 (± 120.9), 61.9 (± 13.4), and 9.3 (± 0.8) ng/mL upon i.v., and 294.3 (± 22.4), 45.5 (± 0.7), and 13 (± 1.0) ng/mL after i.p. application, respectively. Accordingly, the formulation of Xanthohumol C/2-hydroxypropyl--cyclodextrin is suitable for further experiments and further pharmaceutical research aiming for the determination of its neuroregenerative potential in animal disease models.

The Prenylflavonoid ENDF1 Overrules Central Nervous System Growth Inhibitors and Facilitates Regeneration of DRG Neurons.
Restoration of neuronal connectivity after lesion of the central nervous system, such as spinal cord injury, is one of the biggest challenges in modern medicine. In particular, the accumulation of axon growth inhibitory factors at the site of injury constitutes a major obstacle to structural and thus functional repair. We previously investigated a group of prenylflavonoids derived from hops for their capacity to promote neuroregeneration. We identified a molecule called ENDF1 that was very potent to enhance regrowth and branching of neurites from dorsal root ganglion neurons in culture on growth promoting substrates. In the present study, we investigated ENDF1's capacity to promote regeneration of rat dorsal root ganglion neurons in the presence of three main components of the extracellular matrix acting as axon growth inhibitors: Semaphorin 3A, Ephrin A4 and mixed chondroitin sulfate proteoglycans. We report that ENDF1 application significantly promoted the percentages of sensory neurons able to regrow their neurites regardless of the presence of those inhibitors, and this to an extent similar to the one obtained after NGF treatment. Moreover, ENDF1 strongly enhanced the total neurite length and the complexity of neurites extending from neurons challenged with axon growth inhibitors. Although the impact of NGF and ENDF1 on the regeneration of neurons was similar, the activity of ENDF1 was not mediated by signaling through the TrkA receptor, indicating that each molecule act through different signaling pathways. In addition, ENDF1 did not decrease the phosphorylation of cofilin, a downstream effector of the regeneration-associated RhoA/ROCK signaling pathway. Hence, ENDF1 is a potent pro-neuroregenerative factors that could help in identifying new efficient targets for regenerative therapies of the nervous system.

Motor deficits following dorsal corticospinal tract transection in rats: voluntary versus skilled locomotion readouts.
Following spinal cord injury, severe deficits result from damages to ascending and descending tracts, such as the corticospinal tract (CST) which is highly relevant for the motor execution in humans. Unfortunately, no curative treatment is available and intensive efforts are deployed in animal models, such as the CST transection model, to identify interventions providing functional regeneration after spinal cord injury. The CatWalk XT is a system for multi-parameter gait analysis of voluntary locomotion. In this study, the performance of the CatWalk XT for monitoring of functional deficits associated with dorsal CST lesion in rats was compared to skilled locomotion tests. Motor deficits associated with dorsal CST transection could be reliably monitored over seven weeks based on skilled locomotion testing, i.e. Horizontal Ladder Walk and Grid Walk. The collateral lesion to the overlaying gracile and cuneate funiculi occurring during dorsal CST transection resulted in slight hyposensitivity and proprioceptive deficit, which likely contributed to the lowered performance in skilled locomotion. In

contrast, parameters of voluntary locomotion were not significantly affected by dorsal CST transection. Finally, an abnormal adduction reflex was detected immediately after lesion of the CST and could be conveniently used to confirm successful CST lesion in rats of experimental groups. The functional relevance of the dorsal CST in locomotion of rats is not as prominent as compared to in humans and thus challenging the motor execution is mandatory to reliably investigate CST function. A detailed analysis of voluntary walking using the CatWalk XT is not adequate to detect deficits following dorsal CST lesion in rats.

Pericytes Stimulate Oligodendrocyte Progenitor Cell Differentiation during CNS Remyelination.
The role of the neurovascular niche in CNS myelin regeneration is incompletely understood. Here, we show that, upon demyelination, CNS-resident pericytes (PCs) proliferate, and parenchymal non-vessel-associated PC-like cells (PLCs) rapidly develop. During remyelination, mature oligodendrocytes were found in close proximity to PCs. In Pdgfb mice, which have reduced PC numbers, oligodendrocyte progenitor cell (OPC) differentiation was delayed, although remyelination proceeded to completion. PC-conditioned medium accelerated and enhanced OPC differentiation in vitro and increased the rate of remyelination in an ex vivo cerebellar slice model of demyelination. We identified Lama2 as a PC-derived factor that promotes OPC differentiation. Thus, the functional role of PCs is not restricted to vascular homeostasis but includes the modulation of adult CNS progenitor cells involved in regeneration.

Expression of Lymphatic Markers in the Adult Rat Spinal Cord.
Under physiological conditions, lymphatic vessels are thought to be absent from the central nervous system (CNS), although they are widely distributed within the rest of the body. Recent work in the eye, i.e., another organ regarded as alymphatic, revealed numerous cells expressing lymphatic markers. As the latter can be involved in the response to pathological conditions, we addressed the presence of cells expressing lymphatic markers within the spinal cord by immunohistochemistry. Spinal cord of young adult Fisher rats was scrutinized for the co-expression of the lymphatic markers PROX1 and LYVE-1 with the cell type markers Iba1, CD68, PGP9.5, OLIG2. Rat skin served as positive control for the lymphatic markers. PROX1-immunoreactivity was detected in many nuclei throughout the spinal cord white and gray matter. These nuclei showed no association with LYVE-1. Expression of LYVE-1 could only be detected in cells at the spinal cord surface and in cells closely associated with blood vessels. These cells were found to co-express Iba1, a macrophage and microglia marker. Further, double labeling experiments using CD68, another marker found in microglia and macrophages, also displayed co-localization in the Iba1+ cells located at the spinal cord surface and those apposed to blood vessels. On the other hand, PROX1-expressing cells found in the parenchyma were lacking Iba1 or PGP9.5, but a significant fraction of those cells showed co-expression of the oligodendrocyte lineage marker OLIG2. Intriguingly, following spinal cord injury, LYVE-1-expressing cells assembled and reorganized into putative pre-vessel structures. As expected, the rat skin used as positive controls revealed classical lymphatic vessels, displaying PROX1+ nuclei surrounded by LYVE-1-immunoreactivity. Classical lymphatics were not detected in adult rat spinal cord. Nevertheless, numerous cells expressing either LYVE-1 or PROX1 were identified. Based on their localization and overlapping expression with Iba1, the LYVE-1+ cell population likely represents a macrophage subpopulation, while a significant fraction of PROX1+ cells belong to the oligodendrocytic lineage based on their distribution and the expression of OLIG2. The response of these LYVE-1+ and PROX1+ cell subpopulations to pathological conditions, especially in spinal cord inflammatory conditions, needs to be further elucidated.

RESTORATION OF ER PROTEOSTASIS AUGMENTS THE AUTOPHAGIC FLUX AND MITIGATES REMOTE DEGENERATION AFTER SPINAL CORD INJURY

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

The pathogenic mechanisms underlying the progression of remote degeneration after axonal damage are not fully understood. In this study, we aimed to assess the relationship between endoplasmic reticulum (ER) stress and autophagy in remote degeneration after axonal damage due to spinal cord injury (SCI). Starting from 1 day after SCI, significant increases in markers of ER stress (activating transcription factor 4 (ATF4), glucose-regulated protein 78 (GRP78/BiP) and C/EBP homologous protein (CHOP) were found in remote axotomized neurons compared with sham-lesioned animals. In SCI animals' ER stress-mediated signaling was parallel to the blockade of the autophagic flux assessed by increase in protein levels of SQSTM1/p62, microtubule-associated protein 2 light chain 3 (LC3-II), and decrease of the lysosomal marker LAMP1, suggesting an accumulation of dysfunctional autophagosomes in axotomized neurons. Pharmacological modulation of UPR by Guanabenz significantly modulated ER stress responses and elicits autophagy machinery homeostasis in remote axotomized neurons, consistent with the detrimental effects of persistent ER stress on the autophagic flux and, consequently, on remote degeneration. These effects correlate with an increased activation of TFEB —the master regulator of autophagy/lysosomes biogenesis— and the halt of neuronal cell death as well as with an improved functional recovery. Thus, our results suggest that therapies aimed to restore ER proteostasis might attenuate the progression of remote degeneration after spinal cord injury

Aims: High-throughput screenings have profiled spinal cord or sciatic nerve tissue responses after lesion, to pave the discovery of new regeneration-associated genes. However, it is difficult to depict the neuronal-specific transcriptional profile from the entire tissue response. In the first hours after injury, alterations in the early transcriptome of the affected neuronal populations may trigger relevant regenerative processes. **Methods:** Rat models of Peripheral Nerve Injury (PNI) and Spinal Cord Injury (SCI), were used. Neuronal bodies of Dorsal Root Ganglia (DRG), Lower Motor Neurons (MN) and Pyramidal Neurons from Cortex Layer V (Py) were collected 24 hours after lesion, using Laser Capture Microdissection. Upon mRNA sequencing, differential expression and gene ontology analyses were performed to identify highly relevant transcripts. The 4 lists of differentially expressed genes were compared to unveil the differences and similarities between cell types and injury locations. **Results:** Principal Component Analysis (PCA) of the sequencing data shows that dimension 1 separates samples by cell-type. Py cells exhibited few transcriptional alterations at an early time-point after injury. Further, injury-induced mRNA regulation was more significant in DRG neurons after PNI (regenerative) than after SCI (non-regenerative), and also more robust than the MNs, after PNI. **Conclusions:** We observed transcriptomic differences in the same injured cell-type, depending on if it was affected its peripheral or central axonal branch. This is highly relevant to understand what is different and similar in the regeneration processes between peripheral and central nervous system.

CD81 Promotes a Migratory Phenotype in Neuronal-Like Cells.

FENS Forum 2022
9-13 July 2022 | Paris, France

Tetraspanins, such as CD81, can form lateral associations with each other and with other transmembrane proteins. These interactions may underlie CD81 functions in multiple cellular processes, such as adhesion, morphology, migration, and differentiation. Since CD81's role in neuronal cells' migration has not been established, we here evaluated effects of CD81 on the migratory phenotype of SH-SY5Y neuroblastoma cells. CD81 was found enriched at SH-SY5Y cell's membrane, co-localizing with its interactor filamentous-actin (F-actin) in migratory relevant structures of the leading edge (filopodia, stress fibers, and adhesion sites). CD81 overexpression increased the number of cells with a migratory phenotype, in a potentially phosphatidylinositol 3 kinase (PI3K)-Ak strain transforming (AKT) mediated manner. Indeed, CD81 also co-localized with AKT, a CD81-interactor and actin remodeling agent, at the inner leaflet of the plasma membrane. Pharmacologic inhibition of PI3K, the canonical AKT activator, led both to a decrease in the acquisition of a migratory phenotype and to a redistribution of intracellular CD81 and F-actin into cytoplasmic agglomerates. These findings suggest that in neuronal-like cells CD81 bridges active AKT and actin, promoting the actin remodeling that leads to a motile cell morphology. Further studies on this CD81-mediated mechanism will improve our knowledge on important physiological and pathological processes such as cell migration and differentiation, and tumor metastasis.

THE ROLE OF MESENCHYMAL STEM CELLS (MSCS) IN SPINE CORD INJURIES: A SYSTEMATIC REVIEW OF THE LITERATURE

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Antonia Vogt[1], Senthooran Kathasamy[2]
[1]University of Cambridge, Department Of Surgery, Cambridge, United Kingdom, [2]University Hospital of Leicester, Department Of Surgery, Leicester, United Kingdom

Objectives Spinal cord injury (SCI) is a devastating condition that leaves patients with permanent neurological deficit as a result of biochemical impairment in neurogenic repair in the central nervous system (CNS). Mesenchymal stem cells (MSCs) have been utilised in regenerative medicine and are shown to differentiate into several lineages including neurons and has implications for potential strategies to combat challenges of CNS repair. **Design**: A systematic review was performed to assess MSCs at a basic science level and to identify further challenges with MSC use in SCI. A PRISM methodology using PubMed, Ovid, EMBASE and MEDLINE to assess available studies looking into the role of MSCs in human neuronal tissue was utilised. Two independent reviewers identified relevant studies. A third senior reviewer was utilised if any discrepancies between reviewers were identified. **Subjects and Methods** We reported the ability of neuronal cell differentiation, capacity to form scaffolding to bridge damaged tissue and capacity for functional return from studies up to November 2021. Exclusion criteria included studies reporting animal tissue, and non-English studies. **Results** This review has identified the role of MSCs in neuronal repair, scaffolding for creation of new neural networks along with paracrine and autocrine effects on neighbouring glial cells. These have proved exciting areas of research and are providing understanding of the role of these MSCs in regeneration. **Conclusion**: By reporting these studies, we highlight and guide readers from our study about future potential questions, challenges and current concepts to help steer future research within this vastly expanding field.

THE PORCINE CORTICAL MOTOR SYSTEM: ANATOMY AND RESPONSE TO SPINAL CORD INJURY (SCI).

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Patricia Del Cerro De Pablo[1], Jorge Collazos-Castro[1], Ángel Rodríguez-De-Lope[2]
[1]Hospital Nacional de Parapléjicos, Neural Repair And Biomaterials Laboratory, Toledo, Spain, [2]Hospital Virgen de la Salud, Neurosurgery, Toledo, Spain

Despite the increasing use of pig as experimental model for neurological diseases, the anatomy of the porcine cortical motor system and its response to injury is mostly unknown. We studied the origin and termination of axons projecting from the cerebral cortex to the brainstem and spinal cord in domestic pigs, in the uninjured state and after a cervical spinal cord hemisection. Two cortical regions, namely the primary motor cortex (M1) and the premotor cortex (PM), sent numerous spinal projections. Anterograde axonal labelling with Alexa-conjugated dextrans showed a grossly similar distribution of corticospinal axons from both cortical areas in the spinal white matter funiculi and gray matter laminae, with some similarities to primates and humans. However, the corticospinal tract (CST) was limited to the cervical and mid-thoracic spinal cord, without relevant innervation of spinal motoneurons. At the brainstem, most corticorubral projections arose from M1, whereas other regions received axonal contacts from both M1 and PM. This general pattern of connectivity was unmodified after the cervical spinal cord hemisection. The lesion eliminated most corticospinal innervation to the caudal, ipsilateral spinal cord, but preserved the possibility of reactive growth from axons descending through the uninjured side and decussating through the spinal commissures. Our data support the usefulness of pigs as a translational model for SCI and other diseases involving the cortical motor system. However, the absence of corticomotoneuronal innervation, as well as the limited extension of CST axons along the spinal cord, must be considered for experiment planning and interpretation of the results.

The Cortical Motor System in the Domestic Pig: Origin and Termination of the Corticospinal Tract and Cortico-Brainstem Projections.
The anatomy of the cortical motor system and its relationship to motor repertoire in artiodactyls is for the most part unknown. We studied the origin and termination of the corticospinal tract (CST) and cortico-brainstem projections in domestic pigs. Pyramidal neurons were retrogradely labeled by injecting aminostilbamidine in the spinal segment C1. After identifying the dual origin of the porcine CST in the primary motor cortex (M1) and premotor cortex (PM), the axons descending from those regions to the spinal cord and brainstem were anterogradely labeled by unilateral injections of dextran alexa-594 in M1 and dextran alexa-488 in PM. Numerous corticospinal projections from M1 and PM were detected up to T6 spinal segment and showed a similar pattern of decussation and distribution in the white matter funiculi and the gray matter laminae. They terminated mostly on dendrites of the lateral intermediate laminae and the internal basilar nucleus, and some innervated the ventromedial laminae, but were essentially absent in lateral laminae IX. Corticofugal axons terminated predominantly ipsilaterally in the midbrain and bilaterally in the medulla oblongata. Most corticorubral projections arose from M1, whereas the mesencephalic reticular formation, superior colliculus, lateral reticular nucleus, gigantocellular reticular nucleus, and raphe received abundant axonal contacts from both M1 and PM. Our data suggest that the porcine cortical motor system has some common features with that of primates and humans and may control posture and movement through parallel motor descending pathways. However, less cortical regions project to the spinal cord in pigs, and the CST neither seems to reach the lumbar enlargement nor to have a significant direct innervation of cervical, foreleg motoneurons.

Neuropathological and Motor Impairments after Incomplete Cervical Spinal Cord Injury in Pigs.
Humans, primates, and rodents with cervical spinal cord injury (SCI) show permanent sensorimotor dysfunction of the upper/forelimb as consequence of axonal damage and local neuronal death. This work aimed at characterizing a model of cervical SCI in domestic pigs in which hemisection with excision of 1 cm of spinal cord was performed to reproduce the loss of neural tissue observed in human neuropathology. Posture and motor control were assessed over 3 months by scales and kinematics of treadmill locomotion. Histological measurements included lesion length, atrophy of the adjacent spinal cord

segments, and neuronal death. In some animals, the retrograde neural tracer aminostilbamidine was injected in segments caudal to the lesion to visualize propriospinal projection neurons. Neuronal loss extended for 4-6 mm from the lesion borders and was more severe in the ipsilateral, caudal spinal cord stump. Axonal Wallerian degeneration was observed caudally and rostrally, associated with marked atrophy of the white matter in the spinal cord segments adjacent to the lesion. The pigs showed chronic monoplegia or severe monoparesis of the foreleg ipsilateral to the lesion, whereas the trunk and the other legs had postural and motor impairments that substantially improved during the first month post-lesion. Adaptations of the walking cycle such as those reported for rats and humans ameliorated the negative impact of focal neurological deficits on locomotor performance. These results provide a baseline of behavior and histology in a porcine model of cervical spinal cord hemisection that can be used for translational research in SCI therapeutics.

SPONTANEOUS REGENERATION OF CHOLECYSTOKINERGIC DESCENDING AXONS AFTER A COMPLETE SPINAL CORD INJURY IN LAMPREYS

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Laura González-Llera[1], Gabriel Santos-Durán[1], Daniel Sobrido-Cameán[1,2], Antón Barreiro-Iglesias[1]
[1]Universidade de Santiago de Compostela, Department Of Functional Biology, Cibus, Faculty Of Biology, Santiago de Compostela, Spain, [2]University of Cambridge, Department Of Zoology, Cambridge, United Kingdom

In contrast to humans, lampreys spontaneously recover locomotion after a complete spinal cord injury (SCI) and the process of recovery involves the regeneration of descending axons. Axon regeneration in lampreys has been mainly studied in giant descending neurons of the brainstem. However, the regeneration of neurochemically distinct descending neuronal populations has been much less studied. Cholecystokinin (CCK) is a regulatory neuropeptide found in the brain and spinal cord that modulates several processes such as satiety, anxiety, nociception or locomotion. This neuropeptide shows high evolutionary conservation and is present in all representative species of vertebrates from agnathans to mammals. Recent work in lampreys has shown that all CCK immunoreactive (CCK-ir) spinal cord axons originate in a neuronal population located in the caudal rhombencephalon (Sobrido-Cameán et al., 2020). Here, we used immunohistochemical methods to quantify the regenerative capacity of descending CCK-ir axons of larval sea lampreys after a complete SCI at the level of the fifth gill. The degree of regeneration of CCK-ir axons was analysed at the level of the sixth gill at 10 weeks post-lesion (wpl), when behavioural analyses showed that injured animals had recovered normal appearing locomotion. The quantification of CCK-ir profiles revealed that, at 10 wpl, larvae recovered 80% of the CCK-ir innervation present at the level of sixth gill in control un-injured animals. These results indicate that descending CCKergic neurons can be used as a model to study spontaneous axonal regeneration by means of immunofluorescence methods in a neurochemically distinct neuronal population after SCI in lampreys.

THE REGENERATIVE ABILITY OF CORTICOSPINAL NEURONS IS LOST IN A SEGMENTALLY-DISTINCT MANNER

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Carolin Ruven, Vibhu Sahni
Weill Cornell Medicine, Burke Neurological Institute, White Plains, United States of America

The neonatal central nervous system (CNS) is known to support long-distance axon regeneration better than the adult CNS after injury. However, the precise time course of this regenerative decline through development has not been investigated to date. We investigated the long-distance regenerative ability of the corticospinal tract (CST) during development. For this, we developed a novel microsurgical approach to axotomize the developing CST, while leaving the spinal environment largely unperturbed. Using this approach, we have identified rather surprisingly that long-distance CST regenerative ability is lost at distinct times at distinct spinal levels. For example, at postnatal day 4 (P4) while the CST is still growing in the lumbar cord, the regenerative ability is robustly maintained at thoracic T11, partially maintained at thoracic T2, but completely abolished at cervical C2. This differential loss of regenerative ability is not due to differences in astrogliosis at these distinct spinal levels. Using intersectional mouse genetics, we further identify that these segmental differences are not due to heterogeneity of corticospinal neurons (CSN). Finally, we establish that long-distance regrowth does not require axons to traverse in their “normal” white matter tract; CSN axons can exhibit long-distance growth even in the dorsolateral funiculus, where only a minority of the CST normally traverses. These results indicate that the loss of long-distance regenerative ability is differentially governed, at least in time, across the length of the CST. Further, this work also suggests that distinct approaches will be required to effect CST regeneration after adult injury at distinct spinal levels.

Enhanced regeneration and functional recovery after spinal root avulsion by manipulation of the proteoglycan receptor PTPσ.
Following root avulsion, spinal nerves are physically disconnected from the spinal cord. Severe motoneuron death and inefficient axon regeneration often result in devastating motor dysfunction. Newly formed axons need to extend through inhibitory scar tissue at the CNS-PNS transitional zone before entering into a pro-regenerative peripheral nerve trajectory. CSPGs are dominant suppressors in scar tissue and exert inhibition via neuronal receptors including PTPσ. Previously, a small peptide memetic of the PTPσ wedge region named ISP (Intracellular Sigma Peptide) was generated, and its capabilities to target PTPσ and relieve CSPG inhibition were validated. Here, we demonstrate that after ventral root avulsion and immediate re-implantation, modulation of PTPσ by systemic delivery of ISP remarkably enhanced regeneration. ISP treatment reduced motoneuron death, increased the number of axons regenerating across scar tissue, rebuilt healthy neuromuscular junctions and enhanced motor functional recovery. Our study shows that modulation of PTPσ is a potential therapeutic strategy for root avulsion.

Combination Treatment With Exogenous GDNF and Fetal Spinal Cord Cells Results in Better Motoneuron Survival and Functional Recovery After Avulsion Injury With Delayed Root Reimplantation.
When spinal roots are torn off from the spinal cord, both the peripheral and central nervous system get damaged. As the motoneurons lose their axons, they start to die rapidly, whereas target muscles atrophy due to the denervation. In this kind of complicated injury, different processes need to be targeted in the search for the best treatment strategy. In this study, we tested glial cell-derived neurotrophic factor (GDNF) treatment and fetal lumbar cell transplantation for their effectiveness to prevent motoneuron death and muscle atrophy after the spinal root avulsion and delayed reimplantation. Application of exogenous GDNF to injured spinal cord greatly prevented the motoneuron death and enhanced the regeneration and axonal sprouting, whereas no effect was seen on the functional recovery. In contrast, cell transplantation into the distal nerve did not affect the host motoneurons but instead mitigated the muscle atrophy. The combination of GDNF and cell graft reunited the positive effects resulting in better functional recovery and could therefore be considered as a promising strategy for nerve and spinal cord injuries that involve the avulsion of spinal roots.

Transplantation of Embryonic Spinal Cord Derived Cells Helps to Prevent Muscle Atrophy after Peripheral Nerve Injury.
Injuries to peripheral nerves are frequent in serious traumas and spinal cord injuries. In addition to surgical approaches, other interventions, such as cell transplantation, should be considered to keep the muscles in good condition until the axons regenerate. In this study, E14.5 rat embryonic spinal cord fetal cells and cultured neural progenitor cells from different spinal cord segments were injected into transected musculocutaneous nerve of 200-300 g female Sprague Dawley (SD) rats, and atrophy in biceps brachii was assessed. Both kinds of cells were able to survive, extend their axons towards the muscle and form neuromuscular junctions that were functional in electromyographic studies. As a result, muscle endplates were preserved and atrophy was reduced. Furthermore, we observed that the fetal cells had a better effect in reducing the muscle atrophy compared to the pure neural progenitor cells, whereas lumbar cells were more beneficial compared to thoracic and cervical cells. In addition, fetal lumbar cells were used to supplement six weeks delayed surgical repair after the nerve transection. Cell transplantation helped to preserve the muscle endplates, which in turn lead to earlier functional recovery seen in behavioral test and electromyography. In conclusion, we were able to show that embryonic spinal cord derived cells, especially the lumbar fetal cells, are beneficial in the treatment of peripheral nerve injuries due to their ability to prevent the muscle atrophy.

Neural tissue has high metabolic requirements. Following spinal cord injury (SCI), the damaged tissue suffers from a severe metabolic impairment, which aggravates axonal degeneration and neuronal loss. Impaired cellular energetic, tricarboxylic acid (TCA) cycle and oxidative phosphorylation metabolism in neuronal cells has been demonstrated to be a major cause of neural tissue death and regeneration failure following SCI. Therefore, rewiring the spinal cord cell metabolism may be an innovative therapeutic strategy for the treatment of SCI. In this study, we evaluated the therapeutic effect of the recovery of oxidative metabolism in a mouse model of severe contusive SCI following oral administration of TCA cycle intermediates, co-factors, essential amino acids, and branched-chain amino acids (α5). The α5 treatment started 3 days post-injury and last for 30 days. At the end of the experiments, animals were sacrificed, and we analyzed the injured spinal cord sections. Specifically, at 14 days post injury, we evaluated whether α5 treatment produced a metabolic modulation of the injured spinal cord through targeted metabolomic analysis. Metabolomic, immunofluorescence and western blot data, revealed that metabolic precursors i) induced TCA and OXPHOS metabolism in spinal cord tissue, ii) increased mTORC1 related proteins (p70S6K, rpS6) in neurons, iii) increased mitochondrial mass and respiration and iv) reduced oxidative stress at the site of the lesion. Lastly, treated animals showed significant, although partial, improvement of the motor functions. Overall, our data demonstrate that rewiring the cellular metabolism may represent an effective strategy to treat SCI.

SCINFLAM: SERUM CHANGES IN INFLAMMATORY ANALYTES IN SPINAL CORD INJURY PATIENTS

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Bárbara Mamede De Sousa[1], Dário Trindade[1], João Correia[1], Inês Piques[2], Maria Ribeiro Da Cunha[1,2], Sandra Vieira[1]

Aims. The inflammatory reaction following a traumatic spinal cord injury (SCI) may highly impact the patients' neurological outcome. We aimed to correlate changes in inflammatory analytes from pre- to post-rehabilitation in serum of sub-acute SCI patients, with their neurological impairment and recovery rates. Methods. Different inflammatory cytokines/chemokines were measured in serum collected at pre- and post-rehabilitation from 21 SCI patients, using the LEGENDplex™ Human Inflammation Panel-1. SCI patients were classified using gold-standard scales for impairment (AIS grade), motor and functional independence scores. Absolute analyte levels and their pre- and post-rehabilitation alterations were associated with patients' better or worse prognosis at discharge from the rehabilitation center, i.e. AIS grade, functional independence and motor scores above or below 70-75%, respectively. Results. With rehabilitation, IL-8 and IL-10 tendentially reduce within the worst prognosis group, and IL-8, IL-10 and IL-17A remain steady or increase within the best prognosis group. Accordingly, variations in IL-8, IL-10 and IL-17A significantly correlated with motor scores' variation. TNF-alpha and IL-18 remain unaltered within the worst prognosis group, while increasing within the best prognosis one, and a negative correlation occurs between both analytes' variations and the recovery rates. MCP-1 presented major increases in patients with better functional score, and pre-rehabilitation MCP-1 levels negatively correlate with functional recovery rate. Conclusions. Overall, variations from pre- to post-rehabilitation for each analyte are similar regardless of the patients' division criteria (by AIS grade, motor score or functional independence post-rehabilitation), although significant correlations were only observed for some of these division criteria.

THE RSK PROTEIN PROMOTE CENTRAL NERVOUS SYSTEM REGENERATION AND FUNCTIONAL RECOVERY VIA TRANSLATIONAL CONTROL.

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Charlotte Decourt[1], Julia Schaeffer[1], Béatrice Blot[1], Antoine Paccard[1], Blandine Excoffier[1], Mario Pende[2], Homaira Nawabi[1], Stephane Belin[1]

Central Nervous System (CNS) is not able to regenerate after injury. Any insult in the CNS will lead to circuit disruption and definitive loss of cognitive and motor functions. Major effort has been done to identify molecules that can promote CNS regeneration. However, building de-novo functional circuit after a lesion remains a great challenge, mostly due to the insufficient number of axons reaching their targets. Thus, there is an urge to uncover molecular pathways critical for promoting extensive axon regeneration and functional recovery. Using the unique model of Dorsal Root Ganglia neurons, we found that the p90 S6 ribosomal kinase (RSK) is key for axon regeneration. Indeed, our work demonstrated that RSK expression is required for both sciatic nerve and spinal cord regeneration and its expression controls functional recovery in mice after injury. We characterized its downstream effectors and our results demonstrate that RSK regulates the level of ribosomal S6 phosphorylation and this modification is determinant to promote axon regeneration. Finally, our work will shed the light on specific mRNA translation control by the RSK-RPS6 axis required for axonal regeneration. Altogether, our study characterizes a new RSK-RPS6 axis that controls both peripheral and central nervous system regeneration via the modulation of specific protein translation. Our results will be determinant in the process of understanding axon regeneration in order to develop innovative therapeutic strategies.

Neuronal circuit formation after adult central nervous system (CNS) injury represents one of the biggest challenges in Neuroscience. Indeed, mature CNS neurons fail to regenerate spontaneously, leading to irreversible loss of sensory-motor and cognitive functions in patients affected by neurodegenerative or traumatic injuries. In the past ten years, major advances in the modulation of neuronal intrinsic properties have unlocked adult axon regeneration. However, regenerative axons fail to make functional circuits, due to lack of sensitivity of some neurons to pathways identified so far and to disorganized axon growth. In this study, we highlight that regulation of protein synthesis from specific mRNAs is a key stone to achieve CNS regeneration. Notably, we show that this process is coordinated by the association of unexpected factors to the ribosome, the functional unit of translation, leading to selective translation of a specific pool of mRNAs that control axon regeneration. Modulation of expression of these translationally-regulated genes favors axon regeneration. Thus, selective protein synthesis stands out as a novel regulatory mechanism in axon regeneration, allowing to coordinate expression of pro-regenerative proteins at the translational level to obtain a functional circuit. Our results will have major implications in the development of therapeutic strategies to trigger CNS regeneration after traumatic injury and in neurodegenerative diseases.

THE TIMING OF ANGIOTENSIN II RECEPTOR REGULATION AFTER SEVERE SPINAL CORD INJURY

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Jaroslav Pavel, Jana Fedorova, Erika Kellerova
Institute of Neurobiology of Biomedical Research Center SAS, Department Of Neurodegeneration, Plasticity And Repair, Kosice, Slovak Republic

Many scientific results in recent decades clearly demonstrated the beneficial effects of the AT1 receptor blockade and the AT2 receptor stimulation. The appropriate timing of receptor blockade or stimulation after a specific lesion is one of the crucial factors affecting the efficiency of the therapeutic approach. Therefore, circulating Angiotensin II in plasma, blood pressure, and the expression of both AT1 and AT2 receptors in spinal cord parenchyma were measured within 4 weeks after compression-induced spinal cord injury (40g lasting 15 minutes at Th9 level). Severe spinal cord compression caused a progressive reduction of the AT1 receptors in lesion epicenter and rostrocaudal extent during the first 2 weeks, which correlates with degradation of highly vascularized grey matter. Then a gradual increase to the control values was detected. Although a significant increase in circulating Angiotensin II was observed only during the first 3 days after trauma, an elevated blood pressure persisted until the 10th day. The temporary upregulated expression of the AT2 receptors was detected from two to three post-injury weeks. Surprisingly, their expression a week later was at the level of control values. Based on these results, we can assume that (a) AT1 receptor blockers can be used immediately after severe trauma and administered at least 10 days, and (b) AT2 receptor agonist after 14 days. *Supported by APVV Grant No. APVV-18-0163.*

Spinal cord injuries lead to functional alteration with important consequences such as motor and sensory disorders. The repair strategies developed to date remain ineffective. The adipose tissue-derived stromal vascular fraction (SVF) is composed of a cocktail of cells with trophic, pro-angiogenic and immunomodulatory effects. Numerous therapeutic benefits were shown for tissue reconstitution, peripheral neuropathy and for the improvement of neurodegenerative diseases. The aim of this study is to evaluate the neuroprotective, neuritogenic and neurotrophic effects of SVF on acute spinal cord contusion in adult rats. A spinal contusion, using a force-controlled impactor, was performed at thoracic level (T_{10}) in adult male Sprague Dawley rats inducing sensory-motor deficits of hindlimbs. A sub-dural injection of NaCl (vehicle) or SVF was performed within 4 to 6 hours after surgery. Sensory-motor recovery of the animals was assessed for 90 days using behavioral tests (BBB test, ladder rung climbing test). At week 12, electrophysiological measurements were recorded. In addition, the spinal cords were collected, and histological and biochemical analyzes were performed at 7, 14, 21, and 90 days post-injury. The preliminary results show an axonal regeneration, a decrease of the inflammation and an increase of the neovascularization around the lesion. Moreover, electrophysiological measurements show i) an adaptation of the ventilation during rhythmic muscle contractions, ii) of the H reflex activity, and iii) an enhancement of the sensory-motor recovery in the SVF group. To conclude, the autograft of SVF could represent an interesting therapeutic strategy to repair spinal cord after contusion and enhance the behavioral recovery.

Edema formation is one of the very first events to occur after spinal cord injury (SCI) leading to an increase of the intrathecal pressure and consequently to serious spinal tissue and functional impairments. Current edema treatments are still symptomatic and/or non-specific. Since edema is mainly described as vasogenic and cytotoxic, it becomes crucial to understand the interplay between these two subtypes. Acting on key targets to inhibit edema formation may reduce secondary damage and related functional impairments. In this study we characterize the edema kinetic after T10 spinal contusion using the Infinite Horizon impactor. We use trifluoperazine (TFP) to block the expression and the functional subcellular localization of aquaporin-4 supposed to be implicated in the cytotoxic edema formation. We also use sodium cromolyn (SC) to deactivate Mast cells degranulation supposed to be implicated in the vasogenic edema formation. The sensorimotor performances were assessed weekly by using the BBB score and the inclined ladder test, then the spinal reflexivity (H-reflex) was evaluated 10 weeks after SCI. The kinetic of the cytokine expression during the edema formation were determined using biochemical assays and the estimation of the tissue loss and the glial scar volumes were estimated using a stereological approach. Our results show a significant reduction of edema after both TFP and SC treatments compared to control. This reduction is correlated with limited sensorimotor impairments. Such results suggest a therapeutic potential of these two compounds and highlight the importance of complementary strategies in edema therapy after SCI.

RESIDENT NEURAL STEM CELLS GUARANTEE THE REGENERATION PROMOTED BY BULBAR OLFACTORY ENSHEATHING CELL TRANSPLANTATION AFTER SPINAL CORD INJURY

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Xiaofei Li[1], Quentin Delarue[2], Axel Honoré[2], Nicolas Guérout[2]
[1]Karolinska Institutet, Department Of Neurobiology, Stockholm, Sweden, [2]Université de Rouen, Ur3830, Ufr Santé De Rouen, Rouen, France

Both cell transplantation and modulating endogenous neural stem cells have raised great hope for regenerative medicine. Recently, clinical data showed that autologous transplantation of bulbar olfactory ensheathing cells (bOECs) enhanced substantial functional recovery in human. However, the cellular mechanisms behind the effects of transplanted bOECs on the injured spinal cord are still poorly understood, which leads to the difficulty in clinical repetitions. Ependymal cells, the endogenous spinal cord stem cells, are shown essential for tissue restriction and neuronal survival after spinal cord injury (SCI). By using FoxJ1-CreER^{T2}-YFP mice to fate-map ependymal cells, we found that bOECs transplantation enhances the stem cell potential of ependymal cells after SCI both *in vivo* and *in vitro*, and it modulates microenvironment for better axonal regrowth and neuronal survival. Surprisingly, by using FoxJ1-Rasless mice to specifically block ependymal cell proliferation, we no longer observed the regenerative effects promoted by bOECs transplantation. Altogether, our data provide a model that the bOECs transplantation therapy is dependent on the activated ependymal cells for the enrichment of the microenvironment and promoting neuronal survival after SCI.

EFFECTS OF DORSAL ROOT AVULSION INJURY ON THE SPINAL GANGLIA AND SPINAL CORD

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Dénes Török, Máté Vass, Krisztián Pajer, Antal Nógrádi
University of Szeged, Albert Szent-Györgyi Medical School, Department Of Anatomy, Histology And Embryology, Szeged, Hungary

High impact vehicle accidents and sport injuries often result in avulsion of the dorsal and ventral roots of the spinal cord. The changes in the ventral horn after ventral root injury are well-known, however, there are only few studies investigating the effect of dorsal root avulsion (DRA). Here we examined the avulsion-induced changes in the affected cell populations of the dorsal root ganglia and spinal cord. The lumbar 4 and 5 (L4-5) dorsal roots were avulsed. Animals were perfused 3, 8, 21 and 90 days after the surgery. The injured and contralateral dorsal root ganglia along with the L4-5 spinal segments were collected. The expression of TrpV1 receptor, CGRP, NF-200kDa and the GSA B4 isolectin was detected. The expression of TrpV-1 increased until day 90. The CGRP expression showed a maximum in the injured ganglia at day 8 while GSA-B4 peaked 21 days after DRA in injured neurons. Significant decrease of NF-200 kDa expression could be found in the affected ganglia and in the ipsilateral gracile tract of the spinal cord 21 days after the injury. The decreased density of CGRP-positive fibers was already significant in the affected dorsal horn as early as 3 days after the injury. In contrast, GSA-B4-positive fibers remained well preserved for at least 3 weeks after the injury. Our data suggest that DRA induces unique expression pattern changes of the investigated markers not only in the injured dorsal root ganglia, but in the contralateral ones, too. Relevant changes appeared in the ipsilateral spinal cord, too.

Spinal cord injury results in irreversible tissue damage followed by limited recovery of function. Interleukin-10 (IL-10) attenuates the effects of pro-inflammatory cytokines and reduces apoptosis. In this study lipid nanoparticle (LNP)-encapsulated human IL-10-encoding nucleoside-modified mRNA (hIL-10 mRNA-LNP) and recombinant hIL-10 loaded via osmotic pump were used to induce neuroprotection and functional recovery following spinal cord contusion injury (at the level of thoracic 10 vertebra) in a rat model. The hIL-10 mRNA LNP or recombinant hIL-10 were administrated 7 days after injury directly into the lesion cavity. The functional analysis showed that hIL-10 in both treatment groups enhanced the coordinated movement relative to controls. Similarly, administration of hIL-10 in both treatment strategies resulted in significantly smaller lesion area at the epicentre of the injury and rescued significantly greater amount of tissue. Analysis of supra and propriospinal connections with the retrograde tracer Fast Blue indicated that hIL-10 treatment enhanced the number of connections between the segments caudal to the lesion and various cranial parts of the CNS. Astrocytes, microglial cells and neurons also expressed hIL-10 protein after hIL-10 mRNA LNP injection up to 5 days in the injured spinal cord. The mRNA treatment induced time-delayed expression of TIMP-1 and CNTF in injured spinal segment. These results demonstrate that the delayed hIL-10 treatment is able to induce morphological and functional improvement after spinal cord contusion. The hIL-10 mRNA LNP provides a simple and controllable new therapeutic approach that is less-invasive than other treatments and does not integrate into the genome.

THE GENETIC DOWNREGULATION OF CALPAIN 1 REVERTS SPINAL HYPEREXCITABILITY IN A NEONATE MOUSE MODEL OF COMPLETE SPINAL CORD INJURY

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Nejada Dingu[1], Rémi Bos[1], Cécile Brocard[1], Florent Krust[1], Marc Bartoli[2], Frédéric Brocard[1]
[1]Faculté de Médicine de la Timone, Institut De Neurosciences De La Timone, Umr7298 Cnrs And Amu, Marseille, France, [2]Aix-Marseille Université, Inserm, Mmg, Umr1251, Marseille, France

We previously described a spinal cord injury (SCI) model in neonate rats consisting in a low-thoracic transection. We reported the emergence of spinal hyperexcitability and signs of spasticity 4–5 days post-injury. We related these physiopathological alterations to an excitatory/inhibitory imbalance in spinal motoneurons where calpains were proved to play a primary role (Plantier et al., 2019). **Aims and Methods.** We recently translated our complete SCI model to neonate mice. We first provided model validation by confirming the appearance of spinal network hyperexcitability in isolated spinal cords. We further characterized passive and active features of lumbar motoneurons and unidentified ventral interneurons surrounding the central canal by means of patch clamp recordings. In a subset of SCI mice, we injected intramuscularly the AAV2-retro containing a shRNA against calpain 1. **Results.** We found out that SCI spinal cords showed huge spontaneous busts and hyperreflexia. Lumbar motoneurons were markedly hyperexcitable, being the resting membrane potential (RMP) notably depolarized. Furthermore, the percentage of sublesional motoneurons exhibiting plateau potentials was increased, providing a sustained excitatory drive supporting exaggerated reflex responses. Noteworthy, fictive locomotion bursts spontaneously occurred in SCI preparations, in line with the presence of autorhythmic interneurons spontaneously oscillating at 1.2 mM of extracellular calcium. The genetic downregulation of calpain 1 reduced both network and cellular hyperexcitability in the sublesional spinal cord. **Conclusion.** A general hyperexcitability was shown to take place in the neonate mouse spinal cord after SCI, which was reverted by an innovative gene therapy approach targeting calpain 1.

ALTERATION OF CEREBROSPINAL FLUID-CONTACTING NEURONS ACTIVITY AFTER A LATERAL CERVICAL SPINAL CORD HEMISECTION

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Anne Kastner[1], Stéphane Vinit[2], Nicolas Wanaverbecq[1]
[1]Aix Marseille Université, Institut Des Neurosciences De La Timone, Marseille, France, [2]Université Paris Saclay, Uvsq, Inserm End-icap, Versailles, France

The central canal ependymal niche of the spinal cord contains cerebrospinal fluid-contacting neurons (CSF-cNs) which are chemosensory and mechanosensory neurons. Since ependymal cells are known to react to spinal cord injury by triggering reparative processes, we assess whether CSF-cNs may also develop a post-injury (PI) reaction, especially since they appear strategically positioned to sense CSF inflammatory molecules. We analysed therefore the reaction of the CSF-cNs (identified by immunofluorescence by their specific PKD2L1 channel) at various time after lateral cervical C2 injury (1 hour to 30D PI) in mice, notably the expression of the neural activity marker c-Fos. CSF inflammatory protein analysis (IL6, IL1, TNF) shows that spinal injury, but also sham chirurgical intervention, induces a strong transient CSF inflammatory response. At this inflammatory peak (1H and 1day post-treatment), we observed a two folds increase of c-Fos+ CSF-cNs (among 15% in injured and sham mice versus 8% in controls) indicating a CSF-cNs activation. In 1H and 1D PI mice (but not in shams) c-Fos was moreover transiently induced in ependymal cells. By contrast, after chronic injury (7D, 15D and 30D PI), the percent of c-Fos+ CSF-cNs was markedly reduced (3-5% versus 8% in shams), indicating a CSF-cNs inactivation in chronic PI conditions. Altogether our results show that CSF-cNs activity may be altered by spinal injury but also by chirurgical and/or inflammatory stress. CSF-cNs and ependymal cells activation in acute conditions may putatively contribute to plasticity processes, whereas CSF-cNs deactivation after chronic injury may reinforce motor disabilities.

Aims: We have recently shown the anti-inflammatory and proregenerative actions of implanted biofunctionalized carbon microfibres (MFs) in a rodent model of spinal cord injury. Based on these promising effects and to potentiate them, we here evaluated the therapeutic potential of a neuroprosthetic implant based on the embedment of several MFs inside a presumably proregenerative fibrin hydrogel matrix. **Methods:** Spinal cord injury was performed on “AMU-Neuroinflam” triple reporter mice to monitor the densities of axons, infiltrated myeloid cells and activated microglial cells by 2P intravital imaging. Density of cell types was precisely measured by automatic computational segmentation and evolution of inflammation and axonal regeneration were characterized in 3 different conditions: treatment with fibrin only, treatment with MFs+fibrin, no treatment. Fibrin bundle was obtained by polymerization of a 1:2 mixture of fibrinogen and thrombin on top of a layered MFs scaffolds. The tailored neuroprosthetic implant was implanted immediately after trauma. **Results**: MFs+fibrin implant boosted the early recruitment of inflammatory cells with an enhanced contribution of monocyte derived Dendritic Cells (moDCs) when compared to fibrin or sham treated lesions. At two weeks, opacification of the transparent fibrin bundles precluded intravital imaging in treated animals. Nevertheless, terminal histology at 3 months demonstrated the significant reduction of chronic inflammation and the enhanced axonal regeneration specifically in MF+fibrin mice. **Conclusions:** Fibrin and carbon appear as a proper combination for the development of biocompatible neuroprosthetic devices to manage spinal cord injury. Moreover, electrical conductivity of carbon is suitable to apply electrotherapeutic strategies to further promote axonal regeneration.

Spinal Cord Injury is a devastating condition resulting in loss of sensory and/or motor function. The use of multipotent Mesenchymal Stromal Cells (MSC) in emerging therapies for the treatment of spinal cord injury may hold the potential to contribute to sensory and/or motor function improvements in the patients. However, the development of cell-based medicines is challenging and a series of preclinical studies addressing quality and safety aspects, in addition to signs of efficacy, need to be performed prior to receiving regulatory approval for clinical testing in humans. Herein we present a series of *in vitro* and *in vivo* studies addressing the characterization of the quality attributes of MSC derived from the Wharton's jelly of the umbilical cord, safety of intrathecal infusion of MSC, and their effect in a rat model of spinal cord injury by controlled impaction after single (at day 7 post-injury) and repeated dose of $1x10^6$ MSC (at days 7 and 14 post-injury). Animals were monitored for 70 days using a broad panel of tests including electrophysiological tests, motor function assessment and histology evaluation. Remarkably, recovery of locomotion was promoted at early time points and safety of repeated doses was demonstrated. The relevance of the data resulting from these studies is discussed in terms of their scientific significance as well as their suitability for being included in the Investigational Medicinal Product Dossier for further consideration by the competent Regulatory Authority.

BET PROTEIN INHIBITION IN MACROPHAGES ENHANCES DORSAL ROOT GANGLION NEURITE OUTGROWTH IN FEMALE MICE

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Georgina Palomés, Clara Penas, Xavier Navarro
Institut of Neurosciences, Department Of Cell Biology, Physiology And Immunology, Centro De Investigación Biomédica En Red Sobre Enfermedades Neurodegenerativas (ciberned), Universitat Autònoma De Barcelona (uab), Bellaterra, Barcelona, Spain

Peripheral nerve regeneration is limited after injury, especially in humans, due to the large distance the axons have to grow in the limbs. Currently, there is a lack of effective treatments in the clinics, subjecting patients to prolonged rehabilitation and poor quality of life. Thus, it is relevant to find novel strategies to enhance nerve regeneration after trauma. For instance, this process is highly dependent on the expression of neuroinflammatory factors produced by macrophages and glial cells. Thus, given the importance of BET proteins on inflammation, we aimed to ascertain if BET inhibition may have an effect on axonal outgrowth. BET proteins are epigenetic readers of acetylated lysine residues that recruit transcriptional complexes. We found that although administration of the BET inhibitor JQ1 in nerve crush-injured female mice provided an increase of GAP-43, IL-4 and IL-13 transcription, the treatment did not produce any enhancement of sensory and motor reinnervation. Then, we assessed the effects of JQ1 *ex vivo*. We observed that JQ1 decreased neurite outgrowth of DRG explants in culture, whereas conditioned media from JQ1-treated macrophages increased DRG neurite number and length. Thus, macrophages were responsible to counteract the negative effects of JQ1 *in vivo*, probably by enhancing anti-inflammatory cytokine production. Finally, we identified the activation of STAT6 pathway on DRG explants treated with conditioned medium from JQ1-treated macrophages. To conclude, this study demonstrates that BET inhibition on macrophages enhances axonal outgrowth. However, a specific targeting on macrophages may be needed to increase functional recovery after injury.

Nerve Excitability and Neuropathic Pain is Reduced by BET Protein Inhibition After Spared Nerve Injury.
Neuropathic pain is a common disability produced by enhanced neuronal excitability after nervous system injury. The pathophysiological changes that underlie the generation and maintenance of neuropathic pain require modifications of transcriptional programs. In particular, there is an induction of pro-inflammatory neuromodulators levels, and changes in the expression of ion channels and other factors intervening in the determination of the membrane potential in neuronal cells. We have previously found that inhibition of the BET proteins epigenetic readers reduced neuroinflammation after spinal cord injury. Within the present study we aimed to determine if BET protein inhibition may also affect neuroinflammation after a peripheral nerve injury, and if this would beneficially alter neuronal excitability and neuropathic pain. For this purpose, C57BL/6 female mice underwent spared nerve injury (SNI), and were treated with the BET inhibitor JQ1, or vehicle. Electrophysiological and algesimetry tests were performed on these mice. We also determined the effects of JQ1 treatment after injury on neuroinflammation, and the expression of neuronal components important for the maintenance of axon membrane potential. We found that treatment with JQ1 affected neuronal excitability and mechanical hyperalgesia after SNI in mice. BET protein inhibition regulated cytokine expression and reduced microglial reactivity after injury. In addition, JQ1 treatment altered the expression of SCN3A, SCN9A, KCNA1, KCNQ2, KCNQ3, HCN1 and HCN2 ion channels, as well as the expression of the Na/K ATPase pump subunits. In conclusion, both, alteration of inflammation, and neuronal transcription, could be the responsible epigenetic mechanisms for the reduction of excitability and hyperalgesia observed after BET inhibition. Inhibition of BET proteins is a promising therapy for reducing neuropathic pain after neural injury. PERSPECTIVE: Neuropathic pain is a common disability produced by enhanced neuronal excitability after nervous system injury. The underlying pathophysiological changes require modifications of transcriptional programs. This study notes that inhibition of BET proteins is a promising therapy for reducing neuropathic pain after neural injury.

INVESTIGATION OF SENSORY NEURON-DERIVED CSF1 AS A POTENTIAL CHEMOATTRACTANT FACTOR FOR MACROPHAGES AFTER PERIPHERAL NERVE INJURY

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Andreea Grosu[1], Marie Pertin[2], Guylène Kirschmann[2], Alexandru Deftu[2], Violeta Ristoiu[1]
[1]University of Bucharest, Department Of Anatomy, Animal Physiology And Biophysics, Bucharest, Romania, [2]Pain Center, Department Of Anesthesiology, Lausanne, Switzerland

Aims: Growing evidence suggests that macrophage activation at the dorsal root ganglia (DRG) level and neuron-macrophage communication are essential mechanisms underlying the pathogenesis of peripheral neuropathic pain. The aim of this study was to investigate the expression of colony-stimulating factor 1 (CSF1) and its potential role in macrophage accumulation in the DRG after spared nerve injury (SNI) model of neuropathic pain. **Methods:** CX3CR1-GFP transgenic mice were assigned to 3 groups: Control (animals did not undergo any kind of surgery), Sham (the sciatic nerve was exposed) and SNI (the tibial and common peroneal rami of sciatic nerve were ligated and cut). Seven days after surgery, L3 and L4 DRGs were collected, frozen and cut and DRG sections were double immunostained using antibodies against NF200 or CGRP and against CSF1. **Results:** CSF1 expression is significantly increased in sensory neurons in both L3/L4 DRGs after SNI, but with a higher expression in L4. This pattern is also observed in the macrophage accumulation, with the highest degree of activation in L4, but still with a significant number of activated cells in L3. Moreover, among CSF1(+) neurons, 40% have peri-neuronal rings of macrophages in L4, while in L3 this percentage decreases to 30%. Lastly, 50% of the CSF1(+) neurons co-express NF200, a marker for large, myelinated neurons, while less than 10% of them are small, peptidergic neurons, co-expressing CGRP. **Conclusions:** The pattern of CSF1 expression after SNI is spatially correlated with macrophage accumulation, suggesting its role in attracting macrophages in DRGs after peripheral nerve injury.

Silencing the Cytoskeleton Protein Iba1 (Ionized Calcium Binding Adapter Protein 1) Interferes with BV2 Microglia Functioning.
Iba1 (ionized calcium binding adapter protein 1) is a cytoskeleton protein specific only for microglia and macrophages, where it acts as an actin-cross linking protein. Although frequently regarded as a marker of activation, its involvement in cell migration, membrane ruffling, phagocytosis or in microglia remodeling during immunological surveillance of the brain suggest that Iba1 is not a simple cytoskeleton protein, but a signaling molecule involved in specific signaling pathways. In this study we investigated if Iba1 could also represent a drug target, and tested the hypothesis that its specific silencing with customized Iba1-siRNA can modulate microglia functioning. The results showed that Iba1-silenced BV2 microglia migrate less due to reduced proliferation and cell adhesion, while their phagocytic activity and P2x7 functioning was significantly increased. Our data are the proof of concept that Iba1 protein is a new microglia target, which opens a new therapeutic avenue for modulating microglia behavior.

ANTINOCICEPTIVE EFFECT OF EHRETIA CYMOSA LEAVES IN STREPTOZOTOCIN-INDUCED DIABETIC NEUROPATHY IN SPRAGUE DAWLEY RATS

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Audrey Akyea Eklemet
University of Ghana, Pharmacology, Legon, Ghana

Background: *Ehretia cymosa* is used as an antihyperglycemic agent among the Akan and Ewe communities in Ghana. Its anticonvulsant, antioxidant, and analgesic properties make it a potential remedy for painful diabetic neuropathy. This study investigated the role of *Ehretia cymosa leaves* as an antinociceptive agent for streptozotocin-induced type 2 diabetic neuropathy in rats. **Method:** The leaves were pulverized, cold macerated with 70% ethanol and rotary-evaporated to obtain a dry extract, ECE. A single intraperitoneal injection of streptozotocin (STZ) 60 mg/kg and nicotinamide 110 mg/kg induced diabetes in male Sprague Dawley rats. Onset of neuropathy was followed with a 7-day treatment with ECE (30, 100, 300) mg/kg and pregabalin (PGB) (10, 30, 100) mg/kg. Fasting blood sugar (FBS), glycated hemoglobin (HbA1c), IL-6, malondialdehyde (MDA), organ to body weight ratio, liver and kidney function, lipid profile, pancreas, kidney, sciatic nerve and hippocampus were assessed. **Results:** Diabetic rats showed reductions in tail-flick ($p<0.0001$) and paw licking ($p<0.0001$) latencies. Thermal hyperalgesia was attenuated with ECE 30mg/kg on days 3 and 4 ($p<0.05$), and with PGB 100 mg/kg on day 1 ($p<0.01$). PGB 30 mg/kg attenuated tail-flick latency. ECE increased IL-6 at 300mg/kg. Characteristic features of beta cells loss; fiber degeneration; axonopathy; schwann cell proliferation; glomerulosclerosis; and loss of granular and pyramidal cells in the dentate gyrus, and CA3 of the hippocampus were observed. **Conclusion:** The ethanolic extract of *Ehretia cymosa* demonstrated antinociceptive effects in thermal hyperalgesia at 30mg/kg ($p<0.05$) in STZ-induced diabetic rats.

An extract of Synedrella nodiflora (L) Gaertn exhibits antidepressant properties through monoaminergic mechanisms. Synedrella nodiflora (SNE) has been used traditionally for many neurological conditions and some of these neuroactive effects have been scientifically substantiated. The usefulness of SNE in depression has however not been investigated despite the availability of data in other disease models indicating it may be useful. The present study therefore examined the effect of SNE in acute murine models of depression and the possible mechanisms mediating its activities in these models. Preliminary qualitative phytochemical and high performance liquid chromatography (HPLC) screening were conducted on SNE. The behavioural effects of SNE (100, 300 and 1000 mg/kg) pre-treated mice were examined in the forced swimming (FST) and tail suspension (TST) tests. Behavioural events such as mobility (swimming, climbing, curling and climbing), and immobility, were scored. The possible involvement of monoamines in the effects of SNE was assessed in the TST by pre-treating mice with α-methyldopa, reserpine and para-chlorophenylalanine (pCPA) in separate experiments. Flavonoids, tannins, saponins, alkaloids, cardiac glycosides, coumarins, triterpenes, sterols, anthraquinones and phenolic compounds were present in SNE. HPLC analysis revealed the presence of two major constituents observed at retention times 42.56 and 46.51 min, with percentage composition of 45.72% and 36.88% respectively. SNE significantly reduced immobility scores in both FST and TST, suggesting antidepressant effects. The antidepressant properties of SNE were reversed by the pre-treatment of α-methyldopa, reserpine and pCPA, suggesting a possible involvement of monoamines (noradrenaline and serotonin) in its mechanism(s) of actions. SNE exhibits antidepressant effects, possibly mediated through an interplay of enhancement of noradrenergic and serotoninergic mechanisms.

OBESITY-INDUCED LEARNING DEFICITS IN THE FEMALE RAT ARE OESTROUS CYCLE-DEPENDENT AND ARE ASSOCIATED WITH IMPAIRED TRYPTOPHAN METABOLISM THROUGH THE KYNURENINE PATHWAY.

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Background: Obesity has a negative impact on memory affecting males more than females. It is believed that females are protected from cognitive decline by estrogens. The concentration of these hormones, peaks during proestrus and gradually declines through estrus, diestrus and metestrus. Estrogens enhance the expression of tryptophan hydroxylase-2, the rate-limiting enzyme in the transformation of tryptophan (TRP) to serotonin. This neurotransmitter, plays a significant role in learning and memory. However, several learning/memory-regulating compounds arise also from tryptophan metabolism through the kynurenine pathway including xanthurenic acid (XA) and NAD+. **Aim:** The aim of the present study was to determine the involvement of the kynurenine pathway of TRP metabolism in the regulation of learning in control and obese female rats. **Methods:** The learning capabilities of control and obese female rats were evaluated using the Novel Object Recognition test. Tryptophan and TRP-derived metabolites were quantified in the hippocampus and frontal cortex by Ultra-performance liquid chromatography-tandem mass spectrometry. **Results:** Control rats in proestrus/estrus performed better than their control mates in diestrus/metestrus. In contrast, while there were no differences in learning between control and obese rats in diestrus/metestrus, obese rats in proestrus/estrus displayed decreased memory capacity along with reduced production of XA and NAD+ and upregulated expression of mRNAs coding for the enzyme Indoleamine 2,3-dioxygenase, that catalyses the transformation of tryptophan to kynurenine. **Conclusions:** The deleterious effects of obesity on learning are closely linked to the oestrous cycle and are mediated, at least in part, by an impairment of the kynurenine pathway of tryptophan metabolism.

BRAIN SIZE, GUT SIZE AND COGNITIVE ABILITIES: EXPERIMENTAL EVOLUTION OF ENERGY TRADE-OFFS

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Anna Goncerzewicz[1], Tomasz Górkiewicz[1], Jakub Dzik[2], Joanna Jędrzejewska-Szmek[2], Ewelina Knapska[1], Marek Konarzewski[3]

The enlarged brains of homeotherms bring behavioural advantages, but also incur high energy expenditures. The 'Expensive Brain' (EB) hypothesis posits that the energetic costs of the enlarged brain and the resulting increased cognitive abilities (CA) were met either by increased energy turnover or reduced allocation to other expensive organs, such as the gut. We tested the directionality of the evolutionary relationships between energy expenditures, brain, gut and CA using an experimental evolution model in which we subjected line types of laboratory mice to artificial selection on basal (BMR) or maximum (VO_{2max}) aerobic metabolism - traits that are implicated in evolution of homeothermy, having been pre-requisites for the encephalisation and exceptional CA of mammals, including humans. High-BMR mice had bigger guts, but not brains. Yet, they performed better on the cognitively demanding tasks carried out in both reward and avoidance learning contexts. Furthermore, the high BMR mice had higher neuronal plasticity (indexed as the long-term potentiation, LTP) than their counterparts. Our data indicate that the evolutionary increase of CA in mammals was initially associated with increased BMR and brain plasticity. It was also fueled by an enlarged gut, which was not traded off for brain size.

MICROGLIA DEPLETION INHIBITS LACTATION BY THE INHIBITION OF PROLACTIN SECRETION IN RODENTS

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Vivien Csikós[1,2], Árpád Dobolyi[1,2]
[1]Eötvös Loránd Research Network, Laboratory Of Molecular And System Neurobiology, Budapest, Hungary, [2]Eötvös Loránd University, Department Of Physiology And Neurobiology, Budapest, Hungary

Microglia are tissue-resident macrophage-like innate immune cells of the central nervous system. In addition, they also contribute to neuroplastic changes of the central nervous system under physiological circumstances. Since maternal behaviour is accompanied by synaptic changes in mothers' brain, we hypothesized the role of microglia in maternal function. The role of microglia was examined in lactation, and also in the formation of maternal behaviour during pregnancy and the postpartum period. The microglial cells were eliminated from the brain by blocking colony stimulating factor 1 receptor. The intensity of maternal behaviour decreased only if mothers were treated during pregnancy, that is postpartum elimination of microglia was without effect on the maternal behaviour. In contrast, the weight gain of pups was reduced in both protocols even if poster pups were used. Suckling induced serum prolactin levels were measured in the blood obtained via jugular cannula. The level of prolactin in treated mothers was markedly reduced as compared to control animals. The results suggest that microglial cells are required for proper lactation but they are not necessary for the general motility or the postpartum emotional changes. Maternal motivation may be normal in the postpartum absence of microglia. In conclusion, microglia play important roles is specific aspects of the maternal adaptation probably by allowing proper prolactin secretion. The work was supported by the Hungarian National Research, Development and Innovation Office NKFIH-4300-1/2017-NKP_17-00002 (National Brain Program 2.0), and OTKA K134221, and also by the ÚNKP-16-3 New National Excellence Program of the Ministry of Human Capacities" program.

The mycotoxin deoxynivalenol activates GABAergic neurons in the reward system and inhibits feeding and maternal behaviours.
Deoxynivalenol (DON) or vomitoxin, is a trichothecene mycotoxin produced mainly by Fusarium graminearum and culmorum. Mycotoxins or secondary metabolic products of mold fungi are micro-pollutants, which may affect human and animal health. The neuronal and behavioural actions of DON were analysed in the present study. To address, which neurons can be affected by DON, the neuronal activation pattern following intraperitoneal injection of DON (1 mg/kg) was investigated in adult male rats and the results were confirmed in mice, too. DON-induced neuronal activation was assessed by c-Fos immunohistochemistry. DON injection resulted in profound c-Fos activation in only the elements of the reward system, such as the accumbens nucleus, the medial prefrontal cortex, and the ventral tegmental area. Further double labelling studies suggested that GABAergic neurons were activated by DON treatment. To study the behavioural relevance of this activation, we examined the effect of DON on feed intake as an example of reward-driven behaviours. Following DON injection, feed consumption was markedly reduced but returned to normal the following day suggesting an inhibitory action of DON on feed intake without forming taste-aversion. To further test how general the effect of DON on goal-directed behaviours is, its actions on maternal behaviour was also examined. Pup retrieval latencies were markedly increased by DON administration, and DON-treated mother rats spent less time with nursing suggesting reduced maternal motivation. In a supplementary control experiment, DON did not induce conditioned place preference arguing against its addictive or aversive actions. The results imply that acute uptake of the mycotoxin DON can influence the reward circuit of the brain and exert inhibitory actions on goal-directed, reward-driven behaviours. In addition, the results also suggest that DON exposure of mothers may have specific implications.

Secretion and Function of Pituitary Prolactin in Evolutionary Perspective.
The hypothalamo-pituitary system developed in early vertebrates. Prolactin is an ancient vertebrate hormone released from the pituitary that exerts particularly diverse functions. The purpose of the review is to take a comparative approach in the

description of prolactin, its secretion from pituitary lactotrophs, and hormonal functions. Since the reproductive and osmoregulatory roles of prolactin are best established in a variety of species, these functions are the primary subjects of discussion. Different types of prolactin and prolactin receptors developed during vertebrate evolution, which will be described in this review. The signal transduction of prolactin receptors is well conserved among vertebrates enabling us to describe the whole subphylum. Then, the review focuses on the regulation of prolactin release in mammals as we have the most knowledge on this class of vertebrates. Prolactin secretion in response to different reproductive stimuli, such as estrogen-induced release, mating, pregnancy and suckling is detailed. Reproduction in birds is different from that in mammals in several aspects. Prolactin is released during incubation in avian species whose regulation and functional significance are discussed. Little information is available on prolactin in reptiles and amphibians; therefore, they are mentioned only in specific cases to explain certain evolutionary aspects. In turn, the osmoregulatory function of prolactin is well established in fish. The different types of pituitary prolactin in fish play particularly important roles in the adaptation of eutherian species to fresh water environments. To achieve this function, prolactin is released from lactotrophs in hyposmolarity, as they are directly osmosensitive in fish. In turn, the released prolactin acts on branchial epithelia, especially ionocytes of the gill to retain salt and excrete water. This review will highlight the points where comparative data give new ideas or suggest new approaches for investigation in other taxa.

Complement component 1q subcomponent binding protein in the brain of the rat.
Complement component 1q subcomponent binding protein (C1qbp) is a multifunctional protein involved in immune response, energy homeostasis of cells as a plasma membrane receptor, and a nuclear, cytoplasmic or mitochondrial protein. Recent reports suggested its neuronal function, too, possibly in axon maintenance, synaptic function, and neuroplasticity. Therefore, we addressed to identify C1qbp in the rat brain using in situ hybridization histochemistry and immunolabelling at light and electron microscopic level. C1qbp has a topographical distribution in the brain established by the same pattern of C1qbp mRNA-expressing and protein-containing neurons with the highest abundance in the cerebral cortex, anterodorsal thalamic nucleus, hypothalamic paraventricular (PVN) and arcuate nuclei, spinal trigeminal nucleus. Double labelling of C1qbp with the neuronal marker NeuN, with the astrocyte marker S100, and the microglia marker Iba1 demonstrated the presence of C1qbp in neurons but not in glial cells in the normal brain, while C1qbp appeared in microglia following their activation induced by focal ischemic lesion. Only restricted neurons expressed C1qbp, for example, in the PVN, magnocellular neurons selectively contained C1qbp. Further double labelling by using the mitochondria marker Idh3a antibody suggested the mitochondrial localization of C1qbp in the brain, confirmed by correlated light and electron microscopy at 3 different brain regions. Post-embedding immunoelectron microscopy also suggested uneven C1qbp content of mitochondria in different brain areas but also heterogeneity within single neurons. These data suggest a specific function of C1qbp in the brain related to mitochondria, such as the regulation of local energy supply in neuronal cells.

Zearalenone alters the excitability of rat neuronal networks after acute in vitro exposure.
Zearalenone (ZEA) is a mycotoxin produced by Fusarium species, detectable in various cereals and processed food products worldwide. ZEA displays a significant estrogenic activity, thus its main health risk is the interference with sexual maturation and reproduction processes. However, in addition to being key hormonal regulators of reproductive function, estrogenic compounds have a widespread role in brain, as neurotrophic and neuroprotective factors, and they may influence the activity of several brain areas not directly linked to reproduction, as well. Therefore, in the present study, acute effects of ZEA were studied on certain neuronal functions in rats. Experiments were performed on rat brain slices or live rats. Slices were incubated in ZEA-containing (10-100 μM) solution for 30 min. Electrically evoked and spontaneous field potentials were studied in the neocortex and in the hippocampus. At higher concentrations, ZEA incubation of the slices altered excitability and the pattern of epileptiform activity in neocortex and inhibited the development of LTP in hippocampus. For the verification of these in vitro results, in vivo electrophysiological and immunohistochemical investigations were also performed. ZEA was administered systemically (5 mg/kg, i.p.) to male rats and somatosensory evoked potentials and neuronal activation studied by c-fos expression were analyzed. No neuronal activation could be demonstrated in the hippocampus within 2 h of the injection. In the somatosensory cortex, ZEA did not change in vivo evoked potential parameters, but the activation of a small neuronal population could be demonstrated with the c-fos technique in this brain area. This result could be associated with the ZEA-induced alteration of epileptiform activity observed in vitro. Altogether, the toxin altered the excitability and plasticity of neuronal networks after direct treatment in slices, but the effects were less prominent on the given brain areas after systemic treatment in vivo. A probable explanation for the partial lack of in vivo effects may be that after a single injection, ZEA did not cross the blood-brain barrier at sufficient rate to allow the build-up of comparable concentrations in the investigated brain areas. However, in case of compromised blood-brain barrier functions or long-term repeated exposure,

alterations in cortical and hippocampal functions cannot be ruled out.

Short-term neuronal effects of fumonisin B1 on neuronal activity in rodents.
Fumonisin B1 (FB1) is a mycotoxin produced by microscopic fungi (mostly Fusarium species), which may infect our major crops. The toxin inhibits the development of these plants and may also have harmful effects on animals and humans consuming the infected crops. FB1 inhibits sphingolipid biosynthesis which leads to altered membrane characteristics and consequently, altered cellular functions. There are some indications that the toxin has inhibitory effects on neuronal activity in case of repeated consumption, presumably due to sphingolipid depletion. However, according to new literature data, FB1 may have acute excitatory neural effects, too, via different mechanisms of action. Therefore, in the present study, we addressed the neuronal network effects of FB1 following acute treatment, using different electrophysiological techniques in vitro and in vivo. Acute treatments with FB1 (10-100 μM) were carried out on brain slices, tissue cultures and live animals. After direct treatment of samples, electrically evoked or spontaneous field potentials were examined in the hippocampus and the neocortex of rat brain slices and in hippocampal cell cultures. In the hippocampus, a short-term increase in the excitability of neuronal networks and individual cells was observed in response to FB1 treatment. In some cases, the initially enhanced excitation was reversed presumably due to overactivation of neuronal networks. Normal spontaneous activity was found to be stimulated in hippocampal cell cultures. Seizure susceptibility was not affected in the neocortex of brain slices. For the verification of the results caused by direct treatment, effects of systemic administration of FB1 (7.5 mg/kg, i.p.) were also examined. Evoked field potentials recorded in vivo from the somatosensory cortex and cell activation measured by the c-fos technique in hippocampus and somatosensory cortex were analyzed. However, the hippocampal and cortical stimulatory effect detected in vitro could not be demonstrated by these in vivo assays. Altogether, the toxin enhanced the basic excitability of neurons and neuronal networks after direct treatment but there were no effects on the given brain areas after systemic treatment in vivo. Based on the observed in vitro FB1 effects and the lack of data on the penetration of FB1 across the blood-brain barrier, we assume that in vivo consequences of FB1 administration can be more prominent in case of perturbed blood-brain barrier functions.

Transcriptome Sequencing in the Preoptic Region of Rat Dams Reveals a Role of Androgen Receptor in the Control of Maternal Behavior.
(1) Background: Preoptic region of hypothalamus is responsible to control maternal behavior, which was hypothesized to be associated with gene expressional changes. (2) Methods: Transcriptome sequencing was first applied in the preoptic region of rat dams in comparison to a control group of mothers whose pups were taken away immediately after parturition and did not exhibit caring behavior 10 days later. (3) Results: Differentially expressed genes were found and validated by quantitative RT-PCR, among them NACHT and WD repeat domain containing 1 (Nwd1) is known to control androgen receptor (AR) protein levels. The distribution of Nwd1 mRNA and AR was similar in the preoptic area. Therefore, we focused on this steroid hormone receptor and found its reduced protein level in rat dams. To establish the function of AR in maternal behavior, its antagonist was administered intracerebroventricularly into mother rats and increased pup-directed behavior of the animals. (4) Conclusions: AR levels are suppressed in the preoptic area of mothers possibly mediated by altered Nwd1 expression in order to allow sustained high-level care for the pups. Thus, our study first implicated the AR in the control of maternal behaviors.

Long-term recording performance and biocompatibility of chronically implanted cylindrically-shaped, polymer-based neural interfaces.
Stereo-electroencephalography depth electrodes, regularly implanted into drug-resistant patients with focal epilepsy to localize the epileptic focus, have a low channel count (6-12 macro- or microelectrodes), limited spatial resolution (0.5-1 cm) and large contact area of the recording sites (~mm2). Thus, they are not suited for high-density local field potential and multiunit recordings. In this paper, we evaluated the long-term electrophysiological recording performance and histocompatibility of a neural interface consisting of 32 microelectrodes providing a physical shape similar to clinical devices. The cylindrically-shaped depth probes made of polyimide (PI) were chronically implanted for 13 weeks into the brain of rats, while cortical or thalamic activity (local field potentials, single-unit and multi-unit activity) was recorded regularly to monitor the temporal change of several features of the electrophysiological performance. To examine the tissue reaction around the probe, neuron-selective and astroglia-selective immunostaining methods were applied. Stable single-unit and multi-unit activity were recorded for several weeks with the implanted depth probes and a weak or moderate tissue reaction was found around the probe track. Our data on biocompatibility presented here and in vivo experiments in non-human primates provide

a strong indication that this type of neural probe can be applied in stereo-electroencephalography recordings of up to 2 weeks in humans targeting the localization of epileptic foci providing an increased spatial resolution and the ability to monitor local field potentials and neuronal spiking activity.

Neonicotinoid insecticides are potential substrates of the multixenobiotic resistance (MXR) mechanism in the non-target invertebrate, Dreissena sp.
Mussels are among the most frequently used invertebrate animals in aquatic toxicology to detect toxic exposure in the environment. The presence and activity of a cellular defence system, the multixenobiotic resistance (MXR) mechanism, was also established in these organisms. In isolated gill tissues of dreissenid mussels (D. bugensis) the MXR activity was assayed after treatment by commercially available insecticides (formulated products) which contain neonicotinoids as their active ingredients: Actara (thiamethoxam), Apacs (clothianidin), Calypso (thiacloprid) and Kohinor (imidacloprid), respectively. While applying the accumulation assay method, 0.5 µM rhodamine B was used as model substrate and 20 µM verapamil as model inhibitor of the MXR mechanism. In acute (in vitro) experiments when isolated gills were co-incubated in graded concentrations of insecticides and rhodamine B simultaneously, Calypso and Kohinor treatment resulted increasing rhodamine accumulation. Chemical analysis of gills in vitro incubated in insecticides demonstrated higher tissue concentrations of thiamethoxam, clothianidin and thiacloprid in the presence of verapamil suggesting that the active ingredients of Actara, Apacs and Calypso are potential substrates of the MXR mediated cellular efflux. In contrast, verapamil did significantly alter the accumulated imidacloprid concentrations in gills, suggesting that the active component of Kohinor is not transported by the MXR mechanism. Chronic (in vivo) exposures of the intact animals in lower, 1, 10 mg/L concentration of neonicotinoid products, resulted in a decreased level of both rhodamine accumulation and verapamil inhibition by the 12th-14th days of treatment. These results suggest an enhancement of MXR activity (chemostimulation), building up gradually in the animals exposed to Actara, Apacs and Kohinor, respectively. Neonicotinoid-type insecticides are generally considered as selective neurotoxins for insects, targeting the nicotinic type acetylcholine receptors (nAChRs) in their central nervous system. Our present results provide the first evidences that neonicotinoid insecticides are also able to alter the transmembrane transport mechanisms related to the MXR system.

INHIBITION OF THE NLRP3 INFLAMMASOME BY OLT1177 INDUCES FUNCTIONAL PROTECTION AND MYELIN PRESERVATION AFTER SPINAL CORD INJURY

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Jesús Amo Aparicio[1], Joana Garcia Garcia[2], Maria Puigdomenech Poch[2], Isaac Francos-Quijorna[3], Damaris Skouras[4], Charles Dinarello[1,5], Rubèn López Vales[2,6]

Spinal cord injury (SCI) leads to irreversible functional deficits due to the disruption of axons and the death of neurons and glial cells. The inflammatory response that occurs in the injured spinal cord results in tissue degeneration; thus, targeting inflammation after acute SCI is expected to ameliorate histopathological evidence indicative of damage and, consequently, reduce functional disabilities. Interleukin 1 beta (IL-1β) and interleukin 18 (IL-18) are pro-inflammatory cytokines members of the IL-1 family that initiate and propagate inflammation. Here, we report that protein levels of IL-1β and IL-18 were increased in spinal cord parenchyma after SCI, but with different expression profiles. Whereas levels of IL-1β were rapidly increased reaching peak levels at 12 h after the injury, levels of IL-18 did not increase until 7 days after the injury. Since activation of the NLRP3 inflammasome is required for the processing and release of IL-1β and IL-18, we intraperitoneally administered OLT1177, a selective inhibitor of the NLRP3 inflammasome, to reduce the contribution of these cytokines to SCI. At a dose of 200 mg/kg, OLT1177 protected against neurological deficits and histological evidence of damage. OLT1177 also reduced the levels of IL-1β in the spinal cord after contusion injury and diminished the accumulation of neutrophils and macrophages at later time points. These data suggest that targeting the NLRP3 inflammasome with OLT1177 could be a novel therapeutic strategy to arrest neuroinflammation and reduce functional impairments after acute SCI in humans.

Monoaminergic descending pathways contribute to modulation of neuropathic pain by increasing-intensity treadmill exercise after peripheral nerve injury.
This study characterizes the impact of increasing-intensity treadmill exercise (iTR) on noradrenergic (NE) and serotonergic (5HT) modulation of neuropathic pain. Following sciatic nerve transection and repair (SNTR) rats developed significant mechanical and thermal hyperalgesia that was partially prevented by iTR performed during the first 2weeks after injury. Marked decrease in the expression of 5HT and α and β-, but not α adrenergic receptors in the spinal cord dorsal horn was associated to SNTR and recovered by iTR, particularly in lamina II. iTR significantly increased 5HT in periaqueductal grey (PAG), raphe magnus (RM) and dorsal raphe nucleus (DRN), with a pattern suggesting reorganization of serotonergic excitatory interconnections between PAG and DRN. iTR also increased the expression of α in locus coeruleus (LC) and DRN, and β in LC, indicating that exercise enhanced activity of NE neurons, likely by activating autologous projections from DRN and PAG. iTR hypoalgesia was antagonized by blockade of β and 5HT receptors with administration of butoxamine and ketanserin. The neurotoxin DSP4 was injected to induce depletion of NE projections from LC before starting iTR. DSP4 treatment worsened mechanical hyperalgesia, but iTR hypoalgesia was similarly produced. Moreover, 5HT expression in LC further increased after DSP4 injection, all these results suggesting an intrinsic regulation of 5HT and NE activity between PAG, DRN and LC neurons activated by iTR. Finally, iTR significantly reduced microglial reactivity in LC and increased non-microglial BDNF expression, an effect that was reverted by butoxamine, implicating BDNF regulation in central 5HT/NE actions on neuropathic pain.

Role of Noradrenergic Inputs From Locus Coeruleus on Changes Induced on Axotomized Motoneurons by Physical Exercise.

Physical rehabilitation is one of the cornerstones for the treatment of lesions of the nervous system. After peripheral nerve injuries, activity dependent therapies promote trophic support for the paralyzed muscles, enhance axonal growth and also modulate the maladaptive plastic changes induced by the injury at the spinal level. We have previously demonstrated that an intensive protocol of treadmill running (TR) in rats reduces synaptic stripping on axotomized motoneurons, preserves their perineuronal nets (PNN) and attenuates microglia reactivity. However, it is not clear through which mechanisms exercise is exerting these effects. Here we aimed to evaluate if activation of the locus coeruleus (LC), the noradrenergic center in the brain stem, plays a role in these effects. Since LC is strongly activated during stressful situations, as during intensive exercise, we selectively destroyed the LC by administering the neurotoxin DPS-4 before injuring the sciatic nerve of adult rats. Animals without LC had increased microglia reactivity around injured motoneurons. In these animals, an increasing intensity protocol of TR was not able to prevent synaptic stripping on axotomized motoneurons and the reduction in the thickness of their PNN. In contrast, TR was still able to attenuate microglia reactivity in DSP-4 treated animals, thus indicating that the noradrenergic projections are important for some but not all the effects that exercise induces on the spinal cord after peripheral nerve injury. Moreover, animals subjected to treadmill training showed delayed muscle reinnervation, more evident if treated with DSP-4. However, we did not find differences in treated animals regarding the H/M amplitude ratio, which increased during the first stages of regeneration in all injured groups.

A Novel Agonist of the Type 1 Lysophosphatidic Acid Receptor (LPA), UCM-05194, Shows Efficacy in Neuropathic Pain Amelioration.
Neuropathic pain (NP) is a complex chronic pain state with a prevalence of almost 10% in the general population. Pharmacological options for NP are limited and weakly effective, so there is a need to develop more efficacious NP attenuating drugs. Activation of the type 1 lysophosphatidic acid (LPA) receptor is a crucial factor in the initiation of NP. Hence, it is conceivable that a functional antagonism strategy could lead to NP mitigation. Here we describe a new series of LPA agonists among which derivative ()- (UCM-05194) stands out as the most potent and selective LPA receptor agonist described so far (= 118%, EC = 0.24 μM, = 19.6 nM; inactive at autotaxin and LPA receptors). This compound induces characteristic LPA-mediated cellular effects and prompts the internalization of the receptor leading to its functional inactivation in primary sensory neurons and to an efficacious attenuation of the pain perception in an model of NP.

FEEDING AND EXERCISE ESSENTIAL VALUES EXAMINED IN CANNABINOID TYPE-1 (CB1) RECEPTOR MUTANT MICE LIVING IN CLOSED ECONOMY

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Imane Hurel[1], Bastien Redon[1,2], Emma Mesguich[1], Giovanni Marsicano[1], Francis Chaouloff[1]

AIMS Pathological imbalances between feeding and exercise find their roots at the motivation level. Using an original instrumental task, we reported that cannabinoid type-1 receptors (CB_1Rs) located on GABAergic neurons are involved in the choice between palatable feeding and wheel-running (Muguruza et al., 2019). However, this task bears translational limits as mice were only daily exposed to it for a limited period (1 h) and were housed in cages without a running apparatus but with unlimited food. We thus investigated the role of CB_1Rs under closed-economy conditions wherein the prices for food and exercise were progressively increased over 12 days. **METHODS** Male/female mice bearing a constitutive (CB_1-KO) or a conditional deletion of CB_1R in GABAergic neurons (GABA-CB_1-KO) lived in operant chambers. Therein, they were able to feed a standard diet and to run, doing so under progressively increased fixed ratio (FR) reinforcement schedules (FR1 up to FR30). Reward essential values were obtained through demand curves (Hursh, 2014). **RESULTS** Compared to their respective wild-type male littermates, CB_1-KO and GABA-CB_1-KO mice displayed a decreased essential value for running, but not feeding. This decrease was amplified in females and partly reversed when CB_1Rs were selectively re-expressed in GABAergic neurons of male/female mice lacking CB_1R expression. **CONCLUSIONS** These findings indicate that CB_1Rs on GABAergic neurons are necessary, but only partly sufficient, for running motivation under closed economy conditions. Combining genetic and viral approaches, our present experiments are aimed at further dissecting the neurobiological circuits involved in running motivation.

Intracellular transport defects are observed in many neurological disorders. Analysis of animal models indicate that impaired transport can cause neurodegeneration or impinge on the development of neural circuits. In support of a similar role in human, mutations in DYNC1H1 encoding the heavy chain of Dynein and its partner BICD2, two core components of the intracellular transport machinery, are causing a rare neurodevelopmental motor neuron (MN) disease termed Spinal Muscular Atrophy with Lower Extremity Dominance (SMALED). Limb and even more leg-innervating MNs are preponderantly affected in SMALED suggesting a graded reliance on axonal transport among neuronal subtypes and that specific MN subtypes might be the most vulnerable cells to defects in this pathway. To approach the basis of this differential vulnerability, we have reprogrammed patient cells carrying a *BICD2* SMALED-inducing mutation into human induced pluripotent stem cells (hiPSC) as well as generated a mouse model with a similar mutation. Differentiating hiPSC into limb-innervating motor neurons and analysis of heterozygous and homozygous mouse embryonic spinal cords indicate that motor neuron subtype specification is not impacted in SMALED. Yet, homozygous mutant mice die at late gestation or early post-natal stages suggesting a deleterious effect of the mutation. We are now investigating in vivo and in vitro the consequences of the mutation on intracellular transport and MN subtype survival. The overarching aim of this study is to determine how mutations in core components of the transport machinery impact globally on intracellular transport but leads to the greater vulnerability of leg-innervating MNs.

Despite recent advances in promoting peripheral nerve regeneration after injury, it has not yet been possible to establish an alternative treatment to supplant traditional surgical methods as gold-standard approaches. Regenerative medicine, a therapeutic field alternative to conventional treatments, drew attention due to its versatility, multifactorial approach, and potential to revolutionize different medical fields, including Peripheral Nerve Injury (PNI). Among all options, the combination of cell-based therapies with biomaterials has been the most promising. In previous works, our research group has extensively studied the functional characteristics of olfactory mucosa mesenchymal stem cells (OM-MSCs), a type of MSCs with a high therapeutic potential for the promotion of nerve regeneration after PNI. In this work, the secretome produced and collected from OM-MSCs and Olfactory Ensheating Cells (OECs) was therapeutically applied to promote PNI. OM-MSCs and OECs in low passages were subjected to a conditioning process for 48h. Subsequently, the concentrated conditioned medium (CM) was applied to sciatic nerves of rats after neurotmesis, using Reaxon® as tube-guides and as containers for CM. Over 20 weeks, the animals were subjected to periodic functional assessments, with evaluation of the motor and sensory recovery, as well as gait pattern characterization. Preliminary functional results demonstrate the capacity of the two types of CM to promote an effective functional recovery over the study period, with results comparable to those observed after the application of the OM-MSCs themselves. The results are identical between OECs and OM-MSCs secretome, and it is not possible, so far, to define which is the best approach.

Spinal cord injury resulting from trauma essentially decreases the quality of human life. Numerous clues indicate that the limited endogenous regenerative potential is a result of interplay between inhibitory nature of mature nervous tissue and inflammatory actions of immune and glial cells. Knowledge gained from comparative studies on juvenile animals could draw attention to factors, which should be removed/added for more effective regenerative therapy of adults. In our study, we introduced the concept of minimal spinal cord injury (mSCI) with comparable impact on the spinal cord of Wistar rats at the age of full adulthood, preadolescence and neonatal period. The mechanism of injury is based on the unilateral incision of either 20 gauge (5% mSCI) needle tip according to stereotaxic coordinates into dorsal horn in lumbar spinal segment L4. The incision should harm similar amount of gray matter on coronal section (five percent) in each group of experimental animals. According to our results, impact causes mild injury with minimal adverse effects on neurological functions of animals, but still with effect on cells residing the ependymal layer, microglia and astroglia. Moreover, developing spinal cord exhibits superior regenerative potential compared to adulthood and thus indicates the importance of comparative neuroregenerative research in the future. The research was supported by Slovak Research and Development Agency under the contract No. APVV-19-0279 and VEGA grant no. 11/0706/20.

A NOVEL HYALURONIC ACID (HLA) BASED HYDROGEL FOR THE ENHANCEMENT OF PERIPHERAL NERVE REGENERATION

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Ciara Buckley[1], Ian Major[1], Therese Montgomery[2]
[1]Technological University of the Shannon, Midlands Midwest, Materials Research Institute, Athlone, Ireland, [2]Atlantic Technological University, School Of Science And Computing, Galway, Ireland

Introduction: Peripheral nerve injuries present significant healthcare and economic burdens with the majority of cases occurring due to trauma in the workforce. Despite all that is known about this condition, complete functional recovery remains difficult to obtain through current surgical methods. **Aim:** The aim of this research was to modify HLA to enable the 3D printing of hydrogel nerve conduits. Also, several neurotrophic compounds were screened in conjunction with HLA to assess any potential neurotrophic benefits to their inclusion in the final formulation. **Methods:** Methacrylated HLA (MeHLA) and thiolated HLA (HLASH) were synthesized to enable hydrogel formation via thiolene click-chemistry. The degree of modification (MoD) was calculated using FTIR and H^1-NMR. The HLA derivatives and photopolymerised samples were screened in a neuronal (SH-SY5Y) and glial (RT4 D6P2T) cell line using the resazaurin reduction assay in the presence and absence of putative neurotrophic compounds. **Results:** HLA was successfully substituted as confirmed by FTIR and H^1-NMR with MoD of 100% and 27% respectively. No cytotoxicity was observed in isolation or synergistically. Screening of the neurotrophic compounds revealed significantly increased glial cell proliferation after exposure to tyrosol (2-(4-Hydroxyphenol) ethanol) (****P<0.0001). **Conclusion:** HLA was modified to allow for thiolene click-chemistry reactions to produce hydrogels with unique viscoelastic properties. Some neurotrophic compounds were identified, and these compounds will be included in the final formulation prior to stereolithography 3D printing of hydrogel nerve conduits. Modulated HLA could have future applications in the development of improved nerve conduits for enhanced peripheral nerve repair post illness or injury.

In the following study we aim to develop a combinatory therapy for the treatment of acute spinal cord injury (SCI) using human fetal neural progenitor cells (hfNPCs) primed with a novel Rock inhibitor (Fasudil) nanoconjugate (PGA-SS-FAS). We have followed GMP-like procedures, which could be easily replicated in a clean room for subsequent clinical use, to isolate, expand and preserve "clinical grade" human neural progenitor cells (hfNPCs) derived from human spinal cords obtained from 19-21 week fetal abortions. *In vitro* expanded hfNPCs retained neuronal characteristics and multipotency after GMP-like procedures and 24h treatment with PGA-SS-FAS on hfNPCs induced neuronal differentiation and overcame neuritic retraction in the presence of lysophosphatidic acid (LPA), a Rho-Rock activator. For *in vivo* studies, immune-deficient female NU(*NCr)*-Foxn1^{nu} mice were subjected to SCI at the thoracic level T8 by compression and a total of 2.5x10^5 hfNPCs primed or not with PGA-SS-FAS (10% w/w; 50mm equimolecular concentration) for 24h were intramedullary injected in the lesion epicenter immediately after SCI induction. Control group of animals instead received injections of culture medium. We found that PGA-SS-FAS priming 1) enhanced hfNPCs activation and migration through the spinal cord injured tissue; 2) increased neuronal activation and 3) enhanced preservation of GABAergic inhibitory Lbx1 and glutamatergic excitatory Tlx3 somatosensory interneurons in the dorsal horns of the spinal cord. Thus, we have developed a "clinical grade" cell therapy using hfNPCs, following GMP guidelines, which in combination with PGA-SS-FAS priming for transplantation shows potential neuroprotective effects for clinical applications and treatment of acute SCIs.

EXTENSIVE OSSIFICATION OF THE PARASPINAL LIGAMENT MISDIAGNOSED AS A SUBDURAL CERVICAL HEMATOMA IN A PATIENT WITH VITAMIN D-RESISTANT RICKETS: A CASE REPORT

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Sang Hee Im[1], Eun Young Han[2], Kye Hee Cho[3]
[1]Severance Hospital, Yonsei University College of Medicine, Department And Research Institute Of Rehabilitation Medicine, Seoul, Korea, Republic of, [2]Jeju National University, Department Of Rehabilitation Medicine, Jeju, Korea, Republic of, [3]CHA Ilsan Medical Center, CHA University School of Medicine, Department Of Rehabilitation Medicine, Goyang, Korea, Republic of

We report a rare case of extensive ossification of the paraspinal ligaments misdiagnosed as subdural hematoma at cervical levels in a patient with vitamin D-resistant rickets. A 49-year-old woman with Vitamin D-resistant rickets (VDRR) reported neck and radiating pain in both shoulder and arm after a traffic accident. Neck and shoulder pain was alleviated after trigger point injection, however, the weakness of the upper extremities and gait disturbance had gradually worsened over 1 year. Magnetic resonance imaging showed hypointensity on T2 weighted imaging chronic spinal subdural hematoma leading to cervical cord compression, which extended on C1-C7 levels with cord signal changes and was diagnosed with chronic subdural hematoma. But CT imaging showed hyperintense ectopic ossification of the spinal ligaments and she was finally diagnosed with extensive ossification of the cervical paraspinal ligaments.

OZONE THERAPY AS A MINIMALLY-INVASIVE ALTERNATIVE IN PATIENTS WITH ACUTE LUMBAR DISC HERNIATION: A RANDOMIZED CLINICAL TRIAL

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Ali Jabbari[1], Ebrahim Rafie[2], Firooz Salehpour[2]
[1]urmia medical science university, Neurology, urmia, Iran, [2]tabriz medical science university, Neurosurgery, tabriz, Iran

Low back pain (LBP) management via conservative therapy with intervention fails in some cases. However, there are still many challenges to choose the best choice. Minimally-invasive techniques such as ozone therapy are emerging choices for surgery. In this Randomized phase III clinical trial (2017-19), one hundred patients admitted to Imam Reza Hospital (Tabriz-Iran) for herniated disk-induced LBP were randomly divided (shape- and color-identical envelopes) into two case and control groups. Patients in the case group were treated with ozone therapy plus medical therapy. Alternatively, patients in the control group received only conventional medical therapy. Primary outcomes such as changes in pain intensity (VAS) and basal test before and after treatment and also secondary outcomes like the amount of analgesic used were evaluated in the patients for two weeks, three months, and six months after surgery. Student T-test and Chi-square were compared for comparing the data. Mean pain intensities estimated by VAS and improvement of restless leg syndrome were not significantly different between the two groups two weeks (p=0.8), three months (p=0.5), and six months (p=0.9) after the intervention. Pain intensity was found to be lower in both groups after the intervention compared with before treatment (p=0.001 for both). Moreover, significant differences were found between the two groups in the Lasegue test two weeks (p=0.02) and six months (p=0.01) after the intervention. The application of ozone therapy not only improves clinical pain syndrome in LBP patients but also leads to improved medical treatment in these patients.

[1]Aix-Marseille University, CNRS, Laboratoire Des Neurosciences Cognitives, Marseille Cedex, France, [2]McGill University, Mcconnell Brain Imaging Centre, Montreal Neurological Institute, Montreal, Canada, [3]Swiss Federal Institute of Technology (EPFL), Lausanne University Hospital (CHUV) and University of Lausanne (UNIL), Defitech Center For Interventional Neurotherapies (neurorestore), Morges, Switzerland, [4]Aix-Marseille University, CNRS, Mri-center@cerimed,institut Des Neurosciences De La Timone (int), Marseille, France, [5]Aix-Marseille Université, INSERM, Institut Des Neurosciences Des Systèmes (ins), Marseille, France

Recent advances in functional magnetic resonance imaging (fMRI) have allowed investigation of the somatosensory and motor networks in the human spinal cord (Landelle et al. 2021; Rowald et al. 2022). Maps of different upper limb myotomes have been revealed by motor tasks (Kinany et al. 2019) but no fMRI study has investigated the precise location of muscle proprioceptive projections in the cervical spinal cord. Here, we explored the rostrocaudal activation patterns during upper limb proprioceptive stimulation to better characterize the spinal proprioceptive circuits in 14 healthy volunteers. We exploited amagnetic vibrators to specifically stimulate proprioceptive afferences innervating six muscles in wrist, elbow and shoulder joints of participants' left arm. This kind of stimulation activates muscle spindles and elicits illusory sensations of movement by recruiting full sensorimotor pathways (Kavounoudias et al. 2008). Functional MR images were acquired between C2 and C8 vertebrae and preprocessed with the Spinal Cord Toolbox (De Leener et al. 2017). Group-level analysis revealed a rostrocaudal organization of proprioceptive projections from C3 to C7-C8 that matched the expected proximo-distal location of upper-limb proprioceptive neurons, although a substantial inter-subject variability was observed. Activations were primarily distributed along the extent of the left dorsal hemicord, though ventral and contralateral hemicords were also activated to a lesser extent. This study reveals muscle proprioceptive maps of the cervical spinal cord based on functional MR recordings. These maps are essential for improving our understanding of the healthy and injured spinal cord, guiding neurosurgical interventions, and helping the design of neuroprosthetic treatments.

Intraoperative CSF pressure (CSFP) monitoring has been previously pioneered in patients with degenerative cervical myelopathy (DCM) aiming to estimate effective cord decompression. The intraoperative setting is different from the postoperative one because of mechanical ventilation and anesthesia, which influence CSFP dynamics due to the interaction between the CSF compartment and the cardiorespiratory system. This is mediated by changes in CSF flow and the effect of variations in CO_2 levels on the vascular bed. Therefore, analyzing CSFP dynamics needs to account for ventilation and anesthesia. In this study, we investigated intrathecal CSFP metrics in 17 patients with DCM who underwent surgical decompression. Intraoperative data (i.e., patients mechanically ventilated and anesthetized) were analyzed in the time window after decompression to limit interference with cord compression. In the postoperative setting, patients were awake and breathing spontaneously. Intraoperative baseline CSFP had a median and interquartile range of 10.8 [4.3] mmHg and increased 1.6-fold to 16.3 [5.8] mmHg post-operatively. Similarly, cardiac-induced CSFP peak-to-trough amplitude (CSFPp) was 0.6 [0.9] and increased 3-fold to 1.7 [3.2]. In contrast, the breathing modulation amplitude declined from 1.9 [1.4] mmHg to 0.7 [1.1] mmHg. During weaning (N=3), there was a continuous rise of CSFP and CSFPp, up to 9.6 [4.2] and 3.9 [3.3] mmHg, respectively. Our findings highlight that intraoperative setting significantly impacts CSFP dynamics and the underlying mechanisms should be carefully considered in data recording and interpretation, in particular when comparing CSFP across different settings.

TEMPORAL DYNAMICS OF NEUROINFLAMMATION FOLLOWING CONTROLLED CORTICAL IMPACT TRAUMATIC BRAIN INJURY IN JUVENILE AND ADULT MICE

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Hasna Boumenar[1], Zahra Al-Khateeb[2], Jordi Tremoleda[2], A. T. Michael-Titus[2]
[1]Queen Mary University of London, London, United Kingdom, School Of Biological And Behavioural Sciences, London, United Kingdom, [2]Queen Mary University of London, Blizard Institute, London, United Kingdom

AIMS: Characterisation of neuroinflammation in juvenile and adult mice following Controlled Cortical Impact Traumatic Brain Injury (TBI) at 5 and 35 days post-injury (dpi), to assess differences in the injury response in the immature vs. the mature brain.
METHODS: TBI was induced using the Controlled Cortical Impact (CCI) model in juvenile postnatal day 30 (P30) and adult (P70-84) CD1 male mice. Mice were humanely killed at 5 and 35 dpi, along with control groups (naïve and craniotomy-sham). Brain tissue was analysed by immunofluorescence using markers for astrocytes (GFAP), and microglia (P2Y12 and Iba1). Expression analysis was carried out, along with morphological analysis, to identify activated microglia and astrocytes. Heat maps were produced to show GFAP and Iba1 distribution patterns, along with the incidence of cellular activation.
RESULTS: A higher P2Y12 expression was seen in juveniles compared to adults post-TBI at 5 dpi ($P= 0.0215$), whilst adults showed a higher expression than juveniles after TBI at 35 dpi ($P = 0.0160$). A reduced P2Y12 expression was seen at 35 dpi in juvenile TBI compared to 5 dpi ($P < 0.001$). Morphology analysis and heat maps showed activated astrocytes in hippocampal and cortical regions around the injury in adults post-CCI at 35 dpi. Higher activated microglia were found around the injury lesion in the adult CCI group at 5 dpi and this persisted at 35 dpi.
CONCLUSIONS: Adult mice experienced sustained neuroinflammation peri-lesionally post-injury, whilst juvenile mice appeared to experience a faster resolving local neuroinflammation reaction than adults.

In children, traumatic brain injury (TBI) is an underestimated pathology that can generate a long-term handicap with difficulties at school, social isolation and possibly a lifelong impact. We used a model of pediatric TBI on postnatal day (P) seven male mice. We investigated microglial activation, astrogliosis, white matter lesions and behavioral disorders on P45 mice. Study of microglial phenotype by RT-qPCR showed that TBI induced a mixed population of microglial cells with pro-inflammatory, anti-inflammatory and immunomodulatory markers particularly three days after the injury; besides seven days after, the TBI microglial activation seemed to be completely resolved. Additionally, immunochemistry labelling revealed an astroglial scar and a neuronal loss in the impact region in association with white matter loss at P45; electronic microscopy showed also a decrease of myelinated axons in TBI mice. This results were also confirmed in diffusion tensor imaging with an important alteration of the anisotropic fraction, also functional ultrasound imaging with fUS showed brain cerebral connectivity alteration. Ultrasonic vocalizations recorded at P8 showed a decrease in the number and the duration of USV calls in TBI mice. Also, TBI led to social deficiency at P45 during a social interaction test adapted from the three-room test. These results are very promising, and encourage the study of the mechanisms involved in post-concussion syndrome and more particularly the involvement of microglial activation. This study could allow identification of signaling pathways and possibly new therapeutic targets in order to care for post- traumatic disorder patients.

A simple novel approach for detecting blood-brain barrier permeability using GPCR internalization.
Impairment of blood-brain barrier (BBB) is involved in numerous neurological diseases from developmental to aging stages. Reliable imaging of increased BBB permeability is therefore crucial for basic research and preclinical studies. Today, the analysis of extravasation of exogenous dyes is the principal method to study BBB leakage. However, these procedures are challenging to apply in pups and embryos and may appear difficult to interpret. Here we introduce a novel approach based on agonist-induced internalization of a neuronal G protein-coupled receptor widely distributed in the mammalian brain, the somatostatin receptor type 2 (SST2).

Global mean diffusivity: A radiomarker discriminating good outcome long term after traumatic brain injury.
Traumatic brain injury (TBI) is a chronic pathology responsible for cognitive disorders impacting outcome. Global clinical outcome several years after TBI may be associated with anatomical sequelae. Anatomical lesions are not well described

because characterizing diffuse axonal injury and brain atrophy require using specific MRI sequences with quantitative measures. The best radiologic parameter to describe the lesions long term after TBI is not known.

Is Anatomical Variations a Risk Factor for Cerebral Vasospasm in Anterior Communicating Complex Aneurysms Rupture?
Background and Purpose- One-third of ruptured aneurysms are located on the anterior communicating complex with high prevalence of anatomic variations of this arterial segment. In this study, we hypothesized that anatomic variations of the anterior communicating complex increase the risk of angiographic vasospasm. Methods- Retrospective study of prospectively collected data from a monocentric subarachnoid hemorrhage cohort of patients admitted to neurointensive care between 2002 and 2018. Univariate followed by multivariate logistic regression analysis was used to identify factors associated with angiographic vasospasm. Results- One thousand three hundred seventy-four patients with aneurismal subarachnoid hemorrhage were admitted to our institution; 29.8% (n=410) were related to an anterior communicating complex aneurysm rupture; 9.2% (n=38) of them showed an anterior communicating artery variation. Angiographic vasospasm was diagnosed in 55.6% of this subgroup (vs 28.1%, =0.003). In the multivariate analysis, external ventricular drain (2.2 [1.32-3.65], =0.003) and anterior communicating artery variation (2.40 [1.2-4.9], =0.04) were independently and significantly associated with angiographic vasospasm, while age above 60 years (0.3 [0.2-0.7]; =0.002) was a protective factor. However, anterior communicating artery variation was not statistically associated with ischemic vasospasm or poor neurological outcome after anterior communicating artery aneurysm rupture. Conclusions- Anatomic variation of anterior communicating artery could be a new biomarker to identify patients at risk to develop angiographic vasospasm post-subarachnoid hemorrhage. External validation cohorts are necessary to confirm these results.

Safe short circuit in cataract surgery: Incidence and risk factors for intraoperative medical action.
Cataract surgery has become the most frequent surgical procedure performed every year in Western countries. Perioperative patient circuit has to be adapted to the important medical needs and progress. Hence, a secure short circuit (SSC) for surgeries of the anterior segment of the eye under topical anaesthesia was created. Patients included in the circuit are selected first by surgeons and answer a medical questionnaire, they do not have any preoperative evaluation by anaesthesiologist, are monitored during surgery by the surgical team and in case of problem an intraoperative medical action (IMA) can be performed. We conducted a retrospective observational incidence study of the occurrence of the IMA, followed by a case control study. The primary outcome was to identify risk factors of IMA among the patients' medical history. Out of 2744 screened patients, 1592 patients were included during the period of November 2015 to November 2017. The rate of

IMA was 5%, 81% of them presenting with intraoperative high blood pressure (HBP). In the case control study part, stepwise regression analysis revealed that a history of HBP and insulin-dependent diabetes (IDD) was significantly correlated with IMA (respectively, adjusted odds ratio 1.7, P=0.005 and 2.6, P=0.002). The low incidence of IMA showed that the SSC is a safe tool thanks to a selection and an optimised and secure pathway. A history of HBP and IDD was significantly associated with the occurrence of IMA. Therefore, an optimisation of the perioperative period would be beneficial in these cases.

KETOGENIC DIET PROTECTS THE BRAIN AGAINST WEIGHT DECREASE AFTER TRAUMATIC BRAIN INJURY

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Zuzanna Rauk, Wojciech Kosiek, Zuzanna Setkowicz-Janeczko
Jagiellonian University, Laboratory Of Experimental Neuropathology, Institute Of Zoology And Biomedical Research, Cracow, Poland

Traumatic brain injury (TBI) is associated with pathological changes in nervous tissue, related to neuronal death and gliosis. Ketogenic diet (KD) is one of the potential neuroprotective strategies, that may prevent brain posttraumatic remodelling. The aim of this study was to determine the influence of KD on animal state after TBI and glial scar formation. Rats were divided into groups obtaining standard or ketogenic diet (SD and KD respectively) from postnatal day 27 (P27). On P30 penetrating brain injury was induced in cerebral cortex in half of the animals from each group. The body weight, blood level of glucose and ketone bodies were monitored after TBI. Different cohorts of rats were perfused 2, 8, 16 and 30 days after TBI, brains were dissected and weighted. Lower body mass of injured KD-fed animals in comparison to SD-fed rats was observed in all age groups, which remains consistent with negative correlation of blood ketone bodies level and body weight. TBI resulted in lower body mass in rats on ketogenic diet on P60, in comparison to KD-fed uninjured group, whereas no such effect was observed in animals on SD. Nonetheless, in SD-fed group brain mass was significantly lower in rats subjected to TBI procedure than in control animals. Interestingly, there were no differences in brain mass between control and injured rats fed with KD. To conclude, KD, despite lowering rats' body mass, prevents brain weight decrease after TBI. Histological analysis will provide information about its influence on glial scar formation.

Ketogenic diet impairs neurological development of neonatal rats and affects biochemical composition of maternal brains: evidence of functional recovery in pups.
The ketogenic diet (KD) is a type of diet in which the intake of fats significantly increases at the cost of carbohydrates while maintaining an adequate amount of proteins. This kind of diet has been successfully used in clinical therapies of drug-resistant epilepsy, but there is still insufficient evidence on its safety when used in pregnancy. To assess KD effects on the course of gestation and fetal development, pregnant females were fed with: (i) KD during pregnancy and lactation periods (KD group), (ii) KD during pregnancy replaced with ND from the day 2 postpartum (KDND group) and (iii) normal diet alone (ND group). The body mass, ketone and glucose blood levels, and food intake were monitored. In brains of KD-fed females, FTIR biochemical analyses revealed increased concentrations of lipids and ketone groups containing molecules. In offspring of these females, significant reduction of the body mass and delays in neurological development were detected. However, replacement of KD with ND in these females at the beginning of lactation period led to regainment of the body mass in their pups as early as on the postnatal day 14. Moreover, the vast majority of our neurological tests detected functional recovery up to the normal level. It could be concluded that the ketogenic diet undoubtedly affects the brain of pregnant females and impairs the somatic and neurological development of their offspring. However, early postnatal withdrawal of this diet may initiate compensatory processes and considerable functional restitution of the nervous system based on still unrecognized mechanisms.

A NOVEL MODEL FOR MULTIPLEXED, TRIDIMENSIONAL ANALYSIS OF CORTICAL REGENERATION UPON BRAIN DAMAGE IN VIVO

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Ana González Manteiga[1], Carmen Navarro-González[1], José Saborit Torres[2], Angela Rodriguez-Prieto[1], Yaiza Domínguez Canterla[1], Tomás Armenteros Barron[1], Valentina Sebestyén[1], Pietro Fazzari[1]
[1]Centro de Investigación Príncipe Felipe, Lab Of Cortical Circuits In Health And Disease, Valencia, Spain, [2]Centro de Investigación Príncipe Felipe, Neurobiology, Valencia, Spain

Brain damage is the major cause of adult disabilities, specifically on the elderly population. In this paradigm, there are a variety of biological events to consider in brain injury: neuronal death, neuroinflammation, loss of synapses and alteration in neuronal circuitry. The rewiring process upon brain damage is poorly understood and there is no pharmacological treatment available. Here, we designed a novel *in vivo* model to investigate cortical rewiring upon brain injury. Briefly, we trace contralateral callosal projection neurons with viral vectors to study the response upon a controlled mechanical lesion of the hindlimb motor cortex. To analyze functional motor outcome after injury, we perform a battery of motor behavioral test. Finally, we design a multiplexed and tridimensional semi-automatic analysis using coronal brain section. This allows us to analyze different labeling from the same animals: since 3D reconstruction of the brain to subcellular resolution, using synaptic markers. This novel model presents a variety of advantages to study cortical regeneration and rewiring upon injury. First, the injury protocol produces a consistent and focal damage on the cortical motor area, facilitating the study of contralateral projections and giving functional motor outcome. Secondly, combining conventional confocal microscopy with semi-automated 3D reconstruction, this methodology permits since the study of subcellular structures, such as synaptic buttons in different brain areas, to a reconstruction of the cortical innervation around the injured area. Hence, this innovative experimental approach will contribute in a deeper understand of molecular and cellular interactions in cortical regeneration upon brain damage.

A Scalable Method to Study Neuronal Survival in Primary Neuronal Culture with Single-cell and Real-Time Resolution.
Neuronal loss is at the core of many neuropathologies, including stroke, Alzheimer's disease, and Parkinson's disease. Different methods were developed to study the process of neuronal survival upon cytotoxic stress. Most methods are based on biochemical approaches that do not allow single-cell resolution or involve complex and costly methodologies. Presented here is a versatile, inexpensive, and effective experimental paradigm to study neuronal survival. This method takes advantage of sparse fluorescent labeling of the neurons followed by live imaging and automated quantification. To this aim, the neurons are electroporated to express fluorescent markers and co-cultured with non-electroporated neurons to easily regulate cell density and increase survival. Sparse labeling by electroporation allows a simple and robust automated quantification. In addition, fluorescent labeling can be combined with the co-expression of a gene of interest to study specific molecular pathways. Here, we present a model of stroke as a neurotoxic model, namely, the oxygen-glucose deprivation (OGD) assay, which was performed in an affordable and robust homemade hypoxic chamber. Finally, two different workflows are described using IN Cell Analyzer 2200 or the open-source ImageJ for image analysis for semi-automatic data processing. This workflow can be easily adapted to different experimental models of toxicity and scaled up for high-throughput screening. In conclusion, the described protocol provides an approachable, affordable, and effective in vitro model of neurotoxicity, which can be suitable for testing the roles of specific genes and pathways in live imaging and for high-throughput drug screening.

Nrg1 haploinsufficiency alters inhibitory cortical circuits.
Neuregulin 1 (NRG1) and its receptor ERBB4 are schizophrenia (SZ) risk genes that control the development of both excitatory and inhibitory cortical circuits. Most studies focused on the characterization ErbB4 deficient mice. However, ErbB4

deletion concurrently perturbs the signaling of Nrg1 and Neuregulin 3 (Nrg3), another ligand expressed in the cortex. In addition, NRG1 polymorphisms linked to SZ locate mainly in non-coding regions and they may partially reduce Nrg1 expression. Here, to study the relevance of Nrg1 partial loss-of-function in cortical circuits we characterized a recently developed haploinsufficient mouse model of Nrg1 (Nrg1). These mice display SZ-like behavioral deficits. The cellular and molecular underpinnings of the behavioral deficits in Nrg1 mice remain to be established. With multiple approaches including Magnetic Resonance Spectroscopy (MRS), electrophysiology, quantitative imaging and molecular analysis we found that Nrg1 haploinsufficiency impairs the inhibitory cortical circuits. We observed changes in the expression of molecules involved in GABAergic neurotransmission, decreased density of Vglut1 excitatory buttons onto Parvalbumin interneurons and decreased frequency of spontaneous inhibitory postsynaptic currents. Moreover, we found a decreased number of Parvalbumin positive interneurons in the cortex and altered expression of Calretinin. Interestingly, we failed to detect other alterations in excitatory neurons that were previously reported in ErbB4 null mice suggesting that the Nrg1 haploinsufficiency does not entirely phenocopies ErbB4 deletions. Altogether, this study suggests that Nrg1 haploinsufficiency primarily affects the cortical inhibitory circuits in the cortex and provides new insights into the structural and molecular synaptic impairment caused by NRG1 hypofunction in a preclinical model of SZ.

OPTIMIZED PROTOCOL REVEALS MODULATION OF ANESTHETIC PRECONDITIONING BY GENETIC BACKGROUND IN A DROSOPHILA MELANOGASTER (FRUIT FLY) MODEL OF POLYTRAUMA WITH TRAUMATIC BRAIN INJURY (TBI)

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Misha Perouansky[1], Dena Jonson-Schlitz[1], David Wassarman[2]
[1]University of Wisconsin SMPH, Anesthesiology, Madison, United States of America, [2]University of Wisconsin, Medical Genetics, Madison, United States of America

Anesthetic preconditioning (AP) with volatile general anesthetics (VGAs) prior to injury protects a variety of organs from damage caused by ischemia and subsequent reperfusion. We have previously shown that exposure of flies to the VGAs isoflurane (ISO) and sevoflurane (SEVO) prior to TBI substantially reduces early mortality and extends lifespan (J. Fischer 2018). The aim of this project is to test the hypothesis that the efficacy of AP is determined by genetic factors. Methods: We subjected different Drosophila strains to TBI with or without AP using exposure to different doses of ISO and compared mortality at 24 h after TBI (Mi_{24}). We used young adult (1-7 day old) w^{1118} and Canton-S flies cultured at 25°C on cornmeal-molasses food. TBI was induced using a High-Impact Trauma (HIT) device (R. Katzenberger 2013), anesthesia was administered using the Serial Anesthesia Array (SAA) (Z. Olufs 2018). Results: Maximal suppression of the Mi_{24} was achieved with 30 min of 2% isoflurane. AP reduced Mi_{24} by >50% in w^{1118} but had no effect in Canton-S flies. Conclusions: Our findings are significant because they demonstrate that a brief exposure to VGAs effectively suppresses mortality after TBI. Since cellular and molecular responses to damage are likely to be similar across tissues and evolutionarily conserved between flies and mammals while exposure to anesthetics is largely disregarded in most animal models of TBI, genetic background may further contribute to the difficulty in translating pharmacologic brain protection strategies into clinical practice.

OCULAR MOTOR DEFICITS AND RECOVERY IN AUSTRALIAN RULES FOOTBALL FOLLOWING A SPORTS-RELATED CONCUSSION

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Georgia F Symons[1], William O'Brien[1], Larry Abel[2], Terence O'Brien[1,3], Scott Kolbe[1], Joanne Fielding[1], Sandy Shultz[1], Meaghan Clough[1]
[1]Monash University, Neuroscience, Melbourne, Australia, [2]The University of Melbourne, Optometry And Vision Sciences, Melbourne, Australia, [3]Alfred Health, Neurology, Melbourne, Australia

Aims: Identifying when a sports-related concussion (SRC) has occurred, and determining when an athlete has recovered, remains a challenge for caretakers as clinical practices remain highly subjective. To assess the utility of ocular motor (OM) assessment, a demonstrated objective marker of cognitive function, to identify cognitive abnormalities and monitor recovery after an SRC. **Methods:**18 footballers with an SRC (12 males, 6 females) completed OM tasks at 2-, 6- and 13-days post-SRC, and performance was compared to their baseline (i.e., preseason before SRC) measures. OM tasks included; visually-guided (VG), antisaccade (AS) and memory-guided saccade (MG) and require an eye movement towards, away from, and to a remembered target respectively. Processing speed and visual spatial accuracy on these tasks was compared over time and between sex using a linear mixed effect model. **Results:** AS processing speed in females was significantly worse at 2-days compared to baseline (p<0.001), improving at 7-days (p=0.004), and returning to baseline as 13-days post-SRC (p<0.001). This recovery trajectory aligned with self-reported post-SRC symptoms. However, both males and females demonstrated significantly poorer visual spatial planning at 2-, 7- and 13-days post-SRC compared to baseline (p<0.05). Findings on the VG and MG tasks were of minimal clinical relevance. **Conclusion:** While AS processing speed recovered within 2-week in females, persistent visual spatial deficits may be indicative of prolonged cognitive dysfunction even after symptom resolution. These findings are consistent with emerging literature, and suggest that the AS task may have utility to objectively monitor cognitive abnormalities and recovery post-SRC.

Serum Protein Biomarkers of Inflammation, Oxidative Stress, and Cerebrovascular and Glial Injury in Concussed Australian Football Players.
Clinical decisions related to sports-related concussion (SRC) are challenging, because of the heterogenous nature of SRC symptoms coupled with the current reliance on subjective self-reported symptom measures. Sensitive and objective methods that can diagnose SRC and determine recovery would aid clinical management, and there is evidence that SRC induces changes in circulating protein biomarkers, indicative of neuroaxonal injury. However, potential blood biomarkers related to other pathobiological responses linked to SRC are still poorly understood. Therefore, here we analyzed blood samples from concussed (male = 30; female = 9) and non-concussed (male = 74; female = 27) amateur Australian rules football players collected during the pre-season (i.e., baseline), and at 2, 6, and 13 days post-SRC to determine time-dependent changes in serum levels of biomarkers related to glial (i.e., brain lipid-binding protein [BLBP]; phosphoprotein enriched in astrocytes 15) and cerebrovascular injury (i.e., von Willebrand factor, claudin-5), inflammation (i.e., fibrinogen, high mobility group box protein 1), and oxidative stress (i.e., 4-hydroxynoneal). In females, BLBP levels were significantly decreased at 2 days post-SRC compared with their pre-season baseline; however, area under the receiver operating characteristic curve (AUROC) analysis found that BLBP was unable to distinguish between SRC and controls. In males, AUROC analysis revealed a statistically significant change at 2 days post-SRC in the serum levels of 4-hydroxynoneal, however the associated AUROC value (0.6373) indicated little clinical utility for this biomarker in distinguishing SRC from controls. There were no other statistically significant findings. These results indicate that the serum biomarkers tested in this study hold little clinical value in the management of SRC at 2, 6, and 13 days post-injury.

Cognitive ocular motor deficits and white matter damage chronically after sports-related concussion.
A history of concussion has been linked to long-term cognitive deficits; however, the neural underpinnings of these abnormalities are poorly understood. This study recruited 26 asymptomatic male Australian footballers with a remote history of concussion (i.e. at least six months since last concussion), and 23 non-collision sport athlete controls with no history of concussion. Participants completed three ocular motor tasks (prosaccade, antisaccade and a cognitively complex switch task) to assess processing speed, inhibitory control and cognitive flexibility, respectively. Diffusion tensor imaging data were acquired using a 3 T MRI scanner, and analysed using tract-based spatial statistics, to investigate white matter abnormalities and how they relate to ocular motor performance. Australian footballers had significantly slower adjusted antisaccade latencies compared to controls (= 0.035). A significant switch cost (i.e. switch trial error > repeat trial error) was also found on the switch task, with Australian footballers performing increased magnitude of errors on prosaccade switch trials relative to prosaccade repeat trials (= 0.023). Diffusion tensor imaging analysis found decreased fractional anisotropy, a marker of white matter damage, in major white matter tracts (i.e. corpus callosum, corticospinal tract) in Australian footballers relative to controls. Notably, a larger prosaccade switch cost was significantly related to reduced fractional anisotropy in anterior white matter regions found to connect to the prefrontal cortex (i.e. a key cortical ocular motor centre involved in executive functioning and task switching). Taken together, Australian footballers with a history of concussion have ocular motor deficits indicative of poorer cognitive processing speed and cognitive flexibility, which are related to reduce white matter integrity in regions projecting to important cognitive ocular motor structures. These findings provide novel insights into the neural mechanisms that may underly chronic cognitive impairments in individuals with a history of concussion.

White and Gray Matter Abnormalities in Australian Footballers With a History of Sports-Related Concussion: An MRI Study.
Sports-related concussion (SRC) is a form of mild traumatic brain injury that has been linked to long-term neurological abnormalities. Australian rules football is a collision sport with wide national participation and is growing in popularity worldwide. However, the chronic neurological consequences of SRC in Australian footballers remain poorly understood. This study investigated the presence of brain abnormalities in Australian footballers with a history of sports-related concussion (HoC) using multimodal MRI. Male Australian footballers with HoC (n = 26), as well as noncollision sport athletes with no HoC (n = 27), were recruited to the study. None of the footballers had sustained a concussion in the preceding 6 months, and all players were asymptomatic. Data were acquired using a 3T MRI scanner. White matter integrity was assessed using diffusion tensor imaging. Cortical thickness, subcortical volumes, and cavum septum pellucidum (CSP) were analyzed using structural MRI. Australian footballers had evidence of widespread microstructural white matter damage and cortical thinning. No significant differences were found regarding subcortical volumes or CSP. These novel findings provide evidence of persisting white and gray matter abnormalities in Australian footballers with HoC, and raise concerns related to the long-term neurological health of these athletes.

Diffusion Imaging Reveals Sex Differences in the White Matter Following Sports-Related Concussion.
Sports-related concussion (SRC) is a serious health concern. However, the temporal profile of neuropathophysiological changes after SRC and how these relate to biological sex are still poorly understood. This preliminary study investigated whether diffusion-weighted magnetic resonance imaging (dMRI) was sensitive to neuropathophysiological changes following SRC; whether these changes were sex-specific; and whether they persisted beyond the resolution of self-reported symptoms. Recently concussed athletes (n = 14), and age- and education-matched nonconcussed control athletes (n = 16), underwent MRI 24-48-h postinjury and again at 2-week postinjury (i.e., when cleared to return-to-play). Male athletes reported more symptoms and greater symptom severity compared with females. dMRI revealed white matter differences between athletes with SRC and their nonconcussed counterparts at 48-h postinjury. These differences were still present at 2-week postinjury, despite SRC athletes being cleared to return to play and may indicate increased cerebral vulnerability beyond the resolution of subjective symptoms. Furthermore, we identified sex-specific differences, with male SRC athletes having significantly greater white matter disruption compared with female SRC athletes. These results have important implications for the management of concussion, including guiding return-to-play decisions, and further improve our understanding regarding the role of sex in SRC outcomes.

Prolonged elevation of serum neurofilament light after concussion in male Australian football players.

Biomarkers that can objectively guide the diagnosis of sports-related concussion, and consequent return-to-play decisions, are urgently needed. In this study, we aimed to determine the temporal profile and diagnostic ability of serum levels of neurofilament light (NfL), ubiquitin carboxy-terminal hydrolase L1 (UCHL1), glial fibrillary acidic protein (GFAP), and tau in concussed male and female Australian footballers.

Elevated Serum Interleukin-1β Levels in Male, but not Female, Collision Sport Athletes with a Concussion History.
It is increasingly reported that a history of concussion may be associated with chronic deleterious consequences. While the pathophysiology that contributes to these consequences is not well understood, neuroinflammation is postulated to be critical. Activation of multi-protein complexes termed inflammasomes, a key component of this inflammatory response, has been reported in more severe TBIs; however, it has not been investigated in milder TBIs, such as concussion. This study investigated serum levels of interleukin (IL)-1β and IL-18 (key proteins activated downstream of these inflammasomes) at acute, sub-acute, and chronic time-points post-concussion. We recruited 105 Australian footballers (65 male, 40 female) during the pre-season, then prospectively followed these players for the occurrence of concussion during the season. At baseline, 58 footballers reported a previous concussion history, and 47 reported no previous concussion history. Additionally, 25 players sustained a mid-season concussion and were sampled at 2, 6, and 13 days post-concussion. Serum levels of IL-1β and IL-18 were quantified using highly sensitive Simoa HD-X Analyzer assays. At baseline, IL-1β levels were higher in male, but not female, footballers with a previous concussion history compared with footballers with no concussion history. There was also a positive correlation between years of collision sport participation and IL-18 levels in males. No evidence was found in males or females to indicate that IL-1β or IL-18 levels differed at 2, 6, or 13 days post-concussion. These findings provide novel insights into potential sex-specific physiological consequences of concussion, and suggest that neuroinflammation may be persistent chronically following concussion in male athletes.

33117257: Major BP, McDonald SJ, O'Brien WT, Symons GF, Clough M, Costello D, Sun M, Brady RD, Mccullough J, Aniceto R, Lin IH, Law M, Mychasiuk R, O'Brien TJ, Agoston DV, Shultz SR
Serum Protein Biomarker Findings Reflective of Oxidative Stress and Vascular Abnormalities in Male, but Not Female, Collision Sport Athletes.
Studies have indicated that concussive and sub-concussive brain injuries that are frequent during collision sports may lead to long-term neurological abnormalities, however there is a knowledge gap on how biological sex modifies outcomes. Blood-based biomarkers can help to identify the molecular pathology induced by brain injuries and to better understand how biological sex affects the molecular changes. We therefore analyzed serum protein biomarkers in male (= 50) and female (= 33) amateur Australian rules footballers (i.e., Australia's most participated collision sport), both with a history of concussion (HoC) and without a history of concussion (NoHoC). These profiles were compared to those of age-matched control male (= 24) and female (= 20) athletes with no history of neurotrauma or participation in collision sports. Serum levels of protein markers indicative of neuronal, axonal and glial injury (UCH-L1, NfL, tau, p-tau, GFAP, BLBP, PEA15), metabolic (4-HNE) and vascular changes (VEGF-A, vWF, CLDN5), and inflammation (HMGB1) were assessed using reverse phase protein microarrays. Male, but not female, footballers had increased serum levels of VEGF-A compared to controls regardless of concussion history. In addition, only male footballers who had HoC had increased serum levels of 4-HNE. These findings being restricted to males may be related to shorter collision sport career lengths for females compared to males. In summary, these findings show that male Australian rules footballers have elevated levels of serum biomarkers indicative of vascular abnormalities (VEGF-A) and oxidative stress (4-HNE) in comparison to non-collision control athletes. While future studies are required to determine how these findings relate to neurological function, serum levels of VEGF-A and 4-HNE may be useful to monitor subclinical neurological injury in males participating in collision sports.

The NLRP3 inflammasome in traumatic brain injury: potential as a biomarker and therapeutic target.
There is a great clinical need to identify the underlying mechanisms, as well as related biomarkers, and treatment targets, for traumatic brain injury (TBI). Neuroinflammation is a central pathophysiological feature of TBI. NLRP3 inflammasome activity is a necessary component of the innate immune response to tissue damage, and dysregulated inflammasome activity has been implicated in a number of neurological conditions. This paper introduces the NLRP3 inflammasome and its implication in the pathogenesis of neuroinflammatory-related conditions, with a particular focus on TBI. Although its role in TBI has only recently been identified, findings suggest that priming and activation of the NLRP3 inflammasome are upregulated following TBI. Moreover, recent studies utilizing specific NLRP3 inhibitors have provided further evidence that this inflammasome is a major driver of neuroinflammation and neurobehavioral disturbances following TBI. In addition, there is emerging evidence

that circulating inflammasome-associated proteins may have utility as diagnostic biomarkers of neuroinflammatory conditions, including TBI. Finally, novel and promising areas of research will be highlighted, including the potential involvement of the NLRP3 inflammasome in mild TBI, how factors such as biological sex may affect NLRP3 activity in TBI, and the use of emerging biomarker platforms. Taken together, this review highlights the exciting potential of the NLRP3 inflammasome as a target for treatments and biomarkers that may ultimately be used to improve TBI management.

The Neurological Consequences of Engaging in Australian Collision Sports.
Collision sports are an integral part of Australian culture. The most common collision sports in Australia are Australian rules football, rugby union, and rugby league. Each of these sports often results in participants sustaining mild brain traumas, such as concussive and subconcussive injuries. However, the majority of previous studies and reviews pertaining to the neurological implications of sustaining mild brain traumas, while engaging in collision sports, have focused on those popular in North America and Europe. As part of this 2020 International Neurotrauma Symposium special issue, which highlights Australian neurotrauma research, this article will therefore review the burden of mild brain traumas in Australian collision sports athletes. Specifically, this review will first provide an overview of the consequences of mild brain trauma in Australian collision sports, followed by a summary of the previous studies that have investigated neurocognition, ocular motor function, neuroimaging, and fluid biomarkers, as well as neuropathological outcomes in Australian collision sports athletes. A review of the literature indicates that although Australians have contributed to the field, several knowledge gaps and limitations currently exist. These include important questions related to sex differences, the identification and implementation of blood and imaging biomarkers, the need for consistent study designs and common data elements, as well as more multi-modal studies. We conclude that although Australia has had an active history of investigating the neurological impact of collision sports participation, further research is clearly needed to better understand these consequences in Australian athletes and how they can be mitigated.

Introduction: The diagnosis and management of sports-related concussion (SRC) remains notoriously difficult due to a significant reliance on subjective signs and symptoms. Recent studies have shown that blood levels of glial fibrillary acidic protein (GFAP) and neurofilament light (NfL) are promising indicators of neuropathology after SRC. Nonetheless, greater understanding of their temporal profiles, and association with clinical and neuropathological recovery, are required to determine exactly when and how these biomarkers might be used to assist clinical decisions. **Aim:** To generate the most comprehensive profile of serum GFAP and NfL changes after SRC to date. **Methods:** Male and female Australian football players with SRC were recruited from amateur Australian football clubs in the 2021 and 2022 seasons. Players that had sustained a musculoskeletal injury, and un-injured players, were recruited as controls. Blood was collected for serum GFAP and NfL quantification with SIMOA assays at 24-hours, and 1-, 2-, 4-, 6-, 8-, 12-, and 26-weeks. SRC-related symptoms and neurocognitive measures were also assessed. **Results:** Recruitment and analysis for this study is ongoing (2021 SRC n = 35); however, group level analysis revealed an acute rise and rapid resolution of serum GFAP after SRC, and a delayed but prolonged elevation of serum NfL. Some heterogeneity was apparent, with preliminary trajectory analysis revealing the likely presence of distinct clusters of biomarker trajectories. Analysis of these profiles and associations with clinical outcomes is ongoing. **Conclusion:** This study provides further evidence of the potential of serum GFAP and NfL as sensitive indicators of neuropathology after SRC.

Serum Protein Biomarkers of Inflammation, Oxidative Stress, and Cerebrovascular and Glial Injury in Concussed Australian Football Players.
Clinical decisions related to sports-related concussion (SRC) are challenging, because of the heterogenous nature of SRC symptoms coupled with the current reliance on subjective self-reported symptom measures. Sensitive and objective methods that can diagnose SRC and determine recovery would aid clinical management, and there is evidence that SRC induces changes in circulating protein biomarkers, indicative of neuroaxonal injury. However, potential blood biomarkers related to other pathobiological responses linked to SRC are still poorly understood. Therefore, here we analyzed blood samples from concussed (male = 30; female = 9) and non-concussed (male = 74; female = 27) amateur Australian rules football players collected during the pre-season (i.e., baseline), and at 2, 6, and 13 days post-SRC to determine time-dependent changes in serum levels of biomarkers related to glial (i.e., brain lipid-binding protein [BLBP]; phosphoprotein enriched in astrocytes 15) and cerebrovascular injury (i.e., von Willebrand factor, claudin-5), inflammation (i.e., fibrinogen, high mobility group box protein 1), and oxidative stress (i.e., 4-hydroxynoneal). In females, BLBP levels were significantly decreased at 2 days post-SRC compared with their pre-season baseline; however, area under the receiver operating characteristic curve (AUROC) analysis found that BLBP was unable to distinguish between SRC and controls. In males, AUROC analysis revealed a statistically significant change at 2 days post-SRC in the serum levels of 4-hydroxynoneal, however the associated AUROC value (0.6373) indicated little clinical utility for this biomarker in distinguishing SRC from controls. There were no other statistically significant findings. These results indicate that the serum biomarkers tested in this study hold little clinical value in the management of SRC at 2, 6, and 13 days post-injury.

Micro-RNA levels and symptom profile after mild traumatic brain injury: A longitudinal cohort study.
Micro riboneucleic acids (miRNAs) may be transcribed after brain injury and be detectable in plasma. This study aimed to assess the discriminative ability of seven miRNAs in plasma to differentiate between patients with mild traumatic brain injury (mTBI) and healthy controls. Changes in miRNA levels over 28 days were compared to changes in self-reported symptom profile. This was a prospective cohort study with longitudinal measurements of miRNA levels and symptom self-report. The Rivermead Post-Concussion Symptom Questionnaire (RPQ) was used to determine symptom severity. Mean normalised expression ratios (NER) of miRNAs at day 0 between mTBI and healthy controls were compared. An analysis of response profiles compared the response over time of miRNA species with RPQ symptom severity. miRNA levels of subjects who were defined to have "recovered" on Day 7 and 28 were compared to "non-recovered" subjects. There were 28 mTBI patients and 30 healthy controls included for analysis. Symptom severity was significantly higher on the day of injury among mTBI subjects ($p < 0.001$), and miRNA 32-5p levels were also higher ($p = 0.009$). Change of miRNA levels were similar to RPQ change at Day 7, but significantly different at Day 28. Differences were observed among miRNA levels of recovered subjects. This study demonstrated differences in miRNA levels among mTBI subjects compared to healthy controls and different miRNA levels among those who had recovered compared to those reporting symptoms. The change in profiles of miRNAs was different to symptom severity, suggesting that the two measures reflect different aspects of brain injury and recovery.

Serum Neurofilament Light as a Biomarker of Traumatic Brain Injury in the Presence of Concomitant Peripheral Injury.
Serum neurofilament light (NfL) is an emerging biomarker of traumatic brain injury (TBI). However, the effect of peripheral injuries such as long bone fracture and skeletal muscle injury on serum NfL levels is unknown. Therefore, the aim of this study was to determine whether serum NfL levels can be used as a biomarker of TBI in the presence of concomitant peripheral injuries.

Temporal profile and utility of serum neurofilament light in a rat model of mild traumatic brain injury.
There is a widely recognized need for blood biomarkers to assist clinical decisions surrounding mild traumatic brain injury (mTBI). Serum neurofilament light (NfL), an indicator of neuroaxonal damage, is one such candidate, with early mTBI clinical investigations demonstrating significant promise. To facilitate the translation of pre-clinical mTBI findings, clinically relevant outcomes should be integrated into animal studies wherever possible. Despite this, the temporal profile and potential utility of NfL as a blood biomarker in pre-clinical mTBI is poorly understood. Here, we quantified serum NfL at 2-h, 1-, 3-, 7- and 14-days following mTBI in rats and compared these to pre-injury levels. We also investigated cumulative effects of repeat-mTBI by delivering 0, 1 or 5 mTBIs separated by 24 h. Sensorimotor performance was evaluated with the beam task at 1- and 4-h after mTBI, and serum was collected 1-day after the final procedure. We found that serum NfL levels were substantially elevated at all acute and sub-acute time-points after a single-mTBI, peaked at 1-day, and remained elevated 14-days post-injury. An mTBI dose-dependent effect on serum NfL levels was also observed, with substantially higher NfL levels found at

1-day post repeat-mTBI when compared to single-mTBI and sham-injured rats. Furthermore, NfL levels were found to be greatest in rats with the highest degree of sensorimotor impairment. In conclusion, these findings have described the temporal profile of serum NfL elevations following a single-mTBI in rats, and indicate a profile with some similarities and differences to that seen in the clinical condition. Moreover, we found that serum NfL levels were potentiated by repeat-mTBI, and that this biomarker may have utility as an indicator of injury severity. As such, future pre-clinical TBI studies may benefit from incorporating measures of serum NfL as an objective injury outcome.

Behavioral, axonal, and proteomic alterations following repeated mild traumatic brain injury: Novel insights using a clinically relevant rat model.
A history of mild traumatic brain injury (mTBI) is linked to a number of chronic neurological conditions, however there is still much unknown about the underlying mechanisms. To provide new insights, this study used a clinically relevant model of repeated mTBI in rats to characterize the acute and chronic neuropathological and neurobehavioral consequences of these injuries. Rats were given four sham-injuries or four mTBIs and allocated to 7-day or 3.5-months post-injury recovery groups. Behavioral analysis assessed sensorimotor function, locomotion, anxiety, and spatial memory. Neuropathological analysis included serum quantification of neurofilament light (NfL), mass spectrometry of the hippocampal proteome, and ex vivo magnetic resonance imaging (MRI). Repeated mTBI rats had evidence of acute cognitive deficits and prolonged sensorimotor impairments. Serum NfL was elevated at 7 days post injury, with levels correlating with sensorimotor deficits; however, no NfL differences were observed at 3.5 months. Several hippocampal proteins were altered by repeated mTBI, including those associated with energy metabolism, neuroinflammation, and impaired neurogenic capacity. Diffusion MRI analysis at 3.5 months found widespread reductions in white matter integrity. Taken together, these findings provide novel insights into the nature and progression of repeated mTBI neuropathology that may underlie lingering or chronic neurobehavioral deficits.

Serum Protein Biomarker Findings Reflective of Oxidative Stress and Vascular Abnormalities in Male, but Not Female, Collision Sport Athletes.

Studies have indicated that concussive and sub-concussive brain injuries that are frequent during collision sports may lead to long-term neurological abnormalities, however there is a knowledge gap on how biological sex modifies outcomes. Blood-based biomarkers can help to identify the molecular pathology induced by brain injuries and to better understand how biological sex affects the molecular changes. We therefore analyzed serum protein biomarkers in male (= 50) and female (= 33) amateur Australian rules footballers (i.e., Australia's most participated collision sport), both with a history of concussion (HoC) and without a history of concussion (NoHoC). These profiles were compared to those of age-matched control male (= 24) and female (= 20) athletes with no history of neurotrauma or participation in collision sports. Serum levels of protein markers indicative of neuronal, axonal and glial injury (UCH-L1, NfL, tau, p-tau, GFAP, BLBP, PEA15), metabolic (4-HNE) and vascular changes (VEGF-A, vWF, CLDN5), and inflammation (HMGB1) were assessed using reverse phase protein microarrays. Male, but not female, footballers had increased serum levels of VEGF-A compared to controls regardless of concussion history. In addition, only male footballers who had HoC had increased serum levels of 4-HNE. These findings being restricted to males may be related to shorter collision sport career lengths for females compared to males. In summary, these findings show that male Australian rules footballers have elevated levels of serum biomarkers indicative of vascular abnormalities (VEGF-A) and oxidative stress (4-HNE) in comparison to non-collision control athletes. While future studies are required to determine how these findings relate to neurological function, serum levels of VEGF-A and 4-HNE may be useful to monitor subclinical neurological injury in males participating in collision sports.

THIS IS AN INJURED BRAIN ON DRUGS: EXAMINING THE EFFECTS OF MODAFINIL ADMINISTRATION ON REPETITIVE MILD TRAUMATIC BRAIN INJURY OUTCOMES IN ADULT RATS

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Jennaya Christensen, Crystal Li, Glenn Yamakawa, Sandy Shultz, Richelle Mychasiuk
Monash University, Neuroscience, Melbourne, Australia

Mild traumatic brain injury (mTBI) is one of the most common neurological disorders, with an exceptionally high incidence rate among males. Modafinil is a wake-promoting substance prescribed to treat hypersomnolence. Modafinil has been found to modulate the immune response while reducing neuroinflammation and neurotoxicity. Since mTBI-associated impairments are induced by these changes, modafinil may be a promising therapeutic prospect. AIM: To examine the effect of chronic modafinil administration on RmTBI-induced behavioural outcomes, and proteomic and metabolomic CSF profile changes in adult male rats. METHODS: An intracerebroventricular (ICV) cannula was implanted into the lateral ventricle of adult male Sprague Dawley rats. Animals underwent either RmTBIs or sham injuries, with injuries being 48 hours apart. An acute behavioural test battery confirmed RmTBI-induced impairments. Animals then received intermittent ICV injections of modafinil or vehicle at the beginning of the light phase. A second behavioural test battery was initiated one week post-ICV injections. CSF was collected at the end of the study to analyze proteomic and metabolomic profiles. RESULTS: Significant ($p<.05$) improvements observed in OF distance travelled, EPM time in open arms, Y maze novelty preference, brain weight, and spleen weight indicate some beneficial effects of modafinil administration for both the sham and RmTBI animals. Injury- and treatment-associated changes ($p<.05$) in the CSF profiles of several proteins and metabolites, including AQP1, thiamine, and CD5L, were also observed. CONCLUSION: Modafinil's ability to modulate the immune response and neuroinflammation likely assists in diminishing deleterious effects induced by RmTBI. Therefore, modafinil exhibits therapeutic potential in treating RmTBI.

A Pilot Study Investigating the Role of Gender in the Intergenerational Relationships between Gene Expression, Chronic Pain, and Adverse Childhood Experiences in a Clinical Sample of Youth with Chronic Pain.
Chronic pain is a highly prevalent and costly issue that often emerges during childhood or adolescence and persists into adulthood. Adverse childhood experiences (ACEs) increase risk for several adverse health conditions, including chronic pain. Recent evidence suggests that parental trauma (ACEs, post-traumatic stress disorder (PTSD) symptoms) confers risk of poor health outcomes in their children. Intergenerational relationships between parental trauma and child chronic pain may be mediated by epigenetic mechanisms. A clinical sample of youth with chronic pain and their parents completed psychometrically sound questionnaires assessing ACEs, PTSD symptoms, and chronic pain, and provided a saliva sample. These were used to investigate the intergenerational relationships between four epigenetic biomarkers (COMT, DRD2, GR, and SERT), trauma, and chronic pain. The results indicated that the significant biomarkers were dependent upon the gender of the child, wherein parental ACEs significantly correlated with changes in DRD2 expression in female children and altered COMT expression in the parents of male children. Additionally, the nature of the ACE (maltreatment vs. household dysfunction) was associated with the specific epigenetic changes. There may be different pathways through which parental ACEs confer risk for poor outcomes for males and females, highlighting the importance of child gender in future investigations.

Is the glymphatic system the missing link between sleep impairments and neurological disorders? Examining the implications and uncertainties.
Until recently, both the purpose of the biological need for sleep and the mechanism by which the central nervous system eliminated metabolic waste products were unknown. The glymphatic system is the recently discovered macroscopic waste clearance system for the CNS, which predominantly functions during sleep states. Important implications for the glymphatic system exist for a significant proportion of neurological disorders, including traumatic brain injury, epilepsy, stroke, migraine,

and Alzheimer's disease. Within the limited amount of research pertaining to this novel system there exists controversy regarding several of the key structural and functional aspects of the glymphatic system. In this review we address evidence from both standpoints regarding the prominent debates surrounding the glymphatic system, including the functional differences in wakefulness vs. sleep, the role of glial aquaporin-4 water channels, and whether it reflects a convective flow or a passive diffusion process. The answers that underlie these questions will have crucial and distinct outcomes for the future of the glymphatic system and the disorders it has been implicated in. However, this review also summarizes the potential role of the glymphatic system in the development and progression of the aforementioned neurological disorders. Furthermore, the possible contribution of the orexinergic system to this relationship between the glymphatic system, sleep, and these neurological disorders is also explored. Overall, in order to develop and utilize therapeutic interventions centred around the glymphatic system we must first dedicate further investigation to elucidating these discrepancies and unanswered questions.

Acute Dilation of Venous Sinuses in Animal Models of Mild Traumatic Brain Injury Detected Using 9.4T MRI.
Mild traumatic brain injury (mTBI) is a debilitating but extremely common form of brain injury that affects a substantial number of people each year. mTBI is especially common in children and adolescents. Our understanding of mTBI pathophysiology is limited, and there is currently no accepted marker for disease severity. A potential marker for disease severity may be cerebrovascular dysfunction. Recent findings have implicated cerebrovascular alteration as an important component of mTBI and suggest it contributes to the development of persistent, long-term symptoms. In this paper, we conducted two studies to investigate whether mTBI affects venous drainage patterns in the central nervous system using alterations in the size of venous sinuses as a marker of changes in drainage. Using a closed head vertical weight-drop model and a lateral impact injury model of mTBI, we imaged and quantified the size of three major draining vessels in the adolescent rat brain using 9.4T MRI. Areas and volumes were quantified in the superior sagittal sinus and left and right transverse sinuses using images acquired from T2w MRI in one study and post-gadolinium T1w MRI in another. Our results indicated that the three venous sinuses were significantly larger in mTBI rats as compared to sham rats 1-day post injury but recovered to normal size 2 weeks after. Acutely enlarged sinuses post-mTBI may indicate abnormal venous drainage, and this could be suggestive of a cerebrovascular response to trauma.

Examining the Effects of Anabolic-Androgenic Steroids on Repetitive Mild Traumatic Brain Injury (RmTBI) Outcomes in Adolescent Rats.
Repetitive mild traumatic brain injury (RmTBI) is increasingly common in adolescents. Anabolic-androgenic steroid (AAS) consumption among younger professional athletes is a significant risk factor for impaired neurodevelopment. Given the increased rates and overlapping symptomology of RmTBI and AAS use, we sought to investigate the behavioural and neuropathological outcomes associated with the AAS Metandienone (Met) and RmTBI on rats.

Repetitive Mild Traumatic Brain Injury Alters Glymphatic Clearance Rates in Limbic Structures of Adolescent Female Rats.
The glymphatic system is the macroscopic waste clearance system for the central nervous system. Glymphatic dysfunction has been linked to several neurological conditions, including traumatic brain injury (TBI). Adolescents are at particularly high risk for experiencing a TBI, particularly mild TBI (mTBI) and repetitive mTBI (RmTBI); however, glymphatic clearance, and how it relates to behavioral outcomes, has not been investigated in this context. Therefore, this study examined glymphatic function in the adolescent brain following RmTBI. Female adolescent Sprague Dawley rats were subjected to either three mTBIs or sham injuries spaced three days apart. One-day after their final injury, the animals underwent a beam walking task to assess sensorimotor function, and contrast-enhanced MRI to visualize glymphatic clearance rate. Behavioural measures indicated that the RmTBI group displayed an increase in loss of consciousness as well as motor coordination and balance deficits consistent with our previous studies. The contrast-enhanced MRI results indicated that the female adolescent glymphatic system responds to RmTBI in a region-specific manner, wherein an increased influx but reduced efflux was observed throughout limbic structures (hypothalamus, hippocampus, and amygdala) and the olfactory bulb but neither the influx or efflux were altered in the cortical structures (primary motor cortex, insular cortex, and dorsolateral prefrontal cortex) examined. This may indicate a role for an impaired and/or inefficient glymphatic system in the limbic structures and cortical structures, respectively, in the development of post-concussive symptomology during adolescence.

Caffeine consumption during development alters spine density and recovery from repetitive mild traumatic brain injury in young adult rats.

Caffeine is the most commonly used psychostimulant throughout the world, with its consumption being especially prevalent among adolescents and young adults, as over 75% of this group consumes caffeine daily. Similarly, the adolescent and young adult age group exhibit the highest incidence of traumatic brain injury (TBI). Given that both caffeine consumption and mild TBI (mTBI) are more prevalent among the late adolescent/young adult age group and that changes in dendritic spine morphology during this developmental period are poorly understood, this study sought to examine the effects of caffeine consumption during late adolescence/early adulthood on recovery from repetitive mTBI (RmTBI). The study specifically focused on changes to neuronal dendritic morphology as synaptic changes likely underlie long-term behavioral outcomes. The results demonstrate that during young adulthood caffeine consumption differentially affects the RmTBI outcomes of males and females, where the effects of caffeine and RmTBI were often additive in males while being equally detrimental, but rarely additive, in females. In general, caffeine and RmTBI induced the greatest impairments in males on cognitive and motor tasks whereas in females the most significant detriments were on pain-related tasks. Both caffeine and RmTBI increased spine density in the Cg3 (medial prefrontal cortex [mPFC]), AID (orbitofrontal cortex [OFC]), and nucleus accumbens (NAc), which is proposed to reflect an impairment in the normal pruning processes. Overall, despite caffeine's neuroprotective abilities among other age groups, this study offers concerning results regarding the detrimental effects of caffeine and RmTBI, in isolation, and especially in combination, in this susceptible population.

When Two Wrongs Make a Right: The Effect of Acute and Chronic Binge Drinking on Traumatic Brain Injury Outcomes in Young Adult Female Rats.
Alcohol is the most commonly abused drug by young adults across North America. Although alcohol consumption itself incurs a risk of neurological damage, it is also a significant risk factor for traumatic brain injury (TBI). TBI among young adults is described as a modern healthcare epidemic. The drastic changes occurring within their neurological networks put young adults at greater risk for developing long-term post-traumatic deficits. Contradictory findings have been indicated regarding the effects of alcohol consumption on TBI outcomes in adults, with some studies demonstrating detrimental effects, whereas others suggest neuroprotective abilities. However, little is known about the effects of alcohol consumption on TBI outcomes during the sensitive stage of early adulthood. Young adult female Sprague-Dawley rats were randomly assigned to one of six experimental conditions: Pre-injury alcohol+TBI; Pre-injury alcohol+Sham; Pre- and Post-injury alcohol+TBI; Pre- and Post-injury alcohol+Sham; No alcohol+TBI; No alcohol+Sham. Alcohol consumption groups received an amount of 10% v/v ethanol solution based on the animals' weight. Following the injury, the rats were subjected to a behavioral test battery to assess post-concussive symptomology. Overall, chronic binge drinking significantly improved TBI outcomes related to motor coordination and balance, whereas binge drinking in general significantly decreased anxiety-like behaviors. Additionally, in many cases, chronic binge drinking appears to return the TBI animal's behavioral outcomes to levels comparable to those of the no alcohol sham animals. Thus, the results suggest that alcohol may exhibit neuroprotective abilities in the context of early adulthood TBI.

Neurobiological mechanisms underlying the sleep-pain relationship in adolescence: A review.
Adolescence characterizes a period of significant change in brain structure and function, causing the neural circuitry to be particularly susceptible to the environment and various other experiences. Chronic pain and sleep deprivation represent major health issues that plague adolescence. A bidirectional relationship exists between sleep and pain; however, emerging evidence suggests that sleep disturbances have a stronger influence on subsequent pain than vice versa. The neurobiological underpinnings of this relationship, particularly during adolescence, are poorly understood. This review examines the current literature regarding sleep and pain in adolescence, with a particular focus on the neurobiological mechanisms underlying pain, sleep problems, and the neural circuitry that potentially links the two. Finally, a research agenda is outlined to stimulate future research on this topic. Given the high prevalence of these health issues during adolescence and the debilitating effects they inflict on nearly every domain of development, it is crucial that we determine the neurobiological mechanisms fundamental to this relationship and identify potential therapeutic strategies.

A Bump on the Head or Late to Bed: Behavioral and Pathophysiological Effects of Sleep Deprivation after Repetitive Mild Traumatic Brain Injury in Adolescent Rats.
An old wives' tale, and strongly held dogma, maintains that one should be kept awake after a mild traumatic brain injury (mTBI) to prevent a coma. This, however, conflicts with the known benefits of sleep: repair and restoration. We therefore sought to examine the effects of sleep deprivation (SD) in the post-traumatic sleep period on post-concussion symptomology (PCS). Adolescent male and female rats were administered repetitive mTBIs (RmTBI) or sham injuries and were then

assigned to 5 h of SD or left undisturbed. All animals were then tested using seven behavioral tasks validated to examine PCS, followed by analysis of serum cytokines, and quantitative real-time PCR for messenger RNA (mRNA) expression. Exposure to 3 SD epochs significantly impaired behavior in 4 of 7 of the measures, while RmTBI also produced dysfunction in 5 of 7 tests, but the effects of SD and RmTBI were not cumulative. SD induced long-lasting changes in serum levels of Tnf-α, IL6, and IL-1ß. mRNA expression in the pre-frontal cortex, hippocampus, hypothalamus, and anterior cingulate cortex was modified in response to SD and RmTBI; but similar to the behavioral measures, the mRNA changes were not cumulative. Consequently, we report that SD often produced impairments similar or worse than RmTBI, and sleep hygiene should become a priority for adolescent health.

Assessment of a nutritional supplement containing resveratrol, prebiotic fiber, and omega-3 fatty acids for the prevention and treatment of mild traumatic brain injury in rats.
Children and adolescents have the highest rates of traumatic brain injury (TBI), with mild TBI (mTBI) accounting for most of these injuries. Adolescents are particularly vulnerable and often suffer from post-injury symptomologies that may persist for months. We hypothesized that the combination of resveratrol (RES), prebiotic fiber (PBF), and omega-3 fatty acids (docosahexaenoic acid (DHA)) would be an effective therapeutic supplement for the mitigation of mTBI outcomes in the developing brain. Adolescent male and female Sprague-Dawley rats were randomly assigned to the supplement (3S) or control condition, which was followed by a mTBI or sham insult. A behavioral test battery designed to examine symptomologies commonly associated with mTBI was administered. Following the test battery, tissue was collected from the prefrontal cortex (PFC) and primary auditory cortex for Golgi-Cox analysis of spine density, and for changes in expression of 6 genes (Aqp4, Gfap, Igf1, Nfl, Sirt1, and Tau). 3S treatment altered the behavioral performance of sham animals indicating that dietary manipulations modify premorbid characteristics. 3S treatment prevented injury-related deficits in the longer-term behavior measures, medial prefrontal cortex (mPFC) spine density, and levels of Aqp4, Gfap, Igf1, Nfl, and Sirt1 expression in the PFC. Although not fully protective, treatment with the supplement significantly improved post-mTBI function and warrants further investigation.

SERUM NEUROFILAMENT LIGHT AS A BIOMARKER OF VULNERABILITY TO REPEATED MILD TRAUMATIC BRAIN INJURY IN ADOLESCENT MALE RATS

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Ashley Van Emmerik[1], William O'Brien[1], Jesse Bain[1], Mastura Monif[2], Sandy Shultz[2], Richelle Mychasiuk[2], Stuart Mcdonald[1]
[1]Monash University, Department Of Neuroscience, Melbourne, Australia, [2]Monash University, Neuroscience, Melbourne, Australia

Introduction: There is concern regarding the effects of repeat mild traumatic brain injury (rmTBI) and premature return to play/duty. There are, however, no validated biomarkers shown to objectively monitor recovery and indicate when the brain is no longer highly vulnerable to rmTBI. One biomarker receiving interest is the neuroaxonal protein neurofilament light (NfL). **Objectives:** To assess the utility of monitoring serum NfL to prevent cumulative effects of rmTBI. **Materials and methods:** Male rats were randomly allocated to receive sham injuries, a single-mTBI, or two mTBIs separated by either 1-day (i.e. peak NfL levels in rats), 3- or 7-days (i.e. during resolution), or 14-days (i.e. following resolution). Serum was collected for NfL quantification at the time of the final injury, and at 3-, 7-, 14- and 28-days. Sensorimotor function, cognition and anxiety-like behaviours were assessed during the 28-day period, followed by *ex vivo* diffusion tensor imaging. Outcomes were compared between the injury groups, and also within rmTBI rats dichotomized into high or low NfL groups based on levels at the time of the second mTBI. **Results:** When compared to rats given single-mTBI, those with rmTBI had a prolonged elevation in serum NfL. Furthermore, rats with high NfL levels had a significantly potentiated NfL response to the second mTBI when compared to rats with low NfL levels. Behavioural and MRI analysis is ongoing. **Conclusion:** This study provides novel evidence that irrespective of recovery interval, monitoring serum NfL levels may have utility to prevent the cumulative effects associated with rmTBI.

EVALUATION OF REPETITIVE MILD TRAUMATIC BRAIN INJURY BY FLUORESCENCE AND FDG PET IMAGING

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Jahae Kim[1,2], A Yeon Kang[1], Dooyoung Kim[2], Jina Hong[1,3], Jihye Kim[3], Hansol Lee[3], Kangho Choi[3]
[1]Chonnam National University Medical School and Hospital, Nuclear Medicine, Gwangju, Korea, Republic of, [2]Chonnam National University, Ai Convergence, Gwangju, Korea, Republic of, [3]Chonnam National University Hospital, Neurology, Gwangju, Korea, Republic of

Background: Repetitive, mild, traumatic brain injury (TBI) can cause minor neurologic impairment, but the imaging assessment of this type of injury are not fully understood. We investigated the effect of TBI and neuroprotective drug using fluorescence and FDG PET imaging system. Methods: TBI was induced by modified Marmarou's method, which was designed to total five successive head impacts with an interval of 12 hours. The experiment was conducted in the untreated TBI and treated TBI with neuroprotective drug. Neurological prognosis was evaluated by NSS 1 hour after each strike, and cellular structure was evaluated by H&E staining. BBB integrity was evaluated after EB injection using the fluorescence imaging system. Cerebral glucose metabolic function was measured by FDG PET images in each cerebral region. Results: NSS and gross changes showed no significant differences. However, fluorescence imaging reflecting BBB integrity demonstrated more severe BBB disruption in the untreated TBI group than in the treated TBI group (p=0.004). Quantitative analysis of FDG PET demonstrated higher glucose uptake in whole brain (p=0.046), striatum (p=0.040), thalamus (p=0.012) and cerebral gray matter (p=0.036) in the untreated TBI group than in the treated TBI group. Conclusion: The fluorescence and FDG PET imaging are more sensitive to evaluate the repetitive, mild TBI, although the neurological function or histologic assessments may not be sufficiently sensitive. These results suggest that fluorescence and FDG PET imaging may be useful for assessment of the degree of severity and the effect of neuroprotective drug in the repetitive, mild, traumatic injury.

TRAUMATIC BRAIN INJURY AND ITS EFFECTS ON THE REACTION OF GLIAL CELLS

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Ester Nespoli[1], Marsela Hakani[1], Tabea Hein[2], Petra Weihrich[2], Bernd Baumann[2], Thomas Wirth[2], Leda Dimou[1]
[1]Ulm University, Molecular And Translational Neuroscience, ulm, Germany, [2]Ulm University, Physiological Chemistry, ulm, Germany

Despite intensive research efforts, treatment options for neurotrauma remain limited, due to the scarce regenerative capacity of the brain. The cellular response to traumatic brain injury (TBI) is primarily carried out by glial cells, namely microglia, NG2-glia -the oligodendrocyte progenitor cells- and astrocytes, whose reactions coordinately contribute to limiting the damage and recovering tissue homeostasis. While the individual reactions of microglia and astrocytes are already partially described, little is known about NG2-glia reaction to TBI and, in general, how glial cells work together to secure trauma resolution. A better understanding of this strictly regulated mechanism could bring us closer to supporting regeneration after trauma. Here, we aimed to investigate the response of NG2-glia, astrocytes, and microglia to TBI in a spatial and temporal resolution and identified extracellular and intracellular conditions that can modify their reaction. The understanding of how glial cells coordinate their global reaction and the identification of factors that could modify or predict TBI outcomes could help us to limit brain damage and to support tissue recovery.

Riluzole Administration to Rats with Levodopa-Induced Dyskinesia Leads to Loss of DNA Methylation in Neuronal Genes.
Dyskinesias are characterized by abnormal repetitive involuntary movements due to dysfunctional neuronal activity. Although levodopa-induced dyskinesia, characterized by tic-like abnormal involuntary movements, has no clinical treatment for Parkinson's disease patients, animal studies indicate that Riluzole, which interferes with glutamatergic neurotransmission, can improve the phenotype. The rat model of Levodopa-Induced Dyskinesia is a unilateral lesion with 6-hydroxydopamine in the medial forebrain bundle, followed by the repeated administration of levodopa. The molecular pathomechanism of Levodopa-Induced Dyskinesia is still not deciphered; however, the implication of epigenetic mechanisms was suggested. In this study, we investigated the striatum for DNA methylation alterations under chronic levodopa treatment with or without co-treatment with Riluzole. Our data show that the lesioned and contralateral striata have nearly identical DNA methylation profiles. Chronic levodopa and levodopa + Riluzole treatments led to DNA methylation loss, particularly outside of promoters, in gene bodies and CpG poor regions. We observed that several genes involved in the Levodopa-Induced Dyskinesia underwent methylation changes. Furthermore, the Riluzole co-treatment, which improved the phenotype, pinpointed specific methylation targets, with a more than 20% methylation difference relative to levodopa treatment alone. These findings indicate potential new druggable targets for Levodopa-Induced Dyskinesia.

Cerebral Immunohistochemical Characterization of the HS and the Oxytocin Systems in a Porcine Model of Acute Subdural Hematoma.
The hydrogen sulfide (HS) and the oxytocin/oxytocin receptor (OT/OTR) systems interact in trauma and are implicated in vascular protection and regulation of fluid homeostasis. Acute brain injury is associated with pressure-induced edema formation, blood brain barrier disruption, and neuro-inflammation. The similarities in brain anatomy: size, gyrencephalic organization, skull structure, may render the pig a highly relevant model for translational medicine. Cerebral biomarkers for pigs for pathophysiological changes and neuro-inflammation are limited. The current study aims to characterize the localization of OT/OTR and the endogenous HS producing enzymes together with relevant neuro-inflammatory markers on available porcine brain tissue from an acute subdural hematoma (ASDH) model. In a recent pilot study, anesthetized pigs underwent ASDH by injection of 20 mL of autologous blood above the left parietal cortex and were resuscitated with neuro-intensive care measures. After 54 h of intensive care, the animals were sacrificed, the brain was removed and analyzed via immunohistochemistry. The endogenous HS producing enzymes cystathionine-ϒ-lyase (CSE) and cystathionine-β-synthase

(CBS), the OTR, and OT were localized in neurons, vasculature and parenchyma at the base of sulci, where pressure-induced injury leads to maximal stress in the gyrencephalic brain. The pathophysiological changes in response to brain injury in humans and pigs, we show here, are comparable. We additionally identified modulators of brain injury to further characterize the pathophysiology of ASDH and which may indicate future therapeutic approaches.

Riluzole Attenuates L-DOPA-Induced Abnormal Involuntary Movements Through Decreasing CREB1 Activity: Insights from a Rat Model.
Chronic administration of L-DOPA, the first-line treatment of dystonic symptoms in childhood or in Parkinson's disease, often leads to the development of abnormal involuntary movements (AIMs), which represent an important clinical problem. Although it is known that Riluzole attenuates L-DOPA-induced AIMs, the molecular mechanisms underlying this effect are not understood. Therefore, we studied the behavior and performed RNA sequencing of the striatum in three groups of rats that all received a unilateral lesion with 6-hydroxydopamine in their medial forebrain bundle, followed by the administration of saline, L-DOPA, or L-DOPA combined with Riluzole. First, we provide evidence that Riluzole attenuates AIMs in this rat model. Subsequently, analysis of the transcriptomics data revealed that Riluzole is predicted to reduce the activity of CREB1, a transcription factor that regulates the expression of multiple proteins that interact in a molecular landscape involved in apoptosis. Although this mechanism underlying the beneficial effect of Riluzole on AIMs needs to be confirmed, it provides clues towards novel or existing compounds for the treatment of AIMs that modulate the activity of CREB1 and, hence, its downstream targets.

Altered dopaminergic regulation of the dorsal striatum is able to induce tic-like movements in juvenile rats.
Motor tics are sudden, repetitive, involuntary movements representing the hallmark behaviors of the neurodevelopmental disease Tourette's syndrome (TS). The primary cause of TS remains unclear. The initial observation that dopaminergic antagonists alleviate tics led to the development of a dopaminergic theory of TS etiology which is supported by post mortem and in vivo studies indicating that non-physiological activation of the striatum could generate tics. The striatum controls movement execution through the balanced activity of dopamine receptor D1 and D2-expressing medium spiny neurons of the direct and indirect pathway, respectively. Different neurotransmitters can activate or repress striatal activity and among them, dopamine plays a major role. In this study we introduced a chronic dopaminergic alteration in juvenile rats, in order to modify the delicate balance between direct and indirect pathway. This manipulation was done in the dorsal striatum, that had been associated with tic-like movements generation in animal models. The results were movements resembling tics, which were categorized and scored according to a newly developed rating scale and were reduced by clonidine and riluzole treatment. Finally, post mortem analyses revealed altered RNA expression of dopaminergic receptors D1 and D2, suggesting an imbalanced dopaminergic regulation of medium spiny neuron activity as being causally related to the observed phenotype.

Aripiprazole Selectively Reduces Motor Tics in a Young Animal Model for Tourette's Syndrome and Comorbid Attention Deficit and Hyperactivity Disorder.
Tourette's syndrome (TS) is a neurodevelopmental disorder characterized primarily by motor and vocal tics. Comorbidities such as attention deficit and hyperactivity disorder (ADHD) are observed in over 50% of TS patients. We applied aripiprazole in a juvenile rat model that displays motor tics and hyperactivity. We additionally assessed the amount of ultrasonic vocalizations (USVs) as an indicator for the presence of vocal tics and evaluated the changes in the striatal neurometabolism using proton magnetic resonance spectroscopy (1H-MRS) at 11.7T. Thirty-one juvenile spontaneously hypertensive rats (SHRs) underwent bicuculline striatal microinjection and treatment with either aripiprazole or vehicle. Control groups were sham operated and sham injected. Behavior, USVs, and striatal neurochemical profile were analyzed at early, middle, and late adolescence (postnatal days 35 to 50). Bicuculline microinjections in the dorsolateral striatum induced motor tics in SHR juvenile rats. Acute aripiprazole administration selectively reduced both tic frequency and latency, whereas stereotypies, USVs, and hyperactivity remained unaltered. The striatal neurochemical profile was only moderately altered after tic-induction and was not affected by systemic drug treatment. When applied to a young rat model that provides high degrees of construct, face, and predictive validity for TS and comorbid ADHD, aripiprazole selectively reduces motor tics, revealing that tics and stereotypies are distinct phenomena in line with clinical treatment of patients. Finally, our 1H-MRS results suggest a critical revision of the striatal role in the hypothesized cortico-striatal dysregulation in TS pathophysiology.

TS-EUROTRAIN: A European-Wide Investigation and Training Network on the Etiology and Pathophysiology of Gilles de la Tourette Syndrome.
Gilles de la Tourette Syndrome (GTS) is characterized by the presence of multiple motor and phonic tics with a fluctuating course of intensity, frequency, and severity. Up to 90% of patients with GTS present with comorbid conditions, most commonly attention-deficit/hyperactivity disorder (ADHD), and obsessive-compulsive disorder (OCD), thus providing an excellent model for the exploration of shared etiology across disorders. TS-EUROTRAIN (FP7-PEOPLE-2012-ITN, Grant Agr.No. 316978) is a Marie Curie Initial Training Network (http://ts-eurotrain.eu) that aims to elucidate the complex etiology of the onset and clinical course of GTS, investigate the neurobiological underpinnings of GTS and related disorders, translate research findings into clinical applications, and establish a pan-European infrastructure for the study of GTS. This includes the challenges of (i) assembling a large genetic database for the evaluation of the genetic architecture with high statistical power; (ii) exploring the role of gene-environment interactions including the effects of epigenetic phenomena; (iii) employing endophenotype-based approaches to understand the shared etiology between GTS, OCD, and ADHD; (iv) establishing a developmental animal model for GTS; (v) gaining new insights into the neurobiological mechanisms of GTS via cross-sectional and longitudinal neuroimaging studies; and (vi) partaking in outreach activities including the dissemination of scientific knowledge about GTS to the public. Fifteen partners from academia and industry and 12 PhD candidates pursue the project. Here, we aim to share the design of an interdisciplinary project, showcasing the potential of large-scale collaborative efforts in the field of GTS. Our ultimate aims are to elucidate the complex etiology and neurobiological underpinnings of GTS, translate research findings into clinical applications, and establish Pan-European infrastructure for the study of GTS and associated disorders.

Addressing the Complexity of Tourette's Syndrome through the Use of Animal Models.
Tourette's syndrome (TS) is a neurodevelopmental disorder characterized by fluctuating motor and vocal tics, usually preceded by sensory premonitions, called premonitory urges. Besides tics, the vast majority-up to 90%-of TS patients suffer from psychiatric comorbidities, mainly attention deficit/hyperactivity disorder (ADHD) and obsessive-compulsive disorder (OCD). The etiology of TS remains elusive. Genetics is believed to play an important role, but it is clear that other factors contribute to TS, possibly altering brain functioning and architecture during a sensitive phase of neural development. Clinical brain imaging and genetic studies have contributed to elucidate TS pathophysiology and disease mechanisms; however, TS disease etiology still is poorly understood. Findings from genetic studies led to the development of genetic animal models, but they poorly reflect the pathophysiology of TS. Addressing the role of neurotransmission, brain regions, and brain circuits in TS disease pathomechanisms is another focus area for preclinical TS model development. We are now in an interesting moment in time when numerous innovative animal models are continuously brought to the attention of the public. Due to the diverse and largely unknown etiology of TS, there is no single preclinical model featuring all different aspects of TS symptomatology. TS has been dissected into its key symptomst hat have been investigated separately, in line with the Research Domain Criteria concept. The different rationales used to develop the respective animal models are critically reviewed, to discuss the potential of the contribution of animal models to elucidate TS disease mechanisms.

Nondopaminergic neurotransmission in the pathophysiology of Tourette syndrome.
A major pathophysiological role for the dopaminergic system in Tourette's syndrome (TS) has been presumed ever since the discovery that dopamine-receptor antagonists can alleviate tics. Especially recent molecular genetic studies, functional imaging studies, and some rare postmortem studies have given more and more hints that other neurotransmitter systems are involved as well. Dysfunction in the dopamine metabolism-in particular during early development-might lead to counter-regulations in the other systems or vice versa. This chapter will give an overview of the studies that prove the involvement of other neurotransmitter systems such as the major monoaminergic neurotransmitters norepinephrine, serotonin, and histamine; the most important excitatory neurotransmitter, the amino acid glutamate; the major inhibitory neurotransmitter y-aminobutyric acid, as well as acetylcholine, endocannabinoid, corticoid; and others. These studies will hopefully lead to fundamental advances in the psychopharmacological treatment of TS. While tic disorders have been previously treated mainly with dopamine antagonists, some authors already favor alpha-agonists. Clinical trials with glutamate agonists and antagonists and compounds influencing the histaminergic system are currently being conducted. Since the different neurotransmitter systems consist of several receptor subtypes which might mediate different effects on locomotor activity, patients with TS may respond differentially to selective agonists or antagonists. Effects of agonistic or antagonistic

compounds on tic symptoms might also be dose dependent. Further studies will lead to a broader spectrum of psychopharmacological treatment options in TS.

CHALLENGING THE ROLE OF OLIGODENDROCYTES UPON TRAUMATIC BRAIN INJURY

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Raquel Garza[1], Yogita Sharma[1], Diahann Atacho[1], Marie Jönsson[2], Jon Matas[2], Jenny Johansson[2], Christopher Douse[2], Niklas Marklund[3], Johan Jakobsson[2]
[1]Lund University, Experimental Medical Sciences, Lund, Sweden, [2]Lund University,, Department Of Experimental Medical Sciences, Lund, Sweden, [3]Lund University, Skåne University Hospital, Clinical Sciences, Lund, Sweden

Traumatic brain injury (TBI), an injury affecting or disabling brain function, is still a major cause of morbidity worldwide. Unlike other brain disorders, TBI involves a sudden event that triggers neuroinflammation, which is key to subsequent pathological processes following TBI. To investigate transcriptional changes related to inflammation as a consequence of TBI, we sequenced bulk and single nuclei RNA from TBI patients and used post-mortem samples with non-neurological deaths as control. We found inflammatory related genes to be upregulated in microglia as well as in oligodendrocytes in TBI patients compared to control. Interestingly, TBI-oligodendrocytes also display a clear upregulation in genes related to viral response and interferon response. This is interesting, as recent studies have linked the expression of endogenous retroviruses (ERVs) to the activation of an interferon response in the brain. Therefore, to investigate the expression of ERVs in TBI, we applied a novel bioinformatical approach to examine the transcriptional activity of these elements in the different cell types. Strikingly, our results show a clear upregulation of human specific ERVs in oligodendrocytes in TBI patients. These observations challenge the role of oligodendrocytes during neuroinflammation, and the consequences of ERV expression during such process.

Distinct subcellular autophagy impairments in induced neurons from Huntington's disease patients.
Huntington's disease (HD) is a neurodegenerative disorder caused by CAG expansions in the huntingtin (HTT) gene. Modelling Huntington's disease is challenging, as rodent and cellular models poorly recapitulate the disease as seen in aging humans. To address this, we generated induced neurons (iNs) through direct reprogramming of human skin fibroblasts, which retain age-dependent epigenetic characteristics. HD-iNs displayed profound deficits in autophagy, characterised by reduced transport of late autophagic structures from the neurites to the soma. These neurite-specific alterations in autophagy resulted in shorter, thinner and fewer neurites specifically in HD-iNs. CRISPRi-mediated silencing of HTT did not rescue this phenotype but rather resulted in additional autophagy alterations in ctrl-iNs, highlighting the importance of wild type HTT in normal neuronal autophagy. In summary, our work identifies a distinct subcellular autophagy impairment in adult patient derived Huntington's disease neurons and provides a new rational for future development of autophagy activation therapies. A cis-acting structural variation at the ZNF558 locus controls a gene regulatory network in human brain development.
The human forebrain has expanded in size and complexity compared to chimpanzees despite limited changes in protein-coding genes, suggesting that gene expression regulation is an important driver of brain evolution. Here, we identify a KRAB-ZFP transcription factor, ZNF558, that is expressed in human but not chimpanzee forebrain neural progenitor cells. ZNF558 evolved as a suppressor of LINE-1 transposons but has been co-opted to regulate a single target, the mitophagy gene SPATA18. ZNF558 plays a role in mitochondrial homeostasis, and loss-of-function experiments in cerebral organoids suggests that ZNF558 influences developmental timing during early human brain development. Expression of ZNF558 is controlled by the size of a variable number tandem repeat that is longer in chimpanzees compared to humans, and variable in the human population. Thus, this work provides mechanistic insight into how a cis-acting structural variation establishes a regulatory network that affects human brain evolution.

Activation of endogenous retroviruses during brain development causes an inflammatory response.
Endogenous retroviruses (ERVs) make up a large fraction of mammalian genomes and are thought to contribute to human disease, including brain disorders. In the brain, aberrant activation of ERVs is a potential trigger for an inflammatory response, but mechanistic insight into this phenomenon remains lacking. Using CRISPR/Cas9-based gene disruption of the epigenetic co-repressor protein Trim28, we found a dynamic H3K9me3-dependent regulation of ERVs in proliferating neural progenitor cells (NPCs), but not in adult neurons. In vivo deletion of Trim28 in cortical NPCs during mouse brain development resulted in viable offspring expressing high levels of ERVs in excitatory neurons in the adult brain. Neuronal ERV expression was linked to activated microglia and the presence of ERV-derived proteins in aggregate-like structures. This study demonstrates that brain development is a critical period for the silencing of ERVs and provides causal in vivo evidence demonstrating that transcriptional activation of ERV in neurons results in an inflammatory response.

Transposable Elements: A Common Feature of Neurodevelopmental and Neurodegenerative Disorders.
The etiology of most neurological disorders is poorly understood and current treatments are largely ineffective. New ideas and concepts are therefore vitally important for future research in this area. This review explores the concept that dysregulation of transposable elements (TEs) contributes to the appearance and pathology of neurodevelopmental and neurodegenerative disorders. Despite TEs making up at least half of the human genome, they are vastly understudied in relation to brain disorders. However, recent advances in sequencing technologies and gene editing approaches are now starting to unravel the pathological role of TEs. Aberrant activation of TEs has been found in many neurological disorders; the resulting pathogenic effects, which include alterations of gene expression, neuroinflammation, and direct neurotoxicity, are starting to be resolved. An increased understanding of the relationship between TEs and pathological processes in the brain improves the potential for novel diagnostics and interventions for brain disorders.

LONG-TERM ENDOSCOPIC CALCIUM IMAGING OF A NOVEL COMPRESSION TBI MOUSE MODEL

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Marta Saez Garcia, Marina Tibeykina, Tamás Kopcsányi, Coralie Di Scala, Claudio Rivera
University of Helsinki, Neuroscience Center, Helsinki, Finland

We have developed a new Traumatic Brain Injury (TBI) mouse model that allows long-term endoscopic calcium imaging of the impact zone. Recordings can be made prior to the injury and after, all the way until the apparition of comorbidities such as memory disorders and epileptic seizures. Our approach combines the high cellular resolution of Inscopix miniendoscopes with a novel impact methodology developed in house. Thanks to this model, we have been able to follow the cellular changes that occur within the impact zone and analyze changes occurring in a single cells during the first two months after impact. This model allows for freely moving imaging of mice and combination with several behavioral tests.

Protective Role of Low Ethanol Administration Following Ischemic Stroke via Recovery of KCC2 and p75 Expression.
A striking result from epidemiological studies show a correlation between low alcohol intake and lower incidence for ischemic stroke and severity of derived brain injury. Although reduced apoptosis and inflammation has been suggested to be involved, little is known about the mechanism mediating this effect in vivo. Increase in intracellular chloride concentration and derived depolarizing GABAR-mediated transmission are common consequences following various brain injuries and are caused by the abnormal expression levels of the chloride cotransporters NKCC1 and KCC2. Downstream pro-apoptotic signaling through p75 may link GABA depolarization with post-injury neuronal apoptosis. Here, we show that changes in GABAergic signaling, Cl homeostasis, and expression of chloride cotransporters in the post-traumatic mouse brain can be significantly reduced by administration of 3% ethanol to the drinking water. Ethanol-induced upregulation of KCC2 has a positive impact on neuronal survival, preserving a large part of the cortical peri-infarct zone, as well as preventing the massive post-ischemic upregulation of the pro-apoptotic protein p75. Importantly, intracortical multisite in vivo recordings showed that ethanol treatment could significantly ameliorate stroke-induced reduction in cortical activity. This surprising finding discloses a pathway triggered by low concentration of ethanol as a novel therapeutically relevant target.

The Kainate Receptor Subunit GluK2 Interacts With KCC2 to Promote Maturation of Dendritic Spines.
Kainate receptors (KAR) play a crucial role in the plasticity and functional maturation of glutamatergic synapses. However, how they regulate structural plasticity of dendritic spines is not known. The GluK2 subunit was recently shown to coexist in a functional complex with the neuronal K-Cl cotransporter KCC2. Apart from having a crucial role in the maturation of GABAergic transmission, KCC2 has a morphogenic role in the maturation of dendritic spines. Here, we show that local inactivation of GluK2 expression in CA3 hippocampal neurons induces altered morphology of dendritic spines and reduction in mEPSC frequency. GluK2 deficiency also resulted in a strong change in the subcellular distribution of KCC2 as well as a smaller somatodendritic gradient in the reversal potential of GABA. Strikingly, the aberrant morphology of dendritic spines in GluK2-deficient CA3 pyramidal neurons was restored by overexpression of KCC2. GluK2 silencing in hippocampal neurons significantly reduced the expression of 4.1N and functional form of the actin filament severing protein cofilin. Consistently, assessment of actin dynamics using fluorescence recovery after photobleaching (FRAP) of β-actin showed a significant increase in the stability of F-actin filaments in dendritic spines. In conclusion, our results demonstrate that GluK2-KCC2 interaction plays an important role in the structural maturation of dendritic spines. This also provides novel insights into the connection between KAR dysfunction, structural plasticity, and developmental disorders.

Revealing subthreshold motor contributions to perceptual confidence.
Established models of perceptual metacognition, the ability to evaluate our perceptual judgements, posit that perceptual

confidence depends on the strength or quality of feedforward sensory evidence. However, alternative theoretical accounts suggest the entire perception-action cycle, and not only variation in sensory evidence, is monitored when evaluating confidence in one's percepts. Such models lead to the counterintuitive prediction that perceptual confidence should be directly modulated by features of motor output. To evaluate this proposal here we recorded electromyographic (EMG) activity of motor effectors while subjects performed a near-threshold perceptual discrimination task and reported their confidence in each response in a pre-registered experiment. A subset of trials exhibited subthreshold EMG activity in response effectors before a decision was made. Strikingly, trial-by-trial analysis showed that confidence, but not accuracy, was significantly higher on trials with subthreshold motor activation. These findings support a hypothesis that preparatory motor activity, or a related latent variable, impacts upon confidence over and above performance, consistent with models in which perceptual metacognition integrates information across the perception-action cycle.

Mild traumatic brain injury (mTBI) is an urgent public health issue, as it is linked to long-term neurological impairment and a propensity towards neurodegenerative disease. The underlying mechanisms driving long-term dysfunction that may be therapeutically targeted remain unclear. In this study, we induced three mild closed-skull injuries or sham procedures, 24h apart, in C57BL/6 mice followed by behavioural tests or sacrifice one week later. Injured mice showed prolonged righting reflex, neurocognitive impairment in the Morris water maze, and increased Iba1 and GFAP reactivity, indicating induction of a mild injury with no gross lesion. The cortical and hippocampal region under impact revealed extensive DNA damage in the form of double-strand breaks, oxidative damage, and R-loops, markers of senescence including p16 and p21, and markers of the senescence-associated secretory phenotype (SASP). Single-cell RNA sequencing revealed activation of the DNA damage response, senescence, and SASP in all cell types, including neurons. Cell-type specific changes were also present with evidence of innate immune activation, synaptic transmission and structural dysfunction, gliosis, and metabolic reprogramming indicative of the DNA damage response. Treatment of injured mice with the senolytic drug ABT263 significantly improved performance in the Morris water maze and reduced markers of DNA damage and senescence. This study is the first to use senolytic therapy in an impact model, providing compelling evidence that targeting senescence may be clinically beneficial. Developing more targeted strategies that do not eliminate cells, such as high capacity multifaceted nanoparticle-mediated therapies, will be critical going forward in the treatment of mTBI.

Temporal patterns of microglial activation in white matter following experimental mild traumatic brain injury: a systematic literature review.
Mild traumatic brain injuries (mTBIs) are a prevalent form of injury that can result in persistent neurological impairments. Microglial activation has become increasingly recognized as a key process regulating the pathology of white matter in a wide range of brain injury and disease contexts. As white matter damage is known to be a major contributor to the impairments that follow mTBI, microglia have rightfully become a common target of investigation for the development of mTBI therapies and biomarkers. Recent work has demonstrated that the efficacy of microglial manipulation as a therapeutic intervention following injury or disease is highly time-sensitive, emphasizing the importance of advancing our understanding of the dynamics of post-mTBI microglial activation from onset to resolution. Current reporting of microglial activation in experimental studies of mTBI is non-standardized, which has limited our ability to identify concrete patterns of post-mTBI microglial activation over time. In this review, we examine preclinical studies of mTBI that report on microglial activation in white matter regions to summarize our current understanding of these patterns. Specifically, we summarize timecourses of post-mTBI microglial activation in white matter regions of the brain, identify factors that influence this activation, examine the temporal relationship between microglial activation and other post-mTBI assessments, and compare the relative sensitivities of various methods for detecting microglial activation. While the lack of replicated experimental conditions has limited the extent of conclusions that can confidently be drawn, we find that microglia are activated over a wide range of timecourses following mTBI and that microglial activation is a long-lasting outcome of mTBI that may resolve after most typical post-mTBI assessments, with the exception of those measuring oligodendrocyte lineage cell integrity. We identify several understudied parameters of post-mTBI microglial activation in white matter, such as the inclusion of female subjects. This review summarizes our current understanding of the progression of microglial activation in white matter structures following experimental mTBI and offers suggestions for important future research directions.

Cellular Senescence in Traumatic Brain Injury: Evidence and Perspectives.
Mild traumatic brain injury (mTBI) can lead to long-term neurological dysfunction and increase one's risk of neurodegenerative disease. Several repercussions of mTBI have been identified and well-studied, including neuroinflammation, gliosis, microgliosis, excitotoxicity, and proteinopathy - however the pathophysiological mechanisms activating these pathways after mTBI remains controversial and unclear. Emerging research suggests DNA damage-induced cellular senescence as a possible driver of mTBI-related sequalae. Cellular senescence is a state of chronic cell-cycle arrest and inflammation associated with physiological aging, mood disorders, dementia, and various neurodegenerative pathologies. This narrative review evaluates the existing studies which identify DNA damage or cellular senescence after TBI (including mild, moderate, and severe TBI) in both experimental animal models and human studies, and outlines how cellular senescence may functionally explain both the molecular and clinical manifestations of TBI. Studies on this subject clearly show accumulation of various forms of DNA damage (including oxidative damage, single-strand breaks, and double-strand breaks) and senescent cells after TBI, and indicate that cellular senescence may be an early event after TBI. Further studies are required to understand the role of sex, cell-type specific mechanisms, and temporal patterns, as senescence may be a pathway of interest to target for therapeutic purposes including prognosis and treatment.

Early onset senescence and cognitive impairment in a murine model of repeated mTBI.
Mild traumatic brain injury (mTBI) results in broad neurological symptoms and an increased risk of being diagnosed with a neurodegenerative disease later in life. While the immediate oxidative stress response and post-mortem pathology of the injured brain has been well studied, it remains unclear how early pathogenic changes may drive persistent symptoms and confer susceptibility to neurodegeneration. In this study we have used a mouse model of repeated mTBI (rmTBI) to identify early gene expression changes at 24 h or 7 days post-injury (7 dpi). At 24 h post-injury, gene expression of rmTBI mice shows activation of the DNA damage response (DDR) towards double strand DNA breaks, altered calcium and cell-cell signalling, and inhibition of cell death pathways. By 7 dpi, rmTBI mice had a gene expression signature consistent with induction of cellular senescence, activation of neurodegenerative processes, and inhibition of the DDR. At both timepoints gliosis, microgliosis, and axonal damage were evident in the absence of any gross lesion, and by 7 dpi rmTBI also mice had elevated levels of IL1β, p21, 53BP1, DNA2, and p53, supportive of DNA damage-induced cellular senescence. These gene expression changes reflect establishment of processes usually linked to brain aging and suggests that cellular senescence occurs early and most likely prior to the accumulation of toxic proteins. These molecular changes were accompanied by spatial learning and memory deficits in the Morris water maze. To conclude, we have identified DNA damage-induced cellular senescence as a repercussion of repeated mild traumatic brain injury which correlates with cognitive impairment. Pathways involved in senescence may represent viable treatment targets of post-concussive syndrome. Senescence has been proposed to promote neurodegeneration and appears as an effective target to prevent long-term complications of mTBI, such as chronic traumatic encephalopathy and other related neurodegenerative pathologies.

Patient values and preferences regarding VTE disease: a systematic review to inform American Society of Hematology guidelines.
Values and preferences relate to the importance that patients place on health outcomes (eg, bleeding, having a deep venous thrombosis) and are essential when weighing benefits and harms in guideline recommendations. To inform the American Society of Hematology guidelines for management of venous thromboembolism (VTE) disease, we conducted a systematic review of patients' values and preferences related to VTE. We searched Medline, Embase, Cochrane Central Register of Controlled Trials, PsycINFO, and the Cumulative Index to Nursing and Allied Health Literature from inception to April of 2018

(PROSPERO-CRD42018094003). We included quantitative and qualitative studies. We followed Grading of Recommendations Assessment, Development and Evaluation (GRADE) guidance for rating the certainty and presenting findings for quantitative research about the relative importance of health outcomes and a grounded theory approach for qualitative thematic synthesis. We identified 14 quantitative studies (2465 participants) describing the relative importance of VTE-related health states in a widely diverse population of patients, showing overall small to important impact on patients' lives (certainty of the evidence from low to moderate). Additionally, evidence from 34 quantitative studies (6424 participants) and 15 qualitative studies (570 participants) revealed that patients put higher value on VTE risk reduction than on the potential harms of the treatment (certainty of evidence from low to moderate). Studies also suggested a clear preference for oral medication over subcutaneous medication (moderate certainty). The observed variability in health state values may be a result of differences in the approaches used to elicit them and the diversity of included populations rather than true variability in values. This finding highlights the necessity to explore the variability induced by different approaches to ascertain values.

DNA repair deficiency and senescence in concussed professional athletes involved in contact sports.

Mild traumatic brain injury (mTBI) leads to diverse symptoms including mood disorders, cognitive decline, and behavioral changes. In some individuals, these symptoms become chronic and persist in the long-term and can confer an increased risk of neurodegenerative disease and dementia diagnosis later in life. Despite the severity of its consequences, the pathophysiological mechanism of mTBI remains unknown. In this post-mortem case series, we assessed DNA damage-induced cellular senescence pathways in 38 professional athletes with a history of repeated mTBI and ten controls with no mTBI history. We assessed clinical presentation, neuropathological changes, load of DNA damage, morphological markers of cellular senescence, and expression of genes involved in DNA damage signaling, DNA repair, and cellular senescence including the senescence-associated secretory phenotype (SASP). Twenty-eight brains with past history of repeated mTBI history had DNA damage within ependymal cells, astrocytes, and oligodendrocytes. DNA damage burden was increased in brains with proteinopathy compared to those without. Cases also showed hallmark features of cellular senescence in glial cells including astrocytic swelling, beading of glial cell processes, loss of H3K27Me3 (trimethylation at lysine 27 of histone H3) and lamin B1 expression, and increased expression of cellular senescence and SASP pathways. Neurons showed a spectrum of changes including loss of emerin nuclear membrane expression, loss of Brahma-related gene-1 (BRG1 or SMARCA4) expression, loss of myelin basic protein (MBP) axonal expression, and translocation of intranuclear tau to the cytoplasm. Expression of DNA repair proteins was decreased in mTBI brains. mTBI brains showed substantial evidence of DNA damage and cellular senescence. Decreased expression of DNA repair genes suggests inefficient DNA repair pathways in this cohort, conferring susceptibly to cellular senescence and subsequent brain dysfunction after mTBI. We therefore suggest that brains of contact-sports athletes are characterized by deficient DNA repair and DNA damage-induced cellular senescence and propose that this may affect neurons and be the driver of brain dysfunction in mTBI, predisposing the progression to neurodegenerative diseases. This study provides novel targets for diagnostic and prognostic biomarkers, and represents viable targets for future treatments.

DNA damage as a marker of brain damage in individuals with history of concussions.

Mild traumatic brain injury (mTBI) is common in many populations, including athletes, veterans, and domestic abuse victims. mTBI can cause chronic symptoms, including depression, irritability, memory problems, and attention deficits. A history of repetitive mTBI has been epidemiologically associated with developing early-onset dementia and neurodegenerative diseases and, in particular, is thought to be the underlying cause of chronic traumatic encephalopathy (CTE)-a progressive tauopathy diagnosed by the presence of perivascular hyperphosphorylated tau protein (p-tau) in the depths of cortical sulci. However, the scarce and focal pathology often seen in CTE does not correlate with the severity of symptoms experienced by patients. This paper proposes accumulation of γH2AX, a marker of double-stranded DNA damage, as a novel pathological marker to identify brain damage post-mTBI. We present two cases of men with history of mTBI. Immunohistochemistry revealed extensive DNA damage throughout the frontal cortex, hippocampus, and brainstem areas. Furthermore, gene expression profiling showed increases of ataxia telangiectasia mutated (ATM) and checkpoint kinase 2 (CHEK2), two serine/threonine kinases recruited in response to double-strand breaks in the DNA damage response pathway. These cases highlight the complex pathophysiology of head trauma, and suggest DNA damage as the molecular mechanism behind mTBI-induced pathology and symptoms.

Assessing the Limitations and Biases in the Current Understanding of Chronic Traumatic Encephalopathy.

Chronic traumatic encephalopathy (CTE) is considered to be a progressive neurodegenerative disease caused by mild

traumatic brain injury (mTBI). Recently there has been a significant amount of media attention surrounding the commonness of CTE in professional athletes, particularly American football, based on several postmortem case series. However, despite the persuasive claims made by the media about CTE, research on the disease and the effects of mTBI in general remain in its infancy. Commonly cited case series studying CTE are limited by methodological biases, pathological inconsistencies, insufficient clinical data, and a reliance on inherently biased postmortem data. These case series do not allow for the collection of any epidemiological data and are not representative of the general population. The exaggerated assumptions and assertions taken from these studies run the risk of creating a self-fulfilling prophecy for individuals who believe they are at risk and have the potential to negatively influence sports-related policymaking. This review outlines the status and limitations of recent CTE case series and calls for future prospective, longitudinal studies to further characterize the pathological and clinical hallmarks of CTE.

THE ACUTE EFFECTS OF PEGYLATED SINGLE-WALLED CARBON NANOTUBES ON THE PROTEIN OXIDATIVE DAMAGE AND HSP-70 LEVELS IN PRIMARY MOUSE ASTROCYTES EXPOSED TO STRETCH INJURY

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Kristina Pilipović[1], Nika Gržeta[1], Anja Harej Hrkać[1], Vladimir Parpura[2]
[1]University of Rijeka, Faculty of Medicine, Department Of Basic And Clinical Pharmacology And Toxicology, Rijeka, Croatia, [2]University of Alabama at Birmingham, Department Of Neurobiology, Birmingham, United States of America

Aims: We have previously shown that the application of single-walled carbon nanotubes chemically functionalized with polyethylene glycol (PEG-SWCNTs) influences the expression of some proteins and causes changes in the cytokine release from the cultured astrocytes exposed to severe *in vitro* traumatic brain injury (TBI). Still, questions remain regarding the potential toxicity of the investigated nanomaterial. Here, using the *in vitro* TBI model, we tested the effects of PEG-SWCNTs on oxidative protein damage and the expression of a stress protein, heat shock protein 70 (HSP-70) in astrocytes. Methods: Primary mouse astrocytes were grown on 6-well plates with deformable membranes and subjected to severe stretch injury. PEG-SWCNTs or vehicle were applied at 1 h post-injury and the astrocytes were collected 23 h later. The dot blot method was used to detect the levels of oxidatively damaged proteins, and the Western blot was used to determine the expression levels of HSP-70. Non-injured, vehicle-treated astrocytes were used as the control group. Results: Stretch injury caused a slight, but non-significant increase in the levels of oxidatively damaged proteins and the application of the PEG-SWCNTs to the injured astrocytes did not cause additional protein oxidation. *In vitro* trauma, with or without PEG-SWCNTs treatment, did not affect the HSP-70 levels in astrocytes. Conclusions: Results of this study suggest that PEG-SWCNTs do not cause oxidative protein damage in astrocytes exposed to *in vitro* TBI, nor do they increase the level of cell stress as determined by measuring the HSP-70 levels. This research was fully supported by the Croatian Science Foundation grant UIP-2017-05-9517 to KP.

Aim. Repetitive mild traumatic brain injury (mTBI) as occurring in contact sports can progress into chronic traumatic encephalopathy (CTE), a neurodegenerative condition leading to severe behavioural changes. Here, we explore sex and age effects on neurological and behavioural outcome parameters in a rat model of CTE. **Methods.** To induce CTE, rats aged 7-weeks (n=8 females; n=6 males) and 14-weeks (n=8, each) underwent 3 mTBIs (induced by weight drop under anaesthesia) with 5-days intervals. Time-to-right was determined immediately after each mTBI and neurological severity score (NSS) at baseline and the first day after each mTBI. Sucrose preference test (SPT) was performed 1 and 2 weeks after CTE induction. At week 12, NSS, SPT, Y-maze and open field tests (OFT) were performed. One-way and two-way ANOVA were used to analyse data pooled by sex and age. **Results.** Independent of sex and age, time-to-right and NSS showed neurological impairment at multiple time-points (up to $p<0.01$), with NSS impairment lasting until week 12 (up to $p<0.0001$), while OFT and Y-maze did not reach significance ($p>0.05$). Interestingly, no age-dependent effects were found. However, male CTE rats showed worse performance than females in the time to right after the second mTBI ($p<0.001$), SPT after 2 weeks (-41% sucrose consumption, $p<0.01$), and NSS after 12 weeks ($p<0.05$). **Conclusion.** Our results do not reveal evidence of age-related effects after CTE-induction. Sex, however seems to be a relevant factor to be included in subsequent investigations.

NEUROPROTECTIVE INCREASE OF A COMBINED TREATMENT OF TWO OXIMES AGAINST VX-EXPOSURE IN MICE

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Alexandre Champault[1], Marilène Trancart[1], Julie Knoertzer[1], Ludovic Jean[2], Nicolas Probst[2], Anne-Sophie Hanak[1], André-Guilhem Calas[1], Gregory Dal Bo[1], Karine Thibault[1]

Organophosphates (OP) are toxic chemical compounds initially developed as pesticides, which still cause several million poisonings and thousand deaths worldwide each year. OP nerve agents, such as sarin or VX, have been used in Syria civil war and in Kim Jong-Nam assassination respectively. Acute exposure to OP could lead to muscle paralysis and respiratory distress resulting to death in few minutes post-exposure. Antidote therapy contains a muscarinic cholinergic receptor antagonist (atropine sulfate) and one oxime, a strong nucleophile, able to reactivate OP-inhibited acetylcholinesterase (AChE). Unfortunately, oximes have limitations in their effectiveness, in particular as they poorly cross the blood brain barrier (BBB) and therefore weakly reactivate central AChE. The goal of this study is to test therapeutic potential of a new oxime, called RM048 which can cross the BBB *in vitro* and its combination with HI-6, known not to cross the BBB. At first, we focused on short term effect of HI-6, RM048 or the mix of both after supralethal doses of VX agent exposure on different physiological parameters. We assessed protective index of each treatment and the corresponding quality of recovery. Cerebral and blood ChE activity inhibition has been measured. Then, we characterized the effect of the different treatments on cerebral electrical activity and in the epileptic seizure occurrence. Finally, we focused on midterm therapy effects of each treatment, one month after VX exposure, and we evaluated behavioural impact on anxiety, cognition, locomotion, and depression.

Aberrant mitochondrial fission has been identified as important in the pathophysiology of traumatic brain injury (TBI), Alzheimer's disease, and related dementias. We aim to determine the nature of mitochondrial fission involvement in TBI, and to use a small peptide inhibitor of mitochondrial fission protein Drp1, called P110, to mitigate downstream neurodegeneration. We subjected C57/bl6 mice to either TBI or sham injury, and subsequently treated them with either P110 or vehicle by daily intraperitoneal injection for 2 weeks. Following treatment, mice were subjected to a battery of neurobehavioral tests, including novel object recognition (NOR), open field test, and others. Brain tissues were then processed for western blot analysis, staining, and electron microscopy. Mice subjected to TBI showed increased Drp1 expression in the hippocampus 24 after injury, which returned to normal 2 weeks later. There were also observed changes in phosphorylation of Drp1, as well as Drp1 oligomerization, indicating altered Drp1-mediated fission activity. Two weeks following TBI, mice showed a memory deficit in the NOR task, against which P110 treatment was protective. At this time, mitochondria show an elongated morphology specifically in the P110-treated TBI group, but not the sham group, suggesting injury-specificity in its therapeutic mechanism. The same mice, when retested in the NOR task 6 and 9 months post-injury, showed sustained memory protection from early P110 treatment. Our data indicate that early specific inhibition of mitochondrial fission after TBI protects mice from developing cognitive impairment at both acute and chronic stages of injury.

Maternal P7C3-A20 Treatment Protects Offspring from Neuropsychiatric Sequelae of Prenatal Stress.
Impaired embryonic cortical interneuron development from prenatal stress is linked to adult neuropsychiatric impairment, stemming in part from excessive generation of reactive oxygen species in the developing embryo. Unfortunately, there are no preventive medicines that mitigate the risk of prenatal stress to the embryo, as the underlying pathophysiologic mechanisms are poorly understood. Our goal was to interrogate the molecular basis of prenatal stress-mediated damage to the embryonic brain to identify a neuroprotective strategy. Chronic prenatal stress in mice dysregulated nicotinamide adenine dinucleotide (NAD) synthesis enzymes and cortical interneuron development in the embryonic brain, leading to axonal degeneration in the hippocampus, cognitive deficits, and depression-like behavior in adulthood. Offspring were protected from these deleterious effects by concurrent maternal administration of the NAD-modulating agent P7C3-A20, which crossed the placenta to access the embryonic brain. Prenatal stress also produced axonal degeneration in the adult corpus callosum, which was not prevented by maternal P7C3-A20. Prenatal stress dysregulates gene expression of NAD-synthesis machinery and GABAergic interneuron development in the embryonic brain, which is associated with adult cognitive impairment and depression-like behavior. We establish a maternally directed treatment that protects offspring from these effects of prenatal stress. NAD-synthesis machinery and GABAergic interneuron development are critical to proper embryonic brain development underlying postnatal neuropsychiatric functioning, and these systems are highly susceptible to prenatal stress. Pharmacologic stabilization of NAD in the stressed embryonic brain may provide a neuroprotective strategy that preserves normal embryonic development and protects offspring from neuropsychiatric impairment. . 35, 511-530.

Loss of Cav1.2 channels impairs hippocampal theta burst stimulation-induced long-term potentiation.

CACNA1 C, which codes for the Ca1.2 isoform of L-type Ca channels (LTCCs), is a prominent risk gene in neuropsychiatric and neurodegenerative conditions. A role forLTCCs, and Ca1.2 in particular, in transcription-dependent late long-term potentiation (LTP) has long been known. Here, we report that elimination of Ca1.2 channels in glutamatergic neurons also impairs theta burst stimulation (TBS)-induced LTP in the hippocampus, known to be transcription-independent and dependent on N-methyl D-aspartate receptors (NMDARs) and local protein synthesis at synapses. Our expansion of the established role of Ca1.2channels in LTP broadens understanding of synaptic plasticity and identifies a new cellular phenotype for exploring treatment strategies for cognitive dysfunction.

FATE MAPPING OF PERIPHERALLY DERIVED MACROPHAGES AFTER TRAUMATIC BRAIN INJURY

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Maria Serena Paladini, Xi Feng, Valentina Frattini, Susanna Rosi
University of California San Francisco, Physical Therapy & Rehabilitation Science, San Francisco, United States of America

Background and Aim Traumatic Brain Injury (TBI) represents a critical health problem for our society, given its increasing occurrence, complex pathophysiology, challenging diagnosis, and long-term neurological disabilities. It is well established that TBI-induced neuroinflammation engages resident microglia as well as infiltrating monocytes (CCR2+) recruited from the periphery, which both contribute to long lasting cognitive deficits. After brain engraftment, peripherally derived macrophages stop expressing their signature marker CCR2, thus making discrimination from reactive microglia cells elusive. **Methods** We took advantage of CCR2CreER:Ai14D mice, where CCR2+ cells are permanently labelled even after *in situ* reprogramming. Adult CCR2CreER:Ai14D mice were injured using the Controlled Cortical Impact (CCI) TBI model. Injury-induced cognitive deficits were measured using the Radial Arm Water Maze. Infiltrated CCR2+ macrophages were traced 7 and 30 days post injury (dpi) and analyzed using flow cytometry, brain clearing and imaging, RNA sequencing and *in vivo* synapses phagocytosis assays. **Results** We are characterizing localization, transcriptomic signatures and functionality of peripherally derived macrophages focusing on how these features change from sub-acute (7 dpi) and chronic (30 dpi) time points. We expect to observe a previously under-reported level of infiltrating monocyte-to-microglia transition after TBI. **Conclusions** Our study uses the novel CCR2CreER:Ai14D mouse model to unravel a more comprehensive understanding of the long-term role of peripherally derived macrophages in TBI-induced cognitive impairment.

Functional role of brain-engrafted macrophages against brain injuries.
Brain-resident microglia have a distinct origin compared to macrophages in other organs. Under physiological conditions, microglia are maintained by self-renewal from the local pool, independent of hematopoietic progenitors. Pharmacological depletion of microglia during whole-brain radiotherapy prevents synaptic loss and long-term recognition memory deficits. However, the origin or repopulated cells and the mechanisms behind these protective effects are unknown.

Microglia: Ally and Enemy in Deep Space.
In 2024 the first female astronaut will land on the moon, advancing our preparations for human missions to Mars. While on Earth we are protected from space radiation by our planet's magnetic field, on such deep space voyages astronauts will be exposed to high energy particles from solar flares and galactic cosmic rays (GCR). This exposure carries risks to the central nervous system (CNS) that could jeopardize the mission and astronaut health. Earth-bound studies have employed a variety of single-beam and sequential radiation exposures to simulate the effects of GCR exposure in rodents. Multiple studies have shown that GCR simulation induces a maladaptive activation of microglia - the brain-resident immune cells. GCR simulation also induced synaptic changes resulting in lasting cognitive and behavioral defects. Female and male mice show different susceptibilities to GCR exposure, and evidence suggests this sexually dimorphic response is linked to microglia. Manipulating microglia can prevent the development of cognitive deficits in male mice exposed to components of GCR. This discovery may provide clues towards how to protect astronauts' cognitive and behavioral health both during deep space missions and upon return to Earth.

Behavioral and molecular effects of the antipsychotic drug blonanserin in the chronic mild stress model.
Psychiatric disorders represent a critical challenge to our society, given their high global prevalence, complex symptomatology, elusive etiology and the variable effectiveness of pharmacological therapies. Recently, there has been a shift in investigating and redefining these diseases by integrating behavioral observations and multilevel neurobiological measures. Accordingly, endophenotype-oriented studies are needed to develop new therapeutic strategies, with the idea of

targeting shared symptoms instead of one defined disease. With these premises, here we investigated the therapeutic properties of chronic treatment with the second-generation antipsychotic blonanserin in counteracting the alterations caused by 7 weeks of Chronic Mild Stress (CMS) in the rat. CMS is a well-established preclinical model able to induce depressive and anxiety-like alterations, which are shared by different psychiatric disorders. Our results demonstrated that the antipsychotic treatment normalizes the CMS-induced emotionality deficits, an effect that may be due to its ability in modulating, within the prefrontal cortex, redox mechanisms, a molecular dysfunction associated with several psychiatric disorders. These evidences provide new insights into the therapeutic properties and potential use of blonanserin as well as in its mechanisms of action and provide further support for the role of oxidative stress in the pathophysiology of psychiatric disorders.

Microglia depletion and cognitive functions after brain injury: From trauma to galactic cosmic ray.
Microglia are the resident immune cells of the central nervous system (CNS). In physiological conditions, microglia contribute to maintaining brain homeostasis by scanning the surrounding parenchyma and acting as scavenger cells. Following different insults to the CNS, microglia turn into a "reactive" state characterized by the production of inflammatory mediators that promote tissue repair to restore homeostasis. Brain insults such as traumatic brain injury, therapeutic brain irradiation and galactic cosmic ray exposure are associated with chronic microglia activation. Chronic microglia activation contributes to injury-related impairments in cognitive functions. Microglia depletion achieved either by pharmacological or genetic techniques represents not only a useful tool for more extensive investigations of microglia roles, but also a potential therapeutic approach to ameliorate or prevent cognitive dysfunctions following brain injury.

Prenatal Stress Impairs Spinal Cord Oligodendrocyte Maturation via BDNF Signaling in the Experimental Autoimmune Encephalomyelitis Model of Multiple Sclerosis.
One of the most substantial and established environmental risk factors for neurological and psychiatric disorders is stress exposure, whose detrimental consequences hinge on several variables including time. In this regard the gestational period is known to present an intrinsic vulnerability to environmental insults and thus stressful events during pregnancy can lead to severe consequences on the offspring's brain development with long-term repercussions throughout adulthood. On this basis, we investigated the long-lasting impact of prenatal stress exposure on the susceptibility to the experimental autoimmune encephalomyelitis (EAE), a well-established murine model of multiple sclerosis. Although stress is considered a triggering factor for this chronic, progressive, autoimmune disease, little is known about the underlying mechanisms. To this end, EAE was induced by immunization with MOG35-55/CFA and pertussis toxin administration in adult female C57BL/6 mice born from control or stressed dams exposed to restraint stress during the last days of gestation. Our results demonstrate that gestational stress induces a marked increase in the severity of EAE symptoms in adulthood. Further, we highlight an altered maturation of oligodendrocytes in the spinal cord of prenatally stressed EAE mice, as indicated by the higher levels of GPR17, a marker of immature oligodendrocyte precursor cells. These behavioral and molecular alterations are paralleled by changes in the expression and signaling of the neurotrophin BDNF, an important mediator of neural plasticity that may contribute to stress-induced impaired remyelination. Since several already marketed drugs are able to modulate BDNF levels, these results pave the way to the possibility of repositioning these drugs in multiple sclerosis.

Oxidation-reduction mechanisms in psychiatric disorders: A novel target for pharmacological intervention.
While neurotransmitter dysfunction represents a key component in mental illnesses, there is now a wide agreement for a central pathophysiological hub that includes hormones, neuroinflammation, redox mechanisms as well as oxidative stress. With respect to oxidation-reduction (redox) mechanisms, preclinical and clinical evidence suggests that an imbalance in the pro/anti-oxidative homeostasis toward the increased production of substances with oxidizing potential may contribute to the etiology and manifestation of different psychiatric disorders. The substantial and continous demand for energy renders the brain highly susceptible to disturbances in its energy supply, especially following exposure to stressful events, which may

lead to overproduction of reactive oxygen and nitrogen species under conditions of perturbed antioxidant defenses. This will eventually induce different molecular alterations, including extensive protein and lipid peroxidation, increased blood-brain barrier permeability and neuroinflammation, which may contribute to the changes in brain function and morphology observed in mental illnesses. This view may also reconcile different key concepts for psychiatric disorders, such as the neurodevelopmental origin of these diseases, as well as the vulnerability of selective cellular populations that are critical for specific functional abnormalities. The possibility to pharmacologically modulate the redox system is receiving increasing interest as a novel therapeutic strategy to counteract the detrimental effects of the unbalance in brain oxidative mechanisms. This review will describe the main mechanisms and mediators of the redox system and will examine the alterations of oxidative stress found in animal models of psychiatric disorders as well as in patients suffering from mental illnesses, such as schizophrenia and major depressive disorder. In addition, it will discuss studies that examined the effects of psychotropic drugs, including antipsychotics and antidepressants, on the oxidative balance as well as studies that investigated the effectiveness of a direct modulation of oxidative mechanisms in counteracting the behavioral and functional alterations associated with psychiatric disorders, which supports the promising role of the redox system as a novel therapeutic target for the improved treatment of brain disorders.

Differential Neuroinflammatory Response in Male and Female Mice: A Role for BDNF.
A growing body of evidence supports the close relationship between major depressive disorder (MDD), a severe psychiatric disease more common among women than men, and alterations of the immune/inflammatory system. However, despite the large number of studies aimed at understanding the molecular bases of this association, a lack of information exists on the potential cross-talk between systems known to be involved in depression and components of the inflammatory response, especially with respect to sex differences. Brain-derived neurotrophic factor (BDNF) is a neurotrophin with a well-established role in MDD etiopathology: it is altered in depressed patients as well as in animal models of the disease and its changes are restored by antidepressant drugs. Interestingly, this neurotrophin is also involved in the inflammatory response. Indeed, it can be secreted by microglia, the primary innate immune cells in the central nervous system whose functions may be in turn regulated by BDNF. With these premises, in this study, we investigated the reciprocal impact of BDNF and the immune system by evaluating the neuroinflammatory response in male and female BDNF-heterozygous mutant mice acutely treated with the cytokine-inducer lipopolysaccharide (LPS). Specifically, we assessed the potential onset of an LPS-induced sickness behavior as well as changes of inflammatory mediators in the mouse hippocampus and frontal cortex, with respect to both genotype and sex. We found that the increased inflammatory response induced by LPS in the brain of male mice was independent of the genotype, whereas in the female, it was restricted to the heterozygous mice with no changes in the wild-type group, suggestive of a role for BDNF in the sex-dependent effect of the inflammatory challenge. Considering the involvement of both BDNF and neuroinflammation in several psychiatric diseases and the diverse incidence of such pathologies in males and females, a deeper investigation of the mechanisms underlying their interaction may have a critical translational relevance.

From Healthy Aging to Frailty: In Search of the Underlying Mechanisms.
Population aging is accelerating rapidly worldwide, from 461 million people older than 65 years in 2004 to an estimated 2 billion people by 2050, leading to critical implications for the planning and delivery of health and social care. The most problematic expression of population aging is the clinical condition of frailty, which is a state of increased vulnerability that develops as a consequence of the accumulation of microscopic damages in many physiological systems that lead to a striking and disproportionate change in health state, even after an apparently small insult. Since little is known about the biology of frailty, an important perspective to understand this phenomenon is to establish how the alterations that physiologically occur during a condition of healthy aging may instead promote cumulative decline with subsequent depletion of homoeostatic reserve and increase the vulnerability also after minor stressor events. In this context, the present review aims to provide a description of the molecular mechanisms that, by having a critical impact on behavior and neuronal function in aging, might be relevant for the development of frailty. Moreover, since these biological systems are also involved in the coping strategies set in motion to respond to environmental challenges, we propose a role for lifestyle stress as an important player to drive frailty in aging.

Chronic Stress Exposure Reduces Parvalbumin Expression in the Rat Hippocampus through an Imbalance of Redox Mechanisms: Restorative Effect of the Antipsychotic Lurasidone.

Psychiatric disorders are associated with altered function of inhibitory neurotransmission within the limbic system, which may be due to the vulnerability of selective neuronal subtypes to challenging environmental conditions, such as stress. In this context, parvalbumin-positive GABAergic interneurons, which are critically involved in processing complex cognitive tasks, are particularly vulnerable to stress exposure, an effect that may be the consequence of dysregulated redox mechanisms. CRANIECTOMY CAMOUFLAGES THE MILD FLUID PERCUSSION INJURY-INDUCED CHANGES IN NEUROGENESIS, NEUROINFLAMMATION, AND BEHAVIOR

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Mohd Aleem, Kailash Manda
Institute of Nuclear Medicine and Allied Sciences, Division Of Behavioral Neuroscience, Delhi, India

Craniectomy procedure is a prerequisite in several commonly used preclinical rodent models of Traumatic Brain Injury (TBI), including Fluid Percussion Injury (FPI). In preclinical TBI, injured animals are often compared with the 'sham' craniectomy. The present study conceptualized to evaluate the neurobehavioral consequences of craniectomy and its additive damaging effect with FPI. For this purpose, C57BL/6J male mice were exposed to lateral FPI and assessed for the potential changes in the structural and functional outcomes of the brain. The results showed a significant increase in immuno-reactivity of neurogenesis markers (DCX & Beta-III tubulin) in the hippocampus in both the craniectomy and mild FPI mice. Similarly, a significant increase in neuroinflammatory markers (GFAP & TMEM) in CA1 and CA3 regions were also reported. Additionally, significant axonal and dendritic structural alterations and cortical neuronal death were also reported following both the craniectomy and FPI. Moreover, both the groups also showed significant changes in neuromuscular strength and affective state. However, cognitive, motor and exploratory functions remain unaffected. In conclusion, we observed that craniectomy alone may cause substantial structural and functional changes in the brain and the magnitude of such alteration is very similar to mild TBI. Since FPI is the model for a mixed (focal & diffused) injury, it is more relevant to compare the results with naive control instead of the sham. However, for the long-term follow-up studies, the craniectomy-induced damage and time-dependent recovery have to be separately quantified. Moreover, procedural improvement is also warranted to minimize the detrimental consequences of craniectomy.

Low-pressure fluid percussion minimally adds to the sham craniectomy-induced neurobehavioral changes: Implication for experimental traumatic brain injury model.
Modeling experimental traumatic brain injury (TBI) in rodents is necessarily required to understand the pathophysiological and neurobehavioral consequences of neurotrauma. Numerous models have been developed to study experimental TBI. Fluid percussion injury (FPI) is the most extensively used model to represent clinical phenotypes. Nevertheless, the surgical 'sham' procedure (craniectomy), a prerequisite of FPI, is the impeding factor in experimental TBI. We hypothesized that if craniectomy causes substantial structural and functional changes in the brain, it might mimic the mild FPI-induced neurobehavioral dysfunctions. To understand the hypothesis, C57BL/6 mice were exposed to lateral FPI at 1.2 atm pressure and changes in the neuronal architecture, hippocampal neurogenesis, neuroinflammation, and behavioral functions were compared to the sham (craniectomy) and control mice at day 7 post-FPI. We observed that both the craniectomy and FPI significantly augmented the ipsilateral hippocampal neurogenesis as evaluated by DCX and Beta-III tubulin immunoreactivity. Similarly, a significant increase in GFAP and TMEM immunoreactivity in CA1 and CA3 regions showed that craniectomy mimics FPI-induced neuroinflammation. The additive damaging effect of craniectomy with FPI was also reported in the term of axonal and dendritic fragmentation, swelling and neuronal death using silver staining, Fluoro-jade, and MAP-2 immunoreactivity. Sham-exposed mice showed a significant functional decrease in grip strength. Our results indicate that sham craniectomy itself is enough to cause TBI like characteristics, and thus fluid percussion at mild pressure is minimally additive with craniectomy. Considering the method as a mixed (focal & diffused) injury model, the 'net neurotrauma severity' should be compared with naïve control instead of the sham as it is an outcome of cumulative damage due to fluid pressure and craniectomy. Nevertheless, to understand the long term consequences of neurotrauma, the extent of recovery in surgical sham may separately be quantified.

Clinical relevance of chronic neuropathic pain phenotypes in mice: A comprehensive behavioral analysis.
Despite a large number of preclinical studies performed each year, the safe and effective therapeutic interventions for chronic

pain are scant. Therefore, it appears that pre-clinical modeling requires a systematically organized behavioral test paradigm to quantify the response of animals for a specific pain state. The present study, therefore, conceptualized a test battery to evaluate the behavioral changes in mice following neuropathic pain. We employed sciatic nerve chronic constriction injury (CCI) in C57BL/6 J mice to model chronic pain state. Mice were monitored for thermal hyperalgesia and grip strength for 30 days. Subsequently, mice underwent a behavioral test battery consisting of the nociceptive threshold, the affective and cognitive functions and motor coordination, and strength. Our results showed that CCI mice are insensitive to thermal stimuli. However, nerve-injured mice showed significant changes in neuromuscular coordination, basal anxiety, and hedonic state. Such impaired neuromuscular coordination is indicative of disability rather than the actual pain phenotype. While using the digital gait analysis, our study revealed rationales for the insensitivity of CCI mice to thermal stimuli. Our results suggest that the predictive validity of the CCI model necessitates a comprehensive behavioral test battery to select the clinically relevant and measurable phenotype to quantify chronic neuropathic pain.

THE IMPACT OF A PRE-EXISTING TOXOPLASMA GONDII INFECTION FOLLOWING TRAUMATIC BRAIN INJURY IN MICE

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Tamara Baker[1], Mujun Sun[1], Bridgette Semple[1,2], Rhys Brady[1,2], Alessandro Uboldi[3,4], Shiraz Tyebji[3], Stuart Mcdonald[1], Christopher Tonkin[3,4], Richelle Mychasiuk[1], Sandy Shultz[1,2]

Introduction: Neuroinflammation is a fundamental response to traumatic brain injury (TBI) and contributes to secondary brain injury. The neurotropic parasite *Toxoplasma gondii* infects one-third globally and as no cure exists, many individuals have a chronic *T. gondii* infection when TBI occurs. Chronic *T. gondii* infection is characterised by parasitic cysts in neurons and low-grade neuroinflammation. **Aims:** To investigate the impact of chronic *T. gondii* infection on TBI outcomes in a mouse model of severe TBI, with the hypothesis that chronic *T. gondii* infection would exacerbate neuroinflammation and behavioural outcomes. **Methods:** Six-week-old male and female C57BL/6 Jax mice were intraperitoneally administered either *T. gondii* tachyzoites or PBS. At six-weeks post-injection, mice received either a controlled cortical impact or sham injury. Behavioural and neuroinflammatory changes were evaluated within 1-week or 3-4 months post-injury. Seizure susceptibility and pathology were assessed 4 months post-injury. **Results:** Gene expression analyses indicate that acutely post-injury, *T. gondii* infection intensified the neuroimmune response in the ipsilateral cortex. In the long-term, both TBI and *T. gondii* infection negatively altered spatial memory in female mice. In both sexes, TBI mice exhibited decreased anxiety levels compared to sham-injured mice. Further, data suggests *T. gondii* infection modified motor function and various gait parameters in female mice. **Conclusions:** Chronic *T. gondii* infection amplified neuroinflammation acutely post-injury; however, findings to date suggest that infection and injury did not alter long-term behavioural outcomes in a synergistic manner. Analysis of seizure susceptibility, as well as brain and peripheral tissue is ongoing.

Catastrophic consequences: can the feline parasite Toxoplasma gondii prompt the purrfect neuroinflammatory storm following traumatic brain injury?
Traumatic brain injury (TBI) is one of the leading causes of morbidity and mortality worldwide; however, treatment development is hindered by the heterogenous nature of TBI presentation and pathophysiology. In particular, the degree of neuroinflammation after TBI varies between individuals and may be modified by other factors such as infection. Toxoplasma gondii, a parasite that infects approximately one-third of the world's population, has a tropism for brain tissue and can persist as a life-long infection. Importantly, there is notable overlap in the pathophysiology between TBI and T. gondii infection, including neuroinflammation. This paper will review current understandings of the clinical problems, pathophysiological mechanisms, and functional outcomes of TBI and T. gondii, before considering the potential synergy between the two conditions. In particular, the discussion will focus on neuroinflammatory processes such as microglial activation, inflammatory cytokines, and peripheral immune cell recruitment that occur during T. gondii infection and after TBI. We will present the notion that these overlapping pathologies in TBI individuals with a chronic T. gondii infection have the strong potential to exacerbate neuroinflammation and related brain damage, leading to amplified functional deficits. The impact of chronic T. gondii infection on TBI should therefore be investigated in both preclinical and clinical studies as the possible interplay could influence treatment strategies.

Targeting the Cerebrovascular System: Next-Generation Biomarkers and Treatment for Mild Traumatic Brain Injury.
The diagnosis, prognosis, and treatment of mild traumatic brain injuries (mTBIs), such as concussions, are significant unmet medical issues. The kinetic forces that occur in mTBI adversely affect the cerebral vasculature, making cerebrovascular injury

(CVI) a pathophysiological hallmark of mTBI. Given the importance of a healthy cerebrovascular system in overall brain function, CVI is likely to contribute to neurological dysfunction after mTBI. As such, CVI and related pathomechanisms may provide objective biomarkers and therapeutic targets to improve the clinical management and outcomes of mTBI. Despite this potential, until recently, few studies have focused on the cerebral vasculature in this context. This article will begin by providing a brief overview of the cerebrovascular system followed by a review of the literature regarding how mTBI can affect the integrity and function of the cerebrovascular system, and how this may ultimately contribute to neurological dysfunction and neurodegenerative conditions. We then discuss promising avenues of research related to mTBI biomarkers and interventions that target CVI, and conclude that a clinical approach that takes CVI into account could result in substantial improvements in the care and outcomes of patients with mTBI.

ROAD TO RECOVERY: EXAMINING THE EFFECTS OF SHIP-1 ON NEUROIMMUNE RESPONSES AFTER PAEDIATRIC HEAD INJURIES

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Erskine Chu[1,2], Akram Zamani[1], Larissa Dill[3], Rishabh Sharma[1], April Raftery[2], Evelyn Tsantikos[2], Richelle Mychasiuk[1], Margaret Hibbs[2], Bridgette Semple[1,4]

Introduction: Recovery after early-life traumatic brain injury (TBI) is often hindered by secondary neuroinflammation, likely driven by chronically activated pro-inflammatory microglia. However, factors that induce aberrant microglial responses have remained elusive. Various studies indicate that loss of SH2 domain-containing inositol 5' phosphatase (SHIP-1) activity dysregulate immunological responses. SHIP-1 negatively regulates the phosphoinositide 3-kinase (PI3K) signalling pathway in immune cells, such that SHIP-1 deficiency results in chronic systemic inflammation. **Aims:** To investigate the role of SHIP-1 in microglial activation and function in a mouse model of severe paediatric TBI, with the hypothesis that SHIP-1 deficiency (-/-) would exacerbate microglial responses and worsen outcomes following severe paediatric TBI. **Methods:** SHIP-1+/- and -/- mice received a controlled cortical impact (n=17; n=11) or sham surgery (n=15; n=10) at postnatal day 21. Behavioural changes, microglial responses (immunostaining and gene expression), and tissue damage were evaluated at 7 days post-injury. **Results:** TBI mice exhibited elevated anxiety levels and altered short-term spatial memory compared to sham animals, alongside a reduction in the volume of healthy cortical tissue, independent of genotype ($p>0.05$). Gene expression analyses of microglial activation markers indicate enhanced microglial responses in SHIP-1-/- mice. However, injury-induced Iba1+ microglial immunofluorescence was similar between genotypes in the ipsilateral cortex, dentate gyrus and dorsolateral thalamus ($p>0.05$), while GFAP+ astrocyte immunoreactivity was elevated 2-fold in SHIP-1-/- mice compared to +/- controls ($p=0.01$). **Conclusion:** SHIP-1 deficiency altered acute neuroimmune responses after paediatric TBI. However, further work is required to understand how SHIP-1 may regulate recovery in this context.

Dysregulated phosphoinositide 3-kinase signaling in microglia: shaping chronic neuroinflammation.
Microglia are integral mediators of innate immunity within the mammalian central nervous system. Typical microglial responses are transient, intending to restore homeostasis by orchestrating the removal of pathogens and debris and the regeneration of damaged neurons. However, prolonged and persistent microglial activation can drive chronic neuroinflammation and is associated with neurodegenerative disease. Recent evidence has revealed that abnormalities in microglial signaling pathways involving phosphatidylinositol 3-kinase (PI3K) and protein kinase B (AKT) may contribute to altered microglial activity and exacerbated neuroimmune responses. In this scoping review, the known and suspected roles of PI3K-AKT signaling in microglia, both during health and pathological states, will be examined, and the key microglial receptors that induce PI3K-AKT signaling in microglia will be described. Since aberrant signaling is correlated with neurodegenerative disease onset, the relationship between maladapted PI3K-AKT signaling and the development of neurodegenerative disease will also be explored. Finally, studies in which microglial PI3K-AKT signaling has been modulated will be highlighted, as this may prove to be a promising therapeutic approach for the future treatment of a range of neuroinflammatory conditions.

A systemic immune challenge to model hospital-acquired infections independently regulates immune responses after pediatric traumatic brain injury.
Traumatic brain injury (TBI) is a major cause of disability in young children, yet the factors contributing to poor outcomes in this population are not well understood. TBI patients are highly susceptible to nosocomial infections, which are mostly acquired within the first week of hospitalization, and such infections may modify TBI pathobiology and recovery. In this study,

we hypothesized that a peripheral immune challenge such as lipopolysaccharide (LPS)-mimicking a hospital-acquired infection-would worsen outcomes after experimental pediatric TBI, by perpetuating the inflammatory immune response. J Neuroinflammation, 2021; 18

Background Adolescence is associated with ongoing maturation in the brain, particularly the medial prefrontal cortex (mPFC), and systemically, whereby the brain-gut-immune axis is developing. Given that adolescents are more likely than adults to experience repetitive mild traumatic brain injuries (RmTBI), they may be at increased risk for worsened outcomes. **Aim** This study aimed to examine how depletion of the gut microbiome mediates behavioural and neuropathological recovery from RmTBI in adolescent rats. **Methods** The rat microbiota was depleted using an antibiotic cocktail which was administered for 14 days prior to receiving 3 mTBIs. Rodent temperament was assessed five days post-injury using a 15-minute video recording. Additionally, we used immunohistochemical staining to examine the number of perineuronal nets (PNNs) and parvalbumin interneurons (PVs) within the mPFC. Three-way ANOVAs with sex, injury, and treatment as factors were run. **Results** We identified significant sex, injury, and treatment effects in adolescent temperament, including modifications to social interactions such as allogrooming and playing ($p<.05$). The number of PNNs increased in males and females that experience RmTBI+Placebo ($p <.05$). Interestingly, for rats that experienced RmTBI+antibiotics, the number of PNNs increased in males but decreased in females ($p<.05$). For PVs there was an increase in RmTBI+placebo treated rats however, in the RmTBI+antibiotic treated rats there was a decrease in females, but an increase in males. **Conclusions** We found that changes within the microbiome can modify behavioural and neuropathological outcomes following RmTBI in adolescence, however contrary to our hypotheses, the effects of RmTBI and microbiome depletion were not additive.

Synchronizing our clocks as we age: the influence of the brain-gut-immune axis on the sleep-wake cycle across the lifespan. The microbes that colonize the small and large intestines, known as the gut microbiome, play an integral role in optimal brain development and function. The gut microbiome is a vital component of the bidirectional communication pathway between the brain, immune system, and gut, also known as the brain-gut-immune axis. To date, there has been minimal investigation into the implications of improper development of the gut microbiome and the brain-gut-immune axis on the sleep-wake cycle, particularly during sensitive periods of physical and neurological development, such as childhood, adolescence, and senescence. Therefore, this review will explore the current literature surrounding the overlapping developmental periods of the gut microbiome, brain, and immune system from birth through to senescence, while highlighting how the brain-gut-immune axis affects the maturation and organization of the sleep-wake cycle. We also examine how a dysfunction to either the microbiome or the sleep-wake cycle negatively affects the bidirectional relationship between the brain and gut, and subsequently the overall health and functionality of this complex system. Additionally, this review integrates therapeutic studies to demonstrate when dietary manipulations, such as supplementation with probiotics and prebiotics, can modulate the gut microbiome to enhance the health of the brain-gut-immune axis and optimize our sleep-wake cycle.

CHRONIC INTRACEREBROVENTRICULAR ADMINISTRATION OF OREXIN-A DOES NOT MODIFY BEHAVIOURAL OUTCOMES FOLLOWING REPETITIVE MILD TRAUMATIC BRAIN INJURY IN RATS

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Crystal Li, Jennaya Christensen, Glenn Yamakawa, Sandy Shultz, Richelle Mychasiuk

AIMS: Sleep-wake disturbances following mild traumatic brain injury (mTBI) are associated with complications to recovery, so it is essential to consider the mechanisms underlying mTBI-induced sleep-wake disturbances. Changes to hypothalamic function, specifically orexinergic function, have been established following mTBI. Considering that orexinergic function plays a dominant role in regulating the sleep-wake cycle, the aim of this study was to assess how pharmacological manipulation of orexinergic signalling influences repetitive mTBI (RmTBI) outcomes. METHODS: Adult male Sprague Dawley rats were randomly assigned to receive either RmTBIs or sham injuries. Following the injuries, intracerebroventricular (ICV) injections of orexin-A (ORXA) or vehicle were administered via cannulas previously implanted into the lateral ventricle. Behavioural testing was conducted to examine the effects of ORXA versus vehicle treatment on RmTBI-induced impairments. Brain tissue was additionally processed for immunohistochemical analysis of hypothalamic regions. RESULTS: RmTBI-driven changes were observed whereby RmTBI groups spent significantly more time in the open arms of the elevated plus maze ($p<.05$) and remained for longer on the rotarod relative to sham groups ($p<.05$). Video-based sleep monitoring confirmed that ORXA increased duration of wakefulness relative to vehicle groups ($p<.05$), but ORXA did not significantly influence behavioural outcomes when compared to vehicle groups ($p>.05$). Immunohistochemical analysis of brain tissue showed RmTBI-driven differences ($p<.05$). DISCUSSION: Sleep-wake disturbances and impairments following Rm-TBI may not be consequences of orexinergic dysregulation. To better understand the basis of these observed outcomes, additional insights into RmTBI-driven alterations in cognition and hypothalamic function are required.

A NOVEL RAT MODEL OF HETEROTOPIC OSSIFICATION AFTER POLYTRAUMA WITH TRAUMATIC BRAIN INJURY

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Rhys Brady[1], Kerrui Wong[1], Stuart Mcdonald[1], Peter Lee[2], Dale Robinson[2], Sandy Shultz[1]
[1]Monash University, Neuroscience, Melbourne, Australia, [2]University of Melbourne, Department Of Biomedical Engineering, Melbourne, Australia

Introduction: Neurological heterotopic ossification (NHO) is characterized by abnormal bone growth in soft tissue and joints that commonly occurs in severe traumatic brain injury (TBI) patients, particularly in the presence of concomitant musculoskeletal injuries (i.e. polytrauma). The ectopic bone frequently causes pain, and restricts mobility. Objectives: There is currently a lack of animal models that mimic these injury combinations, which has limited our understanding of NHO pathobiology, biomarkers, and treatments. To address this shortcoming, here we present a novel rat model that combines TBI, femoral fracture, and muscle crush injury. Materials and Methods: Young adult male Sprague Dawley rats were randomly assigned into three different injury groups: triple sham-injury, peripheral injury only (i.e., sham-TBI + fracture + muscle injury) or triple injury (i.e., TBI + fracture + muscle injury). Results and Discussion: Evidence of ectopic bone in the injured hind-limb, as confirmed by micro-computed tomography was found at 6-weeks post-injury in 70% of triple injury rats, 20% of peripheral injury rats, and 0% of the sham-injured controls. Furthermore, the triple injury rats had higher ectopic bone severity scores than the sham-injured group. We also have muscle and blood samples from rats at 2-, and 7 days post injury and at 12 weeks post injury. Analysis to identify blood biomarkers and novel mechanisms of NHO formation is ongoing. Conclusion: This model will provide a platform for future studies to identify underlying mechanisms, biomarkers, and develop evidence based pharmacological treatments to combat this debilitating long-term complication of TBI and polytrauma.

Aims: Traumatic brain injury (TBI) is becoming not only a global health problem but also a serious socioeconomic burden. TBI patients may develop persistent cognitive impairments such as loss of attention and memory, increasing risk of neurodegenerative disorders. Our previous study has proven the correlation of BMX to severity of TBI in rat model. TBI patients with an increased level of BMX in the first 3 weeks of their injury are more prone to have a greater severity of dizziness at 6 weeks post-injury. Additionally, BMX single nucleotide polymorphism is associated with post-TBI dizziness and anxiety. However, mechanisms behind the role of BMX in TBI are not yet understood completely. Here, we aim to investigate the role of BMX in cognitive impairment after TBI. **Methods:** We induced TBI in C57BL/6 (WT) mice and BMX knockout (BMX-KO) mice using controlled cortical impact. Cognitive and memory functions were analyzed by novel object recognition (NOR) and water maze test. Motor functions were analyzed by open field and beam walking. **Results:** NOR and water maze analysis showed that cognitive and memory function in WT mice decreased 7 days post-injury but there was no significant difference in BMX-KO mice after injury. Open field analysis revealed BMX-KO mice exhibited less anxiety than WT mice. Interestingly, balance function is worse in BMX-KO mice comparing to WT mice. **Conclusions:** Depletion of BMX can improve cognitive and motor function after TBI. Targeting BMX and its downstream molecules may be a good diagnostic and therapeutic strategy for TBI.

Introduction: After traumatic brain injury (TBI), evolving changes include abnormal brain metabolism, contributing to secondary injury. High brain extracellular lactate/pyruvate ratio (LPR), indicating increased glycolysis and reduced mitochondrial activity, correlates with unfavourable patient outcome. In-vitro, succinate partially protected rat glia against rotenone-induced metabolic dysfunction. Rotenone inhibits complex I of the mitochondrial electron transport chain (ETC). Succinate, a tricarboxylic acid cycle intermediate, interacts with complex II of the ETC, bypassing complex I. **Objectives:** To study metabolic dysfunction in human induced neurons (iNs) as a model for TBI and assess the putative neurotherapeutic agent succinate for metabolic protection. **Materials and Methods:** We used an established protocol Optimised Inducible Overexpression, producing iNs by overexpression of transcription factor Neurogenin-2. After differentiation, rotenone at 10- or 25-uM and disodium succinate at 5-, 10-, 25- or 50-mM were added to iNs, evaluated at 12-, 24- and 48-h. Hoechst 33342 and propidium iodide staining quantified viability. Metabolism was assessed by ISCUSflex analysis of LPR in the extracellular medium. **Results:** At 24h and 48h (but not at 12h), LPR increased significantly in rotenone-treated iNs, indicating metabolic dysfunction as expected. However, succinate did not protect iNs against rotenone at any of the concentrations and timepoints we tested. **Conclusion:** We showed that neurons' mitochondria were inhibited by rotenone but not protected by succinate, unlike our earlier study where succinate protected glia against rotenone. We postulate that a mechanism whereby succinate might rescue neurons is via interaction between glia and neurons. Future investigations will thus include co-culture of iNs and glia.

ELECTROPHYSIOLOGICAL AND BEHAVIORAL CHARACTERIZATION OF MURINE MODEL EXPOSED TO ACUTE SARIN SUBLETHAL DOSES AND ANTIDOTE THERAPY EVALUATION

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Pauline Thiebot, Mélanie Lagadec, Julie Knoertzer, Karine Thibault, Gregory Dal Bo
French Armed Forces Biomedical Research Institute, Departement Of Toxicology And Chemical Risks, Brétigny-sur-orge, France

Warfare neurotoxicants such as sarin, soman or VX, are organophosphorus compounds which irreversibly inhibit cholinesterase. High-dose exposure with nerve agents (NA) is known to produce seizure activity and related brain damage, while less is known about the effects of acute sublethal dose exposure. The aim of this study is to characterize behavioral, brain activity and neuroinflammatory modifications at different time points after exposure to sublethal doses of sarin. First, we conducted a behavioral analysis of symptoms during the first hour following sarin challenge and reported the intoxication severity using a specific scoring scale. The toxidrome intensity was dose-dependent and proportional to the cholinesterase activity inhibition evaluated in mice brain. Electrocorticographic (ECoG) recording revealed an altered cerebral activity early after sarin exposure, with a disruption of brainwave power in a dose-dependent manner and persistent up to 24 hours. To evaluate long lasting changes and protective effects of emergency treatment (ET; atropine + pralidoxime), we conducted ECoG recording for 30 days on mice exposed to 0.9 LD50 of sarin with or without ET. Only mice exposed to sarin without ET showed long-lasting impairment of theta and beta rhythms 1-month post-exposure. The administration of the ET seems to restore cerebral activity in sarin-exposed mice. Our findings identified both transient and long-term ECoG alterations following exposure to sub-lethal doses of sarin, effects partially ameliorated by the administration of ET. In addition, we plan to evaluate ET effects on neuroinflammation, cognitive behavior and histopathologies in sarin-exposed mice.

ACUTE MICROGLIAL INTERVENTION BY CMET INHIBITOR ELICITS NEURONAL SURVIVAL AND MOTOR RECOVERY IN MURINE MILD BLUNT TBI MODEL

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Rida Rehman[1], Michael Miller[2], Lobna Elsayed[1], Aya Takeoka[2], Francesco Roselli[3,4]
[1]Ulm University, Neurology, Ulm, Germany, [2]KULeuven, Neuro-electronics Research Flanders (nerf), Leuven, Belgium, [3]Ulm University, German Center For Neurodegenerative Diseases, Ulm, Germany, [4]ZBMF, Neurology, Ulm, Germany

Traumatic Brain Injury (TBI) is a highly complicated pathology involving multiple events occurring simultaneously including, but not limited to, neuroinflammation, blood brain barrier disruption, apoptosis and alteration in neuronal signaling. Microglia acts as a double-edged sword in brain trauma and plays a critical role in injury-related neuroinflammation. To understand the temporal dynamics of signaling processes in traumatic Brain Injury (TBI), we performed an advanced unbiased approach using large-scale array phosphoproteomics to map receptor tyrosine kinase (RTK) mediated acute signaling in a murine mild blunt TBI model. Our results revealed that phosphorylated levels of B-cell specific Bruton's tyrosine kinase (Btk) and wound healing associated cMet (HGFR) were upregulated as early as 3h post injury in microglial cells. Small molecule inhibition of Btk failed to produce an effect in signaling pattern or behavioral assessment however cMet emerged as a selective modifier of the early microglial response. cMet blockade prevented the induction of microglial inflammatory mediators, reactive microglia morphology, and TBI-associated responses in neurons, vessels, and brain extracellular matrix. Acute or prolonged cMet inhibition altered microglial morphology to ramified (resting state), compared to amebiod (activated) in sham controls, ameliorated neuronal survival and significantly improved motor performance. Our findings identify cMet as a modulator of early neuroinflammation in TBI with translational potential and indicate several RTK families as possible targets for TBI treatment. We conclude that acute microglia inactivation by cMet (expressed in microglia) inhibition and promotion of resting microglial state mitigates pathological response as early as 1-day post TBI and ensures neuronal protection.

Differential effect of ethanol intoxication on peripheral markers of cerebral injury in murine blunt traumatic brain injury.
Blood-based biomarkers have proven to be a reliable measure of the severity and outcome of traumatic brain injury (TBI) in both murine models and patients. In particular, neuron-specific enolase (NSE), neurofilament light (NFL) and S100 beta (S100B) have been investigated in the clinical setting post-injury. Ethanol intoxication (EI) remains a significant comorbidity in TBI, with 30-40% of patients having a positive blood alcohol concentration post-TBI. The effect of ethanol on blood-based biomarkers for the prognosis and diagnosis of TBI remains unclear. In this study, we investigated the effect of EI on NSE, NFL and S100B and their correlation with blood-brain barrier integrity in a murine model of TBI.

Acute TBK1/IKK-ε Inhibition Enhances the Generation of Disease-Associated Microglia-Like Phenotype Upon Cortical Stab-Wound Injury.
Traumatic brain injury has a poorer prognosis in elderly patients, possibly because of the enhanced inflammatory response characteristic of advanced age, known as "inflammaging." Recently, reduced activation of the TANK-Binding-Kinase 1 (Tbk1) pathway has been linked to age-associated neurodegeneration and neuroinflammation. Here we investigated how the blockade of Tbk1 and of the closely related IKK-ε by the small molecule Amlexanox could modify the microglial and immune response to cortical stab-wound injury in mice. We demonstrated that Tbk1/IKK-ε inhibition resulted in a massive expansion of microglial cells characterized by the TMEM119/CD11c phenotype, expressing high levels of CD68 and CD317, and with the upregulation of Cst7a, Prgn and Ccl4 and the decrease in the expression levels of Tmem119 itself and P2yr12, thus a profile close to Disease-Associated Microglia (DAM, a subset of reactive microglia abundant in Alzheimer's Disease and other neurodegenerative conditions). Furthermore, Tbk1/IKK-ε inhibition increased the infiltration of CD3 lymphocytes, CD169 macrophages and CD11c/CD169 cells. The enhanced immune response was associated with increased expression of Il-33, Ifn-g, Il-17, and Il-19. This upsurge in the response to the stab wound was associated with the expanded astroglial scars and

increased deposition of chondroitin-sulfate proteoglycans at 7 days post injury. Thus, Tbk1/IKK-ε blockade results in a massive expansion of microglial cells with a phenotype resembling DAM and with the substantial enhancement of neuroinflammatory responses. In this context, the induction of DAM is associated with a detrimental outcome such as larger injury-related glial scars. Thus, the Tbk1/IKK-ε pathway is critical to repress neuroinflammation upon stab-wound injury and Tbk1/IKK-ε inhibitors may provide an innovative approach to investigate the consequences of DAM induction.

STAT6 mediates the effect of ethanol on neuroinflammatory response in TBI.
Traumatic brain injury (TBI) and ethanol intoxication (EI) frequently coincide, particularly in young subjects. However, the mechanisms of their interaction remain poorly understood. Among other pathogenic pathways, TBI induces glial activation and neuroinflammation in the hippocampus, resulting in acute and chronic hippocampal dysfunction. In this regard, we investigated the role of EI affecting these responses unfolding after TBI. We used a blunt, weight-drop approach to model TBI in mice. Male mice were pre-administered with ethanol or vehicle to simulate EI. The neuroinflammatory response in the hippocampus was assessed by monitoring the expression levels of >20 cytokines, the phosphorylation status of transcription factors and the phenotype of microglia and astrocytes. We used AS1517499, a brain-permeable STAT6 inhibitor, to elucidate the role of this pathway in the EI/TBI interaction. We showed that TBI causes the elevation of IL-33, IL-1β, IL-38, TNF-α, IFN-α, IL-19 in the hippocampus at 3 h time point and concomitant EI results in the dose-dependent downregulation of IL-33, IL-1β, IL-38, TNF-α and IL-19 (but not of IFN-α) and in the selective upregulation of IL-13 and IL-12. EI is associated with the phosphorylation of STAT6 and the transcription of STAT6-controlled genes. Moreover, ethanol-induced STAT6 phosphorylation and transcriptional activation can be recapitulated in vitro by concomitant exposure of neurons to ethanol, depolarization and inflammatory stimuli (simulating the acute trauma). Acute STAT6 inhibition prevents the effects of EI on IL-33 and TNF-α, but not on IL-13 and negates acute EI beneficial effects on TBI-associated neurological impairment. Additionally, EI is associated with reduced microglial activation and astrogliosis as well as preserved synaptic density and baseline neuronal activity 7 days after TBI and all these effects are prevented by acute administration of the STAT6 inhibitor concomitant to EI. EI concomitant to TBI exerts significant immunomodulatory effects on cytokine induction and microglial activation, largely through the activation of STAT6 pathway, ultimately with beneficial outcomes.

29774782: Chandrasekar A, Olde Heuvel F, Wepler M, Rehman R, Palmer A, Catanese A, Linkus B, Ludolph A, Boeckers T, Huber-Lang M, Radermacher P, Roselli F
The Neuroprotective Effect of Ethanol Intoxication in Traumatic Brain Injury Is Associated with the Suppression of ErbB Signaling in Parvalbumin-Positive Interneurons.
Ethanol intoxication (EI) is a frequent comorbidity of traumatic brain injury (TBI), but the impact of EI on TBI pathogenic cascades and prognosis is unclear. Although clinical evidence suggests that EI may have neuroprotective effects, experimental support is, to date, inconclusive. We aimed at elucidating the impact of EI on TBI-associated neurological deficits, signaling pathways, and pathogenic cascades in order to identify new modifiers of TBI pathophysiology. We have shown that ethanol administration (5 g/kg) before trauma enhances behavioral recovery in a weight-drop TBI model. Neuronal survival in the injured somatosensory cortex was also enhanced by EI. We have used phospho-receptor tyrosine kinase (RTK) arrays to screen the impact of ethanol on TBI-induced activation of RTK in somatosensory cortex, identifying ErbB2/ErbB3 among the RTKs activated by TBI and suppressed by ethanol. Phosphorylation of ErbB2/3/4 RTKs were upregulated in vGlut2 excitatory synapses in the injured cortex, including excitatory synapses located on parvalbumin (PV)-positive interneurons. Administration of selective ErbB inhibitors was able to recapitulate, to a significant extent, the neuroprotective effects of ethanol both in sensorimotor performance and structural integrity. Further, suppression of PV interneurons in somatosensory cortex before TBI, by engineered receptors with orthogonal pharmacology, could mimic the beneficial effects of ErbB inhibitors. Thus, we have shown that EI interferes with TBI-induced pathogenic cascades at multiple levels, with one prominent pathway, involving ErbB-dependent modulation of PV interneurons.

Neuroinflammation after Traumatic Brain Injury Is Enhanced in Activating Transcription Factor 3 Mutant Mice.
Traumatic brain injury (TBI) induces a neuroinflammatory response resulting in astrocyte and microglia activation at the lesion site. This involves upregulation of neuroinflammatory genes, including chemokines and interleukins. However, so far, there is lack of knowledge on transcription factors (TFs) modulating this TBI-associated gene expression response. Herein, we analyzed activating transcription factor 3 (ATF3), a TF encoding a regeneration-associated gene (RAG) predominantly studied in peripheral nervous system (PNS) injury. ATF3 contributes to PNS axon regeneration and was shown before to regulate inflammatory processes in other injury models. In contrast to PNS injury, data on ATF3 in central nervous system

(CNS) injury are sparse. We used Atf3 mouse mutants and a closed-head weight-drop-based TBI model in adult mice to target the rostrolateral cortex resulting in moderate injury severity. Post-TBI, ATF3 was upregulated already at early time points (i.e,. 1-4 h) post-injury in the brain. Mortality and weight loss upon TBI were slightly elevated in Atf3 mutants. ATF3 deficiency enhanced TBI-induced paresis and hematoma formation, suggesting that ATF3 limits these injury outcomes in wild-type mice. Next, we analyzed TBI-associated RAG and inflammatory gene expression in the cortical impact area. In contrast to the PNS, only some RAGs (Atf3, Timp1, and Sprr1a) were induced by TBI, and, surprisingly, some RAG encoding neuropeptides were downregulated. Notably, we identified ATF3 as TF-regulating proneuroinflammatory gene expression, including CCL and CXCL chemokines (Ccl2, Ccl3, Ccl4, and Cxcl1) and lipocalin. In Atf3 mutant mice, mRNA abundance was further enhanced upon TBI compared to wild-type mice, suggesting immune gene repression by wild-type ATF3. In accord, more immune cells were present in the lesion area of ATF3-deficient mice. Overall, we identified ATF3 as a new TF-mediating TBI-associated CNS inflammatory responses.

29306704: Chandrasekar A, Aksan B, Heuvel FO, Förstner P, Sinske D, Rehman R, Palmer A, Ludolph A, Huber-Lang M, Böckers T, Mauceri D, Knöll B, Roselli F

Neuroprotective effect of acute ethanol intoxication in TBI is associated to the hierarchical modulation of early transcriptional responses.

Ethanol intoxication is a risk factor for traumatic brain injury (TBI) but clinical evidence suggests that it may actually improve the prognosis of intoxicated TBI patients. We have employed a closed, weight-drop TBI model of different severity (2cm or 3cm falling height), preceded (-30min) or followed (+20min) by ethanol administration (5g/Kg). This protocol allows us to study the interaction of binge ethanol intoxication in TBI, monitoring behavioral changes, histological responses and the transcriptional regulation of a series of activity-regulated genes (immediate early genes, IEGs). We demonstrate that ethanol pretreatment before moderate TBI (2cm) significantly reduces neurological impairment and accelerates recovery. In addition, better preservation of neuronal numbers and cFos+cells was observed 7days after TBI. At transcriptional level, ethanol reduced the upregulation of a subset of IEGs encoding for transcription factors such as Atf3, c-Fos, FosB, Egr1, Egr3 and Npas4 but did not affect the upregulation of others (e.g. Gadd45b and Gadd45c). While a subset of IEGs encoding for effector proteins (such as Bdnf, InhbA and Dusp5) were downregulated by ethanol, others (such as Il-6) were unaffected. Notably, the majority of genes were sensitive to ethanol only when administered before TBI and not afterwards (the exceptions being c-Fos, Egr1 and Dusp5). Furthermore, while severe TBI (3cm) induced a qualitatively similar (but quantitatively larger) transcriptional response to moderate TBI, it was no longer sensitive to ethanol pretreatment. Thus, we have shown that a subset of the TBI-induced transcriptional responses were sensitive to ethanol intoxication at the instance of trauma (ultimately resulting in beneficial outcomes) and that the effect of ethanol was restricted to a certain time window (pre TBI treatment) and to TBI severity (moderate). This information could be critical for the translational value of ethanol in TBI and for the design of clinical studies aimed at disentangling the role of ethanol intoxication in TBI.

EFFECTS OF PIOGLITAZONE ON THE CORTICAL DAMAGE AND MOTOR PERFORMANCE FOLLOWING TRAUMATIC BRAIN INJURY IN THE RAT

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Petra Dolenec
University of Rijeka Faculty of Medicine, Department Of Basic And Clinical Pharmacology And Toxicology, Rijeka, Croatia

Aims: Pioglitazone has shown some beneficial effects in various animal models of brain injury. In this study, we investigated whether pioglitazone has effects on some parameters of the parietal cortex tissue damage as well as on the motoric performance following traumatic brain injury (TBI) in rats. Methods: Pioglitazone (3 mg/kg) or vehicle were administered i.p. at 10 minutes, 12, 24 and 48 hours after the TBI induced by the lateral fluid percussion brain injury method. Motor functions were evaluated at post-injury day (PID) 1, 2 and 3 using the modified neurological severity score (mNSS) and rotarod test (RRT). Rats were sacrificed 72 h after TBI and their brains were prepared for histologic analyses. Results: In all the brain-injured animals significant decrease in the mNSS at all investigated time points was detected, with no difference between the vehicle and pioglitazone groups. At PID1, same results were detected using RRT, but on PID2, pioglitazone treated animals seemed to return to the control values while vehicle treated rats still showed motor impairment. On PID3, no difference between the groups was evident. Apoptotic cells were present in parietal cortex of both brain-injured groups but pioglitazone did not have significant effects on this parameter. Significant synaptic perturbations, using synaptophysin as a marker, were not detected. Conclusions: Preliminary results of our study imply limited beneficial effects of pioglitazone on motoric performance in traumatized rats but not on the other investigated parameters in used experimental conditions. This work was supported by project uniri-biomed-18-204 to PD.

CELLULAR SENESCENCE AND NEUROINFLAMMATION FOLLOWING CONTROLLED CORTICAL IMPACT TRAUMATIC BRAIN INJURY IN JUVENILE MICE

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Zahra Al-Khateeb[1], Shenel Shekerzade[1], Hasna Boumenar[2], Sian Henson[3], Jordi Tremoleda[1], A. T. Michael-Titus[1]
[1]Queen Mary University of London, Blizard Institute, London, United Kingdom, [2]Queen Mary University of London, London, United Kingdom, School Of Biological And Behavioural Sciences, London, United Kingdom, [3]Queen Mary University of London, London, United Kingdom, The William Harvey Research Institute, London, United Kingdom

Traumatic brain injury (TBI) is the leading cause of disability and death in young adults, and also increases the risk of neurodegeneration. The mechanisms linking moderate to severe TBI to neurodegeneration are not known. It has been proposed that cellular senescence induction post-injury could amplify neuroinflammation and induce long-term changes. The impact of these processes after injury to an immature brain has not been characterised. We carried out a controlled cortical impact injury (CCI) in juvenile 1 month-old male CD1 mice. Animals were anesthetised and received a unilateral CCI injury. The sham group received anaesthesia and had a craniotomy. A naïve group had no intervention. The brain tissue was analysed at 5 days and 35 days post-injury using immunohistochemistry and markers for microglia, astrocytes and senescence. Compared to naïve animals, injured mice showed an increased microglial and astrocytic reaction early post-injury, as reflected in Iba1 and GFAP markers, respectively; the GFAP increase persisted in the later phase. The senescence analysis showed a significant increase in γH2AX-53BP1 nuclear foci, 8-oxoguanine, $p19^{ARF}$, $p16^{INK4a}$ and p53 expressions in naïve vs. sham groups and naïve vs. CCI groups, at 5-dpi. At 35 days, the difference was no longer statistically significant. The injury induced a decrease p21 expression vs. the naïve group, at 35-dpi. These results indicate the induction of a complex senescence response after immature brain injury. Some changes occur early and may reflect the activation/proliferation of non-neuronal cells post-injury, whereas changes such as p21 downregulation, may reflect a delayed response and pro-repair processes.

INTERACTION BETWEEN NO AND ITS DERIVATIVES WITH OGDHC IN CEREBRAL CORTEX UPON BRAIN INJURY

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Annette Vaglio[1], Adelheid Weidinger[1], Vanessa Goeschl[2], Matej Hotka[2], Helmut Kubista[2], Andrey Kozlov[1]
[1]Ludwig Boltzmann Institute for Trauma, Molecular Basis Of Organ Failure And Regeneration, Vienna, Austria, [2]Center of Physiology and Pharmacology, Department Of Neurophysiology And Neuropharmacology, Medical University Of Vienna, Vienna, Austria

Hemorrhage, cerebral ischemia, and neuro-inflammation are the major features of Trauma Brain Injury (TBI). Neuro-inflammation is accompanied by the elevated expression and the release of inflammatory mediators, such as nitric oxide (NO) synthetized by inducible NO synthase (iNOS), while upon ischemia NO can be released by the reduction of nitrite. NO has been shown to inhibit complex I and IV of the electron transport chain in the mitochondria. More recently, it has been shown that (i) NO also inhibits oxoglutarate dehydrogenase complex (OGDHC) an enzyme of the tricarboxylic acid cycle (TCA), and (ii) nitrite, an oxidative product of NO, accumulates in the brain tissue upon trauma. The aim of this study was to clarify whether NO or nitrite or both can inhibit OGDHC in the brain. We used adult Sprague Dawley cerebral cortex to analyze the OGDHC enzymatic activity. We have shown that both NO and nitrite can modulate OGDHC activity at hypoxic and normoxic conditions, but only NO has pronounced inhibitory effect on OGDHC catalisis at concentrations observed in the brain tissue. In addition, we have examined the susceptibility of OGDHC activity to nitrite at different incubation temperatures. We conclude that in vivo, OGDHC can be inhibited only by NO originating from iNOS rather than by reduction of NO from nitrite under hypoxic conditions.

Isolation of T5 from Water: Characterization of Its Pathogenic Potential, Including the Production of Extracellular Vesicles.
is a genus of free-living amoebae widely distributed in nature, associated with the development of encephalitis and keratitis. Despite the fact that it is common to find genotype T5 in environmental samples, only a few cases have been associated with clinical cases in humans. The wide distribution of , the characteristic of being amphizoic and the severity of the disease motivate researchers to focus on the isolation of these organisms, but also in demonstrating direct and indirect factors that could indicate a possible pathogenic potential. Here, we performed the characterization of the pathogenic potential of an T5 isolate collected from a water source in a hospital. Osmo- and thermotolerance, the secretion of proteases and the effect of trophozoites over cell monolayers were analyzed by different methodologies. Additionally, we confirm the secretion of extracellular vesicles (EVs) of this isolate incubated at two different temperatures, and the presence of serine and cysteine proteases in these vesicles. Finally, using atomic force microscopy, we determined some nanomechanical properties of the secreted vesicles and found a higher value of adhesion in the EVs obtained at 37 °C, which could have implications in the parasite´s survival and damaging potential in two different biological environments.

Traumatic brain injury (TBI) can lead to major brain anatomopathological damages underlined by neuroinflammation, oxidative stress and progressive neurodegeneration, ultimately leading to motor and cognitive deterioration. Thus, TBI has been described as a risk factor for neurodegenerative disorders including Alzheimer's disease and Parkinson's disease. Unfortunately, the multiple pathological events resulting from TBI can be addressed not by a single therapeutic approach, but rather by a synergistic biotherapy capable of activating a complementary set of signaling pathways that provide synergistic neuroprotective, anti-inflammatory, antioxidative, and neurorestorative activities. The human platelet lysate (HPL) might constitute a potential candidate. HPL is a reliable source of accessible human biomaterial containing biomolecules that are accessible therapeutics for TBI or neurodegenerative diseases. Here, we prepared HPL from clinical grade human platelet concentrates and tested the therapeutic potential HPL using two mouse models of TBI: the controlled cortical impact (CCI) and the in-house developed cortical brain scratch (CBS). The HPL was administrated by topical application and intranasal delivery. We demonstrated, that topical application and intranasal HPL mitigates cortical neuroinflammation, oxidative stress, and synaptic alterations, ultimately improving motor and cognitive functions. Moreover, proteomics analyses revealed that HPL attenuated multiple detrimental cortical pathways and mitigated disease-associated microglia (DAMs) and astrocytes (DAAs) changes triggered by the brain injuries. Brain administration of HPL is a therapeutical strategy that deserves serious consideration for TBI treatment or neurodegenerative diseases.

NEUROPROTECTIVE EFFECT OF PHYSICAL EXERCISE AFTER TRAUMATIC BRAIN INJURY: INFLUENCE OF THE ONSET DELAY AND PRE-INJURY FITNESS.

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Tanit Sánchez, Meritxell Torras, Laura Amorós, Isabel Portell, Margalida Coll, David Costa
Universidad Autónoma de Barcelona, Psicobiology, Barcelona, Spain

Traumatic brain injury (TBI) remains one of the leading causes of morbidity and mortality worldwide and it is a risk factor of dementia later in life. Different studies demonstrated that physical exercise provides strong neuroprotection effects in an experimental animal model of TBI[MCA1]. However, when addressing physical exercise in the context of TBI, additional factors such as pre-trauma fitness, post-injury delay onset and duration of exercise will dictate whether exercise has a beneficial effect on recovery. We evaluated the long-term effects (14 days after TBI) of pre-injury exercise alone, post-injury (early and late onset) exercise and the combination of both treatments after controlled cortical impact injury, on hippocampal volume, density of NeuN+ cells and Iba1 staining (CCI). METHODS: rats were distributed into Sham and TBI condition. TBI subjects were distributed into: sedentary (TBI), pre-injury exercise (E-TBI), early (24 hours, TBI-eE) or late (6 days, TBI-lE) onset of exercise after TBI, and a combination of pre-injury and early (E-TBI-eE) or late (E-TBI-lE) post-injury exercise. RESULTS: TBI decreased hippocampal volume, and increased neuronal loss and neuroinflammation. Pre-injury exercise alone seems to slightly reduce this effect. Post-injury exercise alone did not modify the neuronal loss and neuroinflammation when initiated early, but late onset completely reverted both the neuronal loss and inflammation. However, when combined with pre-injury exercise, none of post-injury treatments had a beneficial effect. CONCLUSION: On the long-term, only post-injury exercise initiated late after injury has a strong neuroprotective and anti-inflammatory effect.

CB1 RECEPTORS REGULATE NEUROMUSCULAR JUNCTION RE-INNERVATION FOLLOWING INJURY

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Roberta Piovesana[1], Luigi Bellocchio[2], Giovanni Marsicano[3], Richard Robitaille[1,4]
[1]Université de Montréal, Département De Neurosciences, Montreal, Canada, [2]University of Bordeaux, Inserm, Neurocentre Magendie - U1215, Bordeaux, France, [3]Inserm U1215 and University of Bordeaux, Neurcentre Magendie, Bordeaux, France, [4]Centre Interdisciplinaire de Recherche sur le Cerveau et l'Apprentissage, University Of Montreal, Montreal, Canada

Peripheral nerves show a great regenerative ability following nerve injury. Not only changes along the damaged nerve occurred but also at the neuromuscular junction (NMJ), where degeneration/re-innervation processes occur in pathological and physiological conditions. Perisynaptic Schwann cells, glial cells at the NMJ, are important for NMJ's repair. Despite evidence for their roles in axonal guidance and synapse formation, Cannabinoids' involvement in nerve injury response remains ill defined. We observed that CB1 receptors are expressed in different muscles and are upregulated immediately after nerve crush. Daily treatment with the CB1 antagonist AM251 (IP injections, 3 mg/kg) during the period of re-innervation following nerve injury caused a downregulation of the CB1 expression and greatly limited re-innervation as indicated with a significant number of denervated NMJs ($p < 0.05$). In EDL muscles, the increased percentage of denervated NMJ was accompanied by a decrease of poly-innervation, likely due to a delay in the reinnervation process. Moreover, this CB1 regulation may be mediated by a c-Jun pathway since we observed a significant decrease of c-Jun expression ($p < 0.05$). These data highlight a novel role of CB1 receptor at NMJ and in the control of NMJ reinnervation after nerve injury. A better understanding of these mechanisms could help address the inadequate NMJ maintenance observed in motor neuron-related neurodegenerative diseases.

The Mechanisms Mediated by α7 Acetylcholine Nicotinic Receptors May Contribute to Peripheral Nerve Regeneration.
Due to the microenvironment created by Schwann cell (SC) activity, peripheral nerve fibers are able to regenerate. Inflammation is the first response to nerve damage and the removal of cellular and myelin debris is essential in preventing the persistence of the local inflammation that may negatively affect nerve regeneration. Acetylcholine (ACh) is one of the neurotransmitters involved in the modulation of inflammation through the activity of its receptors, belonging to both the muscarinic and nicotinic classes. In this report, we evaluated the expression of α7 nicotinic acetylcholine receptors (nAChRs) in rat sciatic nerve, particularly in SCs, after peripheral nerve injury. α7 nAChRs are absent in sciatic nerve immediately after dissection, but their expression is significantly enhanced in SCs after 24 h in cultured sciatic nerve segments or in the presence of the proinflammatory neuropeptide Bradykinin (BK). Moreover, we found that activation of α7 nAChRs with the selective partial agonist ICH3 causes a decreased expression of c-Jun and an upregulation of uPA, MMP2 and MMP9 activity. In addition, ICH3 treatment inhibits IL-6 transcript level expression as well as the cytokine release. These results suggest that ACh, probably released from regenerating axons or by SC themselves, may actively promote through α7 nAChRs activation an anti-inflammatory microenvironment that contributes to better improving the peripheral nerve regeneration.

Cholinergic Modulation of Neuroinflammation: Focus on α7 Nicotinic Receptor.
All nervous system pathologies (e.g., neurodegenerative/demyelinating diseases and brain tumours) develop neuroinflammation, a beneficial process during pathological events, aimed at removing damaged cells, toxic agents, and/or pathogens. Unfortunately, excessive inflammation frequently occurs during nervous system disorders, becoming a detrimental event capable of enhancing neurons and myelinating glial cell impairment, rather than improving their survival and activity. Consequently, targeting the neuroinflammation could be relevant for reducing brain injury and rescuing neuronal and glial cell functions. Several studies have highlighted the role of acetylcholine and its receptors in the regulation of central and peripheral inflammation. In particular, α7 nicotinic receptor has been described as one of the main regulators of the "brain

cholinergic anti-inflammatory pathway". Its expression in astrocytes and microglial cells and the ability to modulate anti-inflammatory cytokines make this receptor a new interesting therapeutic target for neuroinflammation regulation. In this review, we summarize the distribution and physiological functions of the α7 nicotinic receptor in glial cells (astrocytes and microglia) and its role in the modulation of neuroinflammation. Moreover, we explore how its altered expression and function contribute to the development of different neurological pathologies and exacerbate neuroinflammatory processes.

Effects mediated by the α7 nicotinic acetylcholine receptor on cell proliferation and migration in rat adipose-derived stem cells.
Adipose-derived stem cells (ASCs) are an attractive source for regenerative medicine as they can be easily isolated, rapidly expandable in culture and show excellent in vitro differentiation potential. Acetylcholine (ACh), one of the main neurotransmitters in central and peripheral nervous systems, plays key roles in the control of several physiological processes also in non-neural tissues. As demonstrated in our previous studies, ACh can contribute to the rat ASCs physiology, negatively modulating ASCs proliferation and migration via M2 muscarinic receptor (mAChR) activation. In the present work we show that rat ASCs also express α7 nicotinic receptors (nAChRs). In particular, we have investigated the effects mediated by the selective activation of α7 nAChRs, which causes a reduction of ASC proliferation without affecting cell survival and morphology, and significantly promotes cell migration via upregulation of the CXCR4 expression. Interestingly, the activation of the α7 nAChR also upregulates the expression of M2 mAChR protein, indicating a cooperation between muscarinic and nicotinic receptors in the inhibition of ASC proliferation.

Functional Characterization of Muscarinic Receptors in Human Schwann Cells.
Functional characterization of muscarinic cholinergic receptors in myelinating glial cells has been well described both in central and peripheral nervous system. Rat Schwann cells (SCs) express different muscarinic receptor subtypes with the prevalence of the M2 subtype. The selective stimulation of this receptor subtype inhibits SC proliferation, improving their differentiation towards myelinating phenotype. In this work, we describe for the first time that human SCs are cholinoceptive as they express several muscarinic receptor subtypes and, as for rat SCs, M2 receptor is one of the most abundant. Human SCs, isolated from adult nerves, were cultured in vitro and stimulated with M2 muscarinic agonist arecaidine propargyl ester (APE). Similarly to that observed in rat, M2 receptor activation causes a decreased cell proliferation and promotes SC differentiation as suggested by increased Egr2 expression with an improved spindle-like shape cell morphology. Conversely, the non-selective stimulation of muscarinic receptors appears to promote cell proliferation with a reduction of SC average cell diameter. The data obtained demonstrate that human SCs are cholinoceptive and that human cultured SCs may represent an interesting tool to understand their physiology and increase the knowledge on how the cholinergic stimulation may contribute to address human SC development in normal and pathological conditions.

M2 receptors activation modulates cell growth, migration and differentiation of rat Schwann-like adipose-derived stem cells.
Schwann cells (SCs) play a central role in peripheral nervous system physiology and in the response to axon injury. The ability of SCs to proliferate, secrete growth factors, modulate immune response, migrate and re-myelinate regenerating axons has been largely documented. However, there are several restrictions hindering their clinical application, such as the difficulty in collection and a slow in vitro expansion. Adipose-derived stem cells (ASCs) present good properties for peripheral nerve regenerative medicine. When exposed to specific growth factors in vitro, they can acquire a SC-like phenotype (dASCs) expressing key SCs markers and assuming spindle-shaped morphology. Nevertheless, the differentiated phenotype is unstable and several strategies, including pharmacological stimulation, are being studied to improve differentiation outcomes. Cholinergic receptors are potential pharmacological targets expressed in glial cells. Our previous work demonstrated that muscarinic cholinergic receptors, in particular M2 subtype, are present in SCs and are able to modulate several physiological processes. In the present work, muscarinic receptors expression was characterised and the effects mediated by M2 muscarinic receptor were evaluated in rat dASCs. M2 receptor activation, by the preferred agonist arecaidine propargyl ester (APE), caused a reversible arrest of dASCs cell growth, supported by the downregulation of proteins involved in the maintenance of cell proliferation and upregulation of proteins involved in the differentiation (i.e., c-Jun and Egr-2), without affecting cell survival. Moreover, M2 receptor activation in dASCs enhances a pronounced spindle-shaped morphology,

supported by Egr2 upregulation, and inhibits cell migration. Our data clearly demonstrate that rat dASCs express functional muscarinic receptors, in particular M2 subtype, which is able to modulate their physiological and morphological processes, as well as SCs differentiation. These novel findings could open new opportunities for the development of combined cell and pharmacological therapies for peripheral nerve regeneration, harnessing the potential of dASCs and M2 receptors.

Mir-34a-5p Mediates Cross-Talk between M2 Muscarinic Receptors and Notch-1/EGFR Pathways in U87MG Glioblastoma Cells: Implication in Cell Proliferation.
Glioblastoma (GBM) is the most aggressive human brain tumor. The high growth potential and decreased susceptibility to apoptosis of the glioma cells is mainly dependent on genetic amplifications or mutations of oncogenic or pro-apoptotic genes, respectively. We have previously shown that the activation of the M2 acetylcholine muscarinic receptors inhibited cell proliferation and induced apoptosis in two GBM cell lines and cancer stem cells. The aim of this study was to delve into the molecular mechanisms underlying the M2-mediated cell proliferation arrest. Exploiting U87MG and U251MG cell lines as model systems, we evaluated the ability of M2 receptors to interfere with Notch-1 and EGFR pathways, whose activation promotes GBM proliferation. We demonstrated that the activation of M2 receptors, by agonist treatment, counteracted Notch and EGFR signaling, through different regulatory cascades depending, at least in part, on p53 status. Only in U87MG cells, which mimic p53-wild type GBMs, did M2 activation trigger a molecular circuitry involving p53, Notch-1, and the tumor suppressor mir-34a-5p. This regulatory module negatively controls Notch-1, which affects cell proliferation mainly through the Notch-1/EGFR axis. Our data highlighted, for the first time, a molecular circuitry that is deregulated in the p53 wild type GBM, based on the cross-talk between M2 receptor and the Notch-1/EGFR pathways, mediated by mir-34a-5p.

29227527: Piovesana R, Melfi S, Fiore M, Magnaghi V, Tata AM
M2 muscarinic receptor activation inhibits cell proliferation and migration of rat adipose-mesenchymal stem cells.
Mesenchymal stem cells (MSCs), also known as stromal mesenchymal stem cells, are multipotent cells, which can be found in many tissues and organs as bone marrow, adipose tissue and other tissues. In particular MSCs derived from Adipose tissue (ADSCs) are the most frequently used in regenerative medicine because they are easy to source, rapidly expandable in culture and excellent differentiation potential into adipocytes, chondrocytes, and other cell types. Acetylcholine (ACh), the most important neurotransmitter in Central nervous system (CNS) and peripheral nervous system (PNS), plays important roles also in non-neural tissue, but its functions in MSCs are still not investigated. Although MSCs express muscarinic receptor subtypes, their role is completely unknown. In the present work muscarinic cholinergic effects were characterized in rat ADSCs. Analysis by RT-PCR demonstrates that ADSCs express M1-M4 muscarinic receptor subtypes, whereas M2 is one of the most expressed subtype. For this reason, our attention was focused on M2 subtype. By using the selective M2 against Arecaidine Propargyl Ester (APE) we performed cell proliferation and migration assays demonstrating that APE causes cell growth and migration inhibition without affecting cell survival. Our results indicate that ACh via M2 receptors, may contribute to the maintaining of the ADSCs quiescent status. These data are the first evidence that ACh, via muscarinic receptors, might contribute to control ADSCs physiology.

Muscarinic receptors modulate Nerve Growth Factor production in rat Schwann-like adipose-derived stem cells and in Schwann cells.
Regenerative capability of the peripheral nervous system after injury is enhanced by Schwann cells (SCs) producing several growth factors. The clinical use of SCs in nerve regeneration strategies is hindered by the necessity of removing a healthy nerve to obtain the therapeutic cells. Adipose-derived stem cells (ASCs) can be chemically differentiated towards a SC-like phenotype (dASCs), and represent a promising alternative to SCs. Their physiology can be further modulated pharmacologically by targeting receptors for neurotransmitters such as acetylcholine (ACh). In this study, we compare the ability of rat dASCs and native SCs to produce NGF in vitro. We also evaluate the ability of muscarinic receptors, in particular the M2 subtype, to modulate NGF production and maturation from the precursor (proNGF) to the mature (mNGF) form. For the first time, we demonstrate that dASCs produce higher basal levels of proNGF and mature NGF compared to SCs. Moreover, muscarinic receptor activation, and in particular M2 subtype stimulation, modulates NGF production and maturation in both SCs and dASCs. Indeed, both cell types express both proNGF A and B isoforms, as well as mNGF. After M2 receptor stimulation, proNGF-B (25 kDa), which is involved in apoptotic processes, is strongly reduced at transcript and protein level. Thus, we demonstrate that dASCs possess a stronger neurotrophic potential compared to SCs. ACh, via M2 muscarinic receptors, contributes to the modulation and maturation of NGF, improving the regenerative properties of dASCs.

LONGITUDINAL CHANGE IN INTERHEMISPHERIC CONNECTIVITY PREDICTS RECOVERY FROM VESTIBULAR AGNOSIA

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Zaeem Hadi, Mohammad Mahmood, Elena Calzolari, Yuscah Pondeca, Mariya Chepisheva, Rebecca Smith, Heiko Rust, David Sharp, Barry Seemungal
Imperial College London, Department Of Brain Sciences, London, United Kingdom

Introduction: Traumatic brain injury (TBI) commonly results in vestibular dysfunction impairing vestibular perception, this later manifesting as a vestibular agnosia (i.e. loss of vertigo sensation despite manifest peripheral and reflex vestibular activation). We recently identified brain regions predicting vestibular agnosia in acute TBI, however, it remains unknown whether longitudinal connectivity changes predict recovery from vestibular agnosia. **Methods:** The data was collected as part of an MRC-funded prospective study (Calzolari et al., 2021). Resting state fMRI was acquired from 39 acute TBI patients with preserved peripheral and reflex vestibular function during acute admission and then after 6 months. Vestibular agnosia was measured via self-motion perceptual thresholds during passive yaw rotations in dark. After accounting for missing scans at any timepoint, and quality control of rsfMRI scans, 17 subjects' longitudinal data were analyzed and using resting state fMRI we looked at the interhemispheric connectivity over time and its link with recovery from Vestibular Agnosia. **Results:** We found that large change in interhemispheric connectivity in the frontal poles (Cluster size: 30; MNI: ± 21, +54, +24) was linked to a large change in perceptual thresholds over time (shown in figure below). **Conclusion:** Frontal poles are part of the salience network, which is known for its role as brain's sensory integration center. We previously reported a link between vestibular agnosia and altered functional connectivity of salience network localized at left frontal pole location. Our data

shows that recovery from vestibular agnosia is also linked to change in interhemispheric connectivity of frontal pole location.

LONGITUDINAL VOLUME LOSS AFTER TRAUMATIC BRAIN INJURY PREDICTS VESTIBULAR DYSFUNCTION

POSTER SESSION 04 - SECTION: TRAUMATIC BRAIN INJURY

Mohammad Mahmud, Zaeem Hadi, Yuscah Pondeca, Elena Calzolari, Barry Seemungal
Imperial College London, Brain Sciences, london, United Kingdom

Introduction: Traumatic brain injury (TBI) nearly always results in vestibular dysfunction impairing balance and vestibular perception. We recently identified brain regions predicting vestibular dysfunction in acute TBI, however, it remains unknown whether longitudinal structural brain changes predict recovery from vestibular dysfunction. **Methods:** The data was collected as part of an MRC-funded prospective study (Calzolari et al., 2021). Structural T1 MRI was acquired from 39 acute TBI patients with preserved peripheral and reflex vestibular function during acute admission and then after 6 months. Imbalance was measured with Posturography on soft surface with eyes closed. Vestibular perception was measured via self-motion perceptual thresholds during passive yaw rotations in dark. After accounting for missing scans at any timepoint, and quality control of MRI scans, 33 subjects' longitudinal data were analyzed and Voxel Based Morphometry we looked at the volume change over time and its link with recovery from vestibular dysfunction. **Results:** We found an interaction (FWE corrected) between recovery of balance and vestibular perception and the left Calcarine and right Supplementary Motor Area. **Conclusion:** Volume loss in left Calcarine and right Supplementary Motor Area are linked to poor recovery of balance and vestibular perception in patients with TBI. This is the first prospective acute TBI follow up study to show structural changes to be directly associated with vestibular recovery which is a core clinical function that improves quality of life and return to work.

Introduction. The immunological response to traumatic brain injury is a complex reaction with the involvement of cells of the cellular immunity, which determines the course of the disease. Aim. It was a study the role of immunological responses in the pathogenesis of concussion and the relationship with cognitive impairment. Materials and methods. In a trial of 22 patients aged 20-45 years with a concussion. The control group consisted of 37 healthy individuals aged 20-46 years. The examination included of complaints, medical history, assessment of neurological status, neuropsychological testing. Venous blood was used as the object of laboratory research. The main attention was paid to T-helpers of central memory (CM, CD45RA-CD62L+), which were carried out using multicolor cytometric analysis (Navios™,Beckman Coulter, USA). Results. Patients with a concussion among Th cells of the central memory decreased (p-value=0.044) the relative content of Th1 cells from 13.57% (11.50;15.91) to 11.47% (7.13;14.03). At the same time, frequency of Th17 cells was significantly higher (p-value<0.001) in patients than controls from 34.35% (31.20;42.04) to 45.03% (39.51;48.12). In addition in our study a direct correlation was established between the content of DN Th17 cells and the results of performing tests as MMSE,MoCA. At the same time, the concentration of Th1 cells had an opposite correlation with these tests. Conclusion. These findings indicate the possible involvement of T-helpers of the central memory in a concussion. Further the data can be validated to better understand the role of Th cells which might help in formulating targeted therapeutic strategy in future.

DISTINCT SUBPOPULATIONS OF CEREBELLAR MOLECULAR LAYER INTERNEURONS IN CRUS1 ENCODE INTENDED WHISKER TRAJECTORIES

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Elisabeth M. M. Meyer, Paul Chadderton
University of Bristol, School Of Physiology, Pharmacology And Neuroscience, Bristol, United Kingdom

Rodents primarily use their whiskers to explore their environment, a behaviour which requires integration of sensory information and motor commands. The cerebellum plays a key role in integrating whisking-related sensorimotor signals arising from a multitude of brain regions. In the cerebellar cortex, molecular layer interneurons (MLIs) receive excitatory drive from granule cells, as do Purkinje cells (PCs). MLIs exclusively provide inhibition to PCs, awarding them a central role for influencing cerebellar output. Previous results generated in the lab showed that individual MLIs in Crus1 linearly encode whisker position during active whisking by increasing or decreasing spiking. Here we use 2-photon imaging in adult head-fixed NOS-Cre mice expressing Cre-dependent GCaMP6f in Crus1 to explore the diversity and topographical organisation of MLI population activity during voluntary whisking. Using unsupervised clustering, a subpopulation of MLIs exhibiting increased neuronal activity upon whisking can be identified. This subpopulation is randomly interspersed with MLIs not excited by whisking. A linear transfer function calculated from MLI Ca^{2+} signals replicates momentary whisker position very reliably, but not slower changes in resting position. Whisking-evoked Ca^{2+} response properties in MLIs are unchanged when the animal is touching a pole at various locations. Furthermore, MLIs do not appear to respond to passive air puff stimulation directed at the whiskers, suggesting that MLI signals constitute primarily internally generated efferent representations of predicted movement. Taken together, these data show that MLI subpopulations in Crus1 represent intended whisker trajectories on a moment-to-moment basis. We are currently exploring the synaptic basis of this encoding motif.

THE ROLE OF CALCIUM CURRENTS IN MAINTAINING TONIC FIRING IN LARVAL ZEBRAFISH PURKINJE NEURONS

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Meha Jadhav, Vatsala Thirumalai
National Centre for Biological Sciences, Vatsala Thirumalai Lab, Bengaluru, India

Purkinje cells of the cerebellum have been shown to display membrane bistability (Williams et 2002,Lowenstein et al, 2005, Sengupta and Thirumalai, 2015). In larval zebrafish the cells display an up state characterized by a depolarized membrane potential and tonic firing of simple spikes while the down state is characterized by a hyperpolarized membrane potential and burst firing. The up state is the default state of the neuron while the down state is a result of network activity (Sengupta and Thirumalai 2015). These cells also have large calcium currents (Raman and Bean, 1999; Womack et al, 2004). We thus wanted to understand the role of cellular currents in maintaining the up state of Purkinje cells. We performed in vivo whole-cell patch clamp recordings to measure these currents and their effects on spontaneous activity of Purkinje cells. By clamping the cells at various voltages, we found that these cells have a large calcium current (~350pA). Further, using various pharmacological agents, we found that the current is mainly contributed by L and T type voltage gated calcium channels. We also measured a small amount of Ih current. We then observed the effect of various channel antagonist on the spontaneous activity of these cells in current clamp. The experiments show that the main effect of calcium current is to facilitate tonic firing of simple spikes via coupling with calcium activated potassium channels. This study shows that calcium and calcium activated potassium currents are key for maintaining the up state of Purkinje cells.

Gjd2b-mediated gap junctions promote glutamatergic synapse formation and dendritic elaboration in Purkinje neurons.
Gap junctions between neurons serve as electrical synapses, in addition to conducting metabolites and signaling molecules. During development, early-appearing gap junctions are thought to prefigure chemical synapses, which appear much later. We present evidence for this idea at a central, glutamatergic synapse and provide some mechanistic insights. Loss or reduction in the levels of the gap junction protein Gjd2b decreased the frequency of glutamatergic miniature excitatory postsynaptic currents (mEPSCs) in cerebellar Purkinje neurons (PNs) in larval zebrafish. Ultrastructural analysis in the molecular layer showed decreased synapse density. Further, mEPSCs had faster kinetics and larger amplitudes in mutant PNs, consistent with their stunted dendritic arbors. Time-lapse microscopy in wild-type and mutant PNs reveals that Gjd2b puncta promote the elongation of branches and that CaMKII may be a critical mediator of this process. These results demonstrate that Gjd2b-mediated gap junctions regulate glutamatergic synapse formation and dendritic elaboration in PNs.

UNIPOLAR BRUSH CELLS IN THE VESTIBULOCEREBELLUM.

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Rachel Koops[1], Cathrin Canto[1], Bin Wu[2], Martijn Schonewille[3], Beerend Winkelman[3], Chris De Zeeuw[1,3]
[1]Royal Netherlands Academy of Arts and Sciences, Netherlands Institute For Neuroscience, Amsterdam, Netherlands, [2]Fudan University, Huashan Hospital Department Of Neurology & National Clinical Research Center For Aging And Medicine, Shanghai, China, [3]Erasmus MC, Department Of Neuroscience, Rotterdam, Netherlands

In mammals, unipolar brush cells (UBCs) have been suggested to enhance the diversity in temporal patterns in the granular layer of the cerebellar cortex to facilitate performance and adaptation of motor activity by generating delayed and/or sustained cerebellar activity. UBCs are prominently distributed in the vestibulocerebellum, but their precise role during vestibular and visual stimulation remains elusive. Here, we describe the distribution of typical ON-UBCs in the flocculus of the vestibulocerebellum in mice and we elaborate on their potential role during compensatory eye movements. Using immunolabelling against Metabotropic glutamate receptor 1 alpha we found that ON-UBCs are predominantly located in the main zone of the flocculus that controls horizontal compensatory eye movements. *Moonwalker* mice, which suffer from a mutation in their cation-permeable transient receptor potential channel type 3 (TRPC3) that leads to an early-onset ablation of ON-UBCs, show significant gain deficits in their horizontal optokinetic reflex at larger amplitudes as well as in their horizontal vestibulo-ocular reflex (VOR) across a broad range of frequencies. In addition, *Moonwalker* mice are significantly impaired in phase reversal learning of the horizontal VOR. Instead, Purkinje cell specific knock-outs of TRPC3 do not show any of these deficits. These data raise the possibility that ON-UBCs in the flocculus receive not only vestibular, but also visual and/or oculomotor mossy fibre inputs, and that they may enhance the diversity of these afferent signals so as to facilitate performance and acquisition of eye movement patterns.

OPTOGENETIC DISSECTION OF THE CEREBELLAR CORTEX OUTPUT IN THE CONTEXT OF POSTURAL MAINTENANCE.

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Aurélien Gouhier, Vincent Villette, Jonathan Bradley, Benjamin Mathieu, Annick Ayon, Stéphane Dieudonne
ENS, Ibens, Paris, France

Posture is defined by the arrangement of body parts resulting from tonic muscle contraction. The vermal part of the cerebellar cortex plays a central role in postural muscle tone control. The cerebellar cortex is organized in parasagittal bands known as “microzones” based on the receptive fields of its inputs. However, whether Purkinje cells (PCs) are organized relative to the motor output they control is not known. Previous studies in head-restrained animals have shown that inhibiting or stimulating PC activity can produce movements either directly or in rebound. To investigate the functional organization of the cerebellar cortex ouput, we performed optogenetic stimulations of PCs in freely moving mice expressing the actuator Channelrodopsin. By using a 3D-printed implant coupled to an optic fiber, we achieve confined optogenetic stimulations at tunable locations over the vermal lobules IV/V/VI. We demonstrate through video analysis that a minimal optogenetic stimulation at the midline evokes a rapid body collapse proprotional to the stimulation, followed by a compensatory reflex movement of the limbs. The short-latency loss of antigravitational tone has never been characterized before. Using electromyograms, we observe that several axial muscles are involved in the compensatory movement but cannot resolve the tone decrease. Displacing laterally the site of stimulation did not show a clear zonation in the motor output. The amplitude of the postural collapse decreases gradually with the distance from the midline and is lateralized in lobule VI. Our results suggest a rate-control of antigravitational posture maintenance by PCs of the vermal lobules IV/V/VI.

ROLE OF THE CEREBELLO-PREFRONTAL COMMUNICATION IN THE TEMPORAL PREDICTION OF EVENTS: IMPLICATION FOR SCHIZOPHRENIA.

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Pierre Le Cabec, Philippe Isope, Federica Lareno-Faccini
CNRS, Institut Des Neurosciences Cellulaires Et Intégratives Upr3212, Strasbourg, France

One of the key feature of the cerebellar computation is its abilities to predict the sensory consequences of motor commands through the cerebro-cerebello-cortical loop. Prediction capabilities of the cerebellum extend to non-motor functions as attested by an extensive bidirectional connectivity between the cerebellum and the prefrontal cortex (PFC). We hypothesize that the cerebellum make predictions based on contextual and goal-directed information enabling smooth transitions from the present to the future in the PFC. An alteration of this pathway may lead to a dysfunction in action sequencing, which is one of the symptom of schizophrenia. Our aim is to understand better the communication between the cerebellum and the PFC during temporal related tasks both in rodent models of schizophrenia. We performed multiunit recordings in the PFC during an interval task paradigm in transgenic animal expressing Channelrhodopsin2 in Purkinje cells. We showed that in WT animals stable and variable delays have distinct electrophysiological signatures. Optogenetic stimulation of Purkinje cells during the task altered these activities in the PFC in a task specific manner, suggesting that cerebellar perturbation can influence the task. We then set out to assess whether the Synapsin II knock-out mice could be used as a model of schizophrenia. To do this, we will use a novel apparatus enabling simultaneous tracking of a group of mice and investigate social abnormalities in synapsin II KO mice. We will then study how KO mice are affected in the interval timing task and assess whether cerebellar stimulation can influence and compensate these alterations.

FAITHFUL ENCODING OF LOCOMOTOR COORDINATION BY INDIVIDUAL PURKINJE CELLS

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Jorge Ramirez-Buritica, Hugo Marques, Pedro Castelhanito, Ana Goncalves, Megan Carey
Champalimaud Foundation, Champalimaud Neuroscience Programme, Lisbon, Portugal

Whole-body locomotion requires precise coordination of movements across the body. Moreover, control needs to be robust and flexible to changes in the body and environment. The cerebellum is critical for coordinating movement; during locomotion it is particularly important for interlimb coordination. Decades of recordings have consistently shown that Purkinje cell modulation (the sole output of the cerebellar cortex) is broadly correlated with the locomotor stride cycle. However, much of the firing rate variability has remained unexplained; moreover, previous analyses do not provide a clear model for how Purkinje cell activity could be read out to control coordination. Here we performed cell-attached recordings from individual Purkinje cells in head-fixed mice during locomotion, along with high-speed 3D tracking of limb and body kinematics. We find that beyond representing the locomotor stride cycle, Purkinje cells are exquisitely sensitive to stride-to-stride kinematic variation. Further, many individual Purkinje cells respond to multiple behavioral events, including movements of multiple limbs. We used several approaches, including Generalized Additive Models, to disentangle the contribution of individual body parts from the highly correlated locomotor pattern. The analyses reveal that a substantial proportion of Purkinje cells simultaneously encode movements of multiple body parts to provide precise representations of temporal coordination across diverse combinations of behavioral events. High prevalence of this non-linear mixed selectivity across the Purkinje cell population resolves long-standing controversies surrounding the role of Purkinje cells in locomotor control and could allow for efficient readouts of whole-body coordination by a simple linear decoder.

Calcium Imaging Reveals Coordinated Simple Spike Pauses in Populations of Cerebellar Purkinje Cells.
The brain's control of movement is thought to involve coordinated activity between cerebellar Purkinje cells. The results reported here demonstrate that somatic Ca imaging is a faithful reporter of Na-dependent "simple spike" pauses and enables us to optically record changes in firing rates in populations of Purkinje cells in brain slices and in vivo. This simultaneous calcium imaging of populations of Purkinje cells reveals a striking spatial organization of pauses in Purkinje cell activity between neighboring cells. The source of this organization is shown to be the presynaptic gamma-Aminobutyric acid producing (GABAergic) network, and blocking ionotropic gamma-Aminobutyric acid receptor (GABARs) abolishes the synchrony. These data suggest that presynaptic interneurons synchronize (in)activity between neighboring Purkinje cells, and thereby maximize their effect on downstream targets in the deep cerebellar nuclei.

OLIVOCEREBELLAR CONTROL OF MOVEMENT SYMMETRY

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Vincenzo Romano
Erasmus MC, Neuroscience, Rotterdam, Netherlands

Coordination of bilateral movements is essential for a large variety of animal behaviors. The olivocerebellar system is critical for the control of movement, but its role in bilateral coordination has yet to be elucidated. Here, we examined whether Purkinje cells encode and influence synchronicity of left-right whisker movements. We found that complex spike activity is correlated with a prominent left-right symmetry of spontaneous whisker movements within parts, but not all, of Crus1 and Crus2. Optogenetic stimulation of climbing fibers in the areas with high and low correlations resulted in symmetric and asymmetric whisker movements, respectively. Moreover, when simple spike frequency prior to the complex spike was higher, the complex spike-related symmetric whisker protractions were larger. This finding alludes to a role for rebound activity in the cerebellar nuclei, which indeed turned out to be enhanced during symmetric protractions. Tracer injections suggest that regions associated with symmetric whisker movements are anatomically connected to the contralateral cerebellar hemisphere. Together, these data point toward the existence of modules on both sides of the cerebellar cortex that can differentially promote or reduce the symmetry of left and right movements in a context-dependent fashion.

ACQUISITION OF A COMPLEX LOCOMOTOR TASK: ACTIVITY OF CEREBELLAR MOLECULAR LAYER INTERNEURONS AND GAIT DYNAMICS.

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Andry Andrianarivelo[1], Heike Stein[2], Jeremy Gabillet[1], Clarisse Batifol[1], N Alex Cayco Gajic[2], Michael Graupner[1]
[1]Université de Paris, Cnrs, Umr8003 - Saints-pères Paris Institute For The Neurosciences (sppin), Paris Cedex, France, [2]École Normale Supérieure, Université Paris Sciences et Lettres, Département D'Études Cognitives, Paris, France

The cerebellum is a key brain region for motor coordination and learning. By processing sensorimotor information, it predicts and refines movements. However, the contribution of the cerebellar cortex neurons in the learning of a challenging motor task remains poorly understood. To study the implication of the cerebellar cortex microcircuit in motor coordination and learning, we combined behavioral analyses and two photon calcium imaging of the molecular layer interneurons (MLI) network which exerts a strong inhibitory control over the activity of cerebellar cortex output neurons, the Purkinje cells. We implemented a challenging locomotor task where we trained the mice to walk on a motorized treadmill with rungs over multiple days while simultaneously recording the activity of the same MLI population in lobulus simplex using 2 photon calcium imaging. We used high-speed behavioral video recordings to extract individual paw and rung locations, which were subsequently divided into swing and stance phases. When studying individual paws movement patterns during the task acquisition, we found that mice performed fewer, longer strides and increased the duration of the stance phase during learning. MLIs exhibit pronounced locomotion-related activity: a global increase in the MLI population upon locomotion onset and rich dynamics during walking. A majority of recorded MLIs show paw specific swing-related transients. Those transients consist of increases or decreases from the baseline activity with a magnitude and sign that vary over days in a non-monotonous fashion. Our results shed light on the involvement of the cerebellar interneurons in generating coordinated movement in mammals.

FUNCTIONAL DIVERSITY OF GLUTAMATE RELEASE AT INDIVIDUAL GRANULE CELL TERMINALS IN THE CEREBELLAR CORTEX

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Théo Rossi, Bernard Poulain, Frédéric Doussau, Philippe Isope
CNRS, Institut Des Neurosciences Cellulaires Et Intégratives Upr3212, Strasbourg, France

The cerebellar cortex is composed of modules that process sensorimotor information and coordinate movements. Information are conveyed to the cerebellar cortex by mossy fibers (MFs) and relayed by granule cells (GCs) up to Purkinje cells (PCs), the sole output of the cerebellar cortex. The T-shaped axon of GCs makes parallel fibers (PF) that also contact molecular layer interneurons (MLI) providing feed-forward inhibition onto PCs and enable communication between cerebellar modules. Incoming information are conveyed as high-frequency bursts. On the MF-GC-(MLI)-PC pathway, bursts of activity trigger several forms of short-term synaptic plasticity (STP) that dynamically and differentially shape the synaptic strength in the millisecond range and shape the PC discharge. While heterogeneous STP properties have been observed at GC-MLI synapses, their organization at GC terminals along the PF is still unknown. We performed *ex-vivo* patch-clamp recordings and two-photon imaging of a genetically-encoded fluorescent glutamate reporter (iGluSnFR) expressed in GCs to monitor STP at single terminals. Using high-frequency electrical stimulation of GCs, we demonstrate that STP profiles are heterogeneous at terminals on the same parallel fiber and independent of the postsynaptic target. Although STP diversity is reduced at 4mM $[Ca^{2+}]_e$, we show that single terminals still strongly sustain glutamate release. These results suggest that GCs terminals recruit a large dynamic range of vesicles to diversify STP providing temporal signatures for PCs to differentially process information between the feed-forward inhibition and the excitatory pathway.

Medulloblastoma is one of the most common malignant tumors of the central nervous system in children and develops in the cerebellum. Four distinct molecular groups of medulloblastoma have been identified: wingless-activated (WNT), sonic hedgehog-activated (SHH), Group 3 and Group 4. Of all medulloblastoma cases, 40% of medulloblastoma patients are diagnosed with Group 4 medulloblastoma. Although Group 4 medulloblastoma is the most prevalent group, their pathogenesis remains poorly understood, mainly because of the lack of good preclinical models. Recently, it was discovered that the transcriptome of Group 4 medulloblastoma matches the unipolar brush cell (UBC) lineage, giving the hint that UBC progenitors might be the cell of origin for this tumor type. The function of UBCs is not well understood, but there are studies showing that UBCs play a role in balance and movement. To better understand UBC biology and function, we will investigate the role of UBCs in the developing cerebellum using mouse models. Based on previous studies, human single cell RNA-sequencing data and immunohistochemistry of the normal developing murine cerebellum, the transcription factors *Tbr2* and *Lmx1a* appear to be essential for UBC development, as well as *Atoh1* for UBC progenitors. We generated conditional knock-out mice where either *Lmx1a* or *Tbr2* is removed from the UBC lineage and are investigating the downstream effect on UBC biology and animal health. By studying the regular function of UBCs and their progenitors, we might get an insight about how UBCs and/or their progenitors are hijacked to give rise to Group 4 medulloblastoma.

Orcokinin in the central complex of the locust Schistocerca gregaria: Identification of immunostained neurons and colocalization with other neuroactive substances.
The central complex is a group of highly interconnected neuropils in the insect brain. It is involved in the control of spatial orientation, based on external compass cues and various internal needs. The functional and neurochemical organization of the central complex has been studied in detail in the desert locust Schistocerca gregaria. In addition to classical neurotransmitters, immunocytochemistry has provided evidence for a major contribution of neuropeptides to neural signaling within the central complex. To complement these data, we have identified all orcokinin-immunoreactive neurons in the locust central complex and associated brain areas. About 50 bilateral pairs of neurons innervating all substructures of the central complex exhibit orcokinin immunoreactivity. Among these were about 20 columnar neurons, 33 bilateral pairs of tangential neurons of the central body, and seven pairs of tangential neurons of the protocerebral bridge. In silico transcript analysis suggests the presence of eight different orcokinin-A type peptides in the desert locust. Double label experiments showed that all orcokinin-immunostained tangential neurons of the lateral accessory lobe cluster were also immunoreactive for GABA and the GABA-synthesizing enzyme glutamic acid decarboxylase. Two types of tangential neurons of the upper division of the central body were, furthermore, also labeled with an antiserum against Dip-allatostatin I. No colocalization was found with serotonin immunostaining. The data provide additional insights into the neurochemical organization of the locust central complex and suggest that orcokinin-peptides of the orcokinin-A gene act as neuroactive substances at all stages of signal processing in this brain area.

AIMS
Cerebellar climbing fibers (CFs) convey a teaching signal to Purkinje cells (PCs) that is crucial for learning. It is known that CFs can undergo activity-dependent synaptic plasticity and that they are able of major lesion-induced structural plasticity. However, it is still not clear whether they are able of structural modifications dependent on their activity during adulthood and how this affects the architecture and function of the olivocerebellar circuit.
Here we investigate whether CF activity controls the morphology of the fiber itself and of its target PC, as well as the underlying molecular mechanism. METHODS
We chronically reduced CF intrinsic excitability in mouse in vivo by knocking-down voltage-gated sodium channels (NaV1.1 and NaV1.2, or NaV1.6) or the growth-associated protein GAP-43 (previously shown to control CF morphology) with lentiviral vectors and used immunofluorescent staining, confocal microscopy and 3D reconstructions to assess morphological effects on CF and PC morphology. RESULTS
We observed that knocking-down NaV1.1/2 causes a CF atrophy (affecting its length and branching), inducing a compensatory increase of density of synaptic terminals as well as of PC dendritic spines. Knocking-down GAP-43 had a similar effect on CF branches but not on synaptic terminals or PC spines suggesting that it may mediate activity-dependent CF structural plasticity. CONCLUSIONS
Our study shows that CFs can undergo activity-dependent structural plasticity affecting PC morphology, that can be potentially relevant for the circuit function, and it suggests that this may be mediated by GAP-43.

MULTIPLE WHISKER REPRESENTATIONS IN THE CEREBELLAR CRUS1 AND PARAMEDIAN LOBULES

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Peipei Zhai
ErasmusMC, Neuroscience, Rotterdam, Netherlands

The whisker system has been widely used for understanding brain functioning and it is suited to clarify how the cerebellum operates sensorimotor integration. The cerebellum could play a role in active whisking because previous studies have shown that Purkinje cells from lobule Crus 1 linearly encode the whisker position, and in particular the whisker setpoint, with their simple spike activity. However, whether active whisking is encoded only in Crus 1 lobule and whether other cerebellar lobules encode other kinematic parameters has been neglected. We performed optogenetic stimulation of the right cerebellar hemisphere on mice expressing channelrhodopsin specifically in Purkinje cells to examine whether other cerebellar lobules also encode and induce whisker movement. Surprisingly, we found the shortest latency of optogenetic-induced whisker movements in the paramedian lobule. Next, we recorded extracellularly single units Purkinje cells from a large part of the right hemisphere, to investigate if whisker velocity is also encoded by simple spikes. We found that about half of the Purkinje cells are tuned more to whisker velocity than whisker position. Finally, we examined whether the cells tuned to whisker velocity were preferably located in the cerebellar area inducing faster whisker movements. It turns out that the Purkinje cells encoding velocity were in medial paramedian, but also lateral Crus1. Taken together, these results indicate that there are multiple whisker representations in the lobules of the cerebellar hemisphere, and this differential topographic organization could be related to the control of different aspects of the whisker movements.

WIDESPREAD FUNCTIONAL CONVERGENCE FROM CEREBELLAR CORTEX TO CEREBELLAR NUCLEI

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Hana Hasanbegovic[1], Jia Zhu[2], Nuo Li[2], Zhenyu Gao[1]
[1]Erasmus MC, Neuroscience, Rotterdam, Netherlands, [2]Baylor College of Medicine, Neuroscience, Houston, United States of America

The cerebellum powerfully influences numerous downstream regions involved in regulation of motor control, reward, and internal brain activity. The output of the cerebellum is funneled through a collection of cerebellar nuclei (CN), namely fastigial, interposed, and dentate nucleus. Purkinje cells in the cerebellar cortex are thought to be organized into parasagittal modules (medial, intermediate, and lateral) which topographically innervate specific cerebellar nuclei. Here we mapped the cerebellar cortico-nuclear connectivity using photoactivation of ChR2 expressed in Purkinje cells and silicon probe recordings in cerebellar nuclei. Interestingly, photoactivation mapping revealed only weak topography in the cerebellar cortex to nucleus connectivity. Activation of Purkinje cell clusters anywhere within a 3 mm medial-to-lateral cortical territory significantly inhibited individual nuclei. Nevertheless, the strongest Purkinje cell influence to the fastigial nucleus was observed near the vermal regions, and the strongest influence to the dentate nucleus was observed near the lateral regions. Retrograde tracing from individual CN labeled Purkinje cells across a large swatch of the cerebellar cortex, similar to the spatial maps obtained from photoactivation mapping. Our results suggest that individual CN integrates spatially broad input from all three longitudinal compartments, the vermis, the paravermis and the hemisphere. Given diffused mossy fiber input to the cerebellar cortex through pontine nucleus, the broad cerebellar output to the nucleus could allow the cerebellum to learn associations of widespread inputs related to sensory, motor and internal signals with specific teaching signals to form internal models.

EFFECTS OF ACETYLCHOLINE RECEPTOR ACTIVATION ON PROPERTIES OF CEREBELLAR NUCLEI NEURONS

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Cristiana Iosif
University of Bristol, Physiology, Pharmacology & Neuroscience, Bristol, United Kingdom

The cerebellum receives neuromodulatory inputs including cholinergic projections from the brainstem. The aim of this work was to determine how acetylcholine influences intrinsic and firing properties of cerebellar nuclear neurons, to further our understanding of the role of acetylcholine in the modulation of cerebellar output. Cerebellar slices were obtained from adult rats, and whole cell current clamp recordings were performed on neurons of the cerebellar nuclei (CN). The spontaneous firing rate of the cells was recorded, and a hyperpolarising current injection step was applied to allow extraction of intrinsic cell properties. Properties were monitored before and after bath application of carbachol (10 uM), a cholinergic agonist. As multiple cell types are present within the CN, principal component analysis and cluster analysis were employed on baseline properties to differentiate cell types. Analysis suggests recordings were obtained from two distinct cell types, and carbachol had a differential effect on the two groups. For the first type of cell, carbachol significantly decreased membrane time constant (by 5.42 +/- 1.84 ms), sag (by 2.91 +/- 1 %), and spontaneous firing rate (by 0.87 +/- 0.34 Hz); for the second type of cells, carbachol significantly decreased input resistance (by 43 +/- 16.5 MOhm) and action potential threshold (by 2.69 +/- 0.85 mV). These results indicate that acetylcholine impacts on cerebellar processing by having distinct effects on different neurons in the CN.

AN FN-OLIVARY FEEDBACK LOOP SHAPES CEREBELLAR OUTPUTS FOR MOVEMENT CONTROL

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Xiaolu Wang
Erasmus MC, Department Of Neuroscience, Rotterdam, Netherlands

Movements can be executed gracefully and effortlessly depending on optimal feedback control of the brain. The cerebello-olivary loop is known to be crucial for motor learning, but its role in the control of body movements is less understood. In this study we described a fastigial nucleus (FN)-olivary pathway that involves in the modulation of rapid body movements. We first characterized the cytoarchitectural and ultrastructural organizations, as well as the synaptic properties of this projection. Using monosynaptic anterograde and retrograde tracing strategies, we identified a closed loop for the nucleo-olivo-cortico module that could be utilized for movement control. Manipulation of the FN neurons directly affects the complex spike (CS) firing probability in vermal Purkinje cells, which could bidirectionally control the output patterns of the medial cerebellum. Activating this FN-olivary module elicited rapid oculomotor and upper body movements. Our study identifies an unique FN-olivary pathway that transmits an efferent feedback copy to the cerebellar cortex, providing a novel substrate for the cerebellar control of movements.

CEREBELLAR CONTROL OF TARGETED MOVEMENTS

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Lorenzo Bina, Camilla Ciapponi, Xiang Wang, Laurens Bosman, Chris De Zeeuw
Erasmus MC, Neuroscience, Rotterdam, Netherlands

Goal-directed movements are often caused by sequential activation of muscles and cerebellar Purkinje cells are vital for the coordination of such muscle synergies. Goal-directed movements are not restricted to the limbs, but for instance also the tongue can reach for specific targets. Of late, directional tongue movements have often been used as behavioural read-out during associative learning paradigms. As Purkinje cells are also known to orchestrate associative learning, we asked to what extent Purkinje cells can encode for the pre-motor or for the motor aspects of directional tongue movements. To this end, we recorded Purkinje cell complex spike and simple spike activity in mice during spontaneous and goal-directed licking. We found that, dependent on their location in the cerebellar cortex, Purkinje cells can encode different aspects of licking, including the direction of tongue protrusion. Optogenetic stimulation experiments confirmed that Purkinje cell activity can be causally linked to the direction of tongue protrusion. Thus, we show that anatomically separate groups of Purkinje cells can be related to differential aspects of targeted movements, with some Purkinje cells being involved in a cycle-by-cycle fashion, while others are more likely to convey a readiness to act signal.

TOPOGRAPHICAL ORGANISATION OF WHISKER MOVEMENT WITHIN PURKINJE CELL MICROZONES

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Simon Bright, Paul Chadderton
University of Bristol, School Of Physiology, Pharmacology And Neuroscience, Bristol, United Kingdom

Whisking is a well-defined paradigm to study active sensory processing and whisker movements are encoded by Crus 1 Purkinje cells (PCs) via linear changes in firing rate. The topographical organisation and functional relevance of these signals are unknown. PCs are the sole output of the cerebellum and can generate powerful depolarising Ca^{2+} events via input from climbing fibres (CFs). Previously, co-ordinated CF -evoked activity has provided insight into the topographical sensorimotor processing in the cerebellum. Here we explored how whisking motor and sensory signals are represented at a population level, by injecting AAV-FLEX-GCaMP6f into Crus 1 lobule of Pcp2-Cre mice, and using 2-photon imaging to image the Ca^{2+}-dynamics during head-fixed voluntary whisking and perturbed whisking behaviours. We observed that whisker movement dynamics are reflected in the Ca^{2+} dynamics of subpopulations of PC dendrites. These subpopulations are spatially clustered into parasagittal bands of varying width (range: 300 to 1000µm), such that synchronised activity correlated with whisking behaviour could span large proportions of Crus 1. Within these bands, PCs activity was synchronised showing a reliable increase in Ca^{2+} during voluntary whisking, while in addition, a small population of dendrites (20-60µm wide parasagittal bands) at the lateral edge of Crus 1 showed heterogeneous responses to air-puff stimulation. Responses from air-puff stimulation varied between decreases or increases in Ca^{2+}, or biphasic reductions followed by increases. These results indicate that discrete subpopulations of PC dendrites may encode information about efferent (motor) and afferent (sensory) signals relating to whisker movement.

EVALUATING THE MODULAR HYPOTHESIS: COMPARISON OF CEREBELLAR MEDIAL NUCLEUS AND LATERAL NUCLEUS ACTIVITY IN A REWARDED SPATIAL MEMORY TASK

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Hayley Reeve, Nadia Cerminara, Jasmine Pickford, Clea Warburton, Richard Apps
University of Bristol, School Of Physiology, Pharmacology And Neuroscience, Bristol, United Kingdom

The cerebellum has a highly organised structure with topographically organised connections linking rostrocaudally-orientated zones of cerebellar cortex with different parts of the inferior olive and cerebellar nuclei, forming a series of distinct olivo-cortico-nuclear modules. Different modules are predicted to preferentially subserve different aspects of behaviour across cognitive and motor domains, however there has been little interrogation of this reported to date. Moreover, while clinical and experimental evidence from humans has implicated the cerebellum in cognition in addition to sensorimotor function, little is known about the physiological correlates of cognition in cerebellar neuronal activity which can readily be investigated in the rodent. We address these two areas of enquiry by: i) investigating the neural correlates of spatial memory in single units of two cerebellar nuclei related to different modules, specifically ii) comparing medial with lateral nucleus across the cognitive and motor components of a spatial memory task. We predict that the medial nucleus (A and AX module output) preferentially relays motor-related information, while lateral nucleus (D1 and D2 module output) preferentially relays cognition-related information, thereby serving the motor and cognitive components respectively of goal-directed behaviour. Tetrode recordings were obtained from medial or lateral nucleus of freely moving rats during a T-maze-like spatial alternation task for food reward. Preliminary findings provide evidence of cells modulated at task-relevant behavioural timepoints, including acquisition of reward. We compare modulation patterns between the nuclei to evaluate the modular hypothesis of cerebellar function, and consider our results within the wider context of neural correlates of memory.

Understanding the cellular counterparts of learning and memory is one of the biggest challenges in neurosciences. In this scenario, the cerebellum plays a pivotal role in motor processing and learning, though the spatiotemporal dynamics and interplay among neuronal subtypes during planning and execution of movements are still largely unknown. Microendoscopic Ca^{2+} imaging through genetically encoded Ca^{2+} indicators represent a cutting-edge approach for monitoring neuronal populations activity in specific brain regions. In this work, we show a pioneering study of Ca^{2+} imaging recordings of cerebellar activity using head-mounted miniscopes in freely-moving mice performing an associative learning task on a custom-built treadmill. Neuronal Ca^{2+} dynamics in the cerebellar cortex were tracked across trial-to-trial repetition of a task in which a conditioned stimulus (CS, the treadmill rotation), was paired to an unconditioned stimulus (US, a sound). Preliminary data show that neuronal activity becomes more uniform from trial to trial and responses to the CS tends to anticipate after the US. Behavioral analysis confirmed that after few days of training, the mice learned the task showing a similar motor response each time after the US (as opposed to the trial-to-trial variability in the first presentations). Further analysis will be necessary to characterize the spatiotemporal dynamics of specific neuronal subtypes and the neuronal correlates of behavior. These preliminary data show the impressive potential of this approach in studying physiological mechanisms of learning in freely-moving rodents, and opens new perspectives in the investigation of the role of cerebellar processing across diverse motor and non-motor behaviors.

Long-Lasting Response Changes in Deep Cerebellar Nuclei Correlate With Low-Frequency Oscillations.
The deep cerebellar nuclei (DCN) have been suggested to play a critical role in sensorimotor learning and some forms of long-term synaptic plasticity observed have been proposed as a possible substrate. However, till now it was not clear whether and how DCN neuron responses manifest long-lasting changes . Here, we have characterized DCN unit responses to tactile stimulation of the facial area in anesthetized mice and evaluated the changes induced by theta-sensory stimulation (TSS), a 4 Hz stimulation pattern that is known to induce plasticity in the cerebellar cortex . DCN units responded to tactile stimulation generating bursts and pauses, which reflected combinations of excitatory inputs most likely relayed by mossy fiber collaterals, inhibitory inputs relayed by Purkinje cells, and intrinsic rebound firing. Interestingly, initial bursts and pauses were often followed by stimulus-induced oscillations in the peri-stimulus time histograms (PSTH). TSS induced long-lasting changes in DCN unit responses. Spike-related potentiation and suppression (SR-P and SR-S), either in units initiating the response with bursts or pauses, were correlated with stimulus-induced oscillations. Fitting with resonant functions suggested the existence of peaks in the theta-band (burst SR-P at 9 Hz, pause SR-S at 5 Hz). Optogenetic stimulation of the cerebellar cortex altered stimulus-induced oscillations suggesting that Purkinje cells play a critical role in the circuits controlling DCN oscillations and plasticity. This observation complements those reported before on the granular and molecular layers supporting the generation of multiple distributed plasticities in the cerebellum following naturally patterned sensory entrainment. The unique dependency of DCN plasticity on circuit oscillations discloses a potential relationship between cerebellar learning and activity patterns generated in the cerebellar network.

The Optogenetic Revolution in Cerebellar Investigations.
The cerebellum is most renowned for its role in sensorimotor control and coordination, but a growing number of anatomical and physiological studies are demonstrating its deep involvement in cognitive and emotional functions. Recently, the

development and refinement of optogenetic techniques boosted research in the cerebellar field and, impressively, revolutionized the methodological approach and endowed the investigations with entirely new capabilities. This translated into a significant improvement in the data acquired for sensorimotor tests, allowing one to correlate single-cell activity with motor behavior to the extent of determining the role of single neuronal types and single connection pathways in controlling precise aspects of movement kinematics. These levels of specificity in correlating neuronal activity to behavior could not be achieved in the past, when electrical and pharmacological stimulations were the only available experimental tools. The application of optogenetics to the investigation of the cerebellar role in higher-order and cognitive functions, which involves a high degree of connectivity with multiple brain areas, has been even more significant. It is possible that, in this field, optogenetics has changed the game, and the number of investigations using optogenetics to study the cerebellar role in non-sensorimotor functions in awake animals is growing. The main issues addressed by these studies are the cerebellar role in epilepsy (through connections to the hippocampus and the temporal lobe), schizophrenia and cognition, working memory for decision making, and social behavior. It is also worth noting that optogenetics opened a new perspective for cerebellar neurostimulation in patients (e.g., for epilepsy treatment and stroke rehabilitation), promising unprecedented specificity in the targeted pathways that could be either activated or inhibited.

RELATIONSHIPS BETWEEN GRANULE CELL LINEAGES AND FUNCTIONAL SYNAPTIC ORGANIZATION IN THE CEREBELLAR CORTEX

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Frédéric Doussau[1], Adriana Basnakova[1], Théo Gagneux[1], Jean Livet[2], Philippe Isope[1]
[1]CNRS, Institut Des Neurosciences Cellulaires Et Intégratives Upr 3212, Strasbourg, France, [2]INSERM, Sorbonne University, Institut De La Vision, Paris, France

The cerebellum's ability to learn multisensory contextual patterns relies on signal integration across the anatomically and functionally diverse cerebellar modules. The intermodular communication is mediated by parallel fibres, the axons of the granule cells (GCs) which integrate mossy fiber (MF) inputs from multiple sensory modalities. During postnatal cerebellar development, groups of clonally related GCs differentiate in a restricted medio-lateral zone. However, relationships between GC clones and the topography of cerebellar inputs or synaptic properties within the cerebellar cortex is unknown. Here, we describe a unique approach using brainbow technology where multicolour label expression is under control of inducible Cre in order to sparsely visualise clonally related GCs. To check wether clonally related GCs receive the same set of sensory modalities, AAV viral vectors will be injected in pre-cerebellar nuclei of Brainbow mice to label MF inputs. In addition, we describe an innovative strategy where GC clones can be identified by novel 'iON' vectors that mediate genomic integration of reporter genes in GC progenitors by DNA electroporation. This method will be used to express opsins in subsets of GC clones, which will allow studying the relationships between GC clones and synaptic organization (topography and synaptic properties of parallel fibers inputs). Together these strategies have the potential to shed light on the unknown links between GC lineages and the functional organisation in the cerebellar cortex.

MOTOR LEARNING AND TEMPORAL DYNAMICS IN THE OLIVARY-CEREBELLAR NETWORK

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Inferior olive (IO) sends Climbing Fiber (CF) axons to Purkinje cells (PC) of the cerebellar cortex. According to classical models of cerebellar learning, CF inputs act as instructive signals causing PC synaptic plasticity by reporting sensory-motor unexpected events. In the context of complex motor learning, those signals and their contribution to postural adaptation are still unknown. To investigate this question, we perform chronic in vivo multiphoton recordings in multiple PC dendrites expressing the calcium indicator GCaMP6f. High temporal resolution allows millisecond precision of calcium transients (CT) onset detection. In order to follow variations of CF firing dynamics during self-generated postural learning, head-fixed mice are placed on a small frictionless wheel and recordings are started on the 1st day of the experiments, without habituation. We find that IO activity is increased over a 200 ms period before postural adjustment onset and is followed by a long-lasting decrease. In addition, this activity comprises 10 ms synchronous population events. Unlearned postural adjustments show an excess of sequences composed of two CTs (50-70ms interval). Strikingly, the second CT is associated with 10ms-tight synchronies, higher amplitudes and is timed at the movement onset. Over the course of postural learning, movement related activity decreases together with CT-doublets occurrence, reaching a steady state the 3rd day and is shifted in time towards movement execution. Reappearance of these features after wheel position modification confirms their causal role in postural learning. These results show that IO contributes to motor learning using exquisite spatio-temporal activity patterns.

LOCOMOTOR ACTIVITY SHIFTS THE TEMPORAL WINDOW FOR CEREBELLAR MEMORY CONSOLIDATION

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

N. Tatiana Silva, Ines Ribeiro, Megan R. Carey
Champalimaud Foundation, Champalimaud Neuroscience Programme, Lisboa, Portugal

Motor learning is present throughout life, from learning how to swim to riding a bicycle. Motor memories are often consolidated over time, becoming less susceptible to interference. Despite its ubiquity, mechanisms for motor memory consolidation are still poorly understood. The cerebellum is crucial for several forms of motor learning, including delay eyeblink conditioning. We previously showed that engaging in locomotor activity enhances eyeblink conditioning in mouse cerebellum. Here we report that locomotor activity also accelerates the consolidation of learned eyeblink responses. Only animals that were not actively locomoting during training sessions were susceptible to pharmacological and optogenetic perturbations of activity in cerebellar cortex immediately following each training session. In contrast, post-session manipulations of neural activity had no effect on memory consolidation in mice that were running on a motorized treadmill throughout training. Conversely, acute optogenetic perturbation of cerebellar granule cells, when presented in between trials within training sessions, impaired learning only in animals that *were* engaged in locomotion during training, but did not affect learning in quiescent animals. These results suggest that locomotor activity drives a shift in the critical time window for motor memory consolidation in the cerebellar cortex, from immediately following, to within training sessions. In ongoing work we are further investigating the mechanisms through which running facilitates consolidation on the cellular and systems levels.

Cannabinoids modulate associative cerebellar learning via alterations in behavioral state.
Cannabinoids are notorious and profound modulators of behavioral state. In the brain, endocannabinoids act via Type 1-cannabinoid receptors (CB1) to modulate synaptic transmission and mediate multiple forms of synaptic plasticity. CB1 knockout (CB1KO) mice display a range of behavioral phenotypes, in particular hypoactivity and various deficits in learning and memory, including cerebellum-dependent delay eyeblink conditioning. Here we find that the apparent effects of CB1 deletion on cerebellar learning are not due to direct effects on CB1-dependent plasticity, but rather, arise as a secondary consequence of altered behavioral state. Hypoactivity of CB1KO mice accounts for their impaired eyeblink conditioning across both animals and trials. Moreover, learning in these mutants is rescued by walking on a motorized treadmill during training. Finally, cerebellar granule-cell-specific CB1KOs exhibit normal eyeblink conditioning, and both global and granule-cell-specific CB1KOs display normal cerebellum-dependent locomotor coordination and learning. These findings highlight the modulation of behavioral state as a powerful independent means through which individual genes contribute to complex behaviors.

Locomotor activity modulates associative learning in mouse cerebellum.
Changes in behavioral state can profoundly influence brain function. Here we show that behavioral state modulates performance in delay eyeblink conditioning, a cerebellum-dependent form of associative learning. Increased locomotor speed in head-fixed mice drove earlier onset of learning and trial-by-trial enhancement of learned responses that were dissociable from changes in arousal and independent of sensory modality. Eyelid responses evoked by optogenetic stimulation of mossy fiber inputs to the cerebellum, but not at sites downstream, were positively modulated by ongoing locomotion. Substituting prolonged, low-intensity optogenetic mossy fiber stimulation for locomotion was sufficient to enhance conditioned responses. Our results suggest that locomotor activity modulates delay eyeblink conditioning through increased activation of the mossy fiber pathway within the cerebellum. Taken together, these results provide evidence for a novel role for behavioral state modulation in associative learning and suggest a potential mechanism through which engaging in movement can improve an individual's ability to learn.

Differentiation of human umbilical cord matrix mesenchymal stem cells into neural-like progenitor cells and maturation into an oligodendroglial-like lineage.
Mesenchymal stem cells (MSCs) are viewed as safe, readily available and promising adult stem cells, which are currently used in several clinical trials. Additionally, their soluble-factor secretion and multi-lineage differentiation capacities place MSCs in the forefront of stem cell types with expected near-future clinical applications. In the present work MSCs were isolated from the umbilical cord matrix (Wharton's jelly) of human umbilical cord samples. The cells were thoroughly characterized and confirmed as bona-fide MSCs, presenting in vitro low generation time, high proliferative and colony-forming unit-fibroblast (CFU-F) capacity, typical MSC immunophenotype and osteogenic, chondrogenic and adipogenic differentiation capacity. The cells were additionally subjected to an oligodendroglial-oriented step-wise differentiation protocol in order to test their neural- and oligodendroglial-like differentiation capacity. The results confirmed the neural-like plasticity of MSCs, and suggested that the cells presented an oligodendroglial-like phenotype throughout the differentiation protocol, in several aspects sharing characteristics common to those of bona-fide oligodendrocyte precursor cells and differentiated oligodendrocytes.

THE ROLE OF DISTINCT CEREBELLAR CIRCUIT ELEMENTS IN LOCOMOTION AND LOCOMOTOR LEARNING

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Jovin Jacobs, Megan Carey
Champalimaud Foundation, Neuroscience, Lisbon, Portugal

The cerebellum is a brain structure involved in various sensorimotor and cognitive functions. For locomotor behaviors, the cerebellum is critical for keeping movements calibrated and coordinated across the body. Further, within the cerebellar circuit, various cell types have been mapped to distinct functions required for proper execution of movement. Here, we sought to ascertain how various cerebellar circuit neurons contribute to overground locomotion and locomotor learning on a split-belt treadmill in adult mice. We targeted Purkinje cells, granule cells, and a combination of granule cells and mossy fiber inputs for ablation via cell-type specific, cre-recombinase mediated expression of the diphtheria toxin receptor (DTR) and subsequent intraperitoneal administration of diphtheria toxin (DT). We found that ablations across all cell types caused an ataxic phenotype and impairments in locomotor learning, both of which scaled with the degree of cell death. Generally, the observed phenotypes in the two behaviours were similar to those previously reported for ataxic mutant mice, as forward motion of individual limbs was largely spared, while other 3D limb movements and interlimb coordination were impaired. Surprisingly, we also found that incomplete granule cell ablation led to outcomes commensurate with near/complete loss of Purkinje cells in both learning and overground locomotion. Overall, our results suggest that cell-specific manipulations within the cerebellar circuit yield overlapping phenotypes but gradations in outcome are observed in a cell-type dependent manner.

It is broadly agreed that synaptic plasticity underlies most forms of learning and memory. There are, however, few situations in which the plastic changes have been observed in vivo and linked to alterations of behaviour. Challenges include targeting high-resolution, longitudinal recordings to causal neurones. Several cerebellar behaviours are thought to offer compact and uniform controlling neuronal populations, yet even here sufficiently long-lasting recordings are rare and have only targeted single neurones. We have performed chronic multi-electrode recordings of Purkinje cell activity during acquisition and extinction of eyeblink conditioning in mice, with an accelerated protocol in which conditioned responses are acquired over two days. These revealed complex dynamics of complex spike activity associated with the conditioned stimulus, the conditioned response and the unconditioned stimulus. In contrast, no systematic modifications of simple spike activity were observed, despite the suitable complex spike activity. The absence of simple spike changes supports neither Marr-Albus-Ito nor Stochastic Gradient Descent theories of cerebellar learning. The perspectives for future experiments testing theories of cerebellar learning are discussed.

TWO-PHOTON IMAGING OF CEREBELLAR PURKINJE CELLS DURING FICTIVE LOCOMOTION DISTINGUISHES SENSORY AND MOTOR COMPONENTS OF LOCOMOTION

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Murat Orynbayev[1], Marin Manuel[2], Brandon Stell[1]
[1]Université de Paris, Cnrs Umr 8003, Paris, France, [2]University of Rhode Island, The George & Anne Ryan Institute, Kingston, United States of America

Locomotion in mammals is driven by central pattern generators located in the spinal cord, but the cerebellum is required for producing well-coordinated movement (Machado et al 2015). The cerebellum is presumed to achieve coordination by comparing sensory information perceived during locomotion to a model of the expected sensory information self-generated by the locomotor activity and output differences to modulate locomotion. One impediment to testing this hypothesis is isolating the self-generated sensory information from the efferent copy of the CPG in the cerebellum during locomotion. Here we use fictive locomotion in decerebrate mice to separate the sensory and motor components of locomotion and test the hypothesis that the efferent copy of the CPG cycle is highly plastic and forms a negative image in Purkinje cells that cancels expected reafference. To test this hypothesis we compared the rate of simple and complex spikes in Purkinje cells in response to Sural nerve stimulation or to the spontaneous CPG signal. Cell-attached recordings and/or calcium imaging was used to monitor Purkinje cell simple and complex spike activity on the surface of lobule IV/V. Activity was recorded either during fictive locomotion, or after stimulation of the Sural nerve of the right hind-limb, or both. We report that a large proportion of Purkinje cells in the region modulate complex or simple spike rates in response to either the efferent copy, the sensory stimuli, or both and show different patterns of spatial/temporal organization of their responses.

IN VIVO TWO-PHOTON IMAGING OF PURKINJE CELL ACTIVITY DURING ADAPTATION TO A NOVEL SENSORIMOTOR MISMATCH PARADIGM

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Vinh Nguyen, Brandon Stell
Université de Paris, Sppin Cnrs Umr8003, Paris, France

The ability to learn precise, coordinated motor programs and adapt them to a changing environment is essential for the survival of all animals. A leading theory for how mammalian brains quickly adapt motor programs proposes that the cerebellum uses forward models to compare perceived reafference to expected reafference and makes adjustments to movements based on any mismatches. However, where and how the cerebellum stores expected reafference and how the activity of the cerebellar cortex is affected by differences in perceived and expected reafference is unknown. To probe this, head-fixed mice were trained to use a joystick to control the position of a lick port that delivered water rewards and were forced to adapt to perturbations of the expected position of the lick port. We simultaneously imaged GCaMP7f or GCaMP8f/m expressed in Purkinje cells and observed that complex spike rate remained stable during control conditions but was modulated in specific dendrites during trials in which the mouse adapted to mismatches between expected and perceived position of the lick port. These findings demonstrate that mice adapt to this sensorimotor mismatch paradigm on the same timescale that humans adapt to similar reaching paradigms (5-10 trials; Martin et al., 1996), and supports classical models of supervised learning in which climbing fibers signal mismatches to Purkinje cells via complex spikes.

Introduction. Although, a direct involvement of the cerebellum in Parkinson's disease and Schizophrenia were indicated. Data on cerebellar dopaminergic innervation and interconnections to the dopaminergic midbrain nuclei are scantly. In rodents, only extrinsic cerebellar dopaminergic fiber system, originating from the A_{10} dopaminergic area, and few dopaminergic neurons composed by Purkinje neurons of the cerebellar cortex were demonstrated. *Aim.* The goal of this translational study is to explore the human cerebellar neuronal dopaminergic system, by means of Diffusion Magnetic Resonance Tractography (DMRT) brain imaging analysis so as to evaluate the cerebellar interconnections with the dopaminergic nuclei of the midbrain. *Material and methods*. Postmortem fragments of human cerebellum were fixed in an aldehyde picric acid solution, embedded in paraffin, cut into 5 µm sections and subjected to light microscopic immunohistochemistry by using rabbit polyclonal antibodies to dopamine transporter (DAT) or dopamine type 2 receptor (DRD_2). In brain imaging analysis 3T Achieva Philips scanner was used for acquiring T1 weighted 3D TFE sequences. DMRT data using diffusion signal modeling techniques were acquired *Results*. DAT and DRD_2 immunoreactivity were observed in the cerebellar Purkinje neurons in some non-traditional neuron types, and in the dentate nucleus in large and small neuron types. Moreover, we detected direct dentato-nigral and dentato-ventro tegmental interconnections. *Conclusions*. This study demonstrates the occurrence of a human cerebellar dopaminergic system and of direct dentate nucleus interconnections to the midbrain dopaminergic nuclei, which allows us to suggest a cerebellar role in dopaminergic brain disorders.

FUNCTIONAL SYNAPTIC CONNECTIVITY IN THE CEREBELLAR CORTEX

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Théo Gagneux[1], Ludovic Spaeth[2], Philippe Isope[1]
[1]CNRS, Institut Des Neurosciences Cellulaires Et Intégratives Upr 3212, Strasbourg, France, [2]Albert Einstein College of Medicine, Dominick P. Purpura Department Of Neuroscience, New York, United States of America

The cerebellum is involved in motor coordination and learning of skilled movements. The cerebellar cortex is divided into repeated anatomo-functional modules that process sensorimotor information from a given body part. This information is conveyed notably by mossy fibres (MF) to granule cells (GC) which send a long axon, the parallel fibres, to Purkinje cells (PC) belonging to several modules. This inter-modular communication may control motor coordination. We have shown that synaptic connectivity at the GC-PC and GC-interneuron connections are stereotyped between individuals (Valera et al, eLife 2016), but individual behavioural features can still be encoded by individual synaptic maps (Spaeth et al., Nat. commun. 2022). Our aims was to determine how inhibitory connectivity maps in the GC-MLI-PC pathway are organized and (2) to investigate these relationships while perturbing behavioural conditions. First, we combined patch clamp recordings of PCs in acute cerebellar slices with systematic photostimulation of RuBi-glutamate using patterned illumination. We showed that inhibitory connectivity maps in the vermal lobule III/IV do not necessarily overlap with excitatory connectivity maps yielding complex intermodular communication rules. Second, we altered the behavioural conditions by allowing mice to run in a wheel for 19 days before establishing the synaptic maps. We found that synaptic maps from trained mice were modified suggesting that both excitatory and inhibitory functional synaptic organization in the cerebellar cortex might be related to locomotor adaptation.

MULTIDIMENSIONAL CEREBELLAR COMPUTATIONS FOR FLEXIBLE KINEMATIC CONTROL OF MOVEMENTS

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Akshay Markanday[1], Sungho Hong[2], Junya Inoue[1,3], Erik De Schutter[2], Peter Thier[1,4,5]
[1]Hertie Institute for Clinical Brain Research, Cognitive Neurology, Tübingen, Germany, [2]Okinawa Institute of Science and Technology, Computational Neuroscience Unit, Okinawa, Japan, [3]Tübingen University, Graduate School Of Neural And Behavioral Sciences, International Max Planck School, Tübingen, Germany, [4]University of Tübingen, Werner Reichardt Centre For Integrative Neuroscience, Tübingen, Germany, [5]Tübingen University, Werner Reichardt Centre For Integrative Neuroscience, Tübingen, Germany

Aims: Maintaining the precision of our movements critically depends on how well our movements adapt to continuously changing environments and states of the body. The cerebellum has been known to be a critical locus for this function, captured by the term sensorimotor adaptation. We addressed the question of circuit-level information processing, which remains poorly understood. Methods: We recorded from mossy fibers (MF, network input) and Purkinje cells (PC, output), from two rhesus monkeys performing a repetitive saccade task. We analyzed the MF firing and PC simple spiking (SS) data to identify a multidimensional, manifold-like structures in both. We also constructed a feed-forward network (FFN) model simulating the MF-to-PC transformation. Results: We found the representations of individual movement parameters in the manifold geometry and dynamics both in MFs and PCs, while they were much more selective in PCs than MFs. Error feedback-driven inputs modulated the PC manifolds in an error-type specific fashion, which predicted the changes in the future movements. Our FFN model revealed that MF activity can accurately predict the PC SS/manifold but only by expanding small variabilities in MF inputs. Conclusion: The cerebellum performs multidimensional adaptive computations by encoding several kinematic parameters concurrently, which enables flexible coordination for sensorimotor learning. A compressed, low dimensional copy of sensorimotor information in the MF inputs transforms to the higher dimensional PC outputs by the cerebellar cortical circuit through variability expansion. This mechanism enables PCs to fine control individual kinematic parameters, which is necessary for the precisions in movements.

MOTOR PERFORMANCE AND REGIONAL BRAIN AND MUSCLE METABOLISM IN MICE SUBJECTED TO HINDLIMB UNLOADING

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Catherine Strazielle, Caroline Jantzen, Jean-Pol Frippiat, Robert Lalonde
University of Lorraine, Lab Simpa (ea7300), Vandoeuvre-les-Nancy, France

Microgravity induced by space flight has been shown to induce oxidative stress and cause neurochemical and metabolic alterations in specific brain regions. To mimic microgravity, young adult mice were exposed to hindlimb unloading by tail suspension or not (control group) over a 21-day period and, after a 15-day period of recovery, evaluated for motor activity and coordination as well as spatial learning to detect possible long-term behavioral alterations. At the end of the behavioral study, animals were killed and brain as well as forelimb and hindlimb muscles removed for measuring regional cytochrome oxydase activity revealed by histochemistry as a good index of cellular metabolic activity. Both groups of mice increased their body weight in an equivalent manner. The hindlimb unloaded group was impaired on stationary beam and rotorod motor coordination tests, whereas no effect was observed on exploratory activity tests or the Morris water maze. Cytochrome oxidase activity 1) decreased in several precerebellar structures as well as regions involved in the planning and control of movements such as the posterior parietal area and the substantia nigra, and 2) increased in hindlimb muscles, specifically in the small fibers involved in tonic function. The present results confirmed a durable effect of microgravity on vestibulo-cerebellar and motor-related pathways as well as muscle function.

[1]Max Planck Institute for Psycholinguistics, Comparative Bioacoustics Research Group, Nijmegen, Netherlands, [2]Max Planck Institute for Psycholinguistics, Neurogenetics Of Vocal Communication Group, Nijmegen, Netherlands, [3]Max Planck Institute for Psycholinguistics, Neurobiology Of Language Department, Nijmegen, Netherlands, [4]Sealcentre Pieterburen, Research Department, Pieterburen, Netherlands, [5]University Medical Center Groningen, Cognitive Neuropsychiatry Group, Groningen, Netherlands, [6]Maastricht University, Department Of Neuropsychology And Psychopharmacology, Maastricht, Netherlands, [7]University of St. Andrews, School Of Biology, St Andrews, United Kingdom, [8]Donders Institute for Brain, Cognition and Behaviour, --, Nijmegen, Netherlands

Seals have two critical prerequisites for studying the evolution of language and music: the ability to flexibly modify their vocalisations (vocal production learning; VPL) and to process rhythm. However, little is known about the neural underpinnings of VPL and rhythm in animal groups other than humans, songbirds, and non-human primates. Here, we investigate the seal's neuroanatomy and connectivity and their possible relationship with VPL and rhythm. Three brains were retrieved post-mortem from weaned seals; one harbour seal—*Phoca vitulina*—and two grey seals—*Halichoerus grypus*) that were either euthanised or had died of natural causes in rehabilitation. Brains were fixed in formalin and scanned with high-resolution MRI to obtain T1, T2, and diffusion weighted images. The anatomical scans were segmented to create an atlas, a labelled template, and a 3D model with volumetric measurements of brain regions. Results show that the seal brain is relatively big and highly convoluted, with a large temporal lobe and cerebellum and similar cortical thickness as found in humans. Planned probabilistic DTI analyses will target the ascending auditory pathway and the pyramidal tracts. We expect to observe strong connections between auditory and motor regions (e.g., Supplementary Motor Area (SMA), dorsal caudate, temporo-parietal area), supporting VPL and rhythmic processing. By bridging the research gap from songbirds to humans and non-human primates, these results will critically inform VPL and rhythm research and may thus elucidate and enrich the ongoing debate on the evolution of language and music.

Can harbor seals () discriminate familiar conspecific calls after long periods of separation?
The ability to discriminate between familiar and unfamiliar calls may play a key role in pinnipeds' communication and survival, as in the case of mother-pup interactions. Vocal discrimination abilities have been suggested to be more developed in pinniped species with the highest selective pressure such as the otariids; yet, in some group-living phocids, such as harbor seals (), mothers are also able to recognize their pup's voice. Conspecifics' vocal recognition in pups has never been investigated; however, the repeated interaction occurring between pups within the breeding season suggests that long-term vocal discrimination may occur. Here we explored this hypothesis by presenting three rehabilitated seal pups with playbacks of vocalizations from unfamiliar or familiar pups. It is uncommon for seals to come into rehabilitation for a second time in their lifespan, and this study took advantage of these rare cases. A simple visual inspection of the data plots seemed to show more reactions, and of longer duration, in response to familiar as compared to unfamiliar playbacks in two out of three pups. However, statistical analyses revealed no significant difference between the experimental conditions. We also found no significant asymmetry in orientation (left . right) towards familiar and unfamiliar sounds. While statistics do not support the hypothesis of an established ability to discriminate familiar vocalizations from unfamiliar ones in harbor seal pups, further investigations with a larger sample size are needed to confirm or refute this hypothesis.

Dysfunctional Timing in Traumatic Brain Injury Patients: Co-occurrence of Cognitive, Motor, and Perceptual Deficits.
Timing is an essential part of human cognition and of everyday life activities, such as walking or holding a conversation. Previous studies showed that traumatic brain injury (TBI) often affects cognitive functions such as processing speed and

time-sensitive abilities, causing long-term sequelae as well as daily impairments. However, the existing evidence on timing capacities in TBI is mostly limited to perception and the processing of isolated intervals. It is therefore open whether the observed deficits extend to motor timing and to continuous dynamic tasks that more closely match daily life activities. The current study set out to answer these questions by assessing audio motor timing abilities and their relationship with cognitive functioning in a group of TBI patients (= 15) and healthy matched controls. We employed a comprehensive set of tasks aiming at testing timing abilities across perception and production and from single intervals to continuous auditory sequences. In line with previous research, we report functional impairments in TBI patients concerning cognitive processing speed and perceptual timing. Critically, these deficits extended to motor timing: The ability to adjust to tempo changes in an auditory pacing sequence was impaired in TBI patients, and this motor timing deficit covaried with measures of processing speed. These findings confirm previous evidence on perceptual and cognitive timing deficits resulting from TBI and provide first evidence for comparable deficits in motor behavior. This suggests basic co-occurring perceptual and motor timing impairments that may factor into a wide range of daily activities. Our results thus place TBI into the wider range of pathologies with well-documented timing deficits (such as Parkinson's disease) and encourage the search for novel timing-based therapeutic interventions (e.g., employing dynamic and/or musical stimuli) with high transfer potential to everyday life activities.

Neuroanatomy of the grey seal brain: bringing pinnipeds into the neurobiological study of vocal learning.
Comparative animal studies of complex behavioural traits, and their neurobiological underpinnings, can increase our understanding of their evolution, including in humans. Vocal learning, a potential precursor to human speech, is one such trait. Mammalian vocal learning is under-studied: most research has either focused on vocal learning in songbirds or its absence in non-human primates. Here, we focus on a highly promising model species for the neurobiology of vocal learning: grey seals (). We provide a neuroanatomical atlas (based on dissected brain slices and magnetic resonance images), a labelled MRI template, a three-dimensional model with volumetric measurements of brain regions, and histological cortical stainings. Four main features of the grey seal brain stand out: (i) it is relatively big and highly convoluted; (ii) it hosts a relatively large temporal lobe and cerebellum; (iii) the cortex is similar to that of humans in thickness and shows the expected six-layered mammalian structure; (iv) there is expression of FoxP2 present in deeper layers of the cortex; is a gene involved in motor learning, vocal learning, and spoken language. Our results could facilitate future studies targeting the neural and genetic underpinnings of mammalian vocal learning, thus bridging the research gap from songbirds to humans and non-human primates. Our findings are relevant not only to vocal learning research but also to the study of mammalian neurobiology and cognition more in general. This article is part of the theme issue 'Vocal learning in animals and humans'.

Preservation of Language Processing and Auditory Performance in Patients With Disorders of Consciousness: A Multimodal Assessment.
The impact of language impairment on the clinical assessment of patients suffering from disorders of consciousness (DOC) is unknown or underestimated and may mask the presence of conscious behavior. In a group of DOC patients (= 11; time post-injury range: 5-252 months), we investigated the main neural functional and structural underpinnings of linguistic processing, and their relationship with the behavioral measures of the auditory function using the Coma Recovery Scale-Revised (CRS-R). We assessed the integrity of the brainstem auditory pathways, of the left superior temporal gyrus and arcuate fasciculus, the neural activity elicited by passive listening of an auditory language task, and the mean hemispheric glucose metabolism. Our results support the hypothesis of a relationship between the level of preservation of the investigated structures/functions and the CRS-R auditory subscale scores. Moreover, our findings indicate that patients in minimally conscious state minus (MCS-): (1) when presenting the (at the CRS-R auditory subscale) might be aphasic in the receptive domain, being severely impaired in the core language structures/functions; (2) when presenting the might retain language processing, being almost intact or intact in the core language structures/functions. Despite the small group of investigated patients, our findings provide a grounding of the clinical measures of the CRS-R auditory subscale in the integrity of the underlying auditory

structures/functions. Future studies are needed to confirm our results that might have important consequences for the clinical practice.

Interactive rhythms across species: the evolutionary biology of animal chorusing and turn-taking.
The study of human language is progressively moving toward comparative and interactive frameworks, extending the concept of turn-taking to animal communication. While such an endeavor will help us understand the interactive origins of language, any theoretical account for cross-species turn-taking should consider three key points. First, animal turn-taking must incorporate biological studies on animal chorusing, namely how different species coordinate their signals over time. Second, while concepts employed in human communication and turn-taking, such as intentionality, are still debated in animal behavior, lower level mechanisms with clear neurobiological bases can explain much of animal interactive behavior. Third, social behavior, interactivity, and cooperation can be orthogonal, and the alternation of animal signals need not be cooperative. Considering turn-taking a subset of chorusing in the rhythmic dimension may avoid overinterpretation and enhance the comparability of future empirical work.

Spatial attention underpins social word learning in the right fronto-parietal network.
In a multi- and inter-cultural world, we daily encounter new words. Adult learners often rely on a situational context to learn and understand a new word's meaning. Here, we explored whether interactive learning facilitates word learning by directing the learner's attention to a correct new word referent when a situational context is non-informative. We predicted larger involvement of inferior parietal, frontal, and visual cortices involved in visuo-spatial attention during interactive learning. We scanned participants while they played a visual word learning game with and without a social partner. As hypothesized, interactive learning enhanced activity in the right Supramarginal Gyrus when the situational context provided little information. Activity in the right Inferior Frontal Gyrus during interactive learning correlated with post-scanning behavioral test scores, while these scores correlated with activity in the Fusiform Gyrus in the non-interactive group. These results indicate that attention is involved in interactive learning when the situational context is minimal and suggest that individual learning processes may be largely different from interactive ones. As such, they challenge the ecological validity of what we know about individual learning and advocate the exploration of interactive learning in naturalistic settings.

The risk of neurodegeneration in REM sleep behavior disorder: A systematic review and meta-analysis of longitudinal studies.
Several studies report an association between REM Sleep Behavior Disorder (RBD) and neurodegenerative diseases, in particular synucleinopathies. Interestingly, the onset of RBD precedes the development of neurodegeneration by several years. This review and meta-analysis aims to establish the rate of conversion of RBD into neurodegenerative diseases. Longitudinal studies were searched from the PubMed, Web of Science, and SCOPUS databases. Using random-effect modeling, we performed a meta-analysis on the rate of RBD conversions into neurodegeneration. Furthermore, we fitted a Kaplan-Meier analysis and compared the differences between survival curves of different diseases with log-rank tests. The risk for developing neurodegenerative diseases was 33.5% at five years follow-up, 82.4% at 10.5 years and 96.6% at 14 years. The average conversion rate was 31.95% after a mean duration of follow-up of 4.75 ± 2.43 years. The majority of RBD patients converted to Parkinson's Disease (43%), followed by Dementia with Lewy Bodies (25%). The estimated risk for RBD patients to develop a neurodegenerative disease over a long-term follow-up is more than 90%. Future studies should include control group for the evaluation of REM sleep without atonia as marker for neurodegeneration also in non-clinical population and target RBD as precursor of neurodegeneration to develop protective trials.

Test-retest reliability of the Battery for the Assessment of Auditory Sensorimotor and Timing Abilities (BAASTA).
Perceptual and sensorimotor timing skills can be thoroughly assessed with the Battery for the Assessment of Auditory Sensorimotor and Timing Abilities (BAASTA). The battery has been used for testing rhythmic skills in healthy adults and patient populations (e.g., with Parkinson disease), showing sensitivity to timing and rhythm deficits. Here we assessed the test-retest reliability of the BAASTA in 20 healthy adults. Participants were tested twice with the BAASTA, implemented on a tablet interface, with a 2-week interval. They completed 4 perceptual tasks, namely, duration discrimination, anisochrony detection with tones and music, and the Beat Alignment Test (BAT). Moreover, they completed motor tasks via finger tapping, including unpaced and paced tapping with tones and music, synchronization-continuation, and adaptive tapping to a sequence with a tempo change. Despite high variability among individuals, the results showed good test-retest reliability in most tasks. A slight but significant improvement from test to retest was found in tapping with music, which may reflect a

learning effect. In general, the BAASTA was found a reliable tool for evaluating timing and rhythm skills.

Help me if I can't: Social interaction effects in adult contextual word learning.
A major challenge in second language acquisition is to build up new vocabulary. How is it possible to identify the meaning of a new word among several possible referents? Adult learners typically use contextual information, which reduces the number of possible referents a new word can have. Alternatively, a social partner may facilitate word learning by directing the learner's attention toward the correct new word meaning. While much is known about the role of this form of 'joint attention' in first language acquisition, little is known about its efficacy in second language acquisition. Consequently, we introduce and validate a novel visual word learning game to evaluate how joint attention affects the contextual learning of new words in a second language. Adult learners either acquired new words in a constant or variable sentence context by playing the game with a knowledgeable partner, or by playing the game alone on a computer. Results clearly show that participants who learned new words in social interaction (i) are faster in identifying a correct new word referent in variable sentence contexts, and (ii) temporally coordinate their behavior with a social partner. Testing the learned words in a post-learning recall or recognition task showed that participants, who learned interactively, better recognized words originally learned in a variable context. While this result may suggest that interactive learning facilitates the allocation of attention to a target referent, the differences in the performance during recognition and recall call for further studies investigating the effect of social interaction on learning performance. In summary, we provide first evidence on the role joint attention in second language learning. Furthermore, the new interactive learning game offers itself to further testing in complex neuroimaging research, where the lack of appropriate experimental set-ups has so far limited the investigation of the neural basis of adult word learning in social interaction.

PURKINJE CELL MICROZONES MEDIATE DISTINCT KINEMATICS OF A SINGLE MOVEMENT

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Francois Blot, Joshua White, Amy Van Hattem, Licia Scotti, Vaishnavi Balaji, Chris De Zeeuw, Martijn Schonewille
Erasmus MC, Department Of Neuroscience, Rotterdam, Netherlands

The classification of neuronal subtypes has significantly advanced, yet its relevance for behavior remains unclear. The highly organized flocculus of the cerebellum, known to fine-tune multi-axial eye movements, is an ideal substrate for the study of potential functions of neuronal heterogeneity. Here, we demonstrate that its recently identified subpopulations of 9+ and 9- Purkinje cells exhibit distinct gene expression and electrophysiological profiles, providing evidence for a graded continuum of intrinsic properties among PC subtypes. By identifying and utilizing two Cre-lines that target these floccular domains, we show with high spatial specificity that these subtypes of Purkinje cells participate in separate micromodules with topographically organized connections. Finally, subtype-specific optogenetic excitation results in movements around the same axis in space, yet with distinct kinematic profiles. These results indicate that Purkinje cell microzones can control particular parameters of single movements independent from the spatial reference frame.

THE PREVALENCE OF DYSTONIC TREMOR AND TREMOR ASSOCIATED WITH DYSTONIA IN PATIENTS WITH CERVICAL DYSTONIA

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Lenka Satke, Martin Nevrly, Pavel Otruba, Petr Kanovsky
University Hospital Olomouc, Department Of Neurology, Olomouc, Czech Republic

The link between dystonia and tremor has been known for decades, but at present the question arises whether they are two separate illnesses or just different manifestations of one disease with same pathophysiological background. We distinguish two types of tremor in dystonia: dystonic tremor, which appears on body part affected by dystonia, and tremor associated with dystonia (TAWD) in locations where dystonia does not occur, commonly described as coincidental essential tremor. Dystonia has always been considered a basal ganglia disease. However, the theory of neuronal network dysfunction, involving many brain areas, currently prevails. The role of cerebellum seems especially important, which promotes the theory that TAWD might not be just a coincidence of essential tremor and cervical dystonia, but one of the symptoms of cerebellar dysfunction in dystonia. The occurrence of different tremor types in a group of patients with cervical dystonia, was determined by a clinical examination. In total, the study included 123 patients with cervical dystonia, 28 men and 95 women, mean age of patients was 59.8 years. Dystonic tremor was present in 70 patients (56.91%). TAWD was in all 14 cases (11.38%) observed on the upper limbs as a static or intentional tremor. In this study, we point out the presence of TAWD as one of the clinical signs of cervical dystonia, occurring in 11.38% of patients in the studied group. Dystonic tremor occurred in more than half of the patients and appears to be a common part of the clinical picture in patients with cervical dystonia.

THE NEURONAL DYNAMICS OF CEREBELLAR NUCLEI AND MEDIAL PREFRONTAL CORTEX IN EYEBLINK CONDITIONING ADAPTATION TASK

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Zhong Ren, Milen Angelov, Xiaolu Wang, Zhenyu Gao
Erasmus MC, Department Of Neuroscience, Rotterdam, Netherlands

Brain can dynamically control the temporal relationship between sensory inputs and desired movements outputs during daily life. Cerebellum is critically involved in eyeblink conditioning, a classical sensorimotor associative learning paradigm. We sought to examine how cerebellum and other brain regions are involved in regulating the precise timing of conditioned eyeblink response (CR). We trained mice with delay (DEC) or trace eyeblink conditioning (TEC) paradigms. We measured the activity of cerebellar interposed nuclei (IpN) and medial prefrontal cortex (mPFC) during TEC, DEC, and during the conversion between these two paradigms. Pharmacological inhibition of mPFC was also performed in a subgroup of animals. We found that TEC trained mice possess a significantly longer latency between the IpN modulation and CR onset, and IpN neurons could encode for CR onset timing with several different modes. Mice showed quasi-instantaneous adaptation of their CR onset timing while we presented the DEC-trained mice with TEC paradigm, and vice versa. The adaptation of IpN neurons was prominent during DEC-to-TEC conversion, but less during TEC-to-DEC conversion. A group of mPFC neurons rapidly altered their modulation patterns during the paradigm conversion. In addition, silencing mPFC activity selectively blocked the adaptation of CR onsets during both the TEC-to-DEC and TEC-to-DEC conversion, suggesting the functional involvement of mPFC in the rapid adaptation of CR timing. These results illustrate diverse electrophysiology properties of IpN and mPFC neurons that might modulate the timing of associative movements and shed new light on the cerebro-cerebellar mechanisms underlying adaptive temporal control.

LOCUS COERULEUS MEDIATED STATE SWITCH IN BRAIN STATE DURING MOTOR BEHAVIOR IN THE ZEBRAFISH LARVA.

POSTER SESSION 04 - SECTION: CEREBELLAR COMPUTATION AND MOTOR LEARNING

Louis Dannatt[1], Emiliano Marachlian[2], German Sumbre[3]
[1]Ecole Normale Superieure, L'institut De Biologie, Paris, France, [2]Ecole Normale Superieure, Ibens, Paris, France, [3]Ecole Normale Superierue, Biology, paris, France

The generation of motor behavior has been a crucial question within neuroscience since its emergence as a scientific field. Previously in Zebrafish models, it has been shown that large behavioral activity is associated with a switch in the brain state. Understanding this type of activity is central to our understanding how the brain produces motor behavior. By using zebrafish larva as experimental model in combination with light-sheet microscopy, we monitored whole-brain dynamics with single-neuron resolution while simultaneously recording free tail movement as a behavioral output. We recorded both spontaneous and stimuli-driven activity to be able to compare motor generation between the two. Results show that following both spontaneous and stimuli induced movement there appears to be a Locus Coeruleus (LC) mediated switch in the brain state of the animals. This is characterized by a long-lasting gradual ramping activity of a subpopulation of neurons which are quickly inhibited at the time of activation of the LC. Then, a significant change occurs in terms of the neuronal assembly dynamics across the entire brain. We focus on the ramping subpopulation of neurons to investigate their role in the change of the brain state, their effect of the LC and the behavior of the animal. We hypothesize that this subpopulation is integrating information across the brain to result in motor movement.

Mammals have a remarkable capacity to precisely coordinate body movements to generate complex and functionally relevant motor behaviors. The spinal cord is the final executor of the neuronal code, translating neural signals into detailed and coherent muscle activity along the body. In order to accomplish complex whole-body movements, spinal circuitries should generate interwoven patterns of detailed activity for multiple muscles along the body starting from a common motor command. Here, we examine the sensory-motor components of a spinal microcircuit for multi-joint movements in which a defined population of propriospinal interneurons, the V2a neurons, represents the core element. Combining mouse intersectional genetics with *in vivo* optogenetic and electrophysiology in adult mice, we show that V2a spinal neurons along the spinal cord activate discrete muscles in a topographic fashion. Anatomical tracing and simultaneous recordings of muscles and opto-tagged V2a neurons allowed detailed anatomical characterization and functional dissection of the V2a sensory-motor maps. V2 neurons together with sensory afferents, motor neurons, and muscles form a feedforward descending excitatory system in the spinal cord that simultaneously drives coordinated activity in multiple muscles. Accordingly, prolonged optical activation of V2a neurons in a specific segment appropriately recruit tens of muscles, while their *in vivo* targeted silencing perturbed the sequence of muscle activation in complex motor task as swimming. These data show the anatomical substrate and identify the functional principles of a spinal microcircuit involved in constructing muscle activation sequences, providing the logic on how spinal circuitries sculpt muscle action over time and space for meaningful motor behaviors.

SPINAL CORD CONTROL OF MANUAL DEXTERITY IN RATS: A FUNCTIONAL MAPPING STUDY

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Diego López-Santos[1], África Flores[2], Guillermo García-Alías[1]
[1]Universitat Autònoma de Barcelona, Department Cell Biology, Physiology And Immunology & Institute Of Neuroscience, Bellaterra, Spain, [2]Universitat de Barcelona, Pharmacology Unit, Department Of Pathology And Experimental Therapy, L'Hospitalet de Llobregat, Spain

Manual dexterity, such as object “reaching and grasping” (R&G), is essential to conduct daily tasks. Stereotypic features of these movements suggest that some level of control may be exerted from the spinal cord (SC). In this project, we aimed to unveil the presence of these networks and their rostrocaudal location within the SC. The approach consisted of inflicting excitotoxic injuries to rats at different SC levels covering from C3 to T3 using kainic acid, for exclusively affecting spinal networks while preserving descending commands. Motor deficits were evaluated by comparing the performance, before *vs* after the intervention, in multiple behavioural tests of forelimb muscles’ function that likely require distinct neuronal networks. One-week post-intervention, C3-injured animals showed a significant impairment in R&G, staircase and horizontal ladder tests, but not on other tasks. The performance of rats receiving more caudal injuries remained grossly unaffected. Histological analysis revealed a grey matter loss that correlated with the segments of injection, and which presumably is accompanied by the loss of spinal premotor circuits. To dismiss the possibility of the concomitant loss of motoneurons and/or sensory feedback being the cause of the behavioural deficits observed, a subsequent experiment was conducted in which the C3 dorsal and ventral roots were sectioned, therefore eliminating all its direct afferences and efferences but preserving spinal networks’ integrity. Those animals did not suffer manual dexterity impairments. Our results suggest the presence, at spinal segment C3, of a neuronal network necessary for properly executing forelimb skilled movements.

SUPRA-PONTINE STRUCTURES MODULATE BRAINSTEM AND SPINAL NETWORKS

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Atiyeh Mohammadshirazi, Monica Colitti, Giuliano Taccola
International School for Advanced Studies, Neuroscience, Trieste, Italy

Supraspinal structures control several spinal motor output and essential rhythmic behaviors. However, current isolated preparations, although of great advantage in deciphering the functional organization of brainstem and spinal networks, are focused on local circuitry. To better characterize the contribution of higher centers to the neuronal pathways involved in respiration and locomotion, we proposed a novel experimental approach. In an in vitro preparation from the isolated CNS of neonatal rodents, a stable respiratory rhythm was simultaneously recorded from cervical and lumbar ventral roots (VRs) with histological morphology preserved for even more than four hours. Selective electrical pulses supplied to pons and medulla evoked distinct responses with staggered onset in rostrocaudal direction, while stimulation of ventrolateral medulla resulted in higher events from homolateral VRs. Moreover, electrical stimulation of a lumbar dorsal root elicited responses even from cervical VRs, albeit smaller and delayed, confirming that ascending pathways were functional. Furthermore, the prototypical fictive locomotion was induced by trains of pulses applied to both the ventrolateral medulla and the dorsal root. When progressively removing higher centers, the frequency of respiration increased after a pontobulbar transection, while burst duration was already reduced after a pre-collicular transection, which also affected the area of lumbar dorsal and ventral root potentials elicited by dorsal root stimulation. In the present study, supra-pontine centers regulate spontaneous respiratory rhythm, as well as electrically-evoked reflex and network responses. Thus, the current approach can clarify the modulatory influence of the brain on caudal micro-circuits.

Combinational therapy of lithium and human neural stem cells in rat spinal cord contusion model.
A large number of treatment approaches have been used for spinal cord injury improvement, a medically incurable disorder, and subsequently stem cell transplantation appears to be a promising strategy. The main objective of this study is to ascertain whether combinational therapy of human neural stem cells (hNSCs) together with lithium chloride improves cell survival, proliferation, and differentiation in a rat spinal contusion model, or not. Contusive spinal cord injury was implemented on Wistar male rats. Experimental groups comprised of: control, hNSCs transplanted, lithium chloride (Li), and hNSCs and lithium chloride (hNSCs + Li). In every experimental group, locomotor activity score and motor evoked potential (MEP) were performed to evaluate motor recovery as well as histological assessments to determine mechanisms of improvement. In accordance with our results, the hNSCs + Li and the Li groups showed significant improvement in locomotor scores and MEP. Also, Histological assessments revealed that transplanted hNSCs are capable of differentiation and migration along the spinal cord. Although NESTIN-positive cells were proliferated significantly in the Lithium group in comparison with control and the hNSCs + Li groups, the quantity of ED1 cells in the hNSCs + Li was significantly larger than the other two groups. Our results demonstrate that combinational therapy of hNSCs with lithium chloride and lithium chloride individually are adequate for ameliorating more than partial functional recovery and endogenous repair in spinal cord-injured rats.

Human embryonic stem cell-derived neural stem cells encapsulated in hyaluronic acid promotes regeneration in a contusion spinal cord injured rat.
spinal cord injury (SCI) is a traumatic damage that can causes a loss of neurons around the lesion site and resulting in locomotor and sensory deficits. Currently, there is widely attempts in improvement of treatment strategy and cell delivering to the central nervous system (CNS). The usage of hyaluronic acid (HA), the main components of the ECM in CNS tissue and neural stem cells (NSCs) niche, is a good selection that can increase of viability and differentiation of NSCs. Importantly, we demonstrate that encapsulation of human embryonic stem cell derived-neural stem cells (hESC-NS) in HA-based hydrogel can increased differentiation these cells into oligodendrocytes and improved locomotor function.

GABAergic Mechanisms Can Redress the Tilted Balance between Excitation and Inhibition in Damaged Spinal Networks.
Correct operation of neuronal networks depends on the interplay between synaptic excitation and inhibition processes leading to a dynamic state termed balanced network. In the spinal cord, balanced network activity is fundamental for the expression of locomotor patterns necessary for rhythmic activation of limb extensor and flexor muscles. After spinal cord lesion, paralysis ensues often followed by spasticity. These conditions imply that, below the damaged site, the state of balanced networks has been disrupted and that restoration might be attempted by modulating the excitability of sublesional spinal neurons. Because of the widespread expression of inhibitory GABAergic neurons in the spinal cord, their role in the early and late phases of spinal cord injury deserves full attention. Thus, an early surge in extracellular GABA might be involved in the onset of spinal shock while a relative deficit of GABAergic mechanisms may be a contributor to spasticity. We discuss the role of GABA A receptors at synaptic and extrasynaptic level to modulate network excitability and to offer a pharmacological target for symptom control. In particular, it is proposed that activation of GABA A receptors with synthetic GABA agonists may downregulate motoneuron hyperexcitability (due to enhanced persistent ionic currents) and, therefore, diminish spasticity. This approach might constitute a complementary strategy to regulate network excitability after injury so that reconstruction of damaged spinal networks with new materials or cell transplants might proceed more successfully.

Effect of Transcranial Direct Current Stimulation on Dorsolateral Prefrontal Cortex to Reduce the Symptoms of the Obsessive-Compulsive Disorder.
Obsessive-Compulsive Disorder (OCD) is one of the most common debilitating mental disorders with a prevalence rate of 2% to 3% in the general population. Previous studies have indicated abnormalities in the dorsolateral prefrontal cortex (DLPFC) of OCD patients; thus, we decided to use transcranial Direct Current Stimulation (tDCS) to decline these patients' symptoms.

PPN-STIMULATION INDUCED FREEZING-RESPONSE AND ITS IMPACT ON THE ACTIVITY OF SPINAL MOTOR CIRCUITS IN FREELY MOVING RATS

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Jaspreet Kaur
University of Copenahgen, Neuroscience, Copenhagen, Denmark

It is well known that stimulation (either electrical or optical) of the midbrain locomotor region (MLR) induces locomotor networks resulting in walking and running gaits (Shik et al 1966). However, it was recently discovered (Carvalho et al 2020) that activating cells in a region within MLR in rats, the pedunculopontine nucleus (PPN), surprisingly induced the opposite effect, which entails a complete arrest of all overt movement including whisking of the vibrissae. To further investigate this paradoxical effect, the PPN region was targeted using the AAV virus with a CamKIIa-dependent expression of an opsin (ChrimsonR) and with an implanted optical fiber (200 µm diameter). After viral expression, approximately 4 weeks later, and confirmation of response, multi-electrode arrays (128-channels, Neuronexus) were implanted in the lumbar spinal cord of adult rats in order to investigate the impact of the PPN stimulation and the freezing response. The lumbar units were recorded before, during and after PPN stimulation. The majority of the spinal units had a reduced neuronal spiking activity during the freezing response. Measurements of motion were performed using accelerometers and video recording. The neuronal subtypes in PPN were investigated using immunohistochemistry, tissue clearing and in-situ hybridization.

Adaptive polymer fiber neural device for drug delivery and enlarged illumination angle for neuromodulation.
. Optical fiber devices constitute significant tools for the modulation and interrogation of neuronal circuitry in the mid and deep brain regions. The illuminated brain area during neuromodulation has a direct impact on the spatio-temporal properties of the brain activity and depends solely on the material and geometrical characteristics of the optical fibers. In the present work, we developed two different flexible polymer optical fibers (POFs) with integrated microfluidic channels (MFCs) and an ultra-high numerical aperture (UHNA) for enlarging the illumination angle to achieve efficient neuromodulation.. Three distinct thermoplastic polymers: polysulfone, polycarbonate, and fluorinated ethylene propylene were used to fabricate two step-index UHNA POF neural devices using a scalable thermal drawing process. The POFs were characterized in terms of their illumination map as well as their fluid delivery capability in phantom and adult rat brain slicesA 100-fold reduced bending stiffness of the proposed fiber devices compared to their commercially available counterparts has been found. The integrated MFCs can controllably deliver dye (trypan blue) on-demand over a wide range of injection rates spanning from 10 nl minto 1000 nl min. Compared with commercial silica fibers, the proposed UHNA POFs exhibited an increased illumination area by 17% and 21% under 470 and 650 nm wavelength, respectively. In addition, a fluorescent light recording experiment has been conducted to demonstrate the ability of our UHNA POFs to be used as optical waveguides in fiber photometry.. Our results overcome the current technological limitations of fiber implants that have limited illumination area and we suggest that soft neural fiber devices can be developed using different custom designs for illumination, collection, and photometry applications. We anticipate our work to pave the way towards the development of next-generation functional optical fibers for neuroscience.

A study of methylprednisolone neuroprotection against acute injury to the rat spinal cord in vitro.
Methylprednisolone sodium succinate (MPSS) has been proposed as a first-line treatment for acute spinal cord injury (SCI). Its clinical use remains, however, controversial because of the modest benefits and numerous side-effects. We investigated if MPSS could protect spinal neurons and glia using an in vitro model of the rat spinal cord that enables recording reflexes, fictive locomotion and morphological analysis of damage. With this model, a differential lesion affecting mainly either neurons or glia can be produced via kainate-evoked excitotoxicity or application of a pathological medium (lacking O2 and glucose), respectively. MPSS (6-10 µM) applied for 24 h after 1-h pathological medium protected astrocytes and oligodendrocytes especially in the ventrolateral white matter. This effect was accompanied by the return of slow, alternating oscillations (elicited

by NMDA and 5-hydroxytryptamine (5-HT)) reminiscent of a sluggish fictive locomotor pattern. MPSS was, however, unable to reverse even a moderate neuronal loss and the concomitant suppression of fictive locomotion evoked by kainate (0.1 mM; 1 h). These results suggest that MPSS could, at least in part, contrast damage to spinal glia induced by a dysmetabolic state (associated to oxygen and glucose deprivation) and facilitate reactivation of spinal networks. Conversely, when even a minority of neurons was damaged by excitotoxicity, MPSS did not protect them nor did it restore network function in the current experimental model.

Neuroprotective effect of propofol against excitotoxic injury to locomotor networks of the rat spinal cord in vitro.
Although neuroprotection to contain the initial damage of spinal cord injury (SCI) is difficult, multicentre studies show that early neurosurgery under general anaesthesia confers positive benefits. An interesting hypothesis is that the general anaesthetic itself might largely contribute to neuroprotection, although in vivo clinical settings hamper studying this possibility directly. To further test neuroprotective effects of a widely used general anaesthetic, we studied if propofol could change the outcome of a rat isolated spinal cord SCI model involving excitotoxicity evoked by 1 h application of kainate with delayed consequences on neurons and locomotor network activity. Propofol (5 μm; 4-8 h) enhanced responses to GABA and depressed those to NMDA together with decrease in polysynaptic reflexes that partly recovered after 1 day washout. Fictive locomotion induced by dorsal root stimuli or NMDA and serotonin was weaker the day after propofol application. Kainate elicited a significant loss of spinal neurons, especially motoneurons, whose number was halved. When propofol was applied for 4-8 h after kainate washout, strong neuroprotection was observed in all spinal areas, including attenuation of motoneuron loss. Although propofol had minimal impact on recovery of electrophysiological characteristics 24 h later, it did not further depress network activity. A significant improvement in disinhibited burst periodicity suggested potential to ameliorate neuronal excitability in analogy to histological data. Functional recovery of locomotor networks perhaps required longer time due to the combined action of excitotoxicity and anaesthetic depression at 24 h. These results suggest propofol could confer good neuroprotection to spinal circuits during experimental SCI.

Pharmacological induction of Heat Shock Protein 70 by celastrol protects motoneurons from excitotoxicity in rat spinal cord in vitro.
The secondary phase of spinal cord injury arising after the primary lesion largely extends the damage severity with delayed negative consequences for sensory-motor pathways. It is, therefore, important to find out if enhancing intrinsic mechanisms of neuroprotection can spare motoneurons that are very vulnerable cells. This issue was investigated with an in vitro model of rat spinal cord excitotoxicity monitored for up to 24 hr after the primary injury evoked by kainate. This study sought to pharmacologically boost the expression of heat shock proteins (HSP) to protect spinal motoneurons using celastrol to investigate if the rat spinal cord can upregulate HSP as neuroprotective mechanism. Despite its narrow range of drug safety in vitro, celastrol was not toxic to the rat spinal cord at 0.75 μM concentration and enhanced the expression of HSP70 by motoneurons. When celastrol was applied either before or after kainate, the number of dead motoneurons was significantly decreased and the nuclear localization of the cell death biomarker AIF strongly inhibited. Nevertheless, electrophysiological recording showed that protection of lumbar motor networks by celastrol was rather limited as reflex activity was impaired and fictive locomotion largely depressed, suggesting that functional deficit persisted, though the networks could express slow rhythmic oscillations. While our data do not exclude further recovery at later times beyond the experimental observations, the present results indicate that the upregulated expression of HSP in the aftermath of acute injury may be an interesting avenue for early protection of spinal motoneurons.

Nicotine-mediated neuroprotection of rat spinal networks against excitotoxicity.
Activation of neuronal nicotinic acetylcholine receptors (nAChRs) by nicotine is reported to protect brain neurons from glutamate excitotoxicity. We inquired whether a similar phenomenon can occur in the rat isolated spinal cord (or spinal slice culture) challenged by a transient (1 hr) application of kainate (a powerful glutamate receptor agonist) to induce excitotoxicity mimicking spinal injury in vitro. We recorded spinal reflexes and fictive locomotion generated by the locomotor central pattern generator before and 24 hr after applying kainate. We also monitored network activity with Ca imaging and counted neurons and glia with immunohistochemical methods. In control conditions, nicotine (1 μM; 4 hr) depressed reflexes and fictive locomotion with slow recovery and no apparent neurotoxicity at 24 hr although synchronous Ca transients appeared in slice cultures. Kainate nearly halved neuron numbers (while sparing glia), decreased reflexes and Ca transients, and suppressed fictive locomotion. When nicotine was applied (4 hr) after washout of kainate, fictive locomotor cycles appeared 24 hr later though with low periodicity, and significant protection of neurons, including motoneurons, was observed. Nicotine applied

together with kainate and maintained for further 4 hr yielded better neuroprotection, improved fictive locomotion expression and reversed the depression of Ca transients. nAChR antagonists did not intensify kainate neurotoxicity and inhibited the neuroprotective effects of nicotine. These data suggest that nicotine was efficacious to limit histological and functional excitotoxic damage probably because it activated and then desensitized nAChRs on excitatory and inhibitory network neurons to prevent triggering intracellular cell death pathways.

Nicotine Neurotoxicity Involves Low Wnt1 Signaling in Spinal Locomotor Networks of the Postnatal Rodent Spinal Cord.
The postnatal rodent spinal cord in-vitro is a useful model to investigate early pathophysiological changes after injury. While low dose nicotine (1 μM) induces neuroprotection, how higher doses affect spinal networks is unknown. Using spinal preparations of postnatal wild-type Wistar rat and Wnt1Cre2:Rosa26Tom double-transgenic mouse, we studied the effect of nicotine (0.5-10 μM) on locomotor networks in-vitro. Nicotine 10 μM induced motoneuron depolarization, suppressed monosynaptic reflexes, and decreased fictive locomotion in rat spinal cord. Delayed fall in neuronal numbers (including motoneurons) of central and ventral regions emerged without loss of dorsal neurons. Conversely, nicotine (0.5-1 μM) preserved neurons throughout the spinal cord and strongly activated the Wnt1 signaling pathway. High-dose nicotine enhanced expression of S100 and GFAP in astrocytes indicating a stress response. Excitotoxicity induced by kainate was contrasted by nicotine (10 μM) in the dorsal area and persisted in central and ventral regions with no change in basal Wnt signaling. When combining nicotine with kainate, the activation of Wnt1 was reduced compared to kainate/sham. The present results suggest that high dose nicotine was neurotoxic to central and ventral spinal neurons as the neuroprotective role of Wnt signaling became attenuated. This also corroborates the risk of cigarette smoking for the foetus/newborn since tobacco contains nicotine.

Intravital Assessment of Cells Responses to Conducting Polymer-Coated Carbon Microfibres for Bridging Spinal Cord Injury.
The extension of the lesion following spinal cord injury (SCI) poses a major challenge for regenerating axons, which must grow across several centimetres of damaged tissue in the absence of ordered guidance cues. Biofunctionalized electroconducting microfibres (MFs) that provide biochemical signals, as well as electrical and mechanical cues, offer a promising therapeutic approach to help axons overcome this blind journey. We used poly(3,4-ethylenedioxythiophene)-coated carbon MFs functionalized with cell adhesion molecules and growth factors to bridge the spinal cord after a partial unilateral dorsal quadrant lesion (PUDQL) in mice and followed cellular responses by intravital two-photon (2P) imaging through a spinal glass window. Thy1-CFP//LysM-EGFP//CD11c-EYFP triple transgenic reporter animals allowed real time simultaneous monitoring of axons, myeloid cells and microglial cells in the vicinity of the implanted MFs. MF biocompatibility was confirmed by the absence of inflammatory storm after implantation. We found that the sprouting of sensory axons was significantly accelerated by the implantation of functionalized MFs after PUDQL. Their implantation produced better axon alignment compared to random and misrouted axon regeneration that occurred in the absence of MF, with a most striking effect occurring two months after injury. Importantly, we observed differences in the intensity and composition of the innate immune response in comparison to PUDQL-only animals. A significant decrease of immune cell density was found in MF-implanted mice one month after lesion along with a higher ratio of monocyte-derived dendritic cells whose differentiation was accelerated. Therefore, functionalized carbon MFs promote the beneficial immune responses required for neural tissue repair, providing an encouraging strategy for SCI management.

A mechanistic overview of spinal cord injury, oxidative DNA damage repair and neuroprotective therapies.
Despite substantial development in medical treatment strategies scientists are struggling to find a cure against spinal cord injury (SCI) which causes long term disability and paralysis. The prime rationale behind it is the enlargement of primary lesion due to an initial trauma to the spinal cord which spreads to the neighbouring spinal tissues It begins from the time of traumatic event happened and extends to hours and even days. It further causes series of biological and functional alterations such as inflammation, excitotoxicity and ischemia, and promotes secondary lesion to the cord which worsens the life of individuals affected by SCI. Oxidative DNA damage is a stern consequence of oxidative stress linked with secondary injury causes oxidative base alterations and strand breaks, which provokes cell death in neurons. It is implausible to stop primary damage however it is credible to halt the secondary lesion and improve the quality of the patient's life to some extent. Therefore it is crucial to understand the hidden perspectives of cell and molecular biology affecting the pathophysiology of SCI. Thus the focus of the review is to connect the missing links and shed light on the oxidative DNA damages and the functional repair mechanisms, as a consequence of the injury in neurons. The review will also probe the significance of neuroprotective strategies in the present scenario. HIGHLIGHTS• Spinal cord injury, a pernicious condition, causes excitotoxicity and

ischemia, ultimately leading to cell death.• Oxidative DNA damage is a consequence of oxidative stress linked with secondary injury, provoking cell death in neurons.• Base excision repair (BER) is one of the major repair pathways that plays a crucial role in repairing oxidative DNA damages.• Neuroprotective therapies curbing SCI and boosting BER include the usage of pharmacological drugs and other approaches.

Dataset on inflammation induced after lumbar puncture.
Neuroinflammation is evident and one of the primary induced responses after central nervous system (CNS) injury, lumbar puncture and CNS surgery. In rare cases, complications could arise after the lumbar puncture or CNS surgery leading to inflammation, bleeding or other problems such as cerebrospinal fluid (CSF) leakage. The present dataset describes the occurrence of such a condition after the dura breakage or postoperative complication leading to the development of neuroinflammation in the adult Wistar rats. Therefore, objective of the study is to report such a rare condition and detect the most reliable glial proteins upregulated 2-3 weeks after the lumbar puncture which may help the neuroscience community to a better understanding their cause of action. In response to neuroinflammation, glial cells leak into the extracellular space, where they can be identified in the CSF or serum and may act as diagnostic biomarkers. Laminectomy was performed at the thoraco-lumbar (T12-L1) region and the dura was punctured. After that, the exposed part was covered with silica gel and adhesive followed by dental cement. The skin was closed using sterile sutures. After, the rats were given buprenorphine (0.05 mg/kg, every 8 h for 3 days) and carprofen (5 mg/kg, once a day for 5 days) as analgesic and anti-inflammatory and baytril (5 mg/kg, once a day for 10 days) as antibiotic drugs. Note, the buprenorphine and lidocaine were also given before starting the procedure. After the laminectomy, the functional outcomes of the rats were tested (starting from the day of surgery to the last day) and the rats which were locomoting normally using all the limbs were included in the study. In case of any decompression, the functional outcomes showing any kind of laming or partial paralysis of hindlimbs were excluded from the study. Unexpected neuroinflammation has occurred 2-3 weeks after performing the given procedure. Data presented in the article implicate active microglia measured by using protein biomarker such as Iba-1 [1, 3] and astrocytes measured by using Glial fibrillary acidic protein (GFAP) [2, 3] and S100 (strongly targets S100B and weakly A1) [7, 8] in the CSF collected two-three weeks after the laminectomy and dura breakage from the adult rats. Later paraformaldehyde (PFA) fixed spinal cord slices were also collected from the animals and immunolabelled with the same biomarkers. Western blots were performed with the collected CSF which showed high expression of glial markers such as GFAP, Iba-1 and S100 which has shown to target S100B with no expression of A1 (or A2, play an important role in neuroprotection) astrocytes which have recently been shown to be produced by microglia at the site of injury [9]. However, S100B [10] and GFAP [2] are known to be adequately discharged by the distinct cells in stress conditions which seems to occur in the present report. In addition, the spinal slices immunolabelled with the same biomarkers also showed increased expression of glia. Cross-talk between microglia-astrocyte in CNS stress is crucial for the neurons to survive and function after the injury. Reactive microglia (shown by high Iba-1 expression) leading to microgliosis comprise the first line of defense to phagocytose the dead cells [11]. Astrocytes act as the second line of defense leading to a process known as astrogliosis and upregulate GFAP and S100B to limit the damage [12]. Further studies are needed to explain the molecular mechanism/s of different astrocytes release such as A2 and their interaction with microglia after the lumbar puncture.

ACTIVATION OF DESCENDING BRAINSTEM COMMANDS REVEALS THE DYNAMICS OF MODULAR ORGANIZATION OF THE LOCOMOTOR NETWORKS IN THE SPINAL CORD

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Li-Ju Hsu[1], Maëlle Bertho[1,2], Ole Kiehn[1,2]
[1]University of Copenhagen, Department Of Neuroscience, Copenhagen, Denmark, [2]Karolinska Institutet, Neuroscience, Solna, Sweden

Locomotion empowers animals to move for survival. Locomotor-initiating signals from the brain are funneled through reticulospinal neurons in the brainstem that act on spinal circuits that transform the signal into rhythmic locomotor output. Knowledge about which spinal circuits are targeted by the descending signal and how this signal is transformed into rhythmicity in the cord is scarce. Here, we first show that a brainstem area – encompassing the caudal ventrolateral reticular nucleus and the lateral paragigantocellular nucleus – contains excitatory neurons that directly act to initiate locomotion. Next, we dissected how this glutamatergic descending command interfaces with spinal locomotor circuitries, and deciphered the functional modules of neurons recruited by descending command signals. By calcium imaging, we captured the locomotor initiating command in the spinal cord and reveal an immediate spinal glutamatergic target (iDT) in the intermediate area of the cord. The iDT converts the descending commands into rhythmicity by starting each locomotor cycle, and the signal from there travels to excitatory premotor circuits on the same side of the cord before entering mirroring circuits on the other side of the cord. Inhibitory networks are recruited in strict left-right alternation. Our study visualizes the spatiotemporal dynamics of the locomotor network operation from the brainstem to the spinal cord in real time and reveals a distinct layered composition of spinal locomotor circuits.

A SENSORY SYSTEM DYNAMICALLY-COUPLED TO THE REISSNER FIBER UNDER TENSION IN THE SPINAL CORD INFORMS STRAIGHTNESS OF THE BODY AXIS

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Celine Bellegarda[1], Guillaume Zavard[1], Yasmine Cantaut-Belarif[1], Lionel Moisan[2], Claire Wyart[1]
[1]Paris Brain Institute, Icm, Inserm U 1127, Cnrs Umr 7725, Sorbonne Université, Paris, France, [2]Université Paris Descartes, Map5, Umr-cnrs 8145, Pres Sorbonne Paris Cité, Paris, France

A decade of work has revealed a sensory system contacting the cerebrospinal fluid (CSF) in the vertebrate spinal cord that detects body curvature and, in turn, modulates posture and locomotor kinematics. This sensory system also informs morphogenesis to straighten the body axis. To detect negative curvature of the spinal cord, CSF-contacting neurons (CSF-cNs) project a ciliated apical extension in close vicinity of the Reissner fiber, a thread-like aggregation of *scospondin* glycoprotein in the CSF that prompts the straightening of the posterior axis. Although recent evidence indicates that the fiber is required for CSF-cN mechanosensory function, the underlying mechanisms and the manner by which it controls morphogenesis are not fully understood. To address these questions, we investigated the dynamic interaction between the Reissner fiber and CSF-cNs in larval zebrafish. We observed that the Reissner fiber is under tension and changes position along the dorsoventral axis. The dynamic mobility of the fiber occurs while nearby CSF-cNs exhibit spontaneous calcium transients, suggesting that physical interaction with the fiber may activate CSF-cNs. To investigate whether the oscillating fiber elicits calcium activity in CSF-cNs, we implemented focal 2-photon-mediated ablation of the fiber and investigated its impact on CSF-cN activity. We further examined the subsequent effect of the Reissner fiber loss on locomotion, posture and morphogenesis. Altogether, our *in vivo* study in larval zebrafish reveals a dynamic interaction between ciliated sensory neurons and the Reissner fiber under tension in the CSF in order to straighten the body axis throughout life.

LHX9-DERIVED EXCITATORY SPINAL INTERNEURONS CONTROL THE FREQUENCY OF LOCOMOTOR RHYTHM.

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Maëlle Bertho[1,2], Li-Ju Hsu[1,2], Péter Lőw[2], Lotta Borgius[2], Ole Kiehn[1,2]
[1]University of Copenhagen, Department Of Neuroscience, Copenhagen, Denmark, [2]Karolinska Institutet, Neuroscience, Solna, Sweden

The ability to move and interact with the surroundings is achieved through a complex motor behaviour called locomotion. Locomotion is controlled by spinal networks that generate rhythm and coordinate left-right and flexor-extensor patterning. Rhythm-generation neurons controlling the frequency of the rhythm are thought to be ipsilaterally projecting and excitatory. Two molecularly-identified glutamatergic neuronal populations, Shox2 non-V2a and Hb9-derived INs, were found to be part of the mouse rhythm-generating networks. However, these molecular classification groups of spinal neurons do not fully account for the entire rhythm-generating population. We have identified new molecular markers using RNA-sequencing of spinal glutamatergic neurons (age P3) that may identify new populations involved in the rhythm-generating circuitries. One of the new populations expresses the transcription factor Lhx9. To uncover the role of this population in the locomotor network, we used tamoxifen-inducible *Lhx9::Cre* mice to genetically manipulate Lhx9::Cre-derived excitatory neurons. We find that this line, throughout the spinal cord, depicts an ipsilaterally-projecting excitatory population in the ventral spinal cord that is non-overlapping with Shox2 neurons. Blocking the synaptic output of Lhx9$^+$ neurons decrease the frequency of locomotor-like activity induced by drug application without affecting the pattern. Optogenetic activation of Lhx9$^+$ neurons at lumbar cord initiates locomotor bursts. It also increases the burst frequency of drug-induced locomotor activities. Together, these data suggest that Lhx9$^+$ neurons are a potential new population involved in the rhythm-generating circuitries of spinal locomotor network.

A Guide to the Generation of a 6-Hydroxydopamine Mouse Model of Parkinson's Disease for the Study of Non-Motor Symptoms.
In Parkinson's disease (PD), a large number of symptoms affecting the peripheral and central nervous system precede, develop in parallel to, the cardinal motor symptoms of the disease. The study of these conditions, which are often refractory to and may even be exacerbated by standard dopamine replacement therapies, relies on the availability of appropriate animal models. Previous work in rodents showed that injection of the neurotoxin 6-hydroxydopamine (6-OHDA) in discrete brain regions reproduces several non-motor comorbidities commonly associated with PD, including cognitive deficits, depression, anxiety, as well as disruption of olfactory discrimination and circadian rhythm. However, the use of 6-OHDA is frequently associated with significant post-surgical mortality. Here, we describe the generation of a mouse model of PD based on bilateral injection of 6-OHDA in the dorsal striatum. We show that the survival rates of males and females subjected to this lesion differ significantly, with a much higher mortality among males, and provide a protocol of enhanced pre- and post-operative care, which nearly eliminates animal loss. We also briefly discuss the utility of this model for the study of non-motor comorbidities of PD.

Inhibition of mTORC1 Signaling Reverts Cognitive and Affective Deficits in a Mouse Model of Parkinson's Disease.
Non-motor symptoms, including cognitive deficits and affective disorders, are frequently diagnosed in Parkinson's disease (PD) patients and are only partially alleviated by dopamine replacement therapy. Here, we used a 6-hydroxydopamine (6-OHDA) mouse model of PD to examine the effects exerted on non-motor symptoms by inhibition of the mammalian target of rapamycin complex 1 (mTORC1), which is involved in the control of protein synthesis, cell growth, and metabolism. We show that rapamycin, which acts as an allosteric inhibitor of mTORC1, counteracts the impairment of novel object recognition. A similar effect is produced by PF-4708671, an inhibitor of the downstream target of mTORC1, ribosomal protein S6 kinase (S6K). Rapamycin is also able to reduce depression-like behavior in PD mice, as indicated by decreased immobility in the forced swim test. Moreover, rapamycin exerts anxiolytic effects, thereby reducing thigmotaxis in the open field and increasing

exploration of the open arm in the elevated plus maze. In contrast to rapamycin, administration of PF-4708671 to PD mice does not counteract depression- and anxiety-like behaviors. Altogether, these results identify mTORC1 as a target for the development of drugs that, in combination with standard antiparkinsonian agents, may widen the efficacy of current therapies for the cognitive and affective symptoms of PD.

CHARACTERIZATION OF LONG PROJECTING PROPRIOSPINAL NEURONS IN THE MOUSE SPINAL CORD

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Elisa Toscano, Niccolò Zampieri
Max-Delbrück-Centrum für Molekulare Medizin (MDC), Development And Function Of Neural Circuits, Berlin, Germany

Locomotion is an innate animal behavior that relies on the precise control of limb activity and postural stability. In order to timely coordinate the patterns of trunk and limb muscles contraction, spinal circuits need to share motor programs and sensory information at different segmental levels. Long projecting propriospinal neurons (L-PNs) have been proposed to coordinate the activity of spinal circuits at the intersegmental level. L-PNs reciprocally connect the lumbar, cervical and thoracic spinal levels and recent studies started addressing their roles in motor control. However, a comprehensive molecular, anatomical and functional characterization to precisely define L-PNs diversity and function is still missing. Here, we started to systematically analyze L-PNs at anatomical and molecular levels, in order to pave the way for unraveling their physiological roles. Taking advantage of retrograde viral tracing, we identified six different populations of propriospinal neurons based on their anatomical position and intersegmental connectivity patterns. Moreover, transcriptome analysis revealed the molecular diversity of L-PNs, highlighting the existence of discrete subsets belonging to cardinal spinal progenitor identities. Finally, by taking advantage of viral and intersectional approaches, we started characterizing connectivity and function of a small subset of long ascending propriospinal neurons residing in the dorsal spinal cord.

RHYTHMIC MOVEMENT BY SPINAL MOTOR NETWORKS IS GOVERNED BY ROTATIONAL POPULATION DYNAMICS

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Rune Berg
University of Copenhagen, Department Of Neuroscience, KBH N, Denmark

Most of the investigations on spinal rhythm generation are based on motor nerve recordings and single neuron recordings. Since flexor/extensor muscles alternate during movements, it has often been assumed that the generation is accomplished by neuronal modules that alternate in opposition, which single neuron recordings seem to support. However, here we argue that when many neurons are monitored simultaneously a different picture emerges. We recorded hundreds of neurons from the lumbar spinal cord of turtles during rhythmic scratching and found that, rather than alternating, the neuronal population is performing a "rotation", i.e. cycling continuously through all phases (Figure). Rotational dynamics are observed across trials as well as behaviors. Since such rotation is difficult to explain with existing models of alternating neuronal groups, we propose a new theory that accounts for the rotational dynamics. Using a simplified network model, we show that in spinal networks with recurrent excitatory and inhibitory connectivity, there is no need for pacemaker activity or modular structures. Tonic input to the network controls the rhythm and pattern depending on the task. The model reproduces other experimental observations and provides a mechanism for multifunctionality. It also predicts that subsets of neurons, with both inhibitory and excitatory members, have the capacity to either speed up or slow down the movement.

Abstract: During locomotion, cutaneous reflexes assist in rapidly responding to perturbations, such as when the foot contacts an obstacle to prevent a fall. In quadrupeds and humans, cutaneous reflexes are distributed to all four limbs, participating in a whole-body response, and are modulated by phase to generate functionally appropriate responses. To date, most studies have evaluated cutaneous reflexes during treadmill locomotion at a single speed. Here, we investigated cutaneous reflexes during quadrupedal locomotion in eight intact cats by electrically stimulating the superficial radial and peroneal nerves in all four limbs and by recording fore- and hindlimb muscle activity during split-belt locomotion, which simulates some aspect of walking along a circular path. We collected data during tied-belt (equal left-right speeds at 0.4 and 0.8 m/s) and split-belt (different left-right speeds of 0.4-0.8 and 0.8-0.4 m/s) locomotion. Results showed phase-dependent modulation of long interlimb (homolateral and diagonal) responses during tied- and split-belt locomotion. Descending responses from the forelimbs to hindlimbs were more prominent than ascending responses, suggesting that forelimb cutaneous inputs are stronger or more distributed than those from the hindlimbs. We are currently analyzing whether differences in reflex amplitudes occur between locomotor conditions, which would indicate that signals related to left–right symmetry regulate interlimb cutaneous reflexes between the fore- and hindlimbs. Our results provide a better understanding of the spinal pathways involved in interlimb coordination during locomotion, serving as a basis to assess changes following incomplete spinal cord injury. **Keywords:** cutaneous reflexes, interlimb coordination, locomotion, split-belt

ELECTROPHYSIOLOGICAL SIGNATURES REVEAL SPINAL INTRINSIC LEARNING MECHANISMS FOR A LASTING SENSORIMOTOR ADAPTATION.

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Simon Lavaud[1,2], Mattia D'Andola[1,2], Charlotte Bichara[1,2], Aya Takeoka[1,2,3]
[1]VIB, Neuroelectronics Research Flanders, Leuven, Belgium, [2]KU Leuven, Department Of Neuroscience And Leuven Brain Institute, Leuven, Belgium, [3]IMEC, Imec, Leuven, Belgium

Neurocircuits within the spinal cord are essential for movement automaticity. However, spinal mechanisms that underlie lasting sensorimotor adaptations remain unclear. Here, we establish a quantitative kinematic framework to characterize a conditioning behavior in which spinal circuits functionally isolated from the brain learn to adapt motor output upon multimodal sensory integration, undergo extinction, and retain learned behavior with repetitive training. *In-vivo* high-density spinal cord recordings from awake behaving mice reveal phase-tuned single unit activities. Using developmental origin as a criterion, optically identified unit recordings uncover that a class of spinal inhibitory interneurons forming recurrent circuits with somatosensory afferents is recruited during learning. We demonstrate that a selective loss-of-function experiment of this dorsally-located population leads to impaired learning. In contrast, population-specific perturbation of any distinct ventral neurons does not disrupt learning. Together, our study reveals neuronal underpinnings that shape lasting motor adaptation, where reliable somatosensory information regulates bottom-up spinal learning.

COMPUTATIONAL MODELING OF SPINAL LOCOMOTOR CIRCUITS AND NEURAL CONTROL OF LOCOMOTION

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Ilya Rybak, Natalia Shevtsova, Kimberly Dougherty, Simon Danner, Jessica Ausborn
Drexel University, Department Of Neurobiology And Anatomy, Philadelphia, United States of America

Neural circuits in the spinal cord comprising the locomotor central pattern generator (CPG) generate the locomotor rhythm, control flexor–extensor and left–right coordination, and mediate the descending control of locomotion. Yet, the organization of these neural circuits remains poorly understood. Significant progress has been achieved due to the molecular/genetic identification of several types of spinal interneurons involved in the neural control of locomotion. The specific functions of these interneurons have been suggested based on changes in the locomotor pattern observed in mutant mice lacking particular neuron types or following selective silencing, suppression, or activation of these interneurons. We have developed a computational model of the spinal circuitry based on a suggested connectome of genetically identified interneurons. The model includes the rhythm-generating (RG) circuits, controlling alternating flexor and extensor activity, and several commissural and propriospinal pathways mediating interactions between the RG circuits and providing interlimb coordination and gait control during locomotion. The model reproduces and proposes explanations for multiple experimental data obtained in different studies performed in vivo and in vitro. This includes changes in the locomotor frequency, locomotor pattern, left–right and flexor–extensor coordination, and frequency-dependent expression of locomotor gait in the intact condition as well as following selective ablation, silencing, or activation of particular types of genetically identified interneurons. The model generates a series of testable predictions and provides important insight into the organization and operation of the locomotor CPG, spinal locomotor circuits, and the supra-spinal control of locomotion.

Of Physiology, Mibu, Japan, [4]Dalhousie University, Dept. Of Medical Neuroscience, Halifax, Canada, [5]Kyoto University, Dept. Of Aeronautics And Astronautics, Kyoto, Japan

To effectively move in complex and changing environments, animals must control locomotor speed and gait, while precisely coordinating and adapting limb movements to the terrain. The underlying neural control involves dynamic interactions between neuronal circuits at different levels of the nervous system, biomechanical properties of the musculoskeletal system, and afferent feedback signals from the periphery. Here, we present a computational neuromechanical model of mouse hindlimb locomotion to study mechanisms of sensorimotor integration and the role of afferent pathways in the stabilization of locomotion at different speeds and under different environmental conditions. The model consists of a neuronal network model of spinal locomotor circuits, coupled with a musculoskeletal model of the mouse hindlimbs. The spinal network includes rhythm-generating and interlimb-coordinating circuits, pattern formation networks forming motor synergies, motoneurons controlling muscle activation and somatosensory afferent feedback connections to all parts of the circuitry. Optimization was used to find connections weights that allow for stable locomotion on different terrains. The proposed connectome of spinal circuits and the organization of afferent feedback allowed the model to closely reproduce characteristics of mouse locomotion at different speeds and gaits; with increasing speed, the model sequentially exhibited walking, running, and hopping gaits. By systematically manipulating feedback gains, we found that feedback pathways serve different functions depending on speed. We suggest that supraspinal control of locomotor speed, besides tonic drive to the rhythm generators and commissural interneurons, includes task-dependent (slow, exploratory, vs. fast, escape-type locomotion) modulation of the gain of sensory afferent pathways to the spinal locomotor circuitry.

The purpose of this study was to assess the effect of stroboscopic glasses, integrated to a specific motor training, in influencing balance and gait performance in individuals with chronic incomplete spinal cord injury (iSCI). Ten patients with iSCI (AIS D) were enrolled for this study and performed a 6-weeks home-based balance training program, 3 times per week. Individuals were randomly assigned to an experimental group (EG) and placebo control group (PCG; n = 5). EG (n = 5) executed balance training program with active stroboscopic glasses (SVT), while PCG (n = 5) completed the same program of exercise with non-active glasses. At baseline and at the end of the training, gait and balance performances were evaluated using the Timed Up and Go Test (TUG) and the 6 Minutes Walking Test (6MWT). Additionally, 6 normal subjects, as healthy control group, underwent the same assessment once and their data were used as a reference of physiological balance and gait. All performances were recorded with a frontal and a lateral video camera. Videos were analyzed with markerless pose estimation of DeepLabCut (DLC) and a 3D reconstruction of motor performance allowed to investigate spatiotemporal and kinematic features during TUG and 6MWT. Preliminary results suggest that specific balance protocol with SVT modulate balance and gait in chronic iSCI subjects.

A PARADIGM TO BEHAVIOURALLY DECOUPLE THE TOP-DOWN AND FEEDBACK INFLUENCES ON LOCOMOTOR GAIT

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Zane Mitrevica, Andrew Murray
UCL, Sainsbury Wellcome Centre, London, United Kingdom

Locomotion is one of the principal behavioural outputs of the mammalian nervous system, but a lot remains unknown about the neural control principles of its defining features, especially gait. The study of gait at a neural level is complicated by its dependence on factors like leg loading and locomotor speed, as well as by the difficulty to reliably evoke a variety of gaits in genetically amenable species like mice. To overcome these limitations, I propose a head-fixed behavioural paradigm that decouples the speed- and leg loading-related effects on gait using a combination of optogenetic stimulation and body tilt modulation. This paradigm reveals a speed-independent shift in gait preference from left-right alternation to bilateral synchrony at more upward oriented body postures, with this change most prominent in homolateral limb coordination. Upward oriented body tilts, in turn, correlate with an increased relative loading of the hindlimbs and display a consistent relationship with gait during freely moving locomotion. These findings suggest distinct, limb-specific control capacities of the descending and feedback influences on gait, and serve as a principled entry point to a circuit-based study of its implementation.

OBSTACLE NEGOTIATION DURING LOCOMOTION BEFORE AND AFTER INCOMPLETE SPINAL CORD INJURY

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Charly Lecomte, Stephen Mari, Audet Johannie, Angèle Merlet, Jonathan Harnie, Alain Frigon
Universite de Sherbrooke, Departement De Pharmacologie-physiologie, Sherbrooke, Canada

During walking, animals avoid and negotiate obstacles. Despite its importance, few studies have investigated obstacle negotiation after incomplete spinal cord injury (SCI). **Aim:** We investigated kinematic and electromyographic adjustments when negotiating obstacles before and after incomplete SCI in adult cats. **Methods: After** training ten cats to negotiate obstacles of different heights (1-9 cm) on a walkway, we implanted electrodes to chronically record fore- and hindlimb muscle activity (EMG, electromyography). After obtaining data in the intact state, we performed a right lateral spinal hemisection at mid-thoracic segments (T6-T7). Data collection resumed 1 week after hemisection for 8 weeks. **Results:** In the intact state, cats stepped over the different obstacles without contact. After hemisection, the right hindpaw (ipsilesional) made frequent contacts (> 50% two and eight weeks after hemisection), and a reflex allowed the limb to step over the obstacle (stumbling corrective response). For 75% of successful crossings, the left hindlimb was the leading limb. In the intact state, right hindlimb flexors, such as sartorius, semitendinosus and tibialis anterior, modulated their activity with obstacle height. However, this modulation was absent after hemisection. Additionally, sartorius EMG amplitude did not increase in unsuccessful crossings, with a delay in activity. Right hindpaw position was also further away from the obstacle in unsuccessful versus successful crossings. **Conclusion:** Incomplete SCI impairs the ability to negotiate obstacles without contact due to improper activation of flexor muscles. A better understanding of the impairments and adjustments after SCI will help develop targeted strategies to restore this voluntary aspect of locomotion.

NEURAL CONTROL AND BIOMECHANICS OF CAT PAW SHAKE RESPONSE

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Boris Prilutsky[1], Jessica Parker[2], Gennady Cymbalyuk[3], Alexander Klishko[1]
[1]Georgia Institute of Technology, Biological Sciences, Atlanta, United States of America, [2]Georgia State University, Neuroscience Institute, Atlanta, United States of America, [3]Georgia State University, Biological Sciences, Atlanta, United States of America

Intact and spinal cats produce fast paw oscillations to remove an irritating light object stuck to the paw. There are complex inter-joint coordination and atypical muscle synergies during paw shaking, i.e., co-activation between ankle flexor tibialis anterior and knee extensors vasti. To achieve the proximal-to-distal gradient of segmental angular velocities and accelerations during paw shaking, the nervous system needs to precisely regulate activities of multiple muscles and joints. The goal of this study was to investigate a possible neural and biomechanical organization of paw shaking. We first show experimentally in intact cats that during paw shaking, energy generated by proximal muscle moments is transmitted to distal segments by joint forces. This energy transfer is mostly responsible for the segmental velocity/acceleration proximal-to-distal gradient. To investigate neural mechanisms of paw shaking, we developed a neuromechanical model comprised a half-center CPG, activating hip flexors and extensors, and passive viscoelastic distal muscles that produced length/velocity-depended force. This model reproduced major features of paw shaking found in intact cats: the proximal-to-distal velocity/acceleration gradient, energy transfer by joint forces and energy absorption by distal muscle moments. We also found the atypical co-activation of ankle flexors with knee extensors. Computer simulations revealed important role of the segmental inertia distribution along the hindlimb and muscle viscoelastic properties in the organization of paw shaking. The results of this study suggest that the muscle and joint coordination appears to emerge from interactions between the half-center CPG, inertial properties of hindlimb segments, and muscle length and stretch-velocity feedback.

Introduction: Optogenetics is known as an advanced biological tool in neuroscience which is able to control the activity of genetically modified cells by light. The goal of this study is to determine optogenetics stimulation in transdifferentiation of Human Dental Pulp Stem Cells (hDPSCs) into functional motor neuron. **Methods:** The hDPSCs impacted third molar were cultured in DMEM/F12 and were infected with lentiviruses carrying CaMKIIa-hChR2 (H134R). To optical stimulation, 5×10^4 Opsin-expressing hDPSCs per well was conducted with blue light (470 nm) pulsing at 15 Hz, 90% Duty Cycle and 10 mW power for 10 s every 90 minutes, 6 times a day for 5 days. Cell viability was evaluated using MTT assay. The expression of motor neuron markers was evaluated by immunocytochemistry (ICC) and motor neuron function was confirmed with co-culture system. **Results:** The reporter gene, mCherry was expressed on hDPSCs 72 hours after lentiviral infection. The highest cell viability was observed in optical stimulated opsin-expressing hDPSCs. The morphological modifications like multiple long dendritic-like cytoplasmic extensions were just seen in Opsin-expressing hDPSCs. Our ICC data revealed islet-1 (motor neuron precursors marker), oligo2 (motor neuron progenitor marker), HB9 (mature motor neuron marker), MAP2 (marker for mature neuron) were just expressed on opsin-expressing hDPSCs and elongated axon-like of differentiated cells had full contact with myotubes. **Conclusion:** Differentiation of hDPSCs using optical stimulation can form functional motor neurons in in vitro situation and might be a suitable option in treatment neurodegenerative disease.

Matrigel enhances differentiation of human adipose tissue-derived stem cells into dopaminergic neuron.
Therapy based stem cells have offered a novel therapeutic approach for the improvement of neurodegenerative diseases, specially Parkinson. Hence, developing a well-established culture model with appropriate stem cells is extremely crucial in regenerative engineering to provide efficient targeted cells. Human adult mesenchymal stem cells derived from adipose tissue (hADSCs) have emerged as a promising source of stem cells due to their unique potentials of self-renewal and differentiation into other stem cells. The purpose of this study was to investigate the differentiation capacity of hADSCs into dopaminergic and neuron-like cells in the 3D culture plate (Matrigel).

Differentiation of human dental pulp stem cells into functional motor neuron: In vitro and ex vivo study.
There are several therapeutic options for spinal cord injury (SCI), among these strategies stem cell therapy is a potential treatment. The stem cells based therapies have been investigating in acute phase of clinical trials for promoting spinal repair in humans through replacement of functional neuronal and glial cells. The aim of this study was to evaluate the differentiation of Human Dental Pulp Stem Cells (hDPSCs) into functional motor neuron like cells (MNLCs) and promote neuroregeneration by stimulating local neurogenesis in the adult spinal cord slice culture. The immunocytochemistry analysis demonstrated that hDPSCs were positive for mesenchymal stem cell markers (CD73, CD90 and CD105) and negative for the hematopoietic markers (CD34 and CD45). hDPSCs were induced to neurospheres (via implementing B27, EGF, and bFGF) and then neural stem cells (NSC). The NSC differentiated into MNLCs in two steps: first by Shh and RA and ; then with GDNF and BDNF administration. The NS and the NSC were assessed for Oct4, nestin, Nanog, Sox2 expression while the MNLCs were

evaluated by ISLET1, Olig2, and HB9 genes. Our results showed that hDPSC can be differentiated into motor neuron phenotype with expression of the motor neuron genes. The functionality of MNLCs was demonstrated by FM1-43, intracellular calcium ion shift and co- culture with C2C12. We co-cultivated hDPSCs with adult rat spinal slices in vitro. Immunostaining and hoechst assay showed that hDPSCs were able to migrate, proliferate and integrate in both the anterolateral zone and the edges of the spinal slices.

Promoting motor functions in a spinal cord injury model of rats using transplantation of differentiated human olfactory stem cells: A step towards future therapy.
Human olfactory ecto-mesenchymal stem cells (hOE-MSCs) derived from the human olfactory mucosa (OM) can be easily isolated and expanded in cultures while their immense plasticity is maintained. To mitigate ethical concerns, the hOE-MSCs can be also transplanted across allogeneic barriers, making them desirable cells for clinical applications. The main purpose of this study was to evaluate the effects of administering the hOE-MSCs on a spinal cord injury (SCI) model of rats. These cells were accordingly isolated and cultured, and then treated in the neurobasal medium containing serum-free Dulbecco's Modified Essential Medium (DMEM) and Ham's F-12 Medium (DMEM/F12) with 2% B27 for two days. Afterwards, the pre-induced cells were incubated in N2B27 with basic fibroblast growth factor (bFGF), fibroblast growth factor 8b (FGF8b), sonic hedgehog (SHH), and ascorbic acid (vitamin C) for six days. The efficacy of the induced cells was additionally evaluated using immunocytochemistry (ICC) and real-time polymerase chain reaction (RT-PCR). The differentiated cells were similarly transplanted into the SC contusions. Functional recovery was further conducted on a weekly basis for eight consecutive weeks. Moreover, cell integration was assessed via conventional histology and ICC, whose results revealed the expression of choline acetyltransferase (ChAT) marker at the induction stage. According to the RT-PCR findings, the highest expression level of insulin gene-enhancer protein (islet-1), oligodendrocyte transcription factor (Olig2), and homeobox protein HB9 was observed at the induction stage. The number of engraftment cells also rose (approximately by 2.5 % ± 0.1) in the motor neuron-like cells derived from the hOE-MSCs-grafted group compared with the OE-MSCs-grafted one. The functional analysis correspondingly revealed that locomotor and sensory scores considerably improved in the rats in the treatment group. These findings suggested that motor neuron-like cells derived from the hOE-MSCs could be utilized as an alternative cell-based therapeutic strategy for SCI.

Role of cerebrospinal fluid in differentiation of human dental pulp stem cells into neuron-like cells.
Human dental pulp stem cells (hDPSCs) could be differentiated into neuron like-cells under particular microenvironments. It has been reported that a wide range of factors, presented in cerebrospinal fluid (CSF), playing part in neuronal differentiation during embryonic stages, we herein introduce a novel culture media complex to differentiate hDPSCs into neuron-like cells. The hDPSCs were initially isolated and characterized. The CSF was prepared from the Cisterna magna of 19-day-old Wistar rat embryos, embryonic cerebrospinal fluid (E-CSF). The hDPSCs were treated by 5% E-CSF for 2 days, then neurospheres were cultured in DMEM/F12 supplemented with 10 µm retinoic acid (RA), glial-derived neurotrophic factor and brain-derived neurotrophic factor for 6 days. The cells which were cultured in basic culture medium were considered as control group. Morphology of differentiated cells as well as process elongation were examined by an inverted microscope. In addition, the neural differentiation markers (Nestin and MAP2) were studied employing immunocytochemistry. Neuronal-like processes appeared 8 days after treatment. Neural progenitor marker (Nestin) and a mature neural marker (MAP2) were expressed in treated group. Moreover Nissl bodies were found in the cytoplasm of treated group. Taking these together, we have designed a simple protocol for generating neuron-like cells using CSF from the hDPSCs, applicable for cell therapy in several neurodegenerative disorders including Alzheimer's disease.

Neurogenic differentiation of human dental pulp stem cells by optogenetics stimulation.

Human dental pulp stem cells (hDPSCs), a promising source for autologous transplantation in regenerative medicine, have been shown to be able to differentiate into neural precursors. Optogenetics is considered as an advanced biological technique in neuroscience which is able to control the activity of genetically modified stem cells by light. The purpose of this study is to investigate the neurogenic differentiation of hDPSCs following optogenetic stimulation.

PuraMatrix hydrogel enhances the expression of motor neuron progenitor marker and improves adhesion and proliferation of motor neuron-like cells.
Cell therapy has provided clinical applications to the treatment of motor neuron diseases. The current obstacle in stem cell therapy is to direct differentiation of stem cells into neurons in the neurodegenerative disorders. Biomaterial scaffolds can improve cell differentiation and are widely used in translational medicine and tissue engineering. The aim of this study was to compare the efficiency of two-dimensional with a three-dimensional culture system in their ability to generate functional motor neuron-like cells from adipose-derived stem cells.

A FORCED PHYSICAL EXERCISE MAINTENANCE PROGRAM AS A MODEL FOR SELECTIVE MANIPULATION OF THE DOPAMINERGIC SYSTEM IN ADOLESCENT RATS.

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Daniel Garrigos[1], Alberto Barreda[1], Marta Martínez-Morga[1], José Ángel Toval[2], Yevheniy Kutsenko[1], Kuei Tseng[3], José Luis Ferrán[1]
[1]University of Murcia, Human Anatomy And Psychobiology, Murcia, Spain, [2]University of Granada, Physical And Sports Education, Granada, Spain, [3]University of Illinois at Chicago, Department Of Anatomy & Cell Biology, Chicago, United States of America

The motor responses during physical activity are the result of a hierarchically arranged central nervous system circuits. Motor programs planned in the prefrontal cortex are refined in different cortical and subcortical circuits. Finally, the motor output arrives to the spinal cord, the first layer in the hierarchy of muscle control. In previous studies we determined that the physical capacity, measured as the maximal response during an incremental test, is dependent of D1 striatal and D2 extra-striatal actions in Sprague-Dawley rats. Here we want to determine the role of dopaminergic antagonists in physical activity maintenance responses. We first defined a model of physical activity maintenance that consisted in performing three incremental tests 72h apart, with active rest in the two sessions between tests to maintain the performance throughout the tests. In the second test, we administered a D1-like receptors antagonist (SCH23390) in a dose of 0.1 mg/kg intraperitoneally or saline (Sodium Chloride 0.9%). Rats administered with SCH23390 decreased the performance in the second test compared to the first and third ones ($p<0.05$). Rats injected with saline were able to maintain the performance throughout the incremental tests. Rats injected with SCH23390 significantly decreased their performance in the second test but recovered performance in the third test. This suggests that a habituation protocol and active rests between tests allow the maintenance of the performance and that the dopaminergic system is involved in the acute maintenance response. Finally, our model reduces the number of experimental animals required for the experimental design.

Hypothalamic /, Plasmatic Glucose and Lactate Remain Unchanged During Habituation to Forced Exercise.
It has been demonstrated that physical activity contributes to a healthier life. However, there is a knowledge gap regarding the neural mechanisms producing these effects. One of the keystones to deal with this problem is to use training programs with equal loads of physical activity. However, irregular motor and stress responses have been found in murine exercise models. Habituation to forced exercise facilitates a complete response to a training program in all rodents, reaching the same load of physical activity among animals. Here, it was evaluated if glucose and lactate - which are stress biomarkers - are increased during the habituation to exercise. Sprague-Dawley rats received an 8-days habituation protocol with progressive increments of time and speed of running. Then, experimental and control (non-habituated) rats were subjected to an incremental test. Blood samples were obtained to determine plasmatic glucose and lactate levels before, immediately after and 30 min after each session of training. and mRNA expression was determined by two-step qPCR. Our results revealed that glucose and lactate levels are not increased during the habituation period and tend to decrease toward the end of the protocol. Also, and were not chronically activated by the habituation program. Lactate and glucose, determined after the incremental test, were higher in control rats without previous contact with the wheel, compared with habituated and wheel control rats. These results suggest that the implementation of an adaptive phase prior to forced exercise programs might avoid non-specific stress responses.

A Handful of Details to Ensure the Experimental Reproducibility on the FORCED Running Wheel in Rodents: A Systematic Review.
A well-documented method and experimental design are essential to ensure the reproducibility and reliability in animal research. Experimental studies using exercise programs in animal models have experienced an exponential increase in the

last decades. Complete reporting of forced wheel and treadmill exercise protocols would help to ensure the reproducibility of training programs. However, forced exercise programs are characterized by a poorly detailed methodology. Also, current guidelines do not cover the minimum data that must be included in published works to reproduce training programs. For this reason, we have carried out a systematic review to determine the reproducibility of training programs and experimental designs of published research in rodents using a forced wheel system. Having determined that most of the studies were not detailed enough to be reproducible, we have suggested guidelines for animal research using FORCED exercise wheels, which could also be applicable to any form of forced exercise.

Dopaminergic Modulation of Forced Running Performance in Adolescent Rats: Role of Striatal D1 and Extra-striatal D2 Dopamine Receptors.
Improving exercise capacity during adolescence impacts positively on cognitive and motor functions. However, the neural mechanisms contributing to enhance physical performance during this sensitive period remain poorly understood. Such knowledge could help to optimize exercise programs and promote a healthy physical and cognitive development in youth athletes. The central dopamine system is of great interest because of its role in regulating motor behavior through the activation of D1 and D2 receptors. Thus, the aim of the present study is to determine whether D1 or D2 receptor signaling contributes to modulate the exercise capacity during adolescence and if this modulation takes place through the striatum. To test this, we used a rodent model of forced running wheel that we implemented recently to assess the exercise capacity. Briefly, rats were exposed to an 8-day period of habituation in the running wheel before assessing their locomotor performance in response to an incremental exercise test, in which the speed was gradually increased until exhaustion. We found that systemic administration of D1-like (SCH23390) and/or D2-like (raclopride) receptor antagonists prior to the incremental test reduced the duration of forced running in a dose-dependent manner. Similarly, locomotor activity in the open field was decreased by the dopamine antagonists. Interestingly, this was not the case following intrastriatal infusion of an effective dose of SCH23390, which decreased motor performance during the incremental test without disrupting the behavioral response in the open field. Surprisingly, intrastriatal delivery of raclopride failed to impact the duration of forced running. Altogether, these results indicate that the level of locomotor response to incremental loads of forced running in adolescent rats is dopamine dependent and mechanistically linked to the activation of striatal D1 and extra-striatal D2 receptors.

Sex-dependent effects of forced exercise in the body composition of adolescent rats.
Determining the body composition during adolescence can predict diseases such as obesity, diabetes, and metabolic syndromes later in life; and physical activity became an effective way to restore changes in body composition. However, current available literature assessing the body composition before, during and after adolescence in female and male rodents by in vivo techniques is scarce. Thus, by using computerized tomography, we aimed to define the baseline of the weight and body composition during the adolescence and young adulthood of female and male Sprague-Dawley rats (on P30, P60 and P90) under standard diet. Then, we determined the effect of 18 days of forced exercise on the body weight and composition during the early adolescence (P27-45). The highest percentual increments in weight, body volume and relative adipose contents occurred during the female and male adolescence. Forced running during the early adolescence decreased weight, body volume and relative adipose delta and increment values in males only. The adolescence of rats is a period of drastic body composition changes, where exercise interventions have sex-dependent effects. These results support a model that could open new research windows in the field of adolescent obesity.

AGE-RELATED DEGENERATION IN THE MOTOR END PLATES AND AXONS OF MICE LEAVES THE MOTONEURON SOMA UNAFFECTED

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Zoltán Fekécs[1], Krisztián Pajer[1], Bernát Nógrádi[2], Roland Patai[2], Antal Nógrádi[1]
[1]University of Szeged, Albert Szent-Györgyi Medical School, Department Of Anatomy, Histology And Embryology, Szeged, Hungary, [2]Biological Research Centre of the Hungarian Academy of Sciences, Department Of Biophysics, Szeged, Hungary

Growing evidence from animal models and patients suggests that aging affects motor end plates and thus the innervation of skeletal muscles. The cause and the time course of these degenerative processes are unknown, and they may involve less exercise associated with age and spontaneous degeneration of the end plates, or both. Here we show that there are minor degenerative changes in the motor axons and their terminals while sensory axons remain largely unaffected. Axonal degeneration is already detectable in some of the axons in both the ventral roots and peripheral nerves of 6 months old C57BL/6 mice. These changes were accompanied by an increased number of pathological motor end plates (as compared to 3 months old mice) involving various forms of degenerating end plates in the EDL and TA muscles. At later time points (12, 18 and 24 months) progressive changes are present in both the peripheral nerves and muscles. Number of motoneurons decreases slowly but axonal transport processes appear to be severely affected by aging. Tension recording from these muscles shows a slightly decreasing tetanic force produced by aging animals, while the number of motor units decreases more progressively. Calcium histochemistry displays differential changes in the motor end plates and in the motoneurons. These changes suggest that aging affects mainly the distal parts of the motor unit while the perikaryon remains preserved for long time.

THE REPRESENTATION OF PROPRIOCEPTIVE SENSORY AND MOTOR ADAPTIVE INFORMATION IN THE CEREBELLUM

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Irina Scheer, Mario Prsa
University of Fribourg, Faculty Of Science And Medicine, Fribourg, Switzerland

Proprioception is the ability to perceive where one's joints and limbs are located in space. It allows the execution of accurate movements and correction of inaccurate movements. The main target of ascending proprioceptive afferents and a key player in motor control is the cerebellum. The cerebellum has been suggested to use proprioceptive signals to compare the expected to the actual sensory consequences of movement, allowing movements to be adapted and accurately executed. Despite its importance, the neural code for proprioception and how it changes during movement adaptation is poorly understood. To understand how proprioceptive signals are encoded in the cerebellum and how these signals change as movements adapt, awake head-restrained mice were subjected to a novel proprioceptive and a velocity-dependent adaptation task, respectively. In the former, mouse forelimbs were passively displaced with a robotic manipulandum in 8-coplanar directions, with different velocities, amplitudes and starting positions. X-ray assisted video tracking allowed identifying the kinematics of joint angles. In the latter task, mice adapted to a velocity-dependent perturbation while actively pushing the manipulandum. During these tasks, we imaged the climbing fibers (CFs) and Granule cells (GCs), two input streams to the cerebellum, with two-photon microscopy. Our findings, so far, indicate that CFs are tuned to movement velocity, weakly tuned by direction, but not by amplitude, showing no obvious joint angle representation. A further quantification of the neural codes underlying proprioceptive inputs and adaptive motor signals will shed light on the role the two cerebellar input streams play during motor learning.

TRIDIMENSIONAL ANALYSIS OF NEUROMUSCULAR CIRCUIT DEVELOPMENT IN HUMAN EMBRYOS

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Raphael Blain, Gérard Couly, Yorick Gitton, Alain Chédotal
Institut de la Vision, Development, Paris, France

Developmental and congenital diseases are a major public health problem but little is known about the ontogeny and morphogenesis of human organs at a cellular scale. Thus, there is a lack of accurate and comprehensive reference human embryology data based on modern technologies. Our lab has recently developed an imaging method combining immunolabelling of human fetal organs or whole embryos, tissue clearing with solvents and 3D imaging with light-sheet microscopy. This has initiated a project aimed at describing the ontogeny of multiple human organs. Here we used this method to analyze the development of the human neuromuscular system during the first trimester of gestation. We are constructing the first accurate map of muscle development (especially of the head) and muscle innervation by simultaneously labelling diverse cell types, such as muscle cells or their precursors, motor and peripheral nerves and progenitors of chondrogenesis and osteogenesis. Datasets were generated from over 20 human embryos and muscles and nerves were segmented individually. This analysis allowed us to follow the development of the orofacial muscles and their motor innervation, which extends and ramifies as development progresses. Furthermore, it enabled us to identify novel muscles at the early stages of development, likely transient as they no longer exist at birth and have never been described before. These data will make possible to build an atlas describing the ontogeneis of muscles and their innervation during the first trimester of development in humans.

UNRAVELLING THE ROLE OF THE MONOAMINE NEURON SYSTEM IN THE PATHOPHYSIOLOGY OF SMA

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Valeria Valsecchi
University of Naples "Federico II", Neuroscience, Reproductive And Dentistry Sciences, Napoli, Italy

Introduction and Aims: Spinal muscular atrophy(SMA) is a severe neuromuscular disease, affecting infants, caused by deletion or mutations in the survival motor neuron(*SMN*) gene, which mainly results in a progressive degeneration of motor neurons(MN) and muscle atrophy. Recently, three SMN-dependent treatments, with costs and time-window limitations, have been approved. Therefore, novel approaches are urgently needed. Interestingly, analysis of the cerebrospinal fluid(CSF) of SMAI patients revealed that the levels of 5-hydroxyindoleacetic acid(5-HIAA) and homovanillic acid(HVA), the main metabolites of serotonin and catecholamine, respectively, were significantly lower than those in controls, suggesting a role for the monoamine neuron system in the pathophysiology of SMA. Therefore, to identify new potential druggable targets, we investigated possible alterations of catecholamine and serotonin pathways in a SMAD7 mouse model. **Methods**: We investigated by means of RT-PCR, WB and confocal microscopy the expression levels of the enzymes involved in these metabolic pathways and quantified the key metabolites by HPLC, in the brain and in the spinal cord of late symptomatic SMAD7 mice. **Results and Conclusions**: In the brain of late symptomatic SMAD7 mice, mRNA and protein levels of the aromatic L-aminoacid decarboxylase(AADC) and dopamine b-hydroxylase (DbH), the enzymes that convert L-DOPA in dopamine and dopamine in noradrenaline, respectively, were strongly reduced. In particular, AADC showed a reduction in substantia nigra(SN), ventral tegmental area(VTA) and in raphe nuclei(RN). The present study highlights the significant role of these pathways in the pathogenesis of SMA and it might represent an important step to define new pharmacological approach.

EFFECTS OF EARLY MOVEMENT RESTRICTION ON HINDLIMB MUSCLE IRIS LEVELS IN RAT

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Orlane Dupuis[1], Marie Hélène Canu[1], Valérie Montel[1], Julie Dereumetz[1], Jacques Olivier Coq[2], Bruno Bastide[1], Erwan Dupont[1]
[1]University of Lille, Urepsss, Lille, France, [2]University of Aix Marseille, Institut Des Sciences Du Mouvement, Marseille, France

Childhood is a period of construction of the organism, during which interactions with the environment and regular physical activity favor the maturation of the neuronal networks. However, some children exhibit a sensorimotor restriction (SMR) because they are bedridden or they suffer from a neurodevelopmental disorder. In order to better understand the central effects of SMR in these children, we have developed a model of SMR in rats. It consists in casting hindlimbs of the pups from postnatal day (PND) 1 to PND 28. We have previously shown that SMR induces a prominent motor phenotype that includes muscle weakness, locomotor disturbances, spinal hyperreflexia but also reduced somatosensory and motor map areas and disturbance of the excitation/inhibition balance in the sensorimotor cortex. Our objective is to better understand the plasticity processes set up during SMR and our research has focused on irisin. Discovered in 2012, this myokine is secreted by skeletal muscles during physical activity and exerts autocrine, paracrine and also endocrine effects in central nervous system. Irisin is notably known to regulate the expression of brain-derived neurotrophic factor (BDNF), a key regulator of brain plasticity. Thus, we determined irisin level in hindlimb muscles and in plasma. We demonstrated that irisin level varies during development in control rats. In addition, changes are observed in SMR rats according to the age. Whether these changes are involved in cortical changes is in progress.

SYNAPTIC DRIVE CONTRIBUTING TO RHYTHM GENERATION IN MOTOR NEURONS OF THE INSECT LEG-MUSCLE CONTROL SYSTEM

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Angelina Ruthe, Charalampos Mantziaris, Ansgar Büschges
University of Cologne, Institute Of Zoology, Cologne, Germany

Leg stepping is a rhythmic motor behavior based on the interaction between central pattern generators (CPGs) and feedback from leg sensory organs. In the stick insect, individual CPGs provide rhythmic synaptic drive to leg motor neurons, innervating antagonistic muscle pairs, resulting in alternating motor activity. Previous studies revealed that the motor neurons innervating the tibial flexor and extensor muscles receive rhythmic inhibitory synaptic drive from respective premotor CPG networks (Büschges, 1998; Büschges et al. 2004). However, it is not known, whether this is a general mechanism of rhythm generation in motor neurons driving the muscles of all leg joints. Therefore, we studied the synaptic drive from the premotor CPGs to the motor neurons of the other main leg joints, i.e. the Thorax-Coxa and Coxa-Trochanter joints. For this, we recorded intracellularly the activity of motor neurons within the deafferented mesothoracic ganglion during pharmacological activation of the premotor networks that elicits rhythmic activity in motor neurons (Büschges et al. 1995). The synaptic drive to motor neurons was assessed by measuring the input resistance and by stepwise altering the membrane potential during rhythmicity. We show that, similarly to flexor and extensor, rhythmic activity of retractor and protractor motor neurons is generated by phasic inhibitory synaptic inputs. Interestingly and unexpectedly, the synaptic drive contributing to rhythm generation in depressor and levator motor neurons appears to differ. This study was funded by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation) - **233886668/ GRK1960**

NEURAL CIRCUIT MECHANISMS UNDERLYING SENSORIMOTOR DECISIONS

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Maxime Lehman[1,2], Sandra Autran[2], Tihana Jovanic[2]
[1]Paris Saclay University, Doctoral Sch. N°568, Le Kremlin Bicêtre, France, [2]Institut des Neurosciences Paris-Saclay, Cognitive And Neural Network, Saclay, France

From finding nearby food to escaping a predator, animals must respond to sensory cues with appropriate motor actions in order to survive. The neural circuit mechanisms underlying the transformation of sensory information into appropriate motor output remain incompletely understood. To understand these mechanisms better, it would be important to map the entire neural circuitry from the sensory to the motor side in a model organism allowing functional testing of such circuits. Thanks to recent progress in connectomics, allowing the mapping of entire neural circuits in electron microscopy (EM) with synaptic resolution and to the genetic toolbox for cell-specific neuronal manipulations and monitoring, Drosophila larva presents itself as such a model. We will here present our progress on the investigation of the neural circuitry underlying larval responses to an aversive mechanosensory stimulus, the air puff. Drosophila larvae typically respond with either startle or escape behaviours to the air-puff. The selection of one action implies the inhibition of other, mutually exclusive, actions. Using inactivation and optogenetic activation of single neurons in behaving larvae combined with video tracking and automated behavioral detection, we determined the role of interneurons at different sensorimotor stages and found they are differentially involved in startle and escape behaviors. We are now mapping the startle and escape sensorimotor pathways and investigating where and how they could interact. Determining the neural circuit mechanisms underlying competitive interactions in a system where we can trace all connections and manipulate single neurons may bring insights into the neural circuit mechanisms of sensorimotor decisions.

Aims: Radiotherapy (RT), a major treatment for brain tumors, can also affect the healthy brain tissue and reduces the quality of life of patients whose feel extreme fatigue during weeks after the brain RT. The etiology of this fatigue remains poorly described. The intimately relationship between brain and muscles could explain the abscopal effects, defined as non-target effects in non-irradiated cells, distant from an irradiated target. The present study aims to assess the impact of brain RT on skeletal muscles and its relationship to fatigue. **Methods:** Adult rats were randomly distributed into control or irradiated groups. Irradiated rats were exposed to a 30 Gy whole-brain irradiation (WBI, 3x10 Gy) with a dedicated irradiator to small animals (X-RAD 225Cx). Complementary approaches: behavioral tests, muscle mass, MRI and histological analyses were employed to examine the effects of cranial irradiation on the skeletal muscles up to 6 months following WBI. **Results:** Irradiated rats displayed fatigue and reduced locomotor activity at short and long terms. The analyzed muscular mass decreased in rats submitted to WBI. Multiparametric MRI imaging of muscles highlighted a dramatic alteration of the fiber organization in irradiated rats as demonstrated by a significant diminution of the mean diffusivity. Moreover, irradiation-induced alteration of fibers was confirmed by histological analyses. These muscular alterations could be attributed to an increased circulating reactive species or pro-inflammatory cytokines. **Conclusions:** This study emphasizes that it is essential to consider skeletal muscle damage resulting from whole-brain irradiation to improve the management of radiotherapy-induced side effects, especially fatigue.

EFFECTS AND INCREMENTAL TEST RESPONSES BY SHORTENING OF HABITUATION PROTOCOLS DURING ADOLESCENCE OF RATS

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Marta Martínez-Morga, José Ángel Toval, Yevheniy Kutsenko, Daniel Garrigos, Alberto Barreda, Bruno Ribeiro Do Couto, José Luis Ferrán, Antonia Alonso
University of Murcia, Human Anatomy And Psychobiology, Murcia, Spain

The brain causal mechanisms working on peripheral tissues during a physical activity are poorly understood. In previous studies we developed a model to analyze motor responses based on a habituation program consisting of a progressive increase of the training load. Determine if shortening the habituation program modify responses in exercise capacity, and if this can be related with muscle peripheral adaptations. Sessions of the habituation were developed throughout 2, 4 and 8 days of training. Once the habituation phases were completed, rats were subjected to an incremental exercise test to determine the physical capacity. Samples of gastrocnemius and soleus were used for qPCR and Western blot analysis of markers involved in muscle adaptation. The total time of running during the incremental test was of 37.78 ± 2.65 min for 8 days habituated rats but 15.84 ± 1.22 min for non-habituated rats. In the case of 4 days habituated rats was 36.02 ± 2.67 min with 17.35 ± 2.86 for the control. Finally, the total time of running was of 28.95 ± 3.94 min for 2 days habituated rats, but 19.97 ± 2.57 min for the control. We didn´t observed any differences in selected muscle markers in terms of mRNA molecules or protein concentrations justifying peripheral adaptations. Shortening of habituation period to 2 days habituation period produce a decreased response during the incremental test compared with 4 and 8 day habituated rats. The differences in running can't be justified in terms of muscle peripheral adaptations, strengthening a central nervous system effect.

Frog metamorphosis captures simple swimming and complex, tetrapod limb movement in one organism. Tadpoles first engage in periodic undulatory swimming (NF 37-38); then switch to constant free-swimming (NF 47-50); and finally, to four-limbed movements such as walking, hopping, and scratching (NF 57-adult). We aim to capitalize on this unique metamorphic behavioral switch to determine how spinal neuron diversity differs for swimming and walking. We focus our analysis on motor neurons (MNs) and V1 interneurons (V1s), a class of spinal inhibitory interneurons that modulate motor neuron firing. We find MN and V1 number and transcriptional heterogeneity scale up with the complexity of behavior. The larval tadpole spinal cord contains a largely uniform population of medial motor column MNs and associated V1s. With the emergence of free swimming, MNs and V1s double in number and begin to diversify in their transcriptional profile, acquiring MN populations equivalent to the mouse hypaxial and preganglionic motor columns and V1 subpopulations equivalent to clades. Finally, at metamorphosis, limb motor column neurons are added and V1 number and diversity increase dramatically, with the same transcriptional V1 clade and subclade diversity observed in froglets as in the developing mouse. Our work maps MN and V1 molecular properties onto swim and limb behavior during frog metamorphosis, defining how transcriptional diversity scales up with behavioral complexity. We additionally demonstrate the conservation of MN and V1 molecular organization between the frog, the most ancient tetrapod, and the mouse, a four-limbed mammal.

Domestic pig is considered to be a good model for testing neurotherapeutics. A study of the kinematic of the walking cycle was performed in pigs after a cervical SCI (right hemisection with excision of 1 cm of spinal cord). Pigs were filmed while walking on a treadmill at 1, 3 and 5 km/h. We measured knee, ankle, elbow and wrist angles, variation of eye and hip height, relative aft-to-forward movement of the distant part of the legs and step cycle parameters. In uninjured animals, the maximum flexion of every joint during the swing phase increased with speed. Hip and eye height displayed two peaks per stride, coincident with the action of diagonal pairs: right foreleg (RF)/left hindleg (LH) and left foreleg (LF)/right hindleg (RH). After SCI, pigs required 62.3% of body weight support (provided by a harness connected by strain gauges) during the stance of the RF/LH pair. Stride and stance durations for all the limbs (excluding the RF) increased progressively. Ankle and knee extension increased at the end of the stance phase, indicating that the RH was functional and overused. However, the RF was retracted, with negative wrist-shoulder position along the stride. Elbow extension was markedly reduced, and wrist flexion was almost lost. In addition, negative eye height values indicated a tendency of the forepart of the body to fall during the stance of the RF/LH pair. Then, motor impairments and compensations following cervical SCI can be readily characterized by kinematic techniques and force measurements during treadmill locomotion.

Neuropathological and Motor Impairments after Incomplete Cervical Spinal Cord Injury in Pigs.
Humans, primates, and rodents with cervical spinal cord injury (SCI) show permanent sensorimotor dysfunction of the upper/forelimb as consequence of axonal damage and local neuronal death. This work aimed at characterizing a model of cervical SCI in domestic pigs in which hemisection with excision of 1 cm of spinal cord was performed to reproduce the loss of neural tissue observed in human neuropathology. Posture and motor control were assessed over 3 months by scales and kinematics of treadmill locomotion. Histological measurements included lesion length, atrophy of the adjacent spinal cord segments, and neuronal death. In some animals, the retrograde neural tracer aminostilbamidine was injected in segments caudal to the lesion to visualize propriospinal projection neurons. Neuronal loss extended for 4-6 mm from the lesion borders and was more severe in the ipsilateral, caudal spinal cord stump. Axonal Wallerian degeneration was observed caudally and rostrally, associated with marked atrophy of the white matter in the spinal cord segments adjacent to the lesion. The pigs showed chronic monoplegia or severe monoparesis of the foreleg ipsilateral to the lesion, whereas the trunk and the other legs had postural and motor impairments that substantially improved during the first month post-lesion. Adaptations of the walking cycle such as those reported for rats and humans ameliorated the negative impact of focal neurological deficits on locomotor performance. These results provide a baseline of behavior and histology in a porcine model of cervical spinal cord hemisection that can be used for translational research in SCI therapeutics.

Expression of the cold thermoreceptor TRPM8 in rodent brain thermoregulatory circuits.
The cold- and menthol-activated ion channel transient receptor potential channel subfamily M member 8 (TRPM8) is the principal detector of environmental cold in mammalian sensory nerve endings. Although it is mainly expressed in a subpopulation of peripheral sensory neurons, it has also been identified in non-neuronal tissues. Here, we show, by in situ hybridization (ISH) and by the analysis of transgenic reporter expression in two different reporter mouse strains, that TRPM8 is also expressed in the central nervous system. Although it is present at much lower levels than in peripheral sensory

neurons, we found cells expressing TRPM8 in restricted areas of the brain, especially in the hypothalamus, septum, thalamic reticular nucleus, certain cortices and other limbic structures, as well as in some specific nuclei in the brainstem. Interestingly, positive fibers were also found traveling through the major limbic tracts, suggesting a role of TRPM8-expressing central neurons in multiple aspects of thermal regulation, including autonomic and behavioral thermoregulation. Additional ISH experiments in rat brain demonstrated a conserved pattern of expression of this ion channel between rodent species. We confirmed the functional activity of this channel in the mouse brain using electrophysiological patch-clamp recordings of septal neurons. These results open a new window in TRPM8 physiology, guiding further efforts to understand potential roles of this molecular sensor within the brain.

Enhanced spinal cord microstimulation using conducting polymer-coated carbon microfibers.
Intraspinal microstimulation (ISMS) may help to restore motor functions after spinal cord injury. ISMS caudal to the lesion activates motoneurons and evokes selective movements with graded force in rats and other mammals. We investigated the safety and effectiveness of conducting polymer (CP)-coated carbon microfibers (CMFs) for ISMS. 7-µm-diameter CMFs coated with poly(3,4-ethylenedioxythiophene) doped with poly[(4-styrenesulfonic acid)-co-(maleic acid)] (PEDOT:PSS-co-MA) were used to apply current-controlled biphasic electric pulses at the cervical spinal cord (C7) of anesthetized rats. Electrode performance and motoneuron activation, as readout by voltage transients, cyclic voltammetry, electrochemical impedance spectroscopy, electromyography (EMG) and foreleg kinematics, were investigated as a function of microfiber length (50 µm vs. 250 µm) and presence of polymer coating. The microfibers were very effective in activating specific spinal motoneurons, with the lowest stimulus thresholds varying between -28 µA and -46 µA in the cathodic phase. EMG and kinematic thresholds decreased when the microfiber tip approached the targeted motor nucleus (triceps brachii, t.b.) from the dorsal spinal cord surface. ISMS with polymer-coated CMFs produced higher electrical activity in the t.b. fascicles compared to bare CMFs. PEDOT:PSS-co-MA coating of 250-µm CMFs avoided the generation of unsafe overvoltages for biphasic pulses up to -80/+40 µA in vivo, although the positive effect of the conducting polymer was lost after the application of a few thousands of electric pulses. Thus, CP-coated CMFs may provide an effective and minimally invasive electrode for ISMS; however, polymer optimization is still required to improve its electrical stability and safety for long-term use. Statement of significance Intraspinal microstimulation may restore motor functions after spinal cord injury. In the present study we demonstrate that carbon microfibers (CMFs) coated with the conducting polymer PEDOT:PSS-co-MA can be advantageously used for this purpose. These microfibers allow for both effective and temporarily safe electrical activation of spinal motor circuits with high spatial resolution. The presence of the polymer enhances the effectiveness of the electrical stimuli to recruit spinal motoneurons. Thus, conducting polymer-coated CMFs have potential for the development of advanced neuroprosthetic devices, although further improvements are needed regarding their electrochemical and mechanical stability.

Endocytosis of synaptic ADAM10 in neuronal plasticity and Alzheimer's disease.
A disintegrin and metalloproteinase 10 (ADAM10), a disintegrin and metalloproteinase that resides in the postsynaptic densities (PSDs) of excitatory synapses, has previously been shown to limit β-amyloid peptide (Aβ) formation in Alzheimer's disease (AD). ADAM10 also plays a critical role in regulating functional membrane proteins at the synapse. Using human hippocampal homogenates, we found that ADAM10 removal from the plasma membrane was mediated by clathrin-dependent endocytosis. Additionally, we identified the clathrin adaptor AP2 as an interacting partner of a previously uncharacterized atypical binding motif in the ADAM10 C-terminal domain. This domain was required for ADAM10 endocytosis and modulation of its plasma membrane levels. We found that the ADAM10/AP2 association was increased in the hippocampi of AD patients compared with healthy controls. Long-term potentiation (LTP) in hippocampal neuronal cultures induced ADAM10 endocytosis through AP2 association and decreased surface ADAM10 levels and activity. Conversely, long-term depression (LTD) promoted ADAM10 synaptic membrane insertion and stimulated its activity. ADAM10 interaction with the synapse-associated protein-97 (SAP97) was necessary for LTD-induced ADAM10 trafficking and required for LTD

maintenance and LTD-induced changes in spine morphogenesis. These data identify and characterize a mechanism controlling ADAM10 localization and activity at excitatory synapses that is relevant to AD pathogenesis.

The influence of cold temperature on cellular excitability of hippocampal networks.
The hippocampus plays an important role in short term memory, learning and spatial navigation. A characteristic feature of the hippocampal region is its expression of different electrical population rhythms and activities during different brain states. Physiological fluctuations in brain temperature affect the activity patterns in hippocampus, but the underlying cellular mechanisms are poorly understood. In this work, we investigated the thermal modulation of hippocampal activity at the cellular network level. Primary cell cultures of mouse E17 hippocampus displayed robust network activation upon light cooling of the extracellular solution from baseline physiological temperatures. The activity generated was dependent on action potential firing and excitatory glutamatergic synaptic transmission. Involvement of thermosensitive channels from the transient receptor potential (TRP) family in network activation by temperature changes was ruled out, whereas pharmacological and immunochemical experiments strongly pointed towards the involvement of temperature-sensitive two-pore-domain potassium channels (K(2P)), TREK/TRAAK family. In hippocampal slices we could show an increase in evoked and spontaneous synaptic activity produced by mild cooling in the physiological range that was prevented by chloroform, a K(2P) channel opener. We propose that cold-induced closure of background TREK/TRAAK family channels increases the excitability of some hippocampal neurons, acting as a temperature-sensitive gate of network activation. Our findings in the hippocampus open the possibility that small temperature variations in the brain in vivo, associated with metabolism or blood flow oscillations, act as a switch mechanism of neuronal activity and determination of firing patterns through regulation of thermosensitive background potassium channel activity.

ERK activation in axonal varicosities modulates presynaptic plasticity in the CA3 region of the hippocampus through synapsin I.
Activity-dependent changes in the strength of synaptic connections in the hippocampus are central for cognitive processes such as learning and memory storage. In this study, we reveal an activity-dependent presynaptic mechanism that is related to the modulation of synaptic plasticity. In acute mouse hippocampal slices, high-frequency stimulation (HFS) of the mossy fiber (MF)-CA3 pathway induced a strong and transient activation of extracellular-regulated kinase (ERK) in MF giant presynaptic terminals. Remarkably, pharmacological blockade of ERK disclosed a negative role of this kinase in the regulation of a presynaptic form of plasticity at MF-CA3 contacts. This ERK-mediated inhibition of post-tetanic enhancement (PTE) of MF-CA3 synapses was both frequency- and pathway-specific and was observed only with HFS at 50 Hz. Importantly, blockade of ERK was virtually ineffective on PTE of MF-CA3 synapses in mice lacking synapsin I, 1 of the major presynaptic ERK substrates, and triple knockout mice lacking all synapsin isoforms displayed PTE kinetics resembling that of wild-type mice under ERK inhibition. These findings reveal a form of short-term synaptic plasticity that depends on ERK and is finely tuned by the firing frequency of presynaptic neurons. Our results also demonstrate that presynaptic activation of the ERK signaling pathway plays part in the activity-dependent modulation of synaptic vesicle mobilization and transmitter release.

Age-dependent alterations of long-term synaptic plasticity in thyroid-deficient rats.
Thyroid hormone deficiency during a critical period of development profoundly affects cognitive functions such as attention, learning, and memory, but the synaptic alterations underlying these deficits remain unexplored. The present study examines the effect of congenital hypothyroidism on long-term synaptic plasticity. This plasticity is believed to be essential for learning and memory and for activity-dependent regulation of synapse formation in the developing brain. We found that the neonatal expression of long-term potentiation (LTP), long-term depression (LTD), depotentiation, and de-depression in hippocampal slices from hypothyroid animals was similar to that of controls. To examine the postnatal development of these plasticities, we used slices from neonatal (2-3 weeks) and adult (7-8 weeks) rats. This work demonstrates that the ability to express all these forms of synaptic plasticity is reduced in an age-dependent manner in control rats. LTP and depotentiation are also downregulated in adult hypothyroid rats, but we have found that de-depression is not affected during maturation. In addition, these animals express LTD at ages at which controls fail to induce it. In contrast, input/output experiments have shown greater levels of basal synaptic efficacy in hypothyroid adults, and this effect is probably related to the higher probability of release observed by paired-pulse experiments. Nevertheless, these effects appear to be unrelated to the differences observed in long-term synaptic plasticity, as no correlation was found between basal synaptic efficacy and the degree of LTD and de-depression. Furthermore, the NMDA-receptor antagonist amino-phosphonopentanoic acid (APV) completely blocked LTD, which suggests a postsynaptic locus of this alteration. Because LTD has been associated with novelty acquisition, we

suggest that the greater LTD observed in adult hypothyroid rats might be related to the hyperactivity of these animals. However, other possibilities such as a retarded maturation of synaptic plasticity must be taken into account.

Thyroid hormone regulates neurotransmitter release in neonatal rat hippocampus.
Thyroid hormone is essential for the normal maturation and function of the mammalian CNS. Thyroid hormone deficiency during a critical period of development profoundly affects cognitive functions such as learning and memory. However, the possible electrophysiological alterations that could underlie these learning deficits in hypothyroid animals remain largely unexplored. In this work, we have studied the possible effect of thyroid hormone on short-term synaptic plasticity, which is hypothesized to be a neural substrate of short-term memory. We compared short-term modification of the excitatory postsynaptic potential in hippocampal slices between control and hypothyroid rats. Electrophysiological studies reveal that paired-pulse facilitation is strongly altered in the hypothyroid rats. In addition, hypothyroid rats exhibit an increase in the Ca(2+)-dependent neurotransmitter release. These alterations are basically reversible when thyroid hormone is administered. In order to examine the possible molecular mechanisms underlying these synaptic changes, we compared the expression of synapsin I, synaptotagmin I, syntaxin, and alpha-Ca(2+)/calmodulin kinase II between control and hypothyroid hippocampus. Our results show that the levels of synapsin I and synaptotagmin I are increased in the hypothyroid rats, which suggests that the genes encoding these proteins are implicated in the action of thyroid hormone on neurotransmitter release. Taken together, the results from this study suggest that thyroid hormone may modulate the probability of neurotransmitter release.

Blocking ADAM10 synaptic trafficking generates a model of sporadic Alzheimer's disease.
We describe here an innovative, non-transgenic animal model of Alzheimer's disease. This model mimics early stages of sporadic disease, which represents the vast majority of cases. The model was obtained by interfering with the complex between a disintegrin and metalloproteinase domain containing protein 10 (ADAM10), the main α-secretase candidate, and its partner, synapse-associated protein 97, a protein of the postsynaptic density-membrane associated guanylate kinase family. Association of ADAM10 with synapse-associated protein 97 governs enzyme trafficking and activity at synapses. Interfering with the ADAM10/synapse-associated protein 97 complex for 2 weeks by means of a cell-permeable peptide strategy is sufficient to shift the metabolism of the amyloid precursor protein towards amyloidogenesis and allows the reproduction of initial phases of sporadic Alzheimer's disease. After 2 weeks of treatment, we detected progressive Alzheimer's disease-like neuropathology, with an increase of β-amyloid aggregate production and of tau hyperphosphorylation, and a selective alteration of N-methyl-d-aspartic acid receptor subunit composition in the postsynaptic compartment of mouse brain. Behavioural and electrophysiological deficits were also induced by peptide treatment.

Complex motor behaviors involve the precise coordination of different body parts. While motor coordination has been extensively studied in expert animals, the behavioral and neural processes involved in its emergence through learning are not well understood. Here, we combined longitudinal behavioral analyses with population recordings from the cerebellum, which is a key region for movement coordination and motor learning. We trained mice to walk on a motorized runged treadmill over multiple days while Ca2+-activity was recorded from cerebellar molecular layer interneurons (MLIs). Motorization and rungs obliged mice to walk slower and with different stride lengths than in their natural gait. High-speed behavioral video recordings allowed us to extract paw trajectories and to assess how mice learned to control stepping patterns in this novel task that required coordination between limbs, and coordination of single limbs with the runged treadmill. Over learning, mice acquired a stable gait pattern (lateral sequence walk). We found that across animals, fixed pairwise swing-stance phase differences between limbs emerge over days. Using a neural population decoder, we show that cerebellar MLIs encode pairwise phase differences of limbs. We finally asked whether fixed pairwise phase relationships emerge through stronger interlimb coupling or rather by an increase in regularity of single-paw stepping patterns. To address these possibilities, we fit paw dynamics to a coupled oscillator model in which intrinsic frequencies change stochastically according to a Hidden Markov Model (HMM). We find that over learning, mice adjust single-limb stepping frequencies so that fixed-point dynamics in interlimb coordination become possible.

SENSORY ASSOCIATION AND MISMATCH IN THE POSTERIOR PARIETAL CORTEX

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Constanze Raltschev, Sergej Kasavica, Shankar Sachidhanandam
University of Bern, Department Of Physiology, Bern, Switzerland

The posterior parietal cortex (PPC) is a multimodal association area involved in higher cognitive functions such as perceptual decision-making, visual attention, navigation and movement planning. Recently, it has been shown that PPC can report mismatches in sensory sequences, such as the omission of an expected stimulus. Using two-photon calcium imaging coupled with a chronic cranial window in awake head-fixed mice, we show that PPC can report auditory and whisker (tactile) stimuli. Furthermore, PPC can make rapid associations between these stimulus sequences and reliably report mismatches, e.g. in the form of stimulus omissions, unexpected stimuli, and varying stimulus intensities. Our findings reaffirm the role of PPC in comparing the internal model of the external world based on incoming sensory information, as proposed within the framework of predictive processing.

TOP-DOWN AND BOTTOM-UP INTERACTIONS AT THE POSTERIOR PARIETAL CORTEX

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Sergej Kasavica, Constanze Raltschev, Shankar Sachidhanandam
University of Bern, Department Of Physiology, Bern, Switzerland

Sensory perception can be represented as the comparison between feedforward bottom-up sensory inputs and feedback top-down expectations of these sensory stimuli. It was recently shown that a subset of posterior parietal cortex (PPC) neurons can report mismatches in audio tactile sensory sequences. We hypothesize that these mismatch neurons report the balance between the bottom-up (sensory input from S1 and A1) and top-down inputs (feedback from premotor M2). To test our hypothesis, we performed simultaneous dual layer two-photon calcium imaging of M2 axons in layer 1 and of layer 2/3 neurons in the PPC. We show that top-down expectancy of the predicted stimuli is reliably reported by M2 axons, while layer 2/3 PPC neurons report auditory and tactile stimuli, as well as mismatches in the sensory sequence. We demonstrate that the PPC can rapidly learn new associations and subsequently report mismatches, while M2 axons update their expectations to the new association. Our results suggest that M2 potentially provides the top-down prediction, which is then compared to the incoming sensory input at PPC. This leads to the subsequent generation of mismatch responses when top-down and bottom up inputs do not match.

AIMS**:** Parabolic-flight studies have shown that the temporal coordination between grip force (GF) and load force (LF) is preserved during object manipulation in extreme gravito-inertial environments such as partial, hyper- or micro- gravity. It was nevertheless observed that participants tended to increase the GF safety margin in microgravity. However, the characteristics of the GF-LF coupling during long-term exposure to microgravity have never been studied. The present experiment aims to fill this gap by studying sensorimotor coordination during object manipulation in astronauts onboard the International Space Station (ISS). METHODS: 10 astronauts performed rhythmic arm movements with an object held in precision grip, both on Earth and during >5-months missions on the ISS. Three different object masses were used, as well as three different oscillation frequencies. RESULTS: A steady GF-LF correlation was rapidly acquired, both on the ground and during spaceflight. Strikingly, the GF/LF ratio at the times of maximum LF was independent of object mass, movement frequency or gravity level. This was achieved by offsetting GF as a function of LF range. Interestingly though, in microgravity the amplitude of GF peaks were dependent on LF direction, despite symmetrical LF peaks. CONCLUSIONS: Our results suggest that tactile and proprioceptive feedback are integrated quickly to update the anticipatory control of grip force and achieve an adequate safety margin in all circumstances. Interestingly, even after several months of exposure to microgravity, up/down asymmetries persisted in the modulation of grip force. Future works should be carried out to pinpoint the cause of this asymmetry.

COMPARISON OF LATERAL DYNAMIC STABILITY BETWEEN WALKING CATS AND WILD-TYPE MICE

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Turgay Akay[1], Alexander Klishko[2], Hangue Park[3], Boris Prilutsky[2]
[1]Dalhousie University, Dept. Of Medical Neuroscience, Halifax, Canada, [2]Georgia Institute of Technology, Biological Sciences, Atlanta, United States of America, [3]Texas A&M University, Department Of Electrical & Computer Engineering, College Station, United States of America

Among all daily activities, walking accounts for highest proportion of falls in elderly (24%), and falls occur more often in the lateral direction (Robinovitch et al. 2013). The compromised proprioceptive and tactile sensation due to aging or illness contributes to falls (Earhart 2013), although precise mechanisms are not well understood. Genetically-modified mice provided insight into the role of somatosensory feedback in locomotor control (Akay et al., 2014). However, mouse's crouched gait may improve stability and thus reduce comparability of this model with humans. On the other hand, there are remarkable similarities in lateral dynamic stability between walking cats and humans (Burke et al. 2019; Latash et al. 2020). Here we compared lateral dynamic stability between cats and wild-type mice during treadmill walking with a normalized speed (Froud number) of 0.05; 0.4 m/s and 0.1 m/s, respectively. We captured center-of-mass and center-of-pressure on the horizontal plane of wild-type mice walking on a treadmill with transparent belt, and mirror. Cat's kinematics was also computed from full-body motion capture. We determined lateral dynamic stability as the distance between the extrapolated center-of-mass and center-of-pressure positions at onset of ipsilateral double support (Latash et al. 2020) and then scale this distance to the hindlimb step width. The scaled lateral dynamic stability was greater in mice than in cats ($p < 0.05$; 0.508±0.066 vs. 0.158±0.044, respectively). For maximal impact of research with animal models on clinical research, future studies should consider advantages and limitations of these two animal models to study neural mechanisms of locomotor stability.

DESCENDING NEURON POPULATION ACTIVITY DRIVING LIMB-DEPENDENT BEHAVIORS

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Florian Aymanns, Pavan Ramdya, Chin-Lin Chen, Jasper Phelps
EPFL, Brain Mind Institute, Lausanne, Switzerland

The brain regulates animal behavior via a population of descending neurons (DNs) projecting to downstream motor circuits in the spinal cord or invertebrate ventral nerve cord (VNC). How DNs as a population efficiently encode the brain's motor intentions remains largely unknown. In *Drosophila melanogaster* the activity of pairs or small sets of `command-like' DNs are sufficient to drive walking, grooming, and escape behaviors. Thus, even a small fraction of ~1300 DNs can elicit complex motor actions. This raises the question of what role the large populations of DNs may play in behaviors. For example, they may modulate core behavioral commands. Alternatively, they may represent parallel pathways eliciting behaviors as a function of sensory context. Here, we address these possibilities using a genetic and optical intersectional approach to record the activity of nearly 100 DNs in the fly during odor-evoked and spontaneous behaviors. We observe that a majority of DNs encode locomotion. Some DNs drive turning and an overlapping set encode walking speed. A small fraction of DNs do not correlate with behavior but appear to encode specific odors. DNs identified from population imaging to encode antennal grooming can be targeted, via their location, functional, and morphological properties, to DNx01 neurons. This highlights the potential for DN population recordings to provide a context for the neural dynamics of genetically-identifiable neurons. These findings reveal that DN populations represent behavior in a largely distributed manner and set the stage for a comprehensive, population-level understanding of how the brain regulates complex limb-dependent motor behaviors

HEMIFACIAL SPASM IN A 66-YEAR-OLD FILIPINO MALE CAUSED BY VERTEBROBASILAR ARTERY DOLICHOECTASIA: A CASE REPORT

POSTER SESSION 04 - SECTION: CLUSTER 90: MOVEMENT: SPINAL CORD AND MOTOR NEURONS

Mary Kemberly Trinidad
Perpetual Succour Hospital, Department Of Internal Medicine, Cebu City, Philippines

Background: Hemifacial spasm (HFS), characterized by unilateral, intermittent contractions of the muscles of facial expression occurs due to vascular compression of the facial nerve at the root exit zone. Its total prevalence is in range of 9.8 to 11 per 100,000 in the total population with very limited knowledge on its prevalence in Asia, most specifically in the Philippines. Direct compression of the facial nerve by Vertebrobasilar dolichoectasia (VBD) is an even rarer cause of HFS, representing 0.7% of cases. **Objective:** This paper presents a case of HFS caused by VBD with multiple cranial nerve compression in a 66-year-old Filipino male presenting with involuntary twitching of the left side of the face. **Case:** A case of a 66-year-old Filipino male who presented with a six-year history of progressive involuntary twitching of the left side of the face, started on Botulinum Toxin periorbital injection treatment. Initial MRI was unremarkable. During subsequent clinic visits, more prominent and sustained contractions of the left side of the face were noted despite more frequent injections with lesser interval. Repeat MRI revealed a tortuous and ectatic vertebrobasilar artery, compressing and dorsally displacing the left Cranial Nerves V, VII and VIII. **Conclusion:** VBD can rarely compress the facial nerve leading to HFS. Although the diagnosis is led by clinical features, MRI is a useful imaging technique for demonstrating the nerve compression. Widely accepted treatment modalities include Botulinum Toxin (BTX) Injections as less invasive procedure, providing symptomatic relief and Microvascular Decompression (MVD) as the more definite treatment.

Due to the columnar organization of sensory cortical regions the tactile information of individual whiskers, or sensation of low and high frequency sounds separates well in corresponding area, however considerable variance of the fine detailed maps among individual animals was found previously. The aim of the given project is to provide a method for fast mapping of topological organization of thalamocortical circuit. Experiments were carried out on C57BL/6 wild type adult mice, under urethane anesthesia. Electrophysiological recordings were made by silicon probes from somatosensory and auditory cortices, while for flavoprotein imaging (FI) continuous 480nm light illumination was applied for image acquisition. Air puff induced single whisker deflection or 12-25 kHz sinusoid sound waveforms were used for stimulation. Both tactile and auditory stimulation resulted in a topological organization of activation. Silicon probe recordings of high optical activity areas showed immediate and robust response in multi-unit activity, while after clustering, in a small number of neurons elevated firing rate was also found. The injection of retrograde choleratoxin subunit B into optically active barrels proved that the sensory information was originated from ventral posteromedial nucleus of thalamus, and multi- or single unit activity of this thalamic region also showed direct lemniscal input. The FI as method for mapping cortical activity over a large region of brain surface proved to be useful to identify the primary sensory field of applied stimuli. Activation pattern maps provided by FI showed topological organization in both sensory cortices which result was proved by anatomical and electrophysiological experiments.

ALTERED BODY SCHEMA AFTER VIRTUAL TOOL-USE TRAINING IS ASSOCIATED WITH THE EMERGENCE OF SENSE OF BODY OWNERSHIP AND SENSE OF AGENCY IN HEALTHY AGING

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Amir Jahanian Najafabadi[1], Dennis Küster[2], Felix Putze[2], Ben Godde[1]
[1]Jacobs University Bremen, Psychology & Methods, Bremen, Germany, [2]Universität Bremen, Cognitive System Lab, Bremen, Germany

Aims: We investigated whether training with a virtual tool in augmented reality (AR) has comparable effects on body schema (BS) and sense of ownership and agency in young and older adults, while leveraging AR to partially decouple contributions by visual and vibro-tactile feedback modalities. **Methods:** 34 young and 30 older adults underwent a virtual tool-use training in AR with and without vibro-tactile feedback and learned controlling a virtual gripper to grasp a virtual object. In the visuo-tactile condition compared with visual only, vibro-tactile feedback was applied to palm, thumb and index fingers when the tool touched the object. A tactile distance judgement task (TDJ) was used to assess changes in the BS where participants judged distances between two tactile stimuli applied to their right forearm either in proximodistal or mediolateral orientation. Sense of body ownership and agency after virtual tool-use training were assessed using a questionnaire. **Results** revealed that TDJ estimation errors were reduced after training only for proximodistal orientations, indicating smaller perceived arm length, while effects were stronger for young as compared to older adults. In both age groups sense of agency increased with training, but only in older adults this effect was modulated by changes in BS. Changes in body ownership were depended on BS plasticity in both age groups. We **conclude** that virtual tools are integrated into the existing BS during training, and the emergence of body ownership and sense of agency in healthy aging depends on BS plasticity and is (partly) moderated by type of feedback.

IDENTIFICATION OF TRIGEMINAL SENSORY NEURONAL TYPES INNERVATING MASSETER MUSCLE

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Karen Lindquist[1], Sergei Belugin[2], Anahit Hovhannisyan[2], Tatiana Corey[3], Adam Salmon[4], Armen Akopian[2]
[1]UT Health San Antonio, Pharmacology, SAN ANTONIO, United States of America, [2]UT Health San Antonio, Endodontics, San Antonio, United States of America, [3]UT Health San Antonio, Laboratory Animal Resources Departments, San Antonio, United States of America, [4]UT Health San Antonio, Molecular Medicine, San Antonio, United States of America

Understanding masseter muscle (MM) innervation is critical for the study of cell-specific mechanisms of pain induced by temporomandibular disorder (TMDs) or after facial surgery. Here, we identified trigeminal (TG) sensory neuronal subtypes (MM TG neurons) innervating MM fibers, masseteric fascia, tendons, and adjusted tissues. A combination of patch clamp electrophysiology and immunohistochemistry (IHC) on TG neurons back-traced from reporter mouse MM found nine distinct subtypes of MM TG neurons. Of these neurons, 24% belonged to non-peptidergic IB-4^{+}/TRPA1^{-} or IB-4^{+}/TRPA1^{+} groups, while two TRPV1^{+} small-sized neuronal groups were classified as peptidergic/CGRP^{+} One small-sized CGRP^{+} neuronal group had a unique electrophysiological profile and were recorded from Nav1.8^{-} or trkC^{+} neurons. The remaining CGRP^{+} neurons were medium-sized, could be divided into Nav1.8^{-}/trkC^{-} and Nav1.8^{low}/trkC^{+} clusters, and showed large 5HT-induced current. The final two MM TG neuronal groups were trkC^{+} and had no Nav1.8 and CGRP. Among MM TG neurons, TRPV1^{+}/CGRP^{-} (somatostatin^{+}), tyrosine hydroxylase (TH)$^{+}$ (C-LTMR), TRPM8^{+}, MrgprA3^{+}, or trkB^{+} (Aδ-LTMR) subtypes have not been detected. Masseteric muscle fibers, tendons and masseteric fascia in mice and the common marmoset, a new world monkey, were exclusively innervated by either CGRP^{+}/NFH^{+} or CGRP^{-}/NFH^{+} medium-to-large neurons, which we found using a Nav1.8-YFP reporter, and labeling with CGRP, TRPV1, neurofilament heavy chain (NFH) and pgp9.5 antibodies. These nerves were mainly distributed in tendon and at junctions of deep-middle-superficial parts of MM. Overall, the data presented here demonstrates that MM is innervated by a distinct subset of TG neurons, which have unique characteristics and innervation patterns.

NEUROANATOMICAL TRACING OF ASCENDING PROPRIOCEPTIVE PATHWAYS

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Noémie Frezel-Jacob[1], Mario Prsa[2]
[1]University of Fribourg, Department Of Medicine, Fribourg, Switzerland, [2]University of Fribourg, Faculty Of Science And Medicine, Fribourg, Switzerland

Proprioception is the sensation of where our limbs and body are positioned in space. Muscle spindles, Golgi tendon organs and mechanoreceptors in the joint capsule detect changes in muscle length, tension and changes in joint position, respectively. These organs are innervated by anatomically distinct classes of sensory neurons whose cell bodies lie in the dorsal root ganglia (DRG) and constitute the main proprioceptive afferent system. Beyond controlling basic reflexes, proprioceptive information also ascends to the brain via two major pathways. One terminates in the cerebellum (spino-and cuneo-cerebellar tracks) and allows adapting movements to unexpected perturbations, while the other innervates the cerebral cortex (dorsal column-medial lemniscus pathway) allowing for conscious access to proprioceptive information. Despite its importance, our understanding of how limb proprioception is transmitted to, and represented, in the cortex and cerebellum is limited. Here we use anterograde transsynaptic tracers to identify where, and the extent to which different proprioceptive channels are integrated along ascending pathways in mice. We show that proprioceptive DRG neurons can be labelled after muscle injection of AAV vectors in adult mice. This allows access to mature proprioceptive circuits, without the high toxicity of other virus classes classically used for anterograde tracing.

In-Depth Characterization of Layer 5 Output Neurons of the Primary Somatosensory Cortex Innervating the Mouse Dorsal Spinal Cord.
Neuronal circuits of the spinal dorsal horn integrate sensory information from the periphery with inhibitory and facilitating input from higher central nervous system areas. Most previous work focused on projections descending from the hindbrain. Less is known about inputs descending from the cerebral cortex. Here, we identified cholecystokinin (CCK) positive layer 5 pyramidal neurons of the primary somatosensory cortex (CCK S1-corticospinal tract [CST] neurons) as a major source of input to the spinal dorsal horn. We combined intersectional genetics and virus-mediated gene transfer to characterize CCK S1-CST neurons and to define their presynaptic input and postsynaptic target neurons. We found that S1-CST neurons constitute a heterogeneous population that can be subdivided into distinct molecular subgroups. Rabies-based retrograde tracing revealed monosynaptic input from layer 2/3 pyramidal neurons, from parvalbumin positive cortical interneurons, and from thalamic relay neurons in the ventral posterolateral nucleus. Wheat germ agglutinin-based anterograde tracing identified postsynaptic target neurons in dorsal horn laminae III and IV. About 60% of these neurons were inhibitory and about 60% of all spinal target neurons expressed the transcription factor c-Maf. The heterogeneous nature of both S1-CST neurons and their spinal targets suggest complex roles in the fine-tuning of sensory processing.

Does toe clipping for genotyping interfere with later-in-life nociception in mice?
Genetically modified mice are widely used in studies on human and animal physiology and pharmacology, including pain research. The experimental design usually includes comparisons of genetically modified mice with wild-type littermates, requiring biopsy material for genotyping and methods for unequivocal identification of individual mice. Ethical standards and, in some countries, legislation require that both needs are reached with a single procedure. Clipping of the most distal phalanx of up to two toes per paw (toe clipping) is the favored procedure in most research fields, but it may be problematic in sensory physiology and pain research.

The mesoSPIM initiative: open-source light-sheet microscopes for imaging cleared tissue.
Light-sheet microscopy is an ideal technique for imaging large cleared samples; however, the community is still lacking instruments capable of producing volumetric images of centimeter-sized cleared samples with near-isotropic resolution within minutes. Here, we introduce the mesoscale selective plane-illumination microscopy initiative, an open-hardware project for building and operating a light-sheet microscope that addresses these challenges and is compatible with any type of cleared or expanded sample (www.mesospim.org).

Spinal nociceptive circuit analysis with recombinant adeno-associated viruses: the impact of serotypes and promoters.
Recombinant adeno-associated virus (rAAV) vector-mediated gene transfer into genetically defined neuron subtypes has become a powerful tool to study the neuroanatomy of neuronal circuits in the brain and to unravel their functions. More recently, this methodology has also become popular for the analysis of spinal cord circuits. To date, a variety of naturally occurring AAV serotypes and genetically modified capsid variants are available but transduction efficiency in spinal neurons, target selectivity, and the ability for retrograde tracing are only incompletely characterized. Here, we have compared the transduction efficiency of seven commonly used AAV serotypes after intraspinal injection. We specifically analyzed local transduction of different types of dorsal horn neurons, and retrograde transduction of dorsal root ganglia (DRG) neurons and of neurons in the rostral ventromedial medulla (RVM) and the somatosensory cortex (S1). Our results show that most of the tested rAAV vectors have similar transduction efficiency in spinal neurons. All serotypes analyzed were also able to transduce DRG neurons and descending RVM and S1 neurons via their spinal axon terminals. When comparing the commonly used rAAV serotypes to the recently developed serotype 2 capsid variant rAAV2retro, a > 20-fold increase in transduction efficiency of descending supraspinal neurons was observed. Conversely, transgene expression in retrogradely transduced neurons was strongly reduced when the human synapsin 1 (hSyn1) promoter was used instead of the strong ubiquitous hybrid cytomegalovirus enhancer/chicken β-actin promoter (CAG) or cytomegalovirus (CMV) promoter fragments. We conclude that the use of AAV2retro greatly increases transduction of neurons connected to the spinal cord via their axon terminals, while the hSyn1 promoter can be used to minimize transgene expression in retrogradely connected neurons of the DRG or brainstem. Peripheral and central neuronal ATF3 precedes CD4+ T-cell infiltration in EAE.
Experimental allergic encephalomyelitis (EAE), an animal model of multiple sclerosis produced by immunization with myelin oligodendrocyte glycoprotein (MOG) and adjuvants, results from profound T-cell mediated CNS demyelination. EAE is characterized by progressive, ascending motor dysfunction and symptoms of ongoing pain and hypersensitivity, in some cases preceding or concomitant with the motor deficits. In this regard, the EAE model mimics major features of multiple sclerosis, where a central neuropathic pain state is common. Although the latter condition is presumed to arise from a CNS loss of inhibitory controls secondary to the demyelination, dysfunction of sensory neurons may also contribute. Based on our previous studies that demonstrated the utility of monitoring expression of activating transcription factor 3 (ATF3), a sensitive marker of injured sensory neurons, here we followed both ATF3 and CD4+ T cells invasion of sensory ganglia (as well as the CNS) at different stages of the EAE model. We found that ATF3 is induced in peripheral sensory ganglia and brainstem well before the appearance of motor deficits. Unexpectedly, the ATF3 induction always preceded T cell infiltration, typically in adjacent, but non-overlapping regions. Surprisingly, control administration of the pertussis toxin and/or Complete Freund's adjuvants, without MOG, induced ATF3 in sensory neurons. In contrast, T cell infiltration only occurred with MOG. Taken together, our results suggest that the clinical manifestations in the EAE result not only from central demyelination but also from neuronal stress and subsequent pathophysiology of sensory neurons.

Expression of Nav1.7 in DRG neurons extends from peripheral terminals in the skin to central preterminal branches and terminals in the dorsal horn.
Sodium channel Nav1.7 has emerged as a target of considerable interest in pain research, since loss-of-function mutations in SCN9A, the gene that encodes Nav1.7, are associated with a syndrome of congenital insensitivity to pain, gain-of-function mutations are linked to the debiliting chronic pain conditions erythromelalgia and paroxysmal extreme pain disorder, and upregulated expression of Nav1.7 accompanies pain in diabetes and inflammation. Since Nav1.7 has been implicated as playing a critical role in pain pathways, we examined by immunocytochemical methods the expression and distribution of Nav1.7 in rat dorsal root ganglia neurons, from peripheral terminals in the skin to central terminals in the spinal cord dorsal

horn.

INVESTIGATION OF AGE-RELATED CHANGES IN THERMAL Aδ FIBERS

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Louise Trocmet[1], Ségolène Lithfous[1], Thierry Pebayle[2], Olivier Despres[1], André Dufour[1,2]
[1]Université de Strasbourg, Lnca Umr 7364 Cnrs, Strasbourg, France, [2]Université de Strasbourg, Ums 3489 - Ci2n - Cnrs, Strasbourg, France

Studies in animals have shown that Aδ fibers, which underlie cold sensations, have an activation range beyond skin temperature, up to 42°C. Studies investigating changes in temperature perception with age have so far never evaluated the cold sensation of elderly people for temperatures above skin temperature (i.e., between 32°C and 42°C). **Aim:** to evaluate the cold sensations conveyed by Aδ fibers over the temperature range 0-40°C in elderly people to better understand the alteration of thermal perception with age. **Method:** two experiments were performed in young adults and healthy seniors. In experiment 1, participants' cold detection threshold was measured with an adaptive staircase method (baseline temperature 40°C). In experiment 2, 10 stimuli between 36 and 0°C (4°C steps, baseline temperature 40°C) were presented 15 times each. We recorded the rate of cold detection and the associated evoked potentials. **Results:** experiment 1 results' showed that, starting from 40°C, younger subjects have an average cold detection threshold higher than elderly subject (i.e. 35°C vs 34°C). Experiment 2 showed that between 24-36°C, cold discrimination was higher in younger subject than elderly, but no differences were observed between both groups below 24°C. Finally, for each stimulus, the latency of N2P2 component would correspond to the conduction velocity of Aδ fibers. **Conclusion:** all participants, regardless of age, perceive cold above skin temperature and this sensation is supported by Aδ fibers' activity. In contrast, cold discrimination is poorer in older subjects in the 24-36°C range, opening new perspectives for assessing age-related changes in cold-sensitive Aδ fibers.

SUSTAINED MOTOR ACTIVITY TRIGGERED BY DIRECT MECHANOSENSORY STIMULATION

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Alexandra Medeiros, Anna Hobbiss, Gonçalo Borges, César Mendes
University of Lisbon, Cedoc Nova Medical School, Lisbon, Portugal

Sensory feedback is key for efficient locomotion. Mechanosensory structures exist along each leg to assist in motor coordination by transmitting external cues or proprioceptive information to motor centers in the central nervous system. Nevertheless, how different mechanosensory structures engage these locomotor centers and their underlying circuits remains poorly understood. Here we took advantage of the sophisticated *Drosophila* genetic toolkit to address this question. We tested the role of mechanosensory structures in movement initiation by optogenetically stimulating specific classes of leg sensory structures. We found that stimulation of a wide variety of leg mechanosensory structures is sufficient to initiate forward movement in immobile animals. We also found that while the stimulation of the leg Chordotonal Organ depends on the presence of the central brain to trigger forward movement, stimulation of leg Mechanosensory Bristles (MsB) could trigger cyclic motor activity independently of central brain circuits. Also, although leg MsB-triggered movement lacks inter-leg and intra-leg coordination, antagonistic muscle activity is nevertheless preserved. Moreover, we showed that MsB-induced movement is specific to leg afferents, since stimulation of MsB in other structures lead to different outcomes. This study sheds light on the ability of specific sensory circuits to modulate motor control, including initiation of movement, and how this information can be automatically translated to a motor command by central neuronal pathways.

COMPARATIVE ANALYSIS OF THE DISTRIBUTION, STRUCTURE AND INNERVATION OF PACINIAN CORPUSCLES ACROSS DIFFERENT MAMMALIAN SPECIES.

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Angie Geraldine Cuenu Velasco[1], Dominica De Thomas Wagner[1], Mario Prsa[2], Christophe Lamy[3], Daniel Huber[4]
[1]University of Geneva, Neurosciences Fondamentales, Genève, Switzerland, [2]University of Fribourg, Faculty Of Science And Medicine, Fribourg, Switzerland, [3]University of Geneva, Department Of Anatomy, Geneva, Switzerland, [4]University of Geneva, Neurosciences Foundamentales, Geneva, Switzerland

Our ability to sense vibrations depends on diverse mechanoreceptors. Among them, Pacinian corpuscles (PCs) are sensitive to high frequency vibrations. Interestingly, the vibration frequencies with the highest sensitivity seem to change across different mammalian species. Whereas humans show the highest sensitivity around 240Hz, mice are most sensitive around 1000Hz. To understand if this difference in vibrotactile tuning can be related to structural aspects of PCs, we conducted a comparative study of the anatomy, distribution and innervation of PCs in the forelimbs of mice, mouse lemurs and humans. To determine the distribution and innervation in situ we adapted whole-limb tissue-clearing, immuno-staining and light-sheet imaging methods. We demonstrate that all three species have dense distributions of PCs around the bones of their forelimbs, which are innervated by the anterior interosseous nerve. Unlike both primate species, mice seem to lack PCs in the glabrous skin of their hands. We also observed a difference in overall size and organization of the outer core across species. Whereas in humans the size of PCs ranged from 100 to 1850µm, mouse lemurs and mice showed much smaller PCs (15 to 200µm, and 20 to 100µm). Finally, we found differences in the shape and size of the inner core, and are currently confirming this with full PC reconstructions using electron microscopy. Although our analysis revealed substantial differences in size and organization of PCs across different mammalian species, more experiments, including single PC electrophysiology, might be necessary to relate these differences to changes in the best frequency tuning observed.

TOWARDS SENSATION RESTORATION THROUGH ELECTRICAL STIMULATION IN DIABETICS

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Lauren Chee, Noemi Gozzi, Andrea Cimolato, Giacomo Valle, Stanisa Raspopovic
ETH Zürich, Department Of Health Sciences And Technology, Zürich, Switzerland

Aims Diabetic Peripheral Neuropathy (DPN) patients suffer from several comorbidities related to their condition including sensory loss which can lead to reduced balance and mobility. The aim of this study is to provide a preliminary understanding of sensory loss and its restoration through transcutaneous electrical nerve stimulation (TENS) to improve treatment. **Methods** The somatosensory function of healthy and diabetic volunteers was evaluated through quantitative sensory testing (QST) and their nerves were stimulated in the peroneal, tibial, and calcaneal branches that innervate the foot dorsum and sole. The sensitivity of these nerves to electrical stimulation was analyzed through just noticeable difference (JND). The overlap between loss (QST) and restored sensation (TENS) was analyzed in diabetic patients and a comparison in sensitivity between healthy and diabetic patients was drawn. **Results** TENS was shown to partially restore lost sensation in diabetic patients. However, the sensitivity of their nerves was shown to be significantly lower with respect to healthy volunteers. **Conclusions** TENS was able to restore lost sensations in individuals with altered sensation or sensory loss in their feet due to nerve damage. Intuitively, the sensitivity of their damaged nerves is lower than in healthy volunteers, but the successful restoration of some lost sensation area shows promise for TENS as an assistive or therapeutic intervention in DPN patients moving forward.

DO NOXIOUS STIMULUS NS4 COUD BE A SENSORY ECLIPSE: A SENSORY MODULATION DISORDER?

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Marc Janin
Podiatry Office and College E2S University of Pau et des Pays de l'Adour, Movement, Balance, Performance And Health Laboratory (ea 4445), POITIERS, France

Introduction: Plantar irritating stimuli: Noxious stimuli type 4 (Ns4) describes in 1945, witch exacerbating reflex mechanisms, increase or maintain an amplification of related influxes perpetuating or amplifying the nociceptive reflex. Ns4 is defined by: 1) pain revealed by pressure but no expressed, 2) asymmetrical perception of pain on the Ns4 area, 3) loss of spatial discrimination and somesthesia. Pressure/pain plantar thresholds are mediated by C-, Aδ- and Aβ-fiber and could induces sensory modulation dysfunction. Following the beneficial effects of sensorimotor orthoses/insoles, we investigating whether Ns4 could be a “sensory eclipse”. *Method:* 80 subjects with Ns4 (first metatarsal head) and 10 without (control, C) were included. Stimuli consisted of 2-point discriminator delivered: static (at the same time, S) and dynamic: distal to proximal (DP) and proximal to distal (PD) with a randomise distances of 5, 7, 9 mm determined initial situation and after 4 weeks of sensorimotor insoles wearing to Ns4 group. *Result:* significant were observed on S DP and PD between t0 and t4 to Ns4.The reduction of the loos of 7 and 9 mm were higher than 5 mm. The discrimination of 7 and 9 mm were higher in DP > PD than S. These effects did not vary on C. *Discussion:* Results indicates that the spatial configuration of Ns4 noxious stimulation may critically influence sensory modulation of local excitatory/inhibitory activity, and underscores the importance of inhibition during nociceptive processing. After treatment, perception/discrimination of two-point is less than control that we could purpose Ns4 would be a sensory Eclipse.

TRANSFORMATION OF NEURAL CODING FOR VIBROTACTILE SENSATION ALONG THE ASCENDING SOMATOSENSORY PATHWAY

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Kuo-Sheng Lee, Dominica De Thomas Wagner, Géraldine Cuenu, Daniel Huber
University of Geneva, Neurosciences Fondamentales, Genève, Switzerland

Perceiving substrate vibrations is a fundamental component of somatosensation. In mammals, action potentials fired by Pacinian corpuscle afferents are known to reliably time lock to the cycles of a vibration. We recently found that neurons in the somatosensory cortex of mice encode vibration frequency with a rate code tuned to a preferred value. Such surprising feature-selective rate coding raises an important question: how are cyclically entrained action potentials (a temporal code), in afferents of peripheral mechanoreceptors, transformed along the ascending neuraxis into a rate code in the cortex? Here, we traced this transformation with electrophysiological recordings and two-photon calcium imaging along all stages of the ascending somatosensory pathway: primary sensory afferents (mechanoreceptors), dorsal root ganglia, dorsal column nuclei, thalamus and cortex. First, recordings from nerve fibers of primary sensory neurons in lightly anesthetized mice showed that rapidly adapting mechanosensitive units (RAII) display phase-locked spiking for vibrations up to 2000 Hz. This precise temporal code was also found in dorsal column nuclei, but not in thalamus. Second, diverse V-shaped vibrotactile sensitivity curves could be derived from RAII responses and their combination closely resembled perceptual threshold curves obtained with behavioral experiments. Finally, calcium imaging in dorsal column nuclei revealed a topological organization of vibration frequency related to the somatotopic arrangement. By comparing the neural codes at different stages of the somatosensory pathway, we discovered that major neural signal transformations occur between dorsal column nuclei and thalamus. This finding allows modeling the underlying computational principle to reveal novel features of vibrotactile sensation.

A sinusoidal transformation of the visual field is the basis for periodic maps in area V2.
Retinotopic maps of many visual areas are thought to follow the fundamental principles described for the primary visual cortex (V1), where nearby points on the retina map to nearby points on the surface of V1, and orthogonal axes of the retinal surface are represented along orthogonal axes of the cortical surface. Here we demonstrate a striking departure from this mapping in the secondary visual area (V2) of the tree shrew best described as a sinusoidal transformation of the visual field. This sinusoidal topography is ideal for achieving uniform coverage in an elongated area like V2, as predicted by mathematical models designed for wiring minimization, and provides a novel explanation for periodic banded patterns of intra-cortical connections and functional response properties in V2 of tree shrews as well as several other species. Our findings suggest that cortical circuits flexibly implement solutions to sensory surface representation, with dramatic consequences for large-scale cortical organization.

34504074: Prsa M, Kilicel D, Nourizonoz A, Lee KS, Huber D
A common computational principle for vibrotactile pitch perception in mouse and human.
We live surrounded by vibrations generated by moving objects. These oscillatory stimuli propagate through solid substrates, are sensed by mechanoreceptors in our body and give rise to perceptual attributes such as vibrotactile pitch (i.e. the perception of how high or low a vibration's frequency is). Here, we establish a mechanistic relationship between vibrotactile pitch perception and the physical properties of vibrations using behavioral tasks, in which vibratory stimuli were delivered to the human fingertip or the mouse forelimb. The resulting perceptual reports were analyzed with a model demonstrating that physically different combinations of vibration frequencies and amplitudes can produce equal pitch perception. We found that the perceptually indistinguishable but physically different stimuli follow a common computational principle in mouse and human. It dictates that vibrotactile pitch perception is shifted with increases in amplitude toward the frequency of highest vibrotactile sensitivity. These findings suggest the existence of a fundamental relationship between the seemingly unrelated

concepts of spectral sensitivity and pitch perception.

Functional Synaptic Architecture of Callosal Inputs in Mouse Primary Visual Cortex.
Callosal projections are thought to play a critical role in coordinating neural activity between the cerebral hemispheres in placental mammals, but the rules that govern the arrangement of callosal synapses on the dendrites of their target neurons remain poorly understood. Here we describe a high-throughput method to map the functional organization of callosal connectivity by combining in vivo 3D random-access two-photon calcium imaging of the dendritic spines of single V1 neurons with optogenetic stimulation of the presynaptic neural population in the contralateral hemisphere. We find that callosal-recipient spines are more likely to cluster with non-callosal-recipient spines with similar orientation preference. These observations, based on optogenetic stimulation, were confirmed by direct anatomical visualization of callosal synaptic connections using post hoc expansion microscopy. Our results demonstrate, for the first time, that functional synaptic clustering in a short dendritic segment could play a role in integrating distinct neuronal circuits.
Neuron, 2019; 101

Topology of ON and OFF inputs in visual cortex enables an invariant columnar architecture.
Circuits in the visual cortex integrate the information derived from separate ON (light-responsive) and OFF (dark-responsive) pathways to construct orderly columnar representations of stimulus orientation and visual space. How this transformation is achieved to meet the specific topographic constraints of each representation remains unclear. Here we report several novel features of ON-OFF convergence visualized by mapping the receptive fields of layer 2/3 neurons in the tree shrew (Tupaia belangeri) visual cortex using two-photon imaging of GCaMP6 calcium signals. We show that the spatially separate ON and OFF subfields of simple cells in layer 2/3 exhibit topologically distinct relationships with the maps of visual space and orientation preference. The centres of OFF subfields for neurons in a given region of cortex are confined to a compact region of visual space and display a smooth visuotopic progression. By contrast, the centres of the ON subfields are distributed over a wider region of visual space, display substantial visuotopic scatter, and have an orientation-specific displacement consistent with orientation preference map structure. As a result, cortical columns exhibit an invariant aggregate receptive field structure: an OFF-dominated central region flanked by ON-dominated subfields. This distinct arrangement of ON and OFF inputs enables continuity in the mapping of both orientation and visual space and the generation of a columnar map of absolute spatial phase.

Periaqueductal gray stimulation suppresses spontaneous pain behavior in rats.
Methods for evaluating analgesic effect for spontaneous pain are increasingly important because it is reported by most patients with neuropathic pain. The present study assessed the analgesic effects of periaqueductal gray (PAG) stimulation in the spared nerve injury (SNI) model of neuropathic pain of the rat. Spontaneous rapid paw withdrawal movements were used as the index of spontaneous pain. Deep-brain stimulation in the PAG was performed in rats 3 weeks after SNI. Significant analgesic effects on spontaneous pain behavior were observed at the same stimulation parameter that reversed the reduced mechanical threshold of the von Frey test. Both analgesic effects lasted 30-40min beyond the 3min stimulation period. In summary, PAG stimulation was effective in alleviating spontaneous pain and mechanical allodynia in the SNI rat. The frequency of spontaneous paw lifting, a behavioral index of spontaneous pain used in this study, will be useful for future testing of therapeutic methods.

Atypical sensory experience occurs almost universally in patients with Autism Spectrum Disorders (ASD) and is a strong determinant of other ASD symptoms. The sense of touch, known as somatosensation, is majorly affected in ASD. Fragile X Syndrome is the leading monogenic cause of ASD, and Fmr1-knockout (*Fmr1*$^{-/y}$) mice exhibit atypical processing of tactile sensory stimulation. Previously, we found a link between dysfunctional large-conductance, voltage- and calcium-sensitive potassium channels (BK_{Ca}), somatosensory cortex (S1) hyperexcitability, and sensory hypersensitivity. Aim: This study aimed to correct atypical tactile processing in the L2/3 pyramidal neurons (PN) of the S1-hindpaw (HP) region *in vivo* by pharmacologically targeting BK_{Ca} channels. Methods: We performed *in vivo* whole-cell patch-clamp electrophysiological recordings from S1-HP L2/3 PN in anesthetized *Fmr1*$^{-/y}$ mice, locally applied a specific, blood-brain barrier impermeant BK_{Ca} agonist, BMS191011, and recorded sensory responses to tactile stimuli. Results: Neocortical application of BMS191011 was surprisingly efficient in correcting several alterations in *Fmr1*$^{-/y}$ L2/3 PN. This included correcting the action potential half-width increase, a prominent neuronal hyperexcitability feature of *Fmr1*$^{-/y}$ PN, reducing the exaggerated spontaneous firing rate, and rescuing the stimuli-evoked EPSP parameters. Additionally, BMS191011 significantly diminished the increased variability of features across both the *Fmr1*$^{-/y}$ neuron population and successive stimulation trials. Few parameters, including a cellular source of noise were not corrected. Conclusions: Overall, our data demonstrate that local BMS191011 application can dampen the excitability of the S1 network, and provide strong evidence for the neocortex-level origin of at least certain atypical sensory information processing aspects in *Fmr1*$^{-/y}$ mice.

ENCODING OF FORELIMB CONSCIOUS PROPRIOCEPTION IN THE MOUSE SOMATOSENSORY CORTEX

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Ignacio Alonso, Mélanie Palacio-Manzano, Mario Prsa
University of Fribourg, Faculty Of Science And Medicine, Fribourg, Switzerland

Proprioception is the sensation of where our limbs and body are positioned in space. Despite its importance for accurate movements, a clear understanding of how conscious proprioceptive information is represented in the mammalian cortex remains elusive. To identify where and how proprioceptive stimuli are encoded in the mouse cortex we performed 2-photon calcium imaging during passive forelimb displacement with a robotic manipulandum and cortical optogenetic silencing during a proprioceptive 2AFC discrimination task. Our results show that proprioceptive information is not only encoded in the primary forelimb somatosensory cortex, but also in the adjacent dysgranular/transitional zones and motor areas. These cortical responses have a strong directional tuning, are sensitive to the amplitude of movement but surprisingly not to its velocity. A model based on joints positions of the limb (tracked with X-ray videography) was found to better explain the neuronal activity compared to a model based on endpoint position only. Our results suggest that the mouse homologue of the primate proprioceptive area 3a comprises several overlapping somatosensory/motor cortical areas rather than a single functionally defined zone. A further understanding of the underlying neuronal codes and pathways is the necessary first step towards the development of biomimetic neuro-prosthetics.

Phase-Specific Motor Efference during a Rhythmic Motor Pattern.
Neuronal circuits that control motor behaviors orchestrate multiple tasks, including the inhibition of self-generated sensory signals. In the hermaphroditic leech, T and P mechanosensory neurons respond to light touch and pressure on the skin, respectively. We show that the low threshold T cells were also sensitive to topological changes of the animal surface, caused by contraction of the muscles that erect the skin annuli. P cells were unresponsive to this movement. Annuli erection is part of the contraction phase of crawling, a leech locomotive behavior. In isolated ganglia, T cells showed phase-dependent IPSPs during dopamine-induced fictive crawling, whereas P cells were unaffected. The timing and magnitude of the T-IPSPs were highly correlated with the activity of the motoneurons excited during the contraction phase. Together, the results suggest that the central network responsible for crawling sends a reafferent signal onto the T cells, concomitant with the signal to the motoneurons. This reafference is specifically targeted at the sensory neurons that are affected by the movements; and it is behaviorally relevant as excitation of T cells affected the rhythmic motor pattern, probably acting upon the rhythmogenic circuit. Corollary discharge is a highly conserved function of motor systems throughout evolution, and we provide clear evidence of the specificity of its targets and timing and of the benefit of counteracting self-generated sensory input. Neuronal circuits that control motor behaviors orchestrate multiple tasks, including inhibition of sensory signals originated by the animal movement, a phenomenon known as corollary discharge. Leeches crawl on solid surfaces through a sequence of elongation and contraction movements. During the contraction, the skin topology changes, affecting a subpopulation of mechanosensory receptors, T (touch) neurons, but not P (pressure) sensory neurons. In the isolated nervous system, T neurons were inhibited during the contraction but not during the elongation phase, whereas P cells were unaffected throughout crawling. Excitation of T cells during the contraction phase temporarily disrupted the rhythmic pattern. Thus, corollary discharge was target (T vs P) and phase (contraction vs elongation) specific, and prevented self-generated signals to perturb motor behaviors.

CORTICAL REORGANIZATION AFTER SPINAL CORD INJURY IS LAYER-SPECIFIC AND TIME-DEPENDENT

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Marta Zaforas Rodríguez, Elena Alonso-Calviño, Elena Fernández-López, Claudia Miguel-Quesada, Juliana M Rosa, Antonio Oliviero, Juan Aguilar
Hospital Nacional de Parapléjicos, Research Unit, Toledo, Spain

The cerebral cortex is organized in six layers characterized by cellular composition, input/output connections and network properties. The spontaneous activity and evoked responses to sensory inputs depends on specific layers. A spinal cord injury (SCI) produces a massive sensory deafferentation of the somatosensory cortex (S1) which alters cortical activity. The main aim of this work is to identify the acute and chronic physiological alterations that take place at each cortical layer after SCI. For this purpose, experiments were performed in anesthetized adult rats under control condition (sham lesion), acute SCI and chronic SCI. A vertical array of 32 microelectrodes was lowered into S1 allowing to obtain extracellular recordings of neuronal activity from each cortical layer. First experimental approach was used to study acute effects of complete thoracic SCI. For this purpose, the recordings were obtained continuously under control and immediately after SCI. Second experimental approach was used to study chronic effects of SCI by weekly recordings from injured and sham groups. Results indicate that under acute SCI the infragranular layers significantly increased their response magnitude to peripheral stimulation while supragranular layers showed increased higher frequencies content and also generate more activated states in S1. On the contrary, under chronic SCI conditions supragranular layers returned to control levels of spontaneous activity excitability, while infragranular layers increased them progressively. In conclusion, SCI alters cortical oscillations in individual cortical layers which indicate changes in the network excitability in a time-dependent manner. Cortical reorganization after SCI emerges from additive effects across layers.

Cortical layer-specific modulation of neuronal activity after sensory deprivation due to spinal cord injury.
Cortical areas have the capacity of large-scale reorganization following sensory deafferentation. However, it remains unclear whether this phenomenon is a unique process that homogeneously affects the entire deprived cortical region or whether it is susceptible to changes depending on neuronal networks across distinct cortical layers. Here, we studied how the local circuitry within each layer of the deafferented cortex forms the basis for neuroplastic changes after immediate thoracic spinal cord injury (SCI) in anaesthetized rats. In vivo electrophysiological recordings from deafferented hindlimb somatosensory cortex showed that SCI induces layer-specific changes mediating evoked and spontaneous activity. In supragranular layer 2/3, SCI increased gamma oscillations and the ability of these neurons to initiate up-states during spontaneous activity, suggesting an altered corticocortical network and/or intrinsic properties that may serve to maintain the excitability of the cortical column after deafferentation. On the other hand, SCI enhanced the infragranular layers' ability to integrate evoked sensory inputs leading to increased and faster neuronal responses. Delayed evoked response onsets were also observed in layer 5/6, suggesting alterations in thalamocortical connectivity. Altogether, our data indicate that SCI immediately modifies the local circuitry within the deafferented cortex allowing supragranular layers to better integrate spontaneous corticocortical information, thus modifying column excitability, and infragranular layers to better integrate evoked sensory inputs to preserve subcortical outputs. These layer-specific neuronal changes may guide the long-term alterations in neuronal excitability and plasticity associated with the rearrangements of somatosensory networks and the appearance of central sensory pathologies usually associated with spinal cord injury. KEY POINTS: Sensory stimulation of forelimb produces cortical evoked responses in the somatosensory hindlimb cortex in a layer-dependent manner. Spinal cord injury favours the input statistics of corticocortical connections between intact and deafferented cortices. After spinal cord injury supragranular layers exhibit better integration of spontaneous corticocortical information while infragranular layers exhibit better integration of evoked sensory stimulation. Cortical reorganization is a layer-specific phenomenon.

SENSORY INPUT MODULATION RESCUES ALTERATIONS IN PARVALBUMIN CELL CONNECTIVITY AND TEXTURE DISCRIMINATION CAUSED BY TSC1 HAPLOINSUFFICIENCY

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Clara Amegandjin[1,2], Maria Carreño-Muñoz[1,2], Antoine Farley[1,2], Antônia Fernandes Do Nascimento[1,2], Graziella Di Cristo[1,2]

Autism spectrum disorders (ASDs) are characterized by social interaction and communication difficulties as well as repetitive or restricted behaviour. However, a growing number of reports suggest that sensory processing is also affected in a majority of patients with ASDs. In fact, sensory abnormalities are now commonly recognized as diagnostic criteria in ASDs. About 90% of ASD individuals have atypical sensory experiences, described as both hyper- and hypo-reactivity, with abnormal responses to tactile stimulation representing a very frequent finding. However, the neurobiological mechanisms that underlie impaired sensory processing associated with ASDs are poorly understood. Dysregulations of the Mechanistic Target Of Rapamycin Complex 1 (mTORC1) signalling pathway are frequently associated with ASDs, however its implications in sensory processing deficits are less clear. Here, we show that haploinsufficiency of the mTORC1 negative regulator Tsc1 restricted to parvalbumin-expressing GABAergic cells (PV cells) is sufficient to cause increased texture discrimination and whisker-evoked responses in somatosensory cortex. We further find that cortical and thalamocortical glutamatergic inputs to PV cells are selectively reduced in adult mice, whereas these inputs did not appear affected yet in pre-adolescent mice. Finally, we identify a sensitive postnatal window during which limiting sensory inputs by whisker trimming is sufficient to normalize PV cell connectivity in pre-adolescent mice, while rescuing deficits in both PV cell outputs and cortical glutamatergic inputs as well as texture discrimination hyper-sensitivity in adult conditional haploinsufficient mice. These results suggest that manipulating inhibition may help ameliorating sensory processing in disorders associated with dysregulated mTORC1 signalling.

Sensitive period for rescuing parvalbumin interneurons connectivity and social behavior deficits caused by TSC1 loss.
The Mechanistic Target Of Rapamycin Complex 1 (mTORC1) pathway controls several aspects of neuronal development. Mutations in regulators of mTORC1, such as Tsc1 and Tsc2, lead to neurodevelopmental disorders associated with autism, intellectual disabilities and epilepsy. The correct development of inhibitory interneurons is crucial for functional circuits. In particular, the axonal arborisation and synapse density of parvalbumin (PV)-positive GABAergic interneurons change in the postnatal brain. How and whether mTORC1 signaling affects PV cell development is unknown. Here, we show that Tsc1 haploinsufficiency causes a premature increase in terminal axonal branching and bouton density formed by mutant PV cells, followed by a loss of perisomatic innervation in adult mice. PV cell-restricted Tsc1 haploinsufficient and knockout mice show deficits in social behavior. Finally, we identify a sensitive period during the third postnatal week during which treatment with the mTOR inhibitor Rapamycin rescues deficits in both PV cell innervation and social behavior in adult conditional haploinsufficient mice. Our findings reveal a role of mTORC1 signaling in the regulation of the developmental time course and maintenance of cortical PV cell connectivity and support a mechanistic basis for the targeted rescue of autism-related behaviors in disorders associated with deregulated mTORC1 signaling.

Prenatal interleukin 6 elevation increases glutamatergic synapse density and disrupts hippocampal connectivity in offspring.
Early prenatal inflammatory conditions are thought to be a risk factor for different neurodevelopmental disorders. Maternal interleukin-6 (IL-6) elevation during pregnancy causes abnormal behavior in offspring, but whether these defects result from altered synaptic developmental trajectories remains unclear. Here we showed that transient IL-6 elevation via injection into pregnant mice or developing embryos enhanced glutamatergic synapses and led to overall brain hyperconnectivity in

offspring into adulthood. IL-6 activated synaptogenesis gene programs in glutamatergic neurons and required the transcription factor STAT3 and expression of the RGS4 gene. The STAT3-RGS4 pathway was also activated in neonatal brains during poly(I:C)-induced maternal immune activation, which mimics viral infection during pregnancy. These findings indicate that IL-6 elevation at early developmental stages is sufficient to exert a long-lasting effect on glutamatergic synaptogenesis and brain connectivity, providing a mechanistic framework for the association between prenatal inflammatory events and brain neurodevelopmental disorders.

KCC2 Regulates Dendritic Spine Formation in a Brain-Region Specific and BDNF Dependent Manner.
KCC2 is the major chloride extruder in neurons. The spatiotemporal regulation of KCC2 expression orchestrates the developmental shift towards inhibitory GABAergic drive and the formation of glutamatergic synapses. Whether KCC2's role in synapse formation is similar in different brain regions is unknown. First, we found that KCC2 subcellular localization, but not overall KCC2 expression levels, differed between cortex and hippocampus during the first postnatal week. We performed site-specific in utero electroporation of KCC2 cDNA to target either hippocampal CA1 or somatosensory cortical pyramidal neurons. We found that a premature expression of KCC2 significantly decreased spine density in CA1 neurons, while it had the opposite effect in cortical neurons. These effects were cell autonomous, because single-cell biolistic overexpression of KCC2 in hippocampal and cortical organotypic cultures also induced a reduction and an increase of dendritic spine density, respectively. In addition, we found that the effects of its premature expression on spine density were dependent on BDNF levels. Finally, we showed that the effects of KCC2 on dendritic spine were dependent on its chloride transporter function in the hippocampus, contrary to what was observed in cortex. Altogether, these results demonstrate that KCC2 regulation of dendritic spine development, and its underlying mechanisms, are brain-region specific.

Regional expression and ultrastructural localization of EphA7 in the hippocampus and cerebellum of adult rat.
EphA7 is expressed in the adult central nervous system (CNS), where its roles are yet poorly defined. We mapped its distribution using in situ hybridization (ISH) and immunohistochemistry (IHC) combined with light (LM) and electron microscopy (EM) in adult rat and mouse brain. The strongest ISH signal was in the hippocampal pyramidal and granule cell layers. Moderate levels were detected in habenula, striatum, amygdala, the cingulate, piriform and entorhinal cortex, and in cerebellum, notably the Purkinje cell layer. The IHC signal distribution was consistent with ISH results, with transport of the protein to processes, as exemplified in the hippocampal neuropil layers and weakly stained pyramidal cell layers. In contrast, in the cerebellum, the Purkinje cell bodies were the most strongly immunolabeled elements. EM localized the cell surface-expression of EphA7 essentially in postsynaptic densities (PSDs) of dendritic spines and shafts, and on some astrocytic leaflets, in both hippocampus and cerebellum. Perikaryal and dendritic labeling was mostly intracellular, associated with the synthetic and trafficking machineries. Immunopositive vesicles were also observed in axons and axon terminals. Quantitative analysis in EM showed significant differences in the frequency of labeled elements between regions. Notably, labeled dendrites were ~3-5 times less frequent in cerebellum than in hippocampus, but they were individually endowed with ~10-40 times higher frequencies of PSDs, on their shafts and spines. The cell surface localization of EphA7, being preferentially in PSDs, and in perisynaptic astrocytic leaflets, provides morphologic evidence that EphA7 plays key roles in adult CNS synaptic maintenance, plasticity, or function. DEMYELINATION IMPAIRS LAYER 5 CORTICOTHALAMIC FEEDBACK IN THE SOMATOSENSORY SYSTEM

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Nora Jamann[1,2], Jorrit Montijn[3], Stan Driessens[1,2], J Alexander Heimel[3], Maarten Kole[1,2]
[1]Netherlands Institute for Neuroscience, Department Of Axonal Signalling, Amsterdam, Netherlands, [2]Utrecht University, Cell Biology, Neurobiology And Biophysics, Department Of Biology, Utrecht, Netherlands, [3]Netherlands Institute for Neuroscience, Cortical Structure And Function, Amsterdam, Netherlands

Myelination is essential for temporally precise AP propagation. There is emerging evidence that myelin sheath properties can differ widely across brain regions to fine tune temporal delays. Here, we studied the role of L5-to-PoM myelination in timing of corticothalamic feedback *in vitro* and *in vivo*. Using a retrograde AAV targeting approach in combination with a L5-specific Cre-driver mouse line (Rbp4-Cre), we investigated morphological parameters of nodes of Ranvier (noR) and internodes along the axonal projections within the cortex, corpus callosum, striatum and thalamus. After 6 weeks of cuprizone-induced demyelination, we observed, besides internode myelin loss, a diverse pattern of disassembly of nodal compartments, most prominently in the cortex (~20%). To test how demyelination-induced changes in axon architecture affect information transmission we used optogenetic stimulation of L5-to-PoM axons in acute brain slices. The results showed a reduced conduction velocity in demyelinated L5-to-PoM axons and a frequency-dependent impairment of synaptic transmission (20% at 20Hz). Furthermore, to investigate whether corticothalamic feedback to PoM is impaired *in vivo,* we are performing juxtacellular recordings of PoM neurons *in vivo*. In addition, we are using extracellular recordings with Neuropixels probes to record at high-density in S1 and PoM. Strikingly, our preliminary data suggests a global increase of spontaneous activity and an increased delay (~50%) as well as a strong jitter of spike-timing after demyelination. We are currently performing dual whisker- and optogenetic stimulations to test sensory detection and the integration of ascending and descending inputs. Taken together, demyelination disrupts sensory computational processing of the corticothalamic circuit.

Activity-dependent axonal plasticity in sensory systems.
The rodent whisker-to-barrel cortex pathway is a classic model to study the effects of sensory experience and deprivation on neuronal circuit formation, not only during development but also in the adult. Decades of research have produced a vast body of evidence highlighting the fundamental role of neuronal activity (spontaneous and/or sensory-evoked) for circuit formation and function. In this context, it has become clear that neuronal adaptation and plasticity is not just a function of the neonatal brain, but persists into adulthood, especially after experience-driven modulation of network status. Mechanisms for structural remodeling of the somatodendritic or axonal domain include microscale alterations of neurites or synapses. At the same time, functional alterations at the nanoscale such as expression or activation changes of channels and receptors contribute to the modulation of intrinsic excitability or input-output relationships. However, it remains elusive how these forms of structural and functional plasticity come together to shape neuronal network formation and function. While specifically somatodendritic plasticity has been studied in great detail, the role of axonal plasticity, (e.g. at presynaptic boutons, branches or axonal microdomains), is rather poorly understood. Therefore, this review will only briefly highlight somatodendritic plasticity and instead focus on axonal plasticity. We discuss (i) the role of spontaneous and sensory-evoked plasticity during critical periods, (ii) the assembly of axonal presynaptic sites, (iii) axonal plasticity in the mature brain under baseline and sensory manipulation conditions, and finally (iv) plasticity of electrogenic axonal microdomains, namely the axon initial segment, during development and in the mature CNS.

Sensory input drives rapid homeostatic scaling of the axon initial segment in mouse barrel cortex.
The axon initial segment (AIS) is a critical microdomain for action potential initiation and implicated in the regulation of neuronal excitability during activity-dependent plasticity. While structural AIS plasticity has been suggested to fine-tune neuronal activity when network states change, whether it acts in vivo as a homeostatic regulatory mechanism in behaviorally relevant contexts remains poorly understood. Using the mouse whisker-to-barrel pathway as a model system in combination

with immunofluorescence, confocal analysis and electrophysiological recordings, we observed bidirectional AIS plasticity in cortical pyramidal neurons. Furthermore, we find that structural and functional AIS remodeling occurs in distinct temporal domains: Long-term sensory deprivation elicits an AIS length increase, accompanied with an increase in neuronal excitability, while sensory enrichment results in a rapid AIS shortening, accompanied by a decrease in action potential generation. Our findings highlight a central role of the AIS in the homeostatic regulation of neuronal input-output relations.

CT-FIBERS DENSITY AND NERVE EFFECTS ON CORTICAL TACTILE PROCESSING: A SOMATOSENSORY EVOKED POTENTIALS (SEP) STUDY

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Marco Guidotti[1,2], Frédérique Bonnet-Brilhault[1,2], Marianne Latinus[2], Claire Wardak[2]
[1]CHRU de Tours, Centre Universitaire De Pédopsychiatrie, Tours, France, [2]Inserm, Umr 1253, Ibrain, Université De Tours, Tours, France

Aims: Somatosensory evoked potentials (SEP) studies essentially characterized short latency components following mainly median nerve stimulations. However, these studies rarely consider 1) the density of C-Tactile fibers, which convey affective information, at the stimulation site, 2) potential difference due to the nerve being stimulated, and 3) middle latency (>30 ms) components. Our aim was to investigate middle latency SEPs following simple mechanical stimulation of two nerves and two skin areas of different CT density. Methods: 18 adults (mean age in years ± sd: 23.2 ± 2.7, 9 males) received 400 vibrotactile stimulations over 4 territories of the right hand (2 nerves: radial/median; 2 CT densities: high (hairy skin)/low (glabrous skin)). A 64-channel ActiveTwo system (Biosemi®, The Netherlands) was used for EEG recording. Results: Four middle latency components were identified: P50, N80, N130 and P200. Significant shorter latency and larger amplitude were found over the contralateral hemisphere. An important fiber effect was found for the N80: high-CT density skin stimulations induced larger amplitude than low-CT density skin stimulations ($F(17) = 15.898$, $p<0.001$). Regarding nerve effects, P50 and N80 amplitudes were more important for median territory than for radial's ($F(17) = 5.946$; $p<0.05$ and $F(17) = 6.336$; $p<0.05$ respectively); N80 latency was longer after median nerve stimulations than radial nerve's ones ($F(17) = 8.266$; $p<0.05$). Conclusions: This study highlighted a CT-fibers density effect, conveying affective information, on the N80. Furthermore, median and radial nerves' stimulations differently affected components before 100 milliseconds, possibly reflecting somatotopy.

AN ALE META-ANALYSIS OF TEXTURE PERCEPTION

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Jessica Henderson[1], Tyler Mari[1], Alice Newton-Fenner[1,2], Danielle Hewitt[1], Timo Giesbrecht[3], Alan Marshall[4], Andrej Stancak[1,2], Nick Fallon[1]
[1]University of Liverpool, Psychology, Liverpool, United Kingdom, [2]University of Liverpool, Institute For Risk And Uncertainty, Liverpool, United Kingdom, [3]Unilever, Research & Development, Wirral, United Kingdom, [4]University of Liverpool, Electrical Engineering And Electronics, GJ, United Kingdom

Aims Humans use active touch to perceive surface characteristics, such as texture, through low-threshold mechanoreceptors in the skin. Previous fMRI studies suggest activations in the primary and secondary somatosensory cortices, primary motor cortex and the premotor cortex for texture perception during active touch. This meta-analysis aimed to collate research articles, using fMRI methods, to identify brain regions associated with texture perception of various stimuli during active touch exploration. Methods A coordinate-based meta-analysis (activation likelihood estimation, ALE) was performed to investigate brain areas implicated in texture discrimination when compared to a non-haptic baseline (e.g. rest or visual control) or to a haptic baseline (e.g. haptic shape or orientation), the latter contrast was employed to highlight areas active due texture processing only. Nine fMRI studies (155 participants; 136 foci) were selected by systematic review. ALE analysis was performed and conjunction and contrast analyses compared processing of texture. Results and conclusions ALE analysis revealed activations in the SI, inferior parietal lobule (IPL), ventral premotor area (PMv) and supramarginal gyrus (SMG) for the texture > non-haptic baseline contrast, as well as the posterior insula (PI) and secondary visual area (VII) for texture > haptic baseline. Activation in the SI and PMv accords with previous investigations of tactile stimulation and voluntary movement. Interestingly, activation identified in the PI may demonstrate sensory processing specific to texture. This meta-analysis reaffirms the role of sensorimotor and posterior parietal regions and uncovered the possible role of the PI in discriminative touch, which has not been elucidated in previous findings.

The effect of increased parasympathetic activity on perceived duration.
Theories of human temporal perception suggest that changes in physiological arousal distort the perceived duration of events. Behavioural manipulations of sympathetic nervous system (SNS) activity support this suggestion, however the effects of behavioural manipulations of parasympathetic (PSNS) activity on time perception are unclear. The current study examined the effect of a paced respiration exercise known to increase PSNS activity on sub-second duration estimates. Participants estimated the duration of negatively and neutrally valenced images following a period of normal and paced breathing. PSNS and SNS activity were indexed by high-frequency heart-rate variability and pre-ejection period respectively. Paced breathing increased PSNS activity and reduced the perceived duration of the negative and neutrally valenced stimuli relative to normal breathing. The results show that manipulations of PSNS activity can distort time in the absence of a change in SNS activity. They also suggest that activities which increase PSNS activity may be effective in reducing the perceived duration of short events.

Time distortion under threat: Sympathetic arousal predicts time distortion only in the context of negative, highly arousing stimuli.
Theoretical models of time perception suggest a simple bottom-up relationship between physiological arousal and perceived duration. Increases in physiological arousal lengthen the perceived duration of events whereas decreases in physiological arousal reduce them. Whilst this relationship has been demonstrated for highly arousing negatively valenced stimuli, it has not been demonstrated for other classes of distorting stimuli (e.g. positively valenced or low arousal stimuli). The current study tested the effect of valence (positive and negative) and arousal level (high and low) on the relationship between physiological arousal and perceived duration. Sympathetic nervous system (SNS) and parasympathetic nervous system (PSNS) activity was measured during a verbal estimation task in which participants judged the duration of high and low

arousal, positive, negative and neutrally valenced IAPS images. SNS and PSNS activity were indexed by measuring Pre-Ejection Period (PEP) and High Frequency Heart-rate Variability (HF-HRV) respectively. SNS reactivity was predicative of perceived duration, but only for high arousal negatively valenced stimuli, with decreases in PEP being associated with longer duration estimates. SNS and PSNS activity was not predictive of perceived duration for the low arousal negative stimuli or the low and high arousal positive stimuli. We therefore propose a new model suggesting that emotional distortions to time result from a combination of bottom-up (physiological arousal) and top-down (threat detection) factors.

Systematic Review of the Effectiveness of Machine Learning Algorithms for Classifying Pain Intensity, Phenotype or Treatment Outcomes Using Electroencephalogram Data.
Recent attempts to utilize machine learning (ML) to predict pain-related outcomes from Electroencephalogram (EEG) data demonstrate promising results. The primary aim of this review was to evaluate the effectiveness of ML algorithms for predicting pain intensity, phenotypes or treatment response from EEG. Electronic databases MEDLINE, EMBASE, Web of Science, PsycINFO and The Cochrane Library were searched. A total of 44 eligible studies were identified, with 22 presenting attempts to predict pain intensity, 15 investigating the prediction of pain phenotypes and seven assessing the prediction of treatment response. A meta-analysis was not considered appropriate for this review due to heterogeneous methods and reporting. Consequently, data were narratively synthesized. The results demonstrate that the best performing model of the individual studies allows for the prediction of pain intensity, phenotypes and treatment response with accuracies ranging between 62 to 100%, 57 to 99% and 65 to 95.24%, respectively. The results suggest that ML has the potential to effectively predict pain outcomes, which may eventually be used to assist clinical care. However, inadequate reporting and potential bias reduce confidence in the results. Future research should improve reporting standards and externally validate models to decrease bias, which would increase the feasibility of clinical translation. PERSPECTIVE: This systematic review explores the state-of-the-art machine learning methods for predicting pain intensity, phenotype or treatment response from EEG data. Results suggest that machine learning may demonstrate clinical utility, pending further research and development. Areas for improvement, including standardized processing, reporting and the need for better methodological assessment tools, are discussed.

Investigating the effect of losses and gains on effortful engagement during an incentivized Go/NoGo task through anticipatory cortical oscillatory changes.
Losses usually have greater subjective value (SV) than gains of equal nominal value but often cause a relative deterioration in effortful performance. Since losses and gains induce differing approach/avoidance behavioral tendencies, we explored whether incentive type interacted with approach/avoidance motor-sets. Alpha- and beta-band event-related desynchronization (ERD) was hypothesized to be weakest when participants expected a loss and prepared an inhibitory motor-set, and strongest when participants expected a gain and prepared an active motor-set. It was also hypothesized that effort would modulate reward and motor-set-related cortical activation patterns. Participants completed a cued Go/NoGo task while expecting a reward (+10p), avoiding a loss (-10p), or receiving no incentive (0p); and while expecting a NoGo cue with a probability of either .75 or .25. Pre-movement alpha- and beta-band EEG power was analyzed using the ERD method, and the SV of effort was evaluated using a cognitive effort discounting task. Gains incentivized faster RTs and stronger preparatory alpha band ERD compared to loss and no incentive conditions, while inhibitory motor-sets resulted in significantly weaker alpha-band ERD. However, there was no interaction between incentive and motor-sets. Participants were more willing to expend effort in losses compared to gain trials, although the SV of effort was not associated with ERD patterns or RTs. Results suggest that incentive and approach/avoidance motor tendencies modulate cortical activations prior to a speeded RT movement independently, and are not associated with the economic value of effort. The present results favor attentional explanations of the effect of incentive modality on effort.

Inhibition of cortical somatosensory processing during and after low frequency peripheral nerve stimulation in humans.
Transcutaneous low-frequency stimulation (LFS) elicits long-term depression-like effects on human pain perception. However, the neural mechanisms underlying LFS are poorly understood. We investigated cortical activation changes occurring during LFS and if changes were associated with reduced nociceptive processing and increased amplitude of spontaneous cortical oscillations post-treatment.

EXPERIENCE-DEPENDENT REPRESENTATION OF SENSORY-, MOTOR- AND DECISION-RELATED ACTIVITY IN PRIMARY SENSORY, MOTOR, AND MEDIAL PREFRONTAL CORTICAL AREAS.

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Anastasiia Oryshchuk[1], Christos Sourmpis[2], Reza Asri[2], Vahid Esmaeili[3], Wulfram Gerstner[2], Carl Petersen[2], Sylvain Crochet[2]
[1]École Polytechnique Fédérale de Lausanne (EPFL), Brain Mind Institute, LAUSANNE, Switzerland, [2]École Polytechnique Fédérale de Lausanne (EPFL), Brain Mind Institute, Lausanne, Switzerland, [3]Université de Genève, Département Des Neurosciences Fondamentales & Service De Neurologie, Genève, Switzerland

Goal-directed behavior requires processing of incoming sensory information, making appropriate decisions, and generating relevant motor outputs. Yet, how these diverse aspects of sensorimotor transformation arise within the intricate neuronal networks of the mammalian brain remains to be determined. Here, we investigated sensory, decision, and motor signals in the whisker primary somatosensory cortex (wS1), the medial prefrontal cortex (mPFC), and the tongue-jaw primary motor cortex (tjM1) in mice trained to lick for reward in response to a brief single-whisker stimulus of varying amplitude. Optogenetic inactivation demonstrated the causal involvement of all three areas during task execution. We then performed high-density extracellular recordings of neuronal firing in wS1, mPFC, and tjM1 of mice trained in the whisker-detection task (Trained mice). To understand task-specific neuronal representations, we recorded in another group of mice that were exposed to the same whisker stimuli, but without being associated to reward (Exposed mice). Sensory-evoked activity in the absence of licking (i.e. Miss trials) was almost exclusively found in wS1 and correlated with stimulus amplitude in both Trained and Exposed mice. All three cortical regions were strongly modulated by licking in both Trained and Exposed mice, but only tjM1 neuronal activity was unchanged comparing spontaneous (False alarms) and whisker-evoked (Hit trials) licking. Finally, decision-encoding neurons - with selective activity for Hit trials, but not Miss or False alarm trials - were found mostly in mPFC and wS1. Our results point to distinct yet inter-related roles of cortical regions for goal-directed sensorimotor transformation.

ULTRASTRUCTURAL COMPARISON OF VPM THALAMOCORTICAL SYNAPSES IN PRIMARY AND SECONDARY SOMATOSENSORY CORTICES

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Pablo J. Martín-Correa[1], Javier Rodriguez-Moreno[1], Astrid Rollenhagen[2], Joachim Lübke[2], Francisco Clascá[1]
[1]Autonomous University of Madrid (UAM), Department Of Anatomy, Histology And Neuroscience. School Of Medicine., Madrid, Spain, [2]Research Center Jülich, Institute For Neuroscience And Medicine Inm-10, Jülich, Germany

Thalamocortical synapses are key cellular links in sensory, motor and cognitive information processing. In rodents, ventral posteromedial thalamic nucleus (VPM) axons innervate both layer 4 cells of the vibrissal primary somatosensory cortex (S1) and layer 4 cells of the secondary somatosensory cortex (S2). Despite the “primary” and “secondary” functional characterization of these two areas, it is unknown if differences exist in VPM axon synapse structure and/or their postsynaptic target elements. Here, we set out to 3D measure and compare the ultrastructure of VPM synapses on these two areas and their postsynaptic targets. We microinjected adult male C57B/L6 mice iontophoretically with biotinylated dextran amine (BDA) in VPM to selectively label thalamocortical axon arborizations. Following a 5 day survival, mice were perfused, and their brains sectioned (50µm) into two
parallel series of coronal sections. BDA-labeled VPM axon arborizations were located on a series of sections. Adjacent sections were stained for BDA and included for electron microscopy. Serial image samples of selected areas were obtained with serial sectioning TEM or FIB/SEM electron microscopy. Using EspINA and OpenCAR software labeled boutons were 3D reconstructed. Our preliminary results are consistent with previous evidence that VPM axon synapses are mostly located (>90%) on spiny cell dendrites, and very few on spineless dendrites. We are currently investigating synapse structure differences between thalamocortical boutons in different layers of S1 and adjacent somatic sensory areas. Selective and quantitative data on the subcellular structure of these synapses are important to model interactions of the somatic sensory thalamus and its target areas.

FUNCTIONAL ADAPTATIONS AND BRAIN-WIDE REMODELING AFTER PERMANENT SENSORY DEPRIVATION IN THE ADULTHOOD.

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Alba Vieites Prado, Charly Rousseau, Sophie Skriabine, Grace Houser, Clara Nguyen, Thomas Topilko, Patricia Gaspar, Nicolas Renier
Paris Brain Institute, Sorbonne Universite, INSERM, Laboratory Of Structural Plasticity, Paris, France

Brain networks are remodeled during critical periods of plasticity in the early life following alterations to sensory experience in early life. However, brain-wide remodeling following alterations to neuronal activity during the adulthood are more limited. Therefore a complete picture of this phenomenon has been yet elusive. We studied changes in neuronal activity and connectivity after altering brain networks with permanent unilateral whisker deprivations to the somatosensory system in adult mice. We followed the functional and structural changes evoked by this loss over 6 months. Using whole-brain mapping of Fos and calcium imaging with fiber photometry, we measured dynamic adaptive changes during the first weeks following deprivation, followed by a chronic hypoactivity in the barrel field region of the primary somatosensory cortex. We mapped structural axonal markers at whole-brain scale to generate unbiased maps of changes to axonal densities following adult deprivation. Finally, we used viral tracers to quantify changes to the connectivity of efferent pathways of the barrel field. Deciphering the nature of adult brain plasticity may lead to a breakthrough in our understanding of physiological and pathological alterations to the wiring of mature circuits.

The ability to represent our body relies on mental body representations (MBR), which are thought to be nourished -and continuously updated- from early stages of tactile input processing in the primary somatosensory cortex (S1). Yet, little is known about MBR susceptibility to changes in S1 plasticity affecting tactile perception. A few studies reported that some interventions, such as local anesthesia, or repetitive transcranial magnetic stimulation, may alter MBR through an induction of plasticity in S1. Repetitive Somatosensory Stimulation (RSS) is a passive mechanical stimulation that, when applied to the index fingertip, changes tactile acuity along with the S1 representation of the stimulated region. Here, we tested whether RSS, beyond affecting tactile perception at relatively low level (spatial discrimination), also alters MBR. To this aim, we ran a double-blind sham-controlled study in thirty-three healthy volunteers performing, before and after 3 hours of RSS on the right index fingertip, three tasks assessing finger size matching, tactile distance judgement and localization abilities on the stimulated finger. Tactile acuity was additionally assessed using the 2-point discrimination task to control for RSS efficacy. The perceived size of the stimulated finger in the template matching task was significantly reduced after RSS only. No differences were observed in the tactile distance judgement nor in the localization abilities. Our results suggest that the perceived finger size is affected by RSS, while other metric aspects appear immune to RSS. The thorough investigation will be presented, deepening our understanding of the building of MBR and enriching its theoretical framework.

INFORMATION THEORETIC CHARACTERIZATION OF CORTICOTHALAMIC SIGNALING IN THE SOMATOSENSORY SYSTEM OF MICE

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Kaushal Kumar
Heidelberg University, Institute For Applied Mathematics, Heidelberg, Germany

The thalamus integrates sensory information with descending corticothalamic (CT) signals from cortical layers 5 (L5) and 6 (L6) and converging studies suggest that these pathways are main determinants of information processing in the thalamus. The properties of CT pathways suggest distinct functions: L6 provides facilitating modulatory input to all thalamic nuclei, while L5 pyramidal tract neurons powerfully excite “higher-order” regions of thalamus via large, depressing synapses. Here, we aimed to quantify how these distinct CT pathways functionally interact to control thalamic encoding of sensory information using information theoretic approaches, specifically transfer entropy and the partial information decomposition. To assess interactions between cortical output layers and target thalamic relay neurons, we first validated our approach on simulated data from simple spiking (Izhikevich) and mechanistic (Hodgkin-Huxley) models. We next analyzed 1) simulated data from simple feedforward CT model networks, and 2) silicon probe extracellular spike train data collected from the thalamocortical system (primary somatosensory cortex and ventral posterolateral and posterior medial thalamic nuclei) of anesthetized Ntstr1-cre or Rbp4-cre mice in which L6 or L5 CT neurons, respectively, were “opto-tagged” by activation of Channelrhodopsin-2. We find that both CT information transfer and the synergistic influence of L5 and L6 on thalamic targets depend on cortical output rate and spike timing, and are controlled by the pathway-specific temporal dynamics of CT short-term synaptic plasticity. These findings support the established layer-specific functional roles for CT feedback pathways but also point to a previously unknown role for cooperativity between the two pathways in controlling sensory processing.

THE STUDY OF TACTILE IMAGERY-INDUCED CHANGES IN SENSORIMOTOR EEG RHYTHMS.

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Lev Yakovlev, Nikolay Syrov, Alexander Kaplan
Immanuel Kant Baltic Federal University, Baltic Center For Neurotechnology And Artificial Intillegence, Kaliningrad, Russian Federation

In this work, the mu-rhythm of EEG was studied during tactile imagery and tactile stimulation. The goal of the study was to evaluate sensorimotor mu-rhythm event related desynchronization/synchronization (ERD/S) patterns during tactile imagery compared to tactile stimulation. Presented results provide similar EEG patterns of ERD/S during tactile stimulation and imagery. The study involved 16 healthy naive volunteers. The subjects received tactile stimulation, using a vibration motor applied to the inner side of the wrist. After several trials of the tactile stimulation each participant was asked to represent somatosensory feelings mentally. 48 channels EEG were recorded during the experimental session. EEG data was used for spectral analysis with the following calculating ERD/S values in each channel and topographical mapping of EEG activity. Stable ERD patterns were obtained in response to tactile stimulation and tactile imagery, mainly localized contralaterally in the central EEG channels. The intensity of the ERD patterns during imagery conditions was weaker than during the actual stimulation, however there were no statistically significant differences between these conditions. It is important to note that both imagery and real stimulation ERS/S patterns were statistically significantly different from the control condition. During the experimental session we also observed significant gradual increase in ERD values with the trial number during tactile imagery trials. Provided results indicate that not only motor imagery leads to ERD in EEG but also somatosensory imagery. The obtained data complement knowledge about the relationship between the sensorimotor input and mu-rhythm ERD.

Assessing motor imagery in brain-computer interface training: Psychological and neurophysiological correlates.
Motor imagery (MI) is considered to be a promising cognitive tool for improving motor skills as well as for rehabilitation therapy of movement disorders. It is believed that MI training efficiency could be improved by using the brain-computer interface (BCI) technology providing real-time feedback on person's mental attempts. While BCI is indeed a convenient and motivating tool for practicing MI, it is not clear whether it could be used for predicting or measuring potential positive impact of the training. In this study, we are trying to establish whether the proficiency in BCI control is associated with any of the neurophysiological or psychological correlates of motor imagery, as well as to determine possible interrelations among them. For that purpose, we studied motor imagery in a group of 19 healthy BCI-trained volunteers and performed a correlation analysis across various quantitative assessment metrics. We examined subjects' sensorimotor event-related EEG events, corticospinal excitability changes estimated with single-pulse transcranial magnetic stimulation (TMS), BCI accuracy and self-assessment reports obtained with specially designed questionnaires and interview routine. Our results showed, expectedly, that BCI performance is dependent on the subject's capability to suppress EEG sensorimotor rhythms, which in turn is correlated with the idle state amplitude of those oscillations. Neither BCI accuracy nor the EEG features associated with MI were found to correlate with the level of corticospinal excitability increase during motor imagery, and with assessed imagery vividness. Finally, a significant correlation was found between the level of corticospinal excitability increase and kinesthetic vividness of imagery (KVIQ-20 questionnaire). Our results suggest that two distinct neurophysiological mechanisms might mediate possible effects of motor imagery: the non-specific cortical sensorimotor disinhibition and the focal corticospinal excitability increase. Acquired data suggests that BCI-based approach is unreliable in assessing motor imagery due to its high dependence on subject's innate EEG features (e.g. resting mu-rhythm amplitude). Therefore, employment of additional assessment protocols, such as TMS and psychological testing, is required for more comprehensive evaluation of the subject's motor imagery training efficiency.

MAPPING TOUCH ON HANDS AND TOOLS INVOLVES SIMILAR BRAIN DYNAMICS

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Cécile Fabio[1], Roméo Salemme[2], Alessandro Farnè[2], Luke Miller[3]
[1]University Claude Bernard - Lyon 1, -, Villeurbanne, France, [2]Lyon Neuroscience Research Centre, Impact Lab, Bron, France, [3]Radboud University, Donders Institute, Nijmegen, Netherlands

Numerous studies have found evidence that tools become incorporated into a plastic neural representation of our body. A prominent hypothesis suggests that our brain re-uses body-based neural processing when we use tools. However, little is known about how this is implemented at the neural level. Here we used the ability to map touch on both tools and body parts as a case study to fill this gap. Neural oscillations in the alpha (8-13 Hz) and beta (15-25 Hz) frequency bands are involved in mapping touch on the body in distinct reference frames. Alpha activity reflects the mapping of touch in external coordinates, whereas beta activity reflects the mapping of touch in skin-centered coordinates. Here, we aimed at pinpointing the role of these oscillations during tool-extended sensing. We recorded participants' oscillatory activity while tactile stimuli were applied to either hands or the tips of hand-held rods. Posture of the hands/tool-tips was uncrossed or crossed at participants' body midline in order for us to disentangle brain responses related to different coordinate systems. Alpha-band activity was modulated similarly across postures when localizing touch on hands and on tools, reflecting the position of touch into external space. Source reconstruction also indicated a similar network of cortical regions involved for tools and hands. The brain seems to use similar oscillatory mechanisms for mapping touch on a rod and on the body, supporting the idea of neural processes being recycled for tool-use. Furthermore, mapping touch on the tool involves mainly the use of external spatial coordinates.

CHARACTERIZING NEURAL SELECTIVITY IN SENSORY SYSTEMS USING A DATA-DRIVEN INTERPRETABLE FEATURE FINDING METHOD

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Sa-Yoon Park[1], Yoo Rim Kim[2], Sang Jeong Kim[2], Chang-Eop Kim[1]
[1]Gachon University, Physiology, Seongnam, Korea, Republic of, [2]Seoul National University, Physiology, Seoul, Korea, Republic of

Characterizing neural selectivity is a common approach to understand how cortical neurons process information, i.e., the first step to understand the computation mechanism of neurons. Although there have been persistent attempts to investigate neural selectivity, mischaracterization often occurs due to the conventional method using researcher-defined features. Despite the importance of this problem, the reason that causes mischaracterization is not defined and the solution has not been proposed. Here, we suggest possible scenarios of mischaracterization and demonstrate that a data-driven interpretable feature finding (DIFF) method for characterizing neural selectivity can solve this problem. We propose the DIFF method that can find all feasible features given stimuli by fitting neural response vector in multidimensional feature space. It suggests possible features with a score, which reflects the p-value of linear regression analysis. To validate our method, we applied it to simulated data with a wide range of variation and to a real data, i.e., in vivo two-photon Ca2+ imaging data of primary somatosensory cortex neurons using peripheral stimulation, e.g., innocuous brush stroke and noxious forceps pinch. As a result of applying our method to the simulation data, we confirmed that our method works well in a wide range as expected. In the real data, among known-features, brush texture, forcpes texture, and noxiousness features are in high rank, while other features have low probability. Also, this method suggests some unknown features in high ranks. In this study, we identify the DIFF method and demonstrate that our method can be used for finding missing features.

INDIVIDUAL AND COLLECTIVE AXONAL PROPERTIES UNDERLYING SIGNAL TRANSMISSION MODULARITY

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Mohd Yaqub Mir[1], László Zalányi[1], Emese Pálfi[2], Mária Ashaber[3], Anna Roe Wang[4], Robert Friedman[5], László Négyessy[1]
[1]Wigner Research Centre For Physics, Theoretical Neuroscience And Complex Systems Group, Department Of Computational Sciences, Budapest, Hungary, [2]Semmelweis University Budapest, Department Of Anatomy, Histology And Embryology, Budapest, Hungary, [3]California Institute of Technology, Department Of Biology And Biological Engineering, Pasadena, United States of America, [4]Zhejiang University, Interdisciplinary Institute Of Neuroscience And Technology, Hangzhou, China, [5]Oregon Health and Science University, Division Of Neuroscience, Portland, United States of America

In the primate cortex, axonal connections appear both as long-distance fibers and as terminal arborization patches. In the visual cortex, axonal patches represent specific target sites, such as columns of similar orientation preference. Both patch and out-patch axons form axon terminal-like structures suggesting their role in synaptic transmission. However, it is not known whether axons play a similar role in the propagation of activity and dissemination of information within and outside the patches. To answer this question, we reconstructed axons and compared individual axonal properties including thickness, tortuosity and variables related to bouton spacing in addition to collective properties characterizing convergence within and outside the patches for intra-areal, feedforward and feedback connections in horizontal sections of the somatosensory cortex of squirrel monkeys. In patches, axons were thinner and had higher bouton density and stronger convergence than no-patch axons. These findings were consistent across intra- and inter-areal connections. Also, tortuosity was an invariant axonal property. Multivariate analyses indicated bouton density and closeness of unconnected boutons as the major determinants of patch formation. Our results provide evidence that axonal patches are sites of synaptic convergence whereas no-patch axons are more involved in the broadcasting of information in the cerebral cortex. SIDE-INVARIANT POSTSYNAPTIC POTENTIALS MEDIATED BY THE CORPUS CALLOSUM IN THE POSTEROLATERAL BARREL CORTEX: MIDLINE FUSION OF THE TWO ROWS A

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Roberto Montanari[1], Alicia Alonso-Andres[1], Jorge Cabrera-Moreno[2], Javier Alegre-Cortes[1], Ramon Reig[1]
[1]Instituto de Neurociencias UMH-CSIC, Systems And Cell Neurobiology Unit, San Joan d'Alacant, Spain, [2]German Primate Center, Auditory Neuroscience And Optogenetics, Göttingen, Germany

The rodent barrel cortex contains a somatotopic representation of the peripheral whiskers. The decussating trigeminothalamic tract activates the thalamocortical circuit contralateral to the side of a stimulated whisker. Yet, also the stimulation of ipsilateral whiskers can activate the barrel cortex thanks to the callosal innervation. This is scant in most of the barrel cortex and concentrates in its posterolateral aspect where row A is represented, the row lying nearest to the facial midline. Despite the widely known callosal innervation pattern, so far, no study has characterised the ipsilateral receptive fields of highly and scantily callosally innervated areas in relation to whiskers identity. Here, by in vivo whole-cell patch-clamp recordings coupled with sensory stimulations, we show that both inhibitory and excitatory postsynaptic potentials are stronger where callosal innervation is higher. Moreover, with excitatory optogenetics and pharmacological inactivation of the opposite hemisphere, we demonstrate that the strong responses depend on contralateral callosally-projecting neurons. Remarkably, neurons in the posterolateral barrel cortex show a nearly identical response to both right and left row A stimulations. This side-invariant response suggests their participation in the representation of the midline of the whiskers somatosensory space.

SENSORY CORTICAL DYNAMICS DURING OPTICAL MICROSTIMULATION TRAINING

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Ravi Pancholi, Lauren Ryan, Simon Peron
New York University, Center For Neural Science, New York, United States of America

Microstimulation of sensory cortex has been used extensively in the study of perception. However, the evolution of neural activity in animals learning to use microstimulation for behavior remains unclear. Here, we employ optical microstimulation of pyramidal neurons in layer (L) 2/3 of mouse primary vibrissal somatosensory cortex (vS1) to study cortical dynamics as mice learn to discriminate the intensity of microstimulation. Tracking activity over weeks using two-photon calcium imaging, we observe a rapid sparsification of the photoresponsive population, with the degree of sparsification predictive of learning speed. Following sparsification, a steady rate of representational drift is attained, with the same number of neurons entering and exiting the photoresponsive population. Moreover, the photoresponsive population comes to increasingly overlap with populations responding to whisker movement and touch. Our results reveal that microstimulation-evoked cortical activity undergoes extensive reorganization during task learning and that the dynamics of this reorganization impact perception.

Recurrent interactions in local cortical circuits.
Most cortical synapses are local and excitatory. Local recurrent circuits could implement amplification, allowing pattern completion and other computations. Cortical circuits contain subnetworks that consist of neurons with similar receptive fields and increased connectivity relative to the network average. Cortical neurons that encode different types of information are spatially intermingled and distributed over large brain volumes, and this complexity has hindered attempts to probe the function of these subnetworks by perturbing them individually. Here we use computational modelling, optical recordings and manipulations to probe the function of recurrent coupling in layer 2/3 of the mouse vibrissal somatosensory cortex during active tactile discrimination. A neural circuit model of layer 2/3 revealed that recurrent excitation enhances sensory signals by amplification, but only for subnetworks with increased connectivity. Model networks with high amplification were sensitive to damage: loss of a few members of the subnetwork degraded stimulus encoding. We tested this prediction by mapping neuronal selectivity and photoablating neurons with specific selectivity. Ablation of a small proportion of layer 2/3 neurons (10-20, less than 5% of the total) representing touch markedly reduced responses in the spared touch representation, but not in other representations. Ablations most strongly affected neurons with stimulus responses that were similar to those of the ablated population, which is also consistent with network models. Recurrence among cortical neurons with similar selectivity therefore drives input-specific amplification during behaviour.

THE ROLE OF CORTICAL BARRELS IN VIBRISSAL OBJECT TOUCH BEHAVIORS

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Lauren Ryan, Maya Laughton, Andrew Sun-Yan, Ravi Pancholi, Simon Peron
New York University, Center For Neural Science, New York, United States of America

Rodent primary vibrissal somatosensory cortex (vS1) is a model system for the study of neural circuits mediating perception due to, among other things, the precise mapping between whiskers and patches of cortex known as ‘barrels’. Perception during single vibrissal behavior may be dependent on individual barrels. However, the specific behaviors for which individual barrels are necessary remains unclear. Lesions in mice performing vibrissal tasks show conflicting effects: both persistent loss of performance several days after vS1 lesion and recovery have been observed. The large spatial extent of most lesion studies further complicates interpretation. We use prolonged exposure to a femtosecond laser beam to induce lesions that typically span 1-2 barrels in mice performing object localization tasks with a single whisker. Mice are pre-implanted with a cranial window over vS1, and lesions are performed without surgery. Lesioning the C2 barrel in mice that must discriminate touch at distinct locations results in persistent, multi-day degradation of task performance. Lesioned mice can nearly immediately learn an object detection task that requires them to simply report the presence of an object. Mice trained on the detection task alone show no deficit upon single barrel lesions in vS1, despite lesions occurring less than an hour prior to the behavioral session. Performance on a more complex detection task featuring multiple response contingencies and a response delay period was also not impaired following single barrel lesion. Thus, individual vS1 barrels are necessary for performing object location discrimination but are not necessary for simple or complex detection behaviors.

PREDICTIVE PROCESSING OF TACTILE SENSORY INFORMATION IN MICE ENGAGED IN A LOCOMOTION TASK

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Max Chalabi Prat, Timothé Jost-Mousseau, Daniel Shulz, Isabelle Ferezou
Paris-Saclay Institute of Neuroscience, Université Paris Saclay, CNRS, Department Of Integrative And Computational Neuroscience, Saclay, France

The ability of the mammalian central nervous system to constantly adapt motor commands and optimise behaviour according to the context does not only rely on the efficient analysis of the incoming sensory flow. The cerebral cortex is indeed thought to compute, based on past experience, a dynamic model of our interactions with our environment, allowing to anticipate future sensory inputs. Sensory perception would therefore imply a continuous comparison of the expected sensory inputs with those actually received. The error signals generated in case of deviation between these two types of information would allow the internal model to be updated thereby optimizing future predictions. We aim to study these predictive mechanisms using mice in the context of a whisker-guided locomotion task. To interrogate the possible emergence of top-down error signals in the primary somatosensory cortex at the mesoscopic scale, we record voltage induced fluorescence changes over this area through a bundle of optical fibres in mice trained to avoid an obstacle on their path in complete darkness. By simultaneously recording the animal's movement and whisker motion, this allows us to link cortical dynamics with behaviour at 500 Hz, whilst the animal is navigating and gathering tactile information in an ethologically relevant manner. Studying the dynamics of these components at the millisecond timescale in a familiar context, but also in unexpected situations such as when the obstacle is suddenly removed, thus creating a mismatch between expected and received tactile inputs, we intend to reveal behavioural and neuronal signatures of tactile sensory prediction.

MAPPING THE PROJECTION FROM BARREL CORTEX TO THE DIRECT AND INDIRECT PATHWAYS OF DORSAL STRIATUM USING A FUNCTIONAL APPROACH

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Kenza Amroune, David Robbe, Ingrid Bureau
Aix Marseille Univ, Inserm, Inmed, Marseille, France

Animals take navigational decisions based on sensory cues. Rodents detect objects with their whiskers and navigate accordingly. Neurons of barrel cortex (BC) integrate tactile information and transfer them to the dorsal striatum, the main input region of basal ganglia involved in decision making and motor control. Striatum has two projection-neuron populations that are in distinct pathways, direct (dSPNs) and indirect (iSPNs), which control with opposite manners a given action. Thus, the corticostriatal projection is one important determinant of d/iSPNs activity and basal ganglia outputs. We study the BC/striatum coupling to better understand its function. Our aim is to investigate (1) the topographic organization of the projection, (2) the cortical layers involved (3) the eventual dSPN/iSPN differences. So far, the topography of this projection has mainly been approached with anatomy, from which an organization of connectivity may only be inferred. Here, we studied it with a functional approach in order to map the actual connections. To do so, we patched d/iSPNs in slices and stimulated BC using Laser Scanning Photo-Stimulation. This method detected the soma of neurons in BC that innervated a recorded d/iSPN: presynaptic cortical cells were at sites where the stimulation evoked EPSC in the d/iSPN. The collection of EPSCs evoked by a grid of stimulations was used to compute connectivity maps. Drd1-tomato mice allowed to distinguish dSPNs and iSPNs. Prior to electrophysiology, the mouse's spontaneous behaviour in an open field was recorded in order to link its locomotion to differences in dSPN and iSPN innervations.

PROCESSING OF TACTILE INPUTS IN THE MOUSE PERIRHINAL CORTEX

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Luis Cobar, Kasper Kjelsberg, Adrian Foroughi, Maximiliano Jose Nigro
Kavli Institute of Systems Neuroscience, Faculty Of Medicine And Health Sciences, Trondheim, Norway

Mammals use their different senses to gather information and interact with our surroundings. Rodents are heavily dependent on their whiskers-mediated touch system to gather information about their surroundings and objects with which they interact with. Tactile information as well as other types of sensory inputs (smell, vision, etc.) converge more prominently in associative cortices, such as the perirhinal cortex (PER), which receives inputs from all sensory areas and other associative regions; however, the topological organization of whiskers-mediated touch system and the circuits processing tactile inputs into the PER remain unclear.
In this work we aim to investigate the neural circuits in the PER involved in the integration of tactile inputs as well as their topological organization. Our retrograde tracing experiments revealed that PER in divided in sensory domains along its rostro-caudal axis. We found that somatosensory areas of the cortex target the rostral part of PER, while more caudal parts receive visual inputs from the postrhinal cortex. We are currently characterizing the circuit architecture integrating tactile inputs in PER with in vitro electrophysiology. Moreover, we aim at unveiling how perirhinal neurons respond to tactile stimulation by performing in vivo electrophysiological recordings with Neuropixel probes in head restrained animals from PER and barrel cortex to characterize population activity in these regions.

Opto-electrical bimodal recording of neural activity in awake head-restrained mice.
Electrical and optical monitoring of neural activity is major approaches for studying brain functions. Each has its own set of advantages and disadvantages, such as the ability to determine cell types and temporal resolution. Although opto-electrical bimodal recording is beneficial by enabling us to exploit the strength of both approaches, it has not been widely used. In this study, we devised three methods of bimodal recording from a deep brain structure in awake head-fixed mice by chronically implanting a gradient-index (GRIN) lens and electrodes. First, we attached four stainless steel electrodes to the side of a GRIN lens and implanted them in a mouse expressing GCaMP6f in astrocytes. We simultaneously recorded local field potential (LFP) and GCaMP6f signal in astrocytes in the hippocampal CA1 area. Second, implanting a silicon probe electrode mounted on a custom-made microdrive within the focal volume of a GRIN lens, we performed bimodal recording in the CA1 area. We monitored LFP and fluorescent changes of GCaMP6s-expressing neurons in the CA1. Third, we designed a 3D-printed scaffold to serve as a microdrive for a silicon probe and a holder for a GRIN lens. This scaffold simplifies the implantation process and makes it easier to place the lens and probe accurately. Using this method, we recorded single unit activity and LFP electrically and GCaMP6f signals of single neurons optically. Thus, we show that these opto-electrical bimodal recording methods using a GRIN lens and electrodes are viable approaches in awake head-fixed mice.

A neurogenic microenvironment defined by excitatory-inhibitory neuronal circuits in adult dentate gyrus.
Adult neurogenesis in the dentate gyrus plays a role in adaptive brain functions such as memory formation. Adding new neurons to a specific locus of a neural circuit with functional needs is an efficient way to achieve such an adaptive function. However, it is unknown whether neurogenesis is linked to local functional demands potentially specified by the activity of neuronal circuits. By examining the distribution of neurogenesis and different types of neuronal activity in the dentate gyrus of freely moving adult rats, we find that neurogenesis is positionally associated with active excitatory neurons, some of which show place-cell activity, but is positionally dissociated from a type of interneuron with high-burst tendency. Our finding suggests that the behaviorally relevant activity of excitatory-inhibitory neuronal circuits can define a microenvironment stimulating/inhibiting neurogenesis. Such local regulation of neurogenesis may contribute to strategic recruitment of new neurons to modify functionally relevant neural circuits.

Place cells and long-term potentiation in the hippocampus.
Place cells show location-specific firing patterns according to an animal's position in an environment and are thought to contribute to the spatial representation required for self-navigation. Decades of study have extensively characterized the properties of place cells and suggested the involvement of long-term potentiation (LTP), a long-lasting synaptic strengthening, in place cell activity. Here, we review the basic characteristics of place cell activity and the findings that support the idea that LTP contributes to the formation, maintenance, and plasticity of place cell activity.

COEXISTENCE OF STATE, CHOICE AND SENSORY INTEGRATION CODING IN BARREL CORTEX OF MICE PERFORMING NEIGHBORING TACTILE INPUT DISCRIMINATION.

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Pierre-Marie Garderes[1,2], Sébastien Le Gal[1], Charly Rousseau[1,3], Alexandre Mamane[1], Dan Alin Ganea[2,4], Florent Haiss[1]
[1]Institut Pasteur, Unit Of Neural Circuits Dynamics And Decision Making, Paris, France, [2]RWTH Aachen, Izkf Aachen, Medical School, Aachen, France, [3]Paris Brain Institute, Laboratory Of Structural Plasticity, Paris, France, [4]Universität Basel, Department Of Biomedicine, Basel, Switzerland

How parallel sensory streams are integrated and compared during sensory discrimination remains poorly understood. Taking advantage of the columnar architecture of the mouse barrel field (wS1), we designed a two alternative forced choice task (2AFC) in which mice successfully compared stimulation frequencies applied to two adjacent whiskers. We used two-photon functional imaging and optogenetic interventions to record and manipulate the two corresponding cortical neuronal populations. We found that multi-whisker suppression, a dominant effect in cortical layer II/III allows for comparison of frequencies across the range of tested stimuli. Additionally, we find that behavioral engagement is associated with selective up-modulation of single whisker preferring neurons as compared to neurons responding to combinations of whiskers. However, choice signals prior to the animal's response were surprisingly weak and their neuronal representation correlated little with sensory encoding of frequencies. Importantly, optogenetic silencing of individual barrels using structured light illumination resulted in predicted shifts of psychometric functions. This approach allowed us to relate causally and quantifiably the studied neuronal populations to sensory perception involved in this task. Therefore, our results illustrate the role of wS1 in forming a reliable sensory substrate for neighboring whisker frequency discrimination during engagement in the task. This sensory information is used by downstream areas from which most behavioral variability and choice signals may arise.

NEURONAL CORRELATE OF MOTIVATIONAL STATES IN THE SECONDARY WHISKER SENSORIMOTOR PATHWAY

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Giulio Matteucci[1], Johannes Mayrhofer[2], Matthieu Auffret[2], Georgios Foustoukos[2], Carl Petersen[2], Sami El-Boustani[1]
[1]University of Geneva, Department Of Basic Neurosciences, Geneva, Switzerland, [2]École Polytechnique Fédérale de Lausanne (EPFL), Brain Mind Institute, Lausanne, Switzerland

Motivational state can influence performance during perceptual decision-making, yet it is unclear how changes in neuronal representations can alter perception in these states. We adopted a two-whisker discrimination task in head-fixed water-restricted mice to study perceptual decision-making in different states of thirst. Whisker discrimination performance varied with decreasing motivation within individual sessions. Learning dynamics was mainly driven by improvements in the control of motivational state rather than sensorimotor associative learning. Using wide field calcium imaging, optogenetics and anatomical tracing we identified the primary and secondary somatosensory cortex as well as the premotor cortex as part of the cortical network involved in the task. Two-photon calcium imaging across cortical layers in these areas revealed that neural representations of whiskers somatosensation were dependent on the motivational state. In particular, whiskers stimuli could be decoded at best during states of high discrimination performance. These results indicate that the secondary sensorimotor pathway plays a pivotal role during whisker-based goal-directed behaviors.

Nonlinear Processing of Shape Information in Rat Lateral Extrastriate Cortex.
In rodents, the progression of extrastriate areas located laterally to primary visual cortex (V1) has been assigned to a putative object-processing pathway (homologous to the primate ventral stream), based on anatomical considerations. Recently, we found functional support for such attribution (Tafazoli et al., 2017), by showing that this cortical progression is specialized for coding object identity despite view changes, the hallmark property of a ventral-like pathway. Here, we sought to clarify what computations are at the base of such specialization. To this aim, we performed multielectrode recordings from V1 and laterolateral area LL (at the apex of the putative ventral-like hierarchy) of male adult rats, during the presentation of drifting gratings and noise movies. We found that the extent to which neuronal responses were entrained to the phase of the gratings sharply dropped from V1 to LL, along with the quality of the receptive fields inferred through reverse correlation. Concomitantly, the tendency of neurons to respond to different oriented gratings increased, whereas the sharpness of orientation tuning declined. Critically, these trends are consistent with the nonlinear summation of visual inputs that is expected to take place along the ventral stream, according to the predictions of hierarchical models of ventral computations and a meta-analysis of the monkey literature. This suggests an intriguing homology between the mechanisms responsible for building up shape selectivity and transformation tolerance in the visual cortex of primates and rodents, reasserting the potential of the latter as models to investigate ventral stream functions at the circuitry level. Despite the growing popularity of rodents as models of visual functions, it remains unclear whether their visual cortex contains specialized modules for processing shape information. To addresses this question, we compared how neuronal tuning evolves from rat primary visual cortex (V1) to a downstream visual cortical region (area LL) that previous work has implicated in shape processing. In our experiments, LL neurons displayed a stronger tendency to respond to drifting gratings with different orientations while maintaining a sustained response across the whole duration of the drift cycle. These trends match the increased complexity of pattern selectivity and the augmented tolerance to stimulus translation found in monkey visual temporal cortex, thus revealing a homology between shape processing in rodents and primates.

Unsupervised experience with temporal continuity of the visual environment is causally involved in the development of V1 complex cells.
Unsupervised adaptation to the spatiotemporal statistics of visual experience is a key computational principle that has long been assumed to govern postnatal development of visual cortical tuning, including orientation selectivity of simple cells and position tolerance of complex cells in primary visual cortex (V1). Yet, causal empirical evidence supporting this hypothesis is

scant. Here, we show that degrading the temporal continuity of visual experience during early postnatal life leads to a sizable reduction of the number of complex cells and to an impairment of their functional properties while fully sparing the development of simple cells. This causally implicates adaptation to the temporal structure of the visual input in the development of transformation tolerance but not of shape tuning, thus tightly constraining computational models of unsupervised cortical learning.

A template-matching algorithm for laminar identification of cortical recording sites from evoked response potentials.
In recent years, the advent of the so-called silicon probes has made it possible to homogeneously sample spikes and local field potentials (LFPs) from a regular grid of cortical recording sites. In principle, this allows inferring the laminar location of the sites based on the spatiotemporal pattern of LFPs recorded along the probe, as in the well-known current source-density (CSD) analysis. This approach, however, has several limitations, since it relies on visual identification of landmark features (i.e., current sinks and sources) by human operators - features that can be absent from the CSD pattern if the probe does not span the whole cortical thickness, thus making manual labelling harder. Furthermore, as any manual annotation procedure, the typical CSD-based workflow for laminar identification of recording sites is affected by subjective judgment undermining the consistency and reproducibility of results. To overcome these limitations, we developed an alternative approach, based on finding the optimal match between the LFPs recorded along a probe in a given experiment and a template LFP profile that was computed using 18 recording sessions, in which the depth of the recording sites had been recovered through histology. We show that this method can achieve an accuracy of 79 μm in recovering the cortical depth of recording sites and a 76% accuracy in inferring their laminar location. As such, our approach provides an alternative to CSD that, being fully automated, is less prone to the idiosyncrasies of subjective judgment and works reliably also for recordings spanning a limited cortical stretch.

Rats spontaneously perceive global motion direction of drifting plaids.
Computing global motion direction of extended visual objects is a hallmark of primate high-level vision. Although neurons selective for global motion have also been found in mouse visual cortex, it remains unknown whether rodents can combine multiple motion signals into global, integrated percepts. To address this question, we trained two groups of rats to discriminate either gratings (G group) or plaids (i.e., superpositions of gratings with different orientations; P group) drifting horizontally along opposite directions. After the animals learned the task, we applied a visual priming paradigm, where presentation of the target stimulus was preceded by the brief presentation of either a grating or a plaid. The extent to which rat responses to the targets were biased by such prime stimuli provided a measure of the spontaneous, perceived similarity between primes and targets. We found that gratings and plaids, when used as primes, were equally effective at biasing the perception of plaid direction for the rats of the P group. Conversely, for the G group, only the gratings acted as effective prime stimuli, while the plaids failed to alter the perception of grating direction. To interpret these observations, we simulated a decision neuron reading out the representations of gratings and plaids, as conveyed by populations of either component or pattern cells (i.e., local or global motion detectors). We concluded that the findings for the P group are highly consistent with the existence of a population of pattern cells, playing a functional role similar to that demonstrated in primates. We also explored different scenarios that could explain the failure of the plaid stimuli to elicit a sizable priming magnitude for the G group. These simulations yielded testable predictions about the properties of motion representations in rodent visual cortex at the single-cell and circuitry level, thus paving the way to future neurophysiology experiments.

LAYER 1 NDNF+ INTERNEURONS CONTROL BILATERAL SENSORY PROCESSING IN A LAYER-DEPENDENT MANNER.

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Angeliki Damilou, Rasmus Vighagen, Lorenzo Gesuita, Anna Cavaccini, Lila Banterle, Veerle Steenhuis, Theofanis Karayannis
University of Zurich, Brain Research Institute, Zurich, Switzerland

Bilateral sensory information is indispensable for navigating the world. In most mammals, signals sensed by either side of the midline will ultimately reach the cortex where they will be integrated for perception and appropriate action selection. Even though information transferred across the hemispheres is routed through the corpus callosum, how and which microcircuits are key in integrating it is not well understood. Here we identify an essential role for layer 1 NDNF+ inhibitory cells of mice in integrating bilateral whisker-evoked information in an NMDA receptor-dependent manner. Direct connections from the contralateral cortex and the ipsilateral side activate NDNF+ neurons, which subsequently inhibit the late spiking activity of underlying layer 2/3 neurons, but not layer 5. Our results identify a feed-forward regulatory pathway for bilateral cortical sensory processing of upper layer cortical neurons actuated via layer 1 NDNF+ interneurons.

Shared and distinct oculomotor function deficits in schizophrenia and obsessive compulsive disorder.
Detailed analysis of oculomotor function phenotypes in antisaccade, smooth eye pursuit, and active fixation tasks was performed in a sample of 44 patients with schizophrenia, 34 patients with obsessive compulsive disorder (OCD), and 45 matched healthy controls. A common pattern of performance deficits in both schizophrenia and OCD emerged including higher antisaccade error rate, increased latency for corrective antisaccades, as well as higher rates of unwanted saccades in smooth eye pursuit compared to healthy controls. This common pattern could be related to the dysfunction of a network of cognitive control that is present in both disorders, including the dorsolateral prefrontal cortex, the posterior parietal cortex, and the anterior cingulate cortex. In contrast, only patients with schizophrenia showed a specific increase for correct antisaccade mean latency and the intrasubject variability of latency for error prosaccades as well as a decrease in the gain for smooth eye pursuit, suggesting a specific deficit in saccadic motor control and the frontal eye field in schizophrenia that is not present in OCD. A specific deficit in fixation stability (increased frequency of unwanted saccades during active fixation) was observed only for OCD patients pointing to a deficit in the frontostriatal network controlling fixation. This deficit was pronounced for OCD patients receiving additional antipsychotic medication. In conclusion, oculomotor function showed shared and distinct patterns of deviance for schizophrenia and OCD pointing toward shared and specific neurobiological substrates for these psychiatric disorders.

CEREBELLAR MODULATION OF SENSORY PROCESSING THROUGH A HIGHER ORDER THALAMIC NUCLEUS

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Accurate sensory acquisition and perception are key features to survival. Though many parameters underlying the processing of sensory information are known, several aspects are still poorly understood, such as the exact contribution of each cerebral structure. Here, we analyze the cerebellar contribution to sensory processing in the mouse whisker system. Using rabies, a transneuronal retrograde tracer, as well as anterograde tracing from the cerebellar nuclei and retrograde tracer from the primary sensory cortex (S1), we identify an anatomical disynaptic projection from the cerebellar nuclei to S1, involving notably the posterior medial thalamus (POm). Optogenetic stimulations of the dentate nucleus of the cerebellum triggered short-latency responses in S1, and in-vitro recordings reveal the presence of driver-like cerebello-thalamic synapses on the POm. Interestingly, the modulation of this DN-POm pathway induces no strong motor whisker impairments, and its co-activation along with sensory peripheral inputs induces the increased recruitment of POm projections to layer I of sensory cortex. Additionally, pharmacogenetic inhibition of this thalamo-cortical projection tends to disrupt intercortical coherences between sensory and motor cortices in the gamma range during exploratory bouts. Taken together, our results show that the cerebellum targets non-motor cortical areas and can directly modulate sensory-motor processing through a high-order thalamic nucleus, the POm.

IDENTIFICATION OF A DEVELOPMENTAL SWITCH IN INFORMATION TRANSFER BETWEEN WHISKER S1 AND S2 CORTEX IN MICE

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Linbi Cai
Brain Research Institute, Science Department, Uzh, Zurich, Switzerland

The whiskers of rodents are a key sensory organ that provides critical tactile information for animal navigation and object exploration throughout life. Previous work has explored the developmental sensory-driven activation of the primary sensory cortex processing whisker information (wS1), also called barrel cortex. This body of work has shown that the barrel cortex is already activated by sensory stimuli during the first post-natal week. However, it is currently unknown when over the course of development these stimuli begin being processed by higher order cortical areas, such as secondary whisker somatosensory area (wS2). Here we investigate the developmental engagement of wS2 by whisker stimuli and the emergence of cortico-cortical communication from wS1 to wS2. Using in vivo wide-field imaging and multi-electrode recordings in control and conditional knock-out mice with thalamocortical innervation defects, we find that wS1 and wS2 are able to process bottom-up information coming from the thalamus from birth. We also identify that it is only at the end of the first postnatal week that wS1 begins to provide functional excitation into wS2, switching to more inhibitory actions after the second postnatal week. Therefore, we have uncovered a developmental window when information transfer between wS1 and wS2 reaches mature function.

Vitamin D Signaling through Induction of Paneth Cell Defensins Maintains Gut Microbiota and Improves Metabolic Disorders and Hepatic Steatosis in Animal Models.
Metabolic syndrome (MetS), characterized as obesity, insulin resistance, and non-alcoholic fatty liver diseases (NAFLD), is associated with vitamin D insufficiency/deficiency in epidemiological studies, while the underlying mechanism is poorly addressed. On the other hand, disorder of gut microbiota, namely dysbiosis, is known to cause MetS and NAFLD. It is also known that systemic inflammation blocks insulin signaling pathways, leading to insulin resistance and glucose intolerance, which are the driving force for hepatic steatosis. Vitamin D receptor (VDR) is highly expressed in the ileum of the small intestine, which prompted us to test a hypothesis that vitamin D signaling may determine the enterotype of gut microbiota through regulating the intestinal interface. Here, we demonstrate that high-fat-diet feeding (HFD) is necessary but not sufficient, while additional vitamin D deficiency (VDD) as a second hit is needed, to induce robust insulin resistance and fatty liver. Under the two hits (HFD+VDD), the Paneth cell-specific alpha-defensins including α-defensin 5 (DEFA5), MMP7 which activates the pro-defensins, as well as tight junction genes, and MUC2 are all suppressed in the ileum, resulting in mucosal collapse, increased gut permeability, dysbiosis, endotoxemia, systemic inflammation which underlie insulin resistance and hepatic steatosis. Moreover, under the vitamin D deficient high fat feeding (HFD+VDD), , a known murine hepatic-pathogen, is substantially amplified in the ileum, while , a beneficial symbiotic, is diminished. Likewise, the VD receptor (VDR) knockout mice exhibit similar phenotypes, showing down regulation of alpha-defensins and MMP7 in the ileum, increased and suppressed . Remarkably, oral administration of DEFA5 restored eubiosys, showing suppression of and increase of in association with resolving metabolic disorders and fatty liver in the HFD+VDD mice. An analysis showed that DEFA5 peptide could directly suppress . Thus, the results of this study reveal critical roles of a vitamin D/VDR axis in optimal expression of defensins and tight junction genes in support of intestinal integrity and eubiosis to suppress NAFLD and metabolic disorders. AN ACTIVE WHISKER-DEPENDENT TASK TO SEEK NEURONAL SIGNATURES OF TACTILE SENSORY PREDICTION IN THE MOUSE SENSORIMOTOR CORTEX

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Fan Yang[1,2], Sophie Hubatz[1,2], Luc Estebanez[1], Thomas Deneux[1], Jean-François Léger[2], Daniel Shulz[1], Laurent Bourdieu[2], Isabelle Ferezou[1]
[1]Paris-Saclay Institute of Neuroscience, Université Paris Saclay, CNRS, Department Of Integrative And Computational Neuroscience, Saclay, France, [2]Institut de Biologie de l'Ecole Normale Superieure, Cortical Dynamics And Coding Mechanisms, Paris, France

Expectancy is an essential function of the nervous system, which allows the organism to react to the external context in an effective way. Cortical circuits are thought to be involved in the computation of an internal model of our interactions with the environment, which generate sensory expectations according to the context, past sensory experience, and current motor actions. According to predictive coding theories, in case of mismatch between such expectations and the actual experience, an error signal is generated, which is key to update the internal model and adjust the motor commands, thus optimising behaviour. To study the neuronal mechanisms underlying predictive coding in active conditions, we designed a new tactile sensorimotor task in which head-fixed mice are trained to contact several times a fixed object with a spared single whisker to obtain a reward. Then, during sessions performed with expert animals, we randomly interleave ‘omission’ trials, in which the object is removed between two whisks, creating a deviance between expected and received tactile inputs. Using high-speed videography of the whisker behaviour, we study how the motor strategy evolves during the learning process, and its rearrangement upon omission trials. Based on this behavioural protocol, which is compatible with chronic and acute electrophysiological recordings, and with wide-field mesoscopic and two-photon optical imaging, we aim to better understand how the primary and secondary somatosensory cortices, in interaction with the primary motor cortex, contribute to the construction of an internal representation of the object, and the emergence of error signals.

MODULATION OF STRIATAL SENSORY PROCESSING BY BEHAVIOR IN HEALTHY AND DOPAMINE-DEPLETED MICE

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Roberto De La Torre-Martínez[1], Maya Ketzef[1], Gilad Silberberg[2]
[1]Karolinska Institutet, Department Of Neuroscience, Sweden, Sweden, [2]Karolinska Institutet, Department Of Neuroscience, Stockholm, Sweden

Sensory and motor excitatory cortical afferents and dopaminergic projections from substantia nigra pars compacta converge in the dorsolateral striatum (DLS). In various cortical regions, motor activity was shown to modulate sensory processing, however little is known about sensorimotor interactions in the DLS and the effects of dopamine (DA) depletion. To determine the impact of whisker-related motor activity in the sensory processing in healthy and DA depleted mice, we obtained whole-cell recordings in the DLS of awake mice during the presentation of tactile stimuli. Recorded neurons in DLS responded to both whisker stimulation and spontaneous whisking. Following DA depletion, the representation of spontaneous whisking was reduced in the direct pathway medium spiny neurons (dMSNs) and not in the indirect population (iMSNs). Spontaneous whisking reduced the magnitude of tactile responses in both MSN types, in both healthy and DA depleted mice. Lastly, as previously reported in anesthetized mice, DA depletion reduced the differences between ipsi- and contralateral sensory responses. Our results provide new insights into the sensorimotor integration in the DLS.

Phenylalanine-Derived β-Lactam TRPM8 Modulators. Configuration Effect on the Antagonist Activity.
Transient receptor potential cation channel subfamily M member 8 (TRPM8) is a Ca non-selective ion channel implicated in a variety of pathological conditions, including cancer, inflammatory and neuropathic pain. In previous works we identified a family of chiral, highly hydrophobic β-lactam derivatives, and began to intuit a possible effect of the stereogenic centers on the antagonist activity. To investigate the influence of configuration on the TRPM8 antagonist properties, here we prepare and characterize four possible diastereoisomeric derivatives of 4-benzyl-1-[(3'-phenyl-2'-dibenzylamino)prop-1'-yl]-4-benzyloxycarbonyl-3-methyl-2-oxoazetidine. In microfluorography assays, all isomers were able to reduce the menthol-induced cell Ca entry to larger or lesser extent. Potency follows the order 342' > 342' 342' 342' with the most potent diastereoisomer showing a half inhibitory concentration (IC) in the low nanomolar range, confirmed by Patch-Clamp electrophysiology experiments. All four compounds display high receptor selectivity against other members of the TRP family. Furthermore, in primary cultures of rat dorsal root ganglion (DRG) neurons, the most potent diastereoisomers do not produce any alteration in neuronal excitability, indicating their high specificity for TRPM8 channels. Docking studies positioned these β-lactams at different subsites by the pore zone, suggesting a different mechanism than the known -(3-aminopropyl)-2-[(3-methylphenyl)methoxy]--(2-thienylmethyl)-benzamide (AMTB) antagonist.

Highly functionalized β-lactams and 2-ketopiperazines as TRPM8 antagonists with antiallodynic activity.
The cool sensor transient receptor potential melastatin channel 8 (TRPM8) is highly expressed in trigeminal and dorsal root ganglia, playing a key role in cold hypersensitivity associated to different peripheral neuropathies. Moreover, these channels are aberrantly expressed in different cancers, and seem to participate in tumor progression, survival and invasion. Accordingly, the search for potent and selective TRPM8 modulators attracted great interest in recent years. We describe new heterocyclic TRPM8 antagonist chemotypes derived from N-cloroalkyl phenylalaninol-Phe conjugates. The cyclization of these conjugates afforded highly substituted β-lactams and/or 2-ketopiperazine (KP) derivatives, with regioselectivity depending on the N-chloroalkyl group and the configuration. These derivatives behave as TRPM8 antagonists in the Ca microfluorometry assay, and confirmed electrophysiologically for the best enantiopure β-lactams 24a and 29a (IC, 1.4 and 0.8 μM). Two putative binding sites by the pore zone, different from those found for typical agonists and antagonists, were

identified by in silico studies for both β-lactams and KPs. β-Lactams 24a and 29a display antitumor activity in different human tumor cell lines (micromolar potencies, A549, HT29, PSN1), but correlation with TRPM8 expression could not be established. Additionally, compound 24a significantly reduced cold allodynia in a mice model of oxaliplatin-induced peripheral neuropathy.

1-(2',5'-Dihydroxyphenyl)-3-(2-fluoro-4-hydroxyphenyl)-1-propanone (RGM079): A Positive Allosteric Modulator of α7 Nicotinic Receptors with Analgesic and Neuroprotective Activity.
Acetylcholine α7 nicotinic receptors are widely expressed in the brain, where they are involved in the central processing of pain as well as in neuropsychiatric, neurodegenerative, and inflammatory processes. Positive allosteric modulators (PAMs) show the advantage of allowing the selective regulation of different subtypes of acetylcholine receptors without directly interacting with the agonist binding site. Here, we report the preparation and biological activity of a fluoro-containing compound, 1-(2',5'-dihydroxyphenyl)-3-(2-fluoro-4-hydroxyphenyl)-1-propanone (,), that behaves as a potent PAM of the α7 receptors and has a balanced pharmacokinetic profile and antioxidant properties comparable or even higher than well-known natural polyphenols. In addition, compound shows neuroprotective properties in Alzheimer's disease (AD)-toxicity related models. Thus, it causes a concentration-dependent neuroprotective effect against the toxicity induced by okadaic acid (OA) in the human neuroblastoma cell line SH-SY5Y. Similarly, in primary cultures of rat cortical neurons, is able to restore the cellular viability after exposure to OA and amyloid peptide Aβ, with cell death almost completely prevented at 10 and 30 μM, respectively. Finally, compound shows analgesic activity in the complete Freund's adjuvant (CFA)-induced paw inflammation model after intraperitoneal administration.

Amino acid and peptide prodrugs of diphenylpropanones positive allosteric modulators of α7 nicotinic receptors with analgesic activity.
α7 Nicotinic acetylcholine receptors (nAChRs) are ion channels implicated in a number of CNS pathological processes, including pain and psychiatric, cognitive and inflammatory diseases. Comparing with orthosteric agonism, positive allosteric modulation of these channels constitutes an interesting approach to achieve selectivity versus other nicotinic receptors. We have recently described new chalcones and 1,3-diphenylpropanones as positive allosteric modulators (PAMs) of α7 nAChRs, which proved to have good analgesic activities but poor pharmacokinetic properties. Here we report the preparation of amino acid and peptide derivatives as prodrugs of these modulators with the aim of improving their in vivo biological activity. While the valine derivative showed very short half life in aqueous solutions to be considered a prodrug, Val-Val and Val-Pro-Val are suitable precursors of the parent 1,3-diphenylpropanones, via chemical and enzymatic transformation, respectively. Compounds 19 (Val-Val) and 21 (Val-Pro-Val), prodrugs of the 2',5',4-trihydroxy-1,3-diphenylpropan-1-one 3, showed significant antinociceptive activity in in vivo assays. The best compound, 21, displayed a better profile in the analgesia test than its parent compound 3, exhibiting about the same potency but long-lasting effects.

Synthesis, high-throughput screening and pharmacological characterization of β-lactam derivatives as TRPM8 antagonists.
The mammalian transient receptor potential melastatin channel 8 (TRPM8), highly expressed in trigeminal and dorsal root ganglia, mediates the cooling sensation and plays an important role in the cold hypersensitivity characteristic of some types of neuropathic pain, as well as in cancer. Consequently, the identification of selective and potent ligands for TRPM8 is of great interest. Here, a series of compounds, having a β-lactam central scaffold, were prepared to explore the pharmacophore requirements for TRPM8 modulation. Structure-activity studies indicate that the minimal requirements for potent β-lactam-based TRPM8 blockers are hydrophobic groups (benzyl preferentially or Bu) on R, R, R and R and a short N-alkyl chain (≤3 carbons). The best compounds in the focused library (41 and 45) showed IC values of 46 nM and 83 nM, respectively, in electrophysiology assays. These compounds selectively blocked all modalities of TRPM8 activation, i.e. menthol, voltage, and temperature. Molecular modelling studies using a homology model of TRPM8 identified two putative binding sites, involving networks of hydrophobic interactions, and suggesting a negative allosteric modulation through the stabilization of the closed state. Thus, these β-lactams provide a novel pharmacophore scaffold to evolve TRPM8 allosteric modulators to treat TRPM8 channel dysfunction.

Effect of econazole and benzydamine on sensory neurons in culture.

Econazole is an anti-mycotic agent widely used for the treatment of cutaneous fungal infections, and for the therapy of vaginal candidiasis. Topical application of this azole is generally safe, although some patients have complained of mild burning sensation/cutaneous irritation and itching, especially when administered intravaginally. The underlying mechanisms responsible of these adverse effects are poorly understood, though they suggest excitation of cutaneous nociceptor terminals. We report that exposure of primary cultures of rat nociceptors to econazole augments neuronal excitability. This effect appears mediated by increments in the intracellular Ca by stimulating Ca entry and release from the endoplasmic reticulum. Ca entry was not due to activation of thermo transient receptor potential (TRP) channels, suggesting a different ion channel targeted by the azole. Noteworthy, econazole-evoked responses were potentiated by a pro-inflammatory agent, which resulted in an increase in neuronal excitability. Econazole-elicited action potential firing was significantly abolished by the inflammatory cytokine inhibiting drug benzydamine via blockade of voltage-gated Na (Nav) channels. Collectively, our results indicate that the burning sensation of econazole is due at least in part to modulation of nociceptor excitability, and such sensation is increased in the presence of pro-inflammatory stimuli and blocked by benzydamine. These findings imply that a combination of the azole with benzydamine has the potential to reduce significantly the unpleasant symptoms related to infection and to the adverse effects of topical econazole formulations.

Tryptamine-Based Derivatives as Transient Receptor Potential Melastatin Type 8 (TRPM8) Channel Modulators.
Pharmacological modulation of the transient receptor potential melastatin type 8 (TRPM8) is currently under investigation as a new approach for the treatment of pain and other diseases. In this study, a series of N-substituted tryptamines was prepared to explore the structural requirements determining TRPM8 modulation. Using a fluorescence-based screening assay, we identified two compounds acting as an activator (2-(1H-indol-3-yl)-N-(4-phenoxybenzyl)ethanamine, 21) or an inhibitor (N,N-dibenzyl-2-(1H-indol-3-yl)ethanamine, 12) of calcium influx in HEK293 cells. In patch-clamp recordings, compound 21 displayed a significantly higher potency (EC50 = 40 ± 4 μM) and a similar efficacy when compared to menthol; by contrast, compound 12 produced a concentration-dependent inhibition of menthol-induced TRPM8 currents (IC50 = 367 ± 24 nM). Molecular modeling studies using a homology model of a single rat TRPM8 subunit identified a putative binding site located between the VSD and the TRP box, disclosing differences in the binding modes for the agonist and the antagonist.

Adamantyl analogues of paracetamol as potent analgesic drugs via inhibition of TRPA1.
Paracetamol also known as acetaminophen, is a widely used analgesic and antipyretic agent. We report the synthesis and biological evaluation of adamantyl analogues of paracetamol with important analgesic properties. The mechanism of nociception of compound 6a/b, an analog of paracetamol, is not exerted through direct interaction with cannabinoid receptors, nor by inhibiting COX. It behaves as an interesting selective TRPA1 channel antagonist, which may be responsible for its analgesic properties, whereas it has no effect on the TRPM8 nor TRPV1 channels. The possibility of replacing a phenyl ring by an adamantyl ring opens new avenues in other fields of medicinal chemistry.

Chalcones as positive allosteric modulators of α7 nicotinic acetylcholine receptors: a new target for a privileged structure.
The α7 acetylcholine nicotine receptor is a ligand-gated ion channel that is involved in cognition disorders, schizophrenia, pain and inflammation among other diseases. Therefore, the development of new agents that target this receptor has great significance. Positive allosteric modulators might be advantageous, since they facilitate receptor responses without directly interacting with the agonist binding site. Here we report the search for and further design of new positive allosteric modulators having the relatively simple chalcone structure. From the natural product isoliquiritigenin as starting point, chalcones substituted with hydroxyl groups at defined locations were identified as optimal and specific promoters of α7 nicotinic function. The most potent compound (2,4,2',5'-tetrahydroxychalcone, 111) was further characterized showing its potential as

neuroprotective, analgesic and cognitive enhancer, opening the way for future developments around the chalcone structure. Eur J Med Chem, 2014; 86

MEASURING NEUROLOGICAL DISEASE PROGRESSION IN RODENT MODELS BY QUANTIFYING WHISKER MOVEMENTS

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Ugne Simanaviciute[1], Aybeniz Ece Cetin[2], Emma Hodson-Tole[3], Andrew Spink[4], Jochen Staiger[2], Robyn Grant[1]
[1]Manchester Metropolitan University, Department Of Natural Sciences, Manchester, United Kingdom, [2]University of Göttingen, Institute For Neuroanatomy, Göttingen, Germany, [3]Manchester Metropolitan University, Department Of Life Sciences, Manchester, United Kingdom, [4]Noldus Information Technology BV, Marketing, Wageningen, Netherlands

The current battery of tests used for assessing rodent behaviour consists of either expensive and intrusive methods or requires extensive animal training. They also result in only simple behavioural measures, such as durations or frequencies. We propose that measuring whisker-related exploratory movements offer an alternative way to observe highly quantitative behavioural changes in mice. We have previously demonstrated this by assessing whisker movement differences in mouse models of a wide range of neurological disorders. However, whisker movements have never been studied in tandem, and compared to, other established laboratory tests. Aim: for the first time, we attempt to integrate whisker tracking with a novel texture recognition task (NTR) and to assess NTR effects on whisker exploratory behaviour. Methods: mice were filmed using a high-speed video camera (500 frames per second) in an open arena during a novel object exploration task (NOE). Their whisker and body positions were tracked using freely available software ARTv2. Results: whisker tracking detected differences between mice that had been exposed to the NTR and naïve mice. Specifically, significant differences were found in pre-contact asymmetry and spread as well as during-contact protraction speed of NOE task. We also succeeded in integrating whisker tracking with the NTR task to provide more quantitative sensory and attentional information about the object contacts. Conclusion: whisker movements are a powerful behavioural measurement tool which incorporated within a standard battery of behavioural tests allows detection of additional exploratory-related parameters.

CORTICAL CIRCUITS FOR CONTEXT-DEPENDENT SENSORIMOTOR TRANSFORMATION

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Parviz Ghaderi, Sylvain Crochet, Carl Petersen
EPFL, Sv-brain Mind Institute, Lausanne, Switzerland

Flexible integration of sensory stimuli in a context-dependent manner is a key cognitive process required to generate appropriate behavior. An intriguing question, then, is how the same sensory stimulus can be interpreted differently according to context in order to generate different behavioral responses. We designed a task in which mice were trained to lick for reward in response to a brief single whisker stimulus if it was preceded by a brief Go-Tone presented one second before the whisker stimulus, but not if it was preceded by a NoGo-Tone. Optogenetic inactivation of primary whisker somatosensory cortex (wS1), secondary whisker somatosensory cortex (wS2), secondary whisker motor cortex (wM2) and anterior lateral motor cortex (ALM) during the presentation of the whisker stimulus decreased the probability of licking in the reward window. Inactivation of wM2 and ALM, but not wS1 or wS2, during the delay between the tone and the whisker stimulus reduced licking in the reward window. We investigated the neuronal correlates of context-dependent sensory processing using high-density extracellular recordings combined with high-speed video filming of facial movements. The neuronal response to the whisker stimulus in wS1 and wS2 was higher in Go-context hit trials than in NoGo-context correct rejection trials. wM2 and ALM also showed much stronger responses to whisker stimulus in the Go-context and had prominent persistent activity during the delay period following the Go-tone presentation, even in trials without anticipatory facial movements. These preliminary results point to an important role of frontal areas wM2 and ALM in context-dependent sensorimotor transformation.

A community-based transcriptomics classification and nomenclature of neocortical cell types.
To understand the function of cortical circuits, it is necessary to catalog their cellular diversity. Past attempts to do so using anatomical, physiological or molecular features of cortical cells have not resulted in a unified taxonomy of neuronal or glial cell types, partly due to limited data. Single-cell transcriptomics is enabling, for the first time, systematic high-throughput measurements of cortical cells and generation of datasets that hold the promise of being complete, accurate and permanent. Statistical analyses of these data reveal clusters that often correspond to cell types previously defined by morphological or physiological criteria and that appear conserved across cortical areas and species. To capitalize on these new methods, we propose the adoption of a transcriptome-based taxonomy of cell types for mammalian neocortex. This classification should be hierarchical and use a standardized nomenclature. It should be based on a probabilistic definition of a cell type and incorporate data from different approaches, developmental stages and species. A community-based classification and data aggregation model, such as a knowledge graph, could provide a common foundation for the study of cortical circuits. This community-based classification, nomenclature and data aggregation could serve as an example for cell type atlases in other parts of the body.

Electrophysiological Profiling of Neocortical Neural Subtypes: A Semi-Supervised Method Applied to Whole-Cell Patch-Clamp Data.
A lot of efforts have been made to understand the structure and function of neocortical circuits. In fact, a promising way to understand the functions of cortical circuits is the classification of the neural types, based on their different properties. Recent studies focused on applying modern computational methods to classify neurons based on molecular, morphological, physiological, or mixed of these criteria. Although there are studies in the literature on /vivo extracellular or intracellular recordings, a study on the classification of neuronal types using whole-cell patch-clamp recordings is still lacking. We thus proposed a novel semi-supervised classification method based on waveform shape of neurons' spikes using whole-cell patch-clamp recordings. We, first, detected spike candidates. Then discriminative features were extracted from the time samples of the spikes using discrete cosine transform. We then extracted the center of clusters using fuzzy c-mean clustering and finally, the neurons were classified using the minimum distance classifier. We distinguished three types of neurons: excitatory pyramidal cells (Pyr) and two types of inhibitory neurons: GABAergic- parvalbumin positive (PV), and somatostatin positive (SST) non-pyramidal cells in layer II/III of the mice primary visual cortex. We used 10-fold cross validation in our study. The classification accuracy for PV, Pyr, and SST was 91.59 ± 1.69, 97.47 ± 0.67, and 89.06 ± 1.99, respectively. Overall, the algorithm correctly classified 92.67 ± 0.54% of the cells, confirming the relative robustness of the discriminant functions. The performance of the method was further assessed on recordings by using a pool of 50 neurons from Allen institute Cell Types Database (5 major subtypes of neurons: Pyr, PV, SST, 5HT3a, and vasoactive intestinal peptide (VIP) cells). Its overall accuracy was 84.13 ± 0.81% on this data set using cross validation framework. The proposed algorithm is thus a promising new tool in recognizing cell's type with high accuracy in laboratories using / whole-cell patch-clamp recording technique. The developed programs and the entire dataset are available online to interested readers.

CELL TYPE-SPECIFIC ORGANIZATION OF GABAERGIC INTERNEURONS IN A CORTICAL COLUMN

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Felipe Yáñez[1], Daniel Udvary[1], Fernando Messore[1], Guanxiao Qi[2], Bert Sakmann[3], Dirk Feldmeyer[2], Marcel Oberländer[1]
[1]Max Planck Institute for Neurobiology of Behavior – caesar, In Silico Brain Sciences, Bonn, Germany, [2]Research Centre Jülich, Institute Of Neuroscience And Medicine, Jülich, Germany, [3]Max Planck Institute for Biological Intelligence, Cortical Column In Silico, Martinsried, Germany

Cortical GABAergic interneurons (INs) have been extensively reported as a rich and diverse class of neurons. At the single cell level, attributes such as morphology and intrinsic physiology exhibit complex patterns of variation, making them difficult to characterize. Here, we systematically assess the degree and character of the variability of these properties across the entire cortical depth of the rat barrel cortex. First, we compute a large set of descriptive features of 306 INs based on (i) their spiking patterns in response to somatic current injections, and (ii) reconstructions of their axon and dendrite morphology, as well as somatic depth location. Then, we group our sample into robust morphological and/or intrinsic physiological types by clustering the extracted features, performing a sensitivity analysis, and evaluating cluster predictability with several classifiers. Finally, we use deep models to provide quantitative insight into the relationships between morphology and intrinsic physiology to group INs, and reveal the degree to which particular features (such as somatic depth location) are predictive of an IN's morphological and/or intrinsic physiological type.

LOCAL NETWORK EFFECTS OF SINGLE CELL STIMULATION IN THE SOMATOSENSORY CORTEX OF ANESTHETIZED RATS

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Beate Knauer, Maik Stüttgen
University Medical Center of the Johannes Gutenberg University Mainz, Institute Of Pathophysiology, Mainz, Germany

Evidence of single cell stimulation affecting cortical activity, animal behavior and presumed percepts keeps accumulating. Nonetheless, the understanding of how these effects are mediated via the local network level remains limited. We aim to complement the current knowledge by investigating the effect of single cell stimulations in rat somatosensory cortex on neurons in the immediate vicinity. To this end, we kept Wistar rats (~300 g) under general anesthesia (Medetomidin, Midazolam, Fentanyl) whilst acutely placing a silicon probe (32 contacts) in the somatosensory cortex and sampling local network activity along the entire cortical depth. At a lateral distance of ~200-300 µm and in any cortical layer, single neurons were stimulated with 220 ms square current pulses (juxtacellular configuration). We stimulated ~100 individual neurons and simultaneously recorded >3000 local network units. On average, the single cells spiked at ~25±15 Hz (maximum instantaneous firing rates of ~100±70 Hz) during stimulation, versus ~3 Hz during baseline. The network recordings contained ~25% single units. While the concerted local network effect of the induced single cell activity was significantly different from baseline, the overall change in firing rate remained below 0.2 Hz. We found that the majority of network units was unaffected by single-cell firing, but a minority of local network units showed significant activity alterations in both directions. In sum, effects of single cell stimulation onto local network units in the somatosensory cortex are small. An in-depth analysis highlights the factors impacting transmission characteristics and helps to understand principles governing single cell effects.

CONTINUITY WITHIN THE SOMATOSENSORY CORTICAL MAP FACILITATES LEARNING

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Henri Lassagne[1], Dorian Goueytes[2], Daniel Shulz[1], Luc Estebanez[2], Valérie Ego-Stengel[1]
[1]Paris-Saclay Institute of Neuroscience, Université Paris Saclay, CNRS, Department Of Integrative And Computational Neuroscience, Saclay, France, [2]Paris-Saclay Institute of Neuroscience, Department Of Integrative And Computational Neuroscience, Gif sur Yvette, France

The topographic organization of sensory cortices is a prominent feature, but its functional role remains controversial. Particularly, it is still unknown how integration of activity within a cortical area depends on its topography during sensory-guided behavior. Here, we trained water-restricted mice expressing channelrhodopsin in cortical excitatory neurons to track a photostimulation bar that rotated continuously over the primary somatosensory cortex (S1). Mice could obtain reward by licking while the photostimulation resided within a specific range of angles. When the photostimulation was aimed at the whisker representation in S1, which contains a continuous representation of the animal whiskers, mice could learn to discriminate angular positions of the bar to obtain rewards. In contrast, they failed to learn the task in three other conditions: 1) when the spatiotemporal continuity of the photostimulation was disrupted, 2) when the photostimulation was aimed at the representation of the trunk and legs in S1, which contains multiple map discontinuities and 3) when the photostimulation was done on the posterior parietal cortex that does not contain a topographic map. Mice demonstrated anticipation of reward availability, specifically when cortical topography enabled to predict future sensory activation. These findings are particularly helpful for designing efficient sensory neuroprostheses that rely on direct cortical stimulation.

BRADYCARDIA INDUCED BY CARDIAC BIOFEEDBACK TO RAT SOMATOSENSORY CORTEX

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Airi Yoshimoto[1], Nobuyoshi Matsumoto[1], Yuji Ikegaya[1,2]
[1]The University of Tokyo, Graduate School Of Pharmaceutical Sciences, Faculty Of Pharmaceutical Sciences, Tokyo, Japan, [2]The University of Tokyo, Institute For Ai And Beyond, Tokyo, Japan

Biofeedback is a therapy that helps humans to recognize and voluntarily control their unconscious bodily functions. The biofeedback-training has been proven effective for clinical application; however, the neural mechanism that enables the biofeedback has not been fully elucidated. Herein, as a pioneer of animals' biofeedback experiments, we established a heartrate (HR)-feedback system using electrocardiograms (ECGs) of rats. We recorded instantaneous HR from ECGs and immediately presented it to rats by electrical stimulation of the right or left barrel cortex depending on whether the current HR was higher or lower than the target HR, respectively. When rats were able to maintain their HRs below the target HR for 10 s, the medial forebrain bundle was stimulated as a neural reward. We demonstrated that rats reduced their HRs by 50% via the cardiac biofeedback. We recorded local field potentials (LFPs) from the anterior cingulate cortex (ACC) and found that the theta oscillation power was enhanced while rats kept their HRs low, consistent with the fact that the theta oscillation power increases in the human ACC during meditation. We investigated the effect of HR-feedback training on anxiety using the elevated plus maze test. The HRs were high when rats walked in the open arms before the feedback training, but the HRs became lower even in the open arms after the training. Our HR-feedback system using model animals will open the door for neuroscientists to investigate the mechanisms and significance of volitional control of cardiac function.

Acute Ramelteon Treatment Maintains the Cardiac Rhythms of Rats during Non-REM Sleep.
Sleep curtailment negatively affects cardiac activities and thus should be ameliorated by pharmacological methods. One of the therapeutic targets is melatonin receptors, which tune circadian rhythms. Ramelteon, a melatonin MT/MT receptor agonist, has recently been developed to modulate sleep-wake rhythms. To date, the sleep-promoting effect of ramelteon has been widely delineated, but whether ramelteon treatment physiologically influences cardiac function is not well understood. To address this question, we recorded electrocardiograms, electromyograms, and electrocorticograms in the frontal cortex and the olfactory bulb of unrestrained rats treated with either ramelteon or vehicle. We detected vigilance states based on physiological measurements and analyzed cardiac and muscular activities. We found that during non-rapid eye movement (non-REM) sleep, heartrate variability was maintained by ramelteon treatment. Analysis of the electromyograms confirmed that neither microarousal during non-REM sleep nor the occupancy of phasic periods during REM sleep was altered by ramelteon. Our results indicate that ramelteon has a remedial effect on cardiac activity by keeping the heartrate variability and may reduce cardiac dysfunction during sleep.

Ramelteon modulates gamma oscillations in the rat primary motor cortex during non-REM sleep.
Sleep disorders adversely affect daily activities and cause physiological and psychiatric problems. The shortcomings of benzodiazepine hypnotics have led to the development of ramelteon, a melatonin MT and MT agonist. Although the sleep-promoting effects of ramelteon have been documented, few studies have precisely investigated the structure of sleep and neural oscillatory activities. In this study, we recorded electrocorticograms in the primary motor cortex, the primary somatosensory cortex and the olfactory bulb as well as electromyograms in unrestrained rats treated with either ramelteon or vehicle. A neural-oscillation-based algorithm was used to classify the behavior of the rats into three vigilance states (e.g., awake, rapid eye movement (REM) sleep, and non-REM (NREM) sleep). Moreover, we investigated the region-, frequency- and state-specific modulation of extracellular oscillations in the ramelteon-treated rats. We demonstrated that in contrast to benzodiazepine treatment, ramelteon treatment promoted NREM sleep and enhanced fast gamma power in the primary motor cortex during NREM sleep, while REM sleep was unaffected. Gamma oscillations locally coordinate neuronal firing, and thus, ramelteon modulates neural oscillations in sleep states in a unique manner and may contribute to off-line

information processing during sleep.

Delayed reinforcement hinders subsequent extinction.
In operant conditioning, animals associate their own behavior with a reinforcer, and the probability of the behavioral responses is increased. This form of learning is called reinforcement. In contrast, when the previously reinforced responses are no longer paired with a reinforcer, these responses are eventually extinguished. The effectiveness of reinforcement depends primarily on time intervals between reinforcers and responses, but it is not fully understood how the intervals affect subsequent extinction. To address this question, we performed electrical stimulation of the rat medial forebrain bundle (MFB), a part of the brain reward system, and an operant task in which the MFB was electrically stimulated 0.1 s (immediate condition) or 1 s (delayed condition) after the rat's nose was poked. During the first half of the task period (a reinforcement period), nose pokes were associated with MFB stimulation. In contrast, during the second half (an extinction period), we did not stimulate the MFB irrespective of nose pokes. We found that rats exhibited increased nose-poke behaviors during the reinforcement period under both conditions, whereas during the extinction period, nose pokes were more persistent in the delayed condition than in the immediate condition. The persistent responses in the extinction period were independent of responses in the reinforcement period. Therefore, reinforcement and extinction are driven by independent neural mechanisms.

BRAIN ACTIVATION DURING AFFECTIVE TOUCH CHANGES WITH THE “HUNGER HORMONE" GHRELIN

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Daniela M. Pfabigan, Uta Sailer
University of Oslo, Department Of Behavioural Medicine, Oslo, Norway

The “hunger hormone” ghrelin stimulates appetite and increases food intake. Evidence in both animals and humans suggests that ghrelin also affects the motivation to obtain and consume other types of rewards such as alcohol or drugs. This pre-registered neuroimaging study investigated whether ghrelin’s effects extend to social rewards, namely affective touch, in humans. Sixty-eight volunteers received social-affective touch and control touch on their shins during 3T functional imaging on two test days. On one day, participants stayed fasted, on the other day they received a meal to change ghrelin levels, assessed in plasma at three time points each day. All touch was rated as more pleasant after the meal, but ghrelin levels were not associated with experienced pleasantness. A region-of-interest associated with reward processing, right medial orbitofrontal cortex (mOFC), showed decreased activation during all touch when ghrelin levels were high. During affective touch, larger ghrelin suppression following the meal was associated with higher mOFC activation, which in turn was associated with higher experienced pleasantness. Overall, high ghrelin levels appear to reduce reward-related brain activation, which is in line with suggestions that ghrelin carries a negative valence signal. However, the negative valence did not transfer to subjective experience. The findings suggest that the effects of naturally circulating ghrelin levels might be restricted to conscious perception. The lower touch pleasantness when fasted can more likely be attributed to other factors that come along with energy deprivation, such as altered interoception.

COEXISTING NEURONAL CODING STRATEGIES IN THE BARREL CORTEX

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Rony Azouz
Ben-Gurion University of The Negev, Physiology And Cell Biology, Beer Sheba, Israel

During tactile sensation by rodents, whisker movements across surfaces generate complex whisker motions, including discrete, transient stick-slip events, which carry information about surface properties. The characteristics of these events and how the brain encodes this tactile information remain enigmatic. We found that cortical neurons show a mixture of synchronized and non-temporally correlated spikes in their tactile responses. Synchronous spikes convey the magnitude of stick-slip events by numerous aspects of temporal coding. These spikes show preferential selectivity for kinetic and kinematic whisker motion. By contrast, asynchronous spikes in each neuron convey the magnitude of stick-slip events by their discharge rates, response probability, and inter-spike intervals. We further show that the differentiation between these two types of activity is highly dependent on the magnitude of stick-slip events and stimulus and response history. These results suggest that cortical neurons transmit multiple components of tactile information through numerous coding strategies.

DISENTANGLING A L2/3 VIP CELL TO L4 SST CELL CIRCUIT MOTIF ACROSS PRIMARY SOMATOSENSORY AND VISUAL CORTICES OF MOUSE

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Jenifer Rachel, Martin Möck, Mirko Witte, Jochen Staiger
Institute for Neuroanatomy, University Medical Centre Göttingen, Göttingen, Germany

Aims: The vasoactive intestinal polypeptide (VIP) to somatostatin (SST) neuron motif has mostly been studied within cortical L2/3. Connectivity across layers and the role of neuronal subtypes as targets remain unknown. Taking advantage of the recently discovered morphological differences between L4 SSTs of primary somatosensory (S1) and visual (V1) cortices, we studied if morphological differences manifest functionally in the L2/3 VIP to L4 SST motif in S1 and V1 cortices. **Methods:** Fluorescence-expressing transgenic mice were used to target VIPs and SSTs. We performed whole-cell patch-clamp recordings in slices to characterize SST cells and performed paired recordings of L2/3 VIP and L4 SST in S1 and V1. Morphology was systematically recovered. **Results:** 81% of SSTs in S1 and 55% in V1 were classified as non-Martinotti and Martinotti-type respectively, based on observable axonal arborization. L4 SSTs in S1 had lower time constant, lower input resistance and higher rheobase compared to V1. In paired recordings, unitary synaptic properties of VIP onto SST were largely similar. Short-term plasticity (STP) was studied at 1, 10, and 50 Hz. Connections in both cortices either showed no STP at any tested frequency or short-term facilitation during 50Hz stimulation. Strikingly, a distinct population of connections in S1, but not V1, exhibited measurable short-term depression at 50Hz. **Conclusion:** The VIP to SST motif is largely comparable between S1 and V1 in unitary connectivity properties, despite differential morphology of target SSTs. However, the equivalent circuit differs in high-frequency responses, resulting in differential electro-morphological circuit motifs across S1 and V1 cortices.

CIRCADIAN DYNAMICS OF PAW WITHDRAWAL RESPONSES IN A MOUSE MODEL OF INFLAMMATORY INDUCED MECHANICAL HYPERSENSITIVITY

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Phong Chau, Somayeh Ezzatpanah, Fred Haugen
National Institute of Occupational Health, Aml, Oslo, Norway

Aims In mammals, the internal molecular circadian systems generate its own oscillation and control the clock genes to keep the daily rhythm of various physiological and behaviour events operated functionally. Understanding of the daily rhythmicity in nociception is important for preventive interventions to minimize occupational pain, as well as standardization of animal studies. Our aim was to investigate daily rhythmicity in nociception and peripheral gene expression. *Methods* To study the phenomenon, we performed the well-established intraplanar Complete Freund's Adjuvant (CFA) model of mechanical allodynia. Mice were housed in a 12:12 hour light-dark cycle and unilaterally injected with CFA in the hind-paw, and saline in the contralateral paw (control). Then, we performed a mechanical stimulation assay of the paw using von-Frey filaments and assayed withdrawal behaviours at specific time points after the onset of light, described as *zeitgeber time* (ZT): 4ZT, 12ZT, 20ZT. Independent behavioural tests were also carried out at different times after CFA injection: 3-, 5- and 7-days post injection. Dorsal root ganglion (DRG) gene expression was studied using mRNA-seq and ddPCR. *Results and conclusions* The mechanical threshold for withdrawal of the CFA-injected paw showed circadian oscillation. It reached the peak during the light phase while it remained lower in the dark phase. The circadian influence on withdrawal behaviour was more evident in the acute phase of inflammation, day 3 after injection and less on day 5, 7. Furthermore, DRG gene expression showed circadian variation. Our data suggest a link between circadian rhythms and mechanical hypersensitivity.

BARREL CORTEX IS NOT NECESSARY FOR GAP-CROSSING BEHAVIOR IN MICE WITH INTACT WHISKER-PAD

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Aron De Miranda, Léa Peltier, Frederic Gambino
Bordeaux University, Interdisciplinary Institute For Neuroscience, Umr 5297 Cnrs, Bordeaux, France

The barrel cortex is claimed to be indispensable for complex behavioral tasks. However, it is common that experimenters use partially sensory deprived rodents for the sake of controlling tactile stimulation. For example, rodents can have all but one facial whisker trimmed, a condition called single-whisker experience (SWE), known to cause a functional reorganization of the primary somatosensory maps. During SWE, whisker-dependent behaviors are initially impaired, but recover after cortical whisker associated regions remap. We asked to what extent barrel cortex task-relevant computations in a complex behavioral task rely on a complete whisker-pad. For that, we examined the effects of excitotoxic lesions of the barrel cortex of mice performing the gap-crossing task, a task that requires mice actively use their whiskers to cross over a gap between the two platforms in order to get a reward. Bilateral barrel cortex lesions induced mild behavioral deficits in expert mice with intact whiskers after re-exposure to the task, with mice recovering full task performance by the subsequent session. Similarly, bilateral barrel cortex lesions had no effect on task learning in mice with all whiskers intact. As expected, pre and post task acquisition lesioned groups submitted to SWE showed impaired recovery of previously learned gap-crossing skills. Our results show mice with an intact whisker-pad can reach full recovery of behavioral skills in the gap-crossing task after bilateral barrel cortex lesions, suggesting the functional relevance of primary somatosensory barrel cortex to active detection may rely on its sensory inputs remapping capacities.

QUANTIFICATION OF AXONAL PROJECTIONS FROM NEURONS LOCATED IN LAYERS 2/3, 5 AND 6 OF MOUSE BARREL CORTEX

POSTER SESSION 04 - SECTION: SOMATOSENSORY PROCESSING

Yanqi Liu, Lucas Délez, Sylvain Crochet, Carl Petersen
Ecole Polytechnique Fédérale de Lausanne (EPFL), Brain Mind Institute, Laboratory Of Sensory Processing, Lausanne, Switzerland

Mice are nocturnal animals that rely heavily on their whiskers to sense the outside world. Whisker sensory information arriving from the ventral posterior medial nucleus of the thalamus is processed in the primary whisker somatosensory cortex (also known as the barrel cortex, S1-bfd). Projection neurons in S1-bfd in turn signal to various downstream brain areas including motor cortex, secondary sensory cortex, striatum, superior colliculus, thalamus, pons and brain stem. Different classes of S1-bfd neurons innervate different targets, but the precise organisation and quantification of axonal innervation remains to be determined. Here, we use adenoassociated viral (AAV) vectors to express fluorescent proteins in genetically-defined neuronal classes in S1-bfd. We injected Cre-dependent AAVs into various Cre-driver mice in order to express GFP and/or tdTomato in layer 2/3 (Rasgrf2-dCre), layer 5 (Sim1-Cre, Tlx3-Cre and Rbp4-Cre) and layer 6 (Ntsr1-Cre). After several weeks of expression, the fixed brains were immunostained and cleared through a variant of iDISCO (Renier et al., Cell 2014). Volumetric brain images were acquired by a MesoSPIM light sheet microscope (Voigt et al., Nat. Methods 2019). Voxels containing axons were segmented using TrailMap, a trained 3D convolutional network (Friedmann et al., PNAS 2020). Finally, images were aligned to the Allen mouse brain atlas (Wang et al., Cell 2020), and axonal length was quantified according to the annotated parcellations. Consistent with previous work, we find different projection patterns from each of the Cre-driver lines. Our results provide anatomical bases for functional connectivity contributing to the brain-wide processing of whisker-related sensorimotor information.

VISUAL PROPERTIES OF CELL-TYPE SPECIFIC CORTICO-COLLICULAR INPUTS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Katja Reinhard[1,2], Chen Li[1,2], Ben Vermaercke[1,2,3], Alex Calzoni[1,2], Norma Kühn[1,2], Karl Farrow[1,2,4]

Innate aversive reactions to threat are mediated by circuits through the superior colliculus. In the mouse superior colliculus, a set of genetically identifiable cell types trigger different reactions by connecting relevant visual information from the retina to distinct behaviour-mediating targets. In addition to retinal inputs, these collicular neurons also receive inputs from the visual cortex. However, it is unknown whether the visual features received from cortex and retina are the same. Alternatively, cortical inputs might alter innate reactions by providing information about other aspects of the animal's environment. To address this question, we set out to characterize visual properties of cell-type specific cortico-collicular inputs. The calcium sensor GCaMP6f was expressed in layer 5 cortical cells projecting to $Ntsr^+$ (involved in freezing) or Grp^+ (involved in escape) collicular neurons using transsynaptic rabies tracing in different mouse lines (NTSR-GN209-Cre and GRP-KH288-Cre). We found that unique combinations of visual cortical areas project to different cell types in the colliculus. Further, 2-photon calcium imaging of cortical inputs to $Ntsr^+$ neurons during visual stimulation revealed preferences for looming disks and various combinations of small/big and fast/slow objects. This only partially overlaps with the information that $Ntsr^+$ neurons receive from the retina. Ongoing analysis will reveal whether different cortical areas send distinct distributions of visual features to the colliculus. Finally, by comparing visual preferences of neurons projecting to $Ntsr^+$ and Grp^+ cells, we will determine if cells involved in different behaviours receive the same or different sets of visual information from the cortex.

FEATURE SELECTIVITY OF COLLICULAR WIDE-FIELD NEURONS IS GENERATED BY STRATIFIED INPUTS AND NONLINEAR DENDRITIC FILTERING

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Norma Kühn, Chen Li, Natalia Baimacheva, Katja Reinhard, Janne Zimmer, Vincent Bonin, Karl Farrow
imec, VIB, KU Leuven, Neuro-electronics Research Flanders (nerf), Leuven, Belgium

The rules by which neurons combine their inputs to generate the appropriate output are key to brain function. While we know about the computational power of dendrites, how they help to filter sensory information to produce a neuron's output and drive behavior is underexplored due to the inability to trace inputs back to their sensory origin. Here, we address this problem using wide-field (WF) neurons of the mouse superior colliculus; a genetically targetable cell-type that receives direct input from the retina and mediates innate orienting behaviors. To understand how WF neurons combine their inputs, we use a combination of viral tracing and two-photon imaging to measure the visual responses in the dendrites and cell-bodies of WF neurons, as well as from their retinal inputs and local inhibitory inputs. Linear mapping of the retinal and inhibitory signals along the dendrites of WF neurons reveals distinct layers where specific inputs arrive. While a linear model fails to reconstruct the responses of WF cell-bodies, a non-linear model with at least two input layers accounts for the identified input structure and adequately reconstructs the cell-body responses. Our findings suggest that WF neuron dendrites have the capability to nonlinearly filter specific feature combinations from their diverse stratified inputs. To which extent each retinal cell-type contributes to WF signaling, remains to be uncovered by targeted manipulation thereof. Here, we established WF neurons as a unique model system to study the role of dendritic processing on the filtering of sensory information and its impact on behavior.

DETERMINING THE ROLE OF DEFINED CELL TYPES OF THE MOUSE SUPERIOR COLLICULUS IN VISUAL FIELD-DEPENDENT BEHAVIORS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Alex Calzoni[1,2,3,4], Chen Li[1,2,3,4], Arnau Sans Dublanc[1,2,3,4], Karl Farrow[1,2,3,4,5]
[1]KU Leuven, Neuro-electronics Research Flanders, Leuven, Belgium, [2]KU Leuven, Vib, Leuven, Belgium, [3]KU Leuven, Department Of Biology & Leuven Brain Institute, Leuven, Belgium, [4]KU Leuven, Imec, Leuven, Belgium, [5]KU Leuven, Biology, Leuven, Belgium

Innate behaviors are essential for survival. Visual cues mimicking a predator elicit freezing or escape reactions, whereas those indicative of prey attract an animal's attention and prompt approach responses. Surprisingly, these different outcomes can be triggered by merely altering the position of the stimulus in the visual field. Both aversion and approach are mediated by a set of visuomotor circuits passing through the superior colliculus (SC). We know that certain collicular cell types subserve specific actions via dedicated output pathways. However, how these neurons encode behaviorally- salient visual features and whether their responses and circuits change according to the portion of the visual field they look at remains unknown. This project aims to investigate the role of genetically identified wide-field (WF) and narrow-field (NF) neurons of the mouse SC in driving behaviors evoked by ethologically-relevant stimuli in the upper and lower visual field. To achieve this, we will delineate the brain-wide circuit motifs of WF and NF neurons in different retinotopic regions via viral tracing methods and characterize their response properties to visual stimuli across the visual field with Neuropixels probe recordings. Finally, we will employ optogenetic inactivation of WF and NF cell activity to determine the effect of their retinotopic location on behavior. Together, these results will provide a structural and functional basis to understand how SC topography and cell types underlie visual field-dependent behaviors, and more generally how visual information is encoded and disseminated to trigger the appropriate motor response.

The output of the retina is carried by retinal ganglion cells (RGCs) along parallel functional pathways to multiple areas distributed across the vertebrate brain. Our aim was to better describe the functional organization of the synaptic connections between RGCs and their postsynaptic target neurons. Using tangential insertions of high-density Neuropixels probes in the mouse Superior Colliculus (SC, *Mus musculus*), we discovered that this method allows the measurement of large populations of RGC axons where they form synaptic contacts in SC, *in vivo*. The electrophysiological signature of RGC afferent inputs is made of a triphasic waveform composed of the axonal action potential, the axonal terminal response and, finally, the corresponding responses from the synaptically connected dendrites. Consequently, SC neurons can be recorded simultaneously with their presynaptic RGC inputs at large scales, which we also confirmed is possible in the avian optic tectum (zebra finch, *Taeniopygia guttata*). Taking advantage of the spatial resolution of high-density Neuropixels probes we studied the spatial location of RGC axons in SC and we discovered that the RGC axons isomorphically map the retinal mosaic into the upper visual layers of SC. Functionally, we show that RGC axons connect to their target neurons with limited functional convergence and log-normally distributed connection strength. Overall these results allow us to conclude that the retinotectal connectivity would possibly follow a common organizing principle in mammals and birds that provides a precise and reliable representation of the visual world to neurons in the midbrain.

THALAMIC PROJECTION GABAERGIC NEURONS: RETINAL INPUT AND FUNCTION IN VIGILANCE STATE TRANSITIONS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Peter Sully[1], Cigdem Gelegen[1], Irene Salgarella[1], Polona Jager[2], Olivier Brock[1], Samuel Cooke[1], Alessio Delogu[1]
[1]King's College London, Basic And Clinical Neuroscience, London, United Kingdom, [2]VIB - KU Leuven, Center For Brain & Disease Research, Leuven, Belgium

Thalamic functions are executed primarily by glutamatergic thalamocortical neurons that extend axons to the cortex and initiate cortico-thalamocortical connectional loops. However, thalamic nucleic can contain GABAergic neurons that project to other subcortical structures but do not directly communicate with the cortex. Recent improvements in the understanding of intergeniculate (IGL) and ventrolateral geniculate (LGv) nuclei development allow us to specifically target and manipulate projecting GABAergic neurons in the mouse thalamus. We mapped the retinal input to thalamus-derived cells in the IGL/LGv complex and discovered that while ipRGC input is dominant, this is not likely to originate from M1-ipRGCs. Using EEG/EMG recordings in freely moving mice kept in standard circadian lighting conditions, we implicate thalamic cells in the IGL/LGv in vigilance state transitions at circadian light changes. Our data suggest that GABA projection neurons play a complementary role to thalamocortical networks in the thalamic control of vigilance states. Keywords: thalamus, intergeniculate leaflet, ventral lateral geniculate nucleus, ipRGCs, sleep, vigilance states, EEG.

THE VISUAL LAYERS OF THE SUPERIOR COLLICULUS ENCODE SACCADE DIRECTION

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Anja Schwartzlose[1], L. Federico Rossi[2], Sylvia Schröder[3]
[1]Universität Basel, Biozentrum, Basel, Switzerland, [2]University College London, Wolfson Institute For Biomedical Research, London, United Kingdom, [3]University of Sussex, School Of Life Sciences, Brighton, United Kingdom

During active exploration, vision must compensate for visual input generated by retinal displacement: for example, visual responses are thought to be suppressed during voluntary eye movements called saccades. Here we investigated how saccades affect neural activity in the visual layers of the mouse superior colliculus (SC), a crucial visuo-motor structure governing orienting movements. We virally expressed GCaMP6f in the visual layers of SC of GAD-tdTomato mice, and used two-photon imaging to record the activity of excitatory and inhibitory neurons during spontaneous eye movements. Mice were head-fixed on a spherical treadmill in front of a gray screen, while we tracked running speed, eye position and pupil size. We found that, despite the absence of visual stimulation, one third (34±15% st.d., 1262 neurons, 8 mice) of SC neurons responded significantly around saccade onset. Inhibitory neurons (40%) responded almost twice as likely as excitatory neurons (24%). These motor responses were selective for saccade direction: ipsilateral saccades elicited responses in more neurons (53%) than contralateral saccades (27%). 50±15% of responsive neurons were suppressed and 44±11% were activated by saccades, while a minority (7±7%) were activated by one saccade direction and suppressed by the other. Saccade responses did not depend on changes in pupil diameter or locomotion, and were also observed during extracellular spike recordings with Neuropixels probes in complete darkness. In conclusion, we demonstrate that saccades do not merely inhibit visual processing in the SC, rather they are encoded through activation or suppression of neurons that are selective to saccade direction.

MODULATION BY SEROTONIN OF RETINAL GANGLION CELL BOUTONS IN THE DORSOLATERAL GENICULATE NUCLEUS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Jasmine Reggiani[1], Qiufen Jiang[2], Melanie Barbini[3], Jesseba Fernando[3], Andrew Lutas[3], Chinfei Chen[2], Mark Andermann[3]
[1]Harvard University, Dms, Boston, United States of America, [2]Boston Children's Hospital, Neurobiology, Boston, United States of America, [3]Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, United States of America

Throughout the brain, the processing of sensory information is modulated to guide adaptive behaviors. Here, we investigate how serotonergic axons may specifically gate visual inputs at the level of retinal ganglion cell (RGC) axon terminals, prior to further integration and processing of sensory information in the thalamus. Bulk recordings of RGC axons showed that baseline and visually evoked calcium activity and glutamate release were suppressed by serotonin axon stimulation. Two-photon calcium imaging revealed that retinal axons preferring fullfield changes in luminance were more suppressed than those driven selectively by spatially localized stimuli, even when accounting for differences in each axon's baseline activity. Slice electrophysiology confirmed that serotonergic axon-evoked suppression of retinal glutamate release depends on presynaptic 5-HT1B receptors. Using single-cell sequencing, whole-mount electrophysiology and immunohistochemistry, we demonstrate differences in 5-HT1B receptor gene expression and axonal protein expression between RGCs that prefer fullfield changes in luminance vs. local stimuli. These data suggest a mechanism by which serotonin axons selectively gate specific visual information channels.

Retinal Inputs to the Thalamus Are Selectively Gated by Arousal.
The brain can flexibly filter out sensory information in a manner that depends on behavioral state. In the visual thalamus and cortex, arousal and locomotion are associated with changes in the magnitude of responses to visual stimuli. Here, we asked whether such modulation of visual responses might already occur at an earlier stage in this visual pathway. We measured neural activity of retinal axons using wide-field and two-photon calcium imaging in awake mouse thalamus across arousal states associated with different pupil sizes. Surprisingly, visual responses to drifting gratings in retinal axonal boutons were robustly modulated by arousal level in a manner that varied across stimulus dimensions and across functionally distinct subsets of boutons. At low and intermediate spatial frequencies, the majority of boutons were suppressed by arousal. In contrast, at high spatial frequencies, boutons tuned to regions of visual space ahead of the mouse showed enhancement of responses. Arousal-related modulation also varied with a bouton's preference for luminance changes and direction or axis of motion, with greater response suppression in boutons tuned to luminance decrements versus increments, and in boutons preferring motion along directions or axes of optic flow. Together, our results suggest that differential modulation of distinct visual information channels by arousal state occurs at very early stages of visual processing, before the information is transmitted to neurons in visual thalamus. Such early filtering may provide an efficient means of optimizing central visual processing and perception across behavioral contexts.

Tbr1 instructs laminar patterning of retinal ganglion cell dendrites.
Visual information is delivered to the brain by >40 types of retinal ganglion cells (RGCs). Diversity in this representation arises within the inner plexiform layer (IPL), where dendrites of each RGC type are restricted to specific sublaminae, limiting the interneuronal types that can innervate them. How such dendritic restriction arises is unclear. We show that the transcription factor Tbr1 is expressed by four mouse RGC types with dendrites in the outer IPL and is required for their laminar specification. Loss of Tbr1 results in elaboration of dendrites within the inner IPL, while misexpression in other cells retargets their neurites to the outer IPL. Two transmembrane molecules, Sorcs3 and Cdh8, act as effectors of the Tbr1-controlled lamination program. However, they are expressed in just one Tbr1 RGC type, supporting a model in which a single transcription factor implements similar laminar choices in distinct cell types by recruiting partially non-overlapping effectors.

ANTAGONISTIC VISUOSPATIAL CIRCUITS IN THE SUPERIOR COLLICULUS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Kuisong Song[1], Peng Cui[1], Arturo Isla[1], Dimitris Mariatos[1], Iakovos Lazaridis[2], Konstantinos Meletis[1], Arvind Kumar[3], Andreas Kardamakis[1]
[1]Karolinska Institutet, Neuroscience, Solna, Sweden, [2]MIT, Mcgovern Institute, Boston, United States of America, [3]KTH Royal Institute of Technology, School Of Electrical Engineering And Computer Science, Stockholm, Sweden

Early visual processes are subject to surround modulation thought to be important for perception, yet the circuit mechanisms still remain under debate. We therefore developed a generic optogenetic-based physiological approach that enables the precise determination and selective activation of a visual neuron's center or surround zone in the superficial layer of the superior colliculus (SCs). To study the synaptic interaction between these areas, we used whole-cell recordings from a wide-range of interneuronal subtypes in response to patterned optostimulation of incoming retinal axonal terminals expressing channelrhodopsin. Together with cell-type-specific transsynaptic mapping, in vivo optostimulation, and computational modelling, we demonstrate how local retinal inputs can trigger a strong regime of recurrent interactions amongst glutamatergic and GABAergic SCs interneurons in center and surround zones across the collicular map of visual space. We show that surround modulation, on the other hand, does not result in increased inhibition but it rather modifies the net excitability by weakening the efficacy of local amplification provided by recurrent excitation. This two-step antagonistic computation, which is carried out within the SCs, may provide the flexibility for upstream circuits to intervene and selectively manipulate downstream visual-based behavior.

A surface-display biohybrid approach to light-driven hydrogen production in air.
Solar-to-chemical production by artificial and bioinspired photosynthetic systems is of tremendous interest to help solve current global energy and environmental problems. We developed a bioinorganic hybrid system for photocatalytic hydrogen production under aerobic conditions by combining light-harvesting semiconductors, hydrogenase catalysis, and self-aggregation of whole bacterial cells. We induced hydrogen production via self-photosynthesis in engineered cells, which were originally designed for bioremediation, with in situ biosynthesis of biocompatible cadmium sulfide nanoparticles using a surface-display system. We also introduced a biomimetic silica encapsulation strategy into the engineered cells, enabling this hybrid system to continuously produce hydrogen for 96 hours, even under natural aerobic conditions. This biohybrid catalytic approach may serve as a general strategy for solar-to-chemical production.

RECURRENT CORTICAL CONNECTIVITY IN THE PRIMARY VISUAL CORTEX SUPPORTS ROBUST ENCODING OF NATURAL SENSORY INPUTS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Hugo Ladret[1,2], Laurent Perrinet[1], Frederic Chavane[1]
[1]Aix-Marseille Université, Institut Des Neurosciences De La Timone, Marseille, France, [2]Université de Montréal, School Of Optometry, Montréal, Canada

Predictive coding (*PC*) describes the brain as an organ of inference which builds an internal model of its environment to optimize its behaviour. This internal model constantly self-updates by computing the error of its predictions compared to the actual sensory input. Said sensory input comes, in our everyday world, in the form of heterogeneous features distributions, whose variances are highly volatile. Given the mounting evidence for PC to take place in the brain, it is physiologically likely, and mathematically required by PC, that the visual cortex possesses a mechanism that estimates the precision of its sensory inputs. Here, we record the electrophysiological responses of primary visual cortex (*V1*) neurons to naturalistic stimuli of varying precision. Using a model-driven analysis, we report two distinct, layer-specific populations in V1 : infragranular neurons encoding the sensory feature of stimuli, and supragranular neurons co-encoding both the feature and its precision. A machine learning-based neural decoder shows that these precision-specific neural units also implement precision-specific population dynamics. We use a recurrent spiking neural network to causally demonstrate that the presence of precision-selective activity stems from the different strength of recurrent inhibition between cortical neurons. Overall, we provide experimental and computational evidences to pinpoint the neural substrate of precision computations, which is a major milestone to support the theory of predictive coding.

ASYMMETRIC INFORMATION FLOW IN MOUSE HIGHER VISUAL AREAS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Hiromichi Ishida[1], Tomonari Murakami[1,2,3], Kenichi Ohki[1,2,3]
[1]University of Tokyo, Department Of Physiology, Tokyo, Japan, [2]University of Tokyo, Wpi-ircn, Tokyo, Japan, [3]Univertiy of Tokyo, Beyond Ai Institute, Tokyo, Japan

In visual areas of mammals, there are functionally parallel ventral and dorsal pathways, and visual information is processed hierarchically in each pathway. Mouse higher visual areas (HVAs) can be grouped into ventral streams (LM, LI, P, POR) and dorsal streams (AL, RL, A, AM, PM). Visual hierarchy in mice has been estimated anatomically and physiologically using response latency and others. However, these estimations did not consider the causal relation between lower and higher areas. If visual information flows mostly from lower to higher areas, inhibition of the lower area will suppress the visual response in the higher area, but inhibition of the higher area will not significantly suppress the response in the lower area. We tested this idea with a combination of wide-field calcium imaging and optogenetics. Excitatory opsin was expressed in the inhibitory neurons of mouse visual cortex. While presenting various drifting gratings, we inhibited a specific visual area at a time, then we compared visual responses of each area with and without opto-inhibition of specific visual areas. We found that LM in mice is a gateway of visual information from V1. Inhibiting LM reduced responses of all other HVAs including AL and LI, while inhibiting AL or LI had a minor effect of LM responses. Similar inhibition asymmetry was also observed in the dorsal stream: AL inhibition suppresses RL responses, but not the other way around. Thus, information flows hierarchically between mouse HVAs. Our new method provides a way to determine the cortical hierarchy based on causal relationships.

A TRANSCRIPTOMIC AXIS PREDICTS STATE MODULATION OF CORTICAL INTERNEURONS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Stephane Bugeon[1], Joshua Duffield[1], Mario Dipoppa[1], Anne Ritoux[1], Isabelle Prankerd[1], Dimitris Nicoloustopoulos[1], David Orme[1], Maxwell Shinn[1], Han Peng[2], Hamish Forrest[1], Aiste Viduolyte[1], Charu Bai Reddy[1], Yoh Isogai[3], Matteo Carandini[4], Kenneth Harris[1]

[Aims] Transcriptomics has revealed that cortical inhibitory neurons exhibit a great diversity of fine molecular subtypes, but it is not known whether these subtypes have correspondingly diverse activity patterns in the living brain. [Methods] We combined in vivo 2-photon calcium imaging of mouse V1 with a novel transcriptomic method to identify mRNAs for 72 selected genes in ex vivo slices. Based on these mRNAs, we classified inhibitory neurons imaged in layers 1-3 into a three-level hierarchy of 5 Families, 11 Types, and 35 Subtypes. [Results] Visual responses differed significantly only across Families: visual stimuli suppressed cells in the Sncg Family while driving cells in the Pvalb, Sst, Vip, and Lamp5 Families. Modulation by brain state differed at all hierarchical levels, but could be largely predicted from a single transcriptomic axis, the first transcriptomic principal component, which also predicted correlations with simultaneously recorded cells. Inhibitory Subtypes that fired more in resting, oscillatory brain states have narrower spikes, lower input resistance, weaker adaptation, and less axon in layer 1 as determined in vitro and express more inhibitory cholinergic receptors, as determined in single-cell RNA sequencing data. Subtypes firing more during arousal have the opposite properties. [Conclusions] We conclude that inhibitory subtypes in primary visual cortex (V1) have diverse correlates with brain state, but that this diversity is organised by a single factor: position along their main axis of transcriptomic variation.

FUNCTIONAL ANATOMICAL ORGANIZATION OF INTRACORTICAL AND THALAMOCORTICAL PATHWAYS UNDERLYING HIGHER VISUAL REPRESENTATIONS IN THE MOUSE CORTEX

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Xu Han, Vincent Bonin
KU Leuven, Neuro-electronics Research Flanders, Heverlee, Belgium

Vision in mammals relies on an intricate network of visual areas that integrate and transform retinal inputs into specialized representations, which enable specific visual perception and behavior; however, the underlying circuit organization remains unclear. Here we study the joint functional and anatomical organization of intracortical and thalamocortical visual pathways underlying visual representations in the mouse cortex. Combining in vivo widefield and cellular calcium imaging and genetic labeling, we characterized the cellular populations providing inputs to three specialized higher visual cortical areas (HVAs), anterolateral (AL), posteromedial (PM), and anterior (A) areas, which show specific connectivity and visual tuning. We found a close agreement between long-range connectivity and functional properties as well as diverse degrees of functional target-specificity. Area A and PM avoid connecting to each other and receive nearly non-overlapping inputs from distinct sets of cortical areas. Inputs from common source areas consist of non-overlapping subsets of neurons. The degree of target-specificity varies across intracortical pathways, depending on the diversity and specificity of neurons in the target areas as well as the laminar position of the intracortical projection cells. Lastly, axonal imaging of projections from the lateral posterior thalamic nucleus to HVAs revealed remarkable target-specificity, even greater than those of the cortical pathways. Our findings suggest the coexistence of multiple long-range wiring rules in the visual cortex: while thalamocortical projections play a possible driving role in the emergence of functional specialization in HVAs, intracortical pathways with distinct specificity might modulate the activities of target areas and establish distributed cortical subnetworks.

Graded and pan-neural disease phenotypes of Rett Syndrome linked with dosage of functional MeCP2.
Rett syndrome (RTT) is a progressive neurodevelopmental disorder, mainly caused by mutations in MeCP2 and currently with no cure. We report here that neurons from R106W MeCP2 RTT human iPSCs as well as human embryonic stem cells after MeCP2 knockdown exhibit consistent and long-lasting impairment in maturation as indicated by impaired action potentials and passive membrane properties as well as reduced soma size and spine density. Moreover, RTT-inherent defects in neuronal maturation could be pan-neuronal and occurred in neurons with both dorsal and ventral forebrain features. Knockdown of MeCP2 led to more severe neuronal deficits as compared to RTT iPSC-derived neurons, which appeared to retain partial function. Strikingly, consistent deficits in nuclear size, dendritic complexity and circuitry-dependent spontaneous postsynaptic currents could only be observed in MeCP2 knockdown neurons but not RTT iPSC-derived neurons. Both neuron-intrinsic and circuitry-dependent deficits of MeCP2-deficient neurons could be fully or partially rescued by re-expression of wild type or T158M MeCP2, strengthening the dosage dependency of MeCP2 on disease phenotypes and also the partial function of the mutant. Our findings thus reveal stable neuronal maturation deficits and unexpectedly, graded sensitivities of neuron-inherent and neural transmission phenotypes towards the extent of MeCP2 deficiency, which is informative for future therapeutic development.

VISION DEPENDENT AND INDEPENDENT PROCESSES SHAPE THE ORGANIZATION OF CORTICO-CORTICAL FEEDBACK IN THE MOUSE VISUAL CORTEX

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Rodrigo Ferreira Dias, Radhika Rajan, Margarida Baeta, Leopoldo Petreanu
Champalimaud Foundation, Champalimaud Research, Lisbon, Portugal

Higher cortical areas influence lower order ones through direct cortico-cortical feedback projections but their precise role in cortical function remains unknown. Feedback connections from lateral-medial visual area (LM) to mouse primary visual cortex (V1) target retinotopically matched locations and their precise organization depends on the tuning properties of individual axons. While the tuning-dependent connectivity of feedback inputs might reflect learned visual statistics, the role of visual experience on the organization of feedback inputs remains uncharacterized. Using simultaneous dual-color 2-photon calcium imaging we recorded from LM axons and V1 neurons in their vicinity and measured the effects of different sensory manipulations on their functional organization. We find that in dark-reared mice, LM inputs remain retinotopically-matched with their targets in V1, but the extent of this alignment depends on the tuning of the feedback axons. Visual experience results in an increase in the proportion of orientation selective distal visual inputs converging into V1 neurons. This increase was mainly from axons representing locations lying along the axis of optic flow expected from forward locomotion. Restricting visual experience to a single specific orientation showed that this experience-dependent increase in feedback innervation is specific for axons tuned to the experienced stimuli. Thus, while the average retinotopic specificity of feedback inputs in V1 is largely independent of visual experience, vision shapes connections between LM and V1 neurons with non-aligned receptive fields to reflect experienced stimulus statistics. Our results suggest that the connectivity of feedback inputs reflects learned spatiotemporal correlations between higher and lower-order neurons.

TWO DISINHIBITORY CIRCUITS MODULATE VISUAL CORTEX ADAPTATION DURING STIMULUS HABITUATION

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Antonio Jesus Hinojosa, Leon Lagnado
University of Sussex, Life Sciences, Falmer, Brighton, United Kingdom

The visual scene is constantly changing, and the detection of novel stimuli among familiar ones can be crucial for survival. In response to a sustained visual stimulus, pyramidal cells (PCs) in primary visual cortex vary in adaptive properties in a balance that is finely modulated by interneuron activity. PC and interneuron responses also change when the animal habituates to the stimulus, but how their adaptive properties adjust, and the underlying circuit mechanisms are poorly understood. To answer this question, we presented a 10 s visual stimulus repeatedly during 6 sessions while monitoring the activity of different cortical neurons with GCaMP6f. We found that PCs decrease their activity and shift from depression to sensitization upon habituation to the stimulus. Somatostatin interneurons (SSTs) increased their activity undergoing a similar change in adaptive properties to PCs, while parvalbumin (PVs) and vasoactive intestinal polypeptide (VIPs) interneurons dramatically decreased their activities. Optogenetically silencing SSTs we showed that they inhibit PCs more strongly when the stimulus is familiar but that does not affect their adaptive properties overall. Conversely, silencing VIPs revealed that SST adaptive properties are tightly linked to VIP inhibition which is stronger when the stimulus is novel. Our results reveal a concerted change of cortical adaptive properties during habituation towards sensitizing adaptation, and how SST to PV and VIP to SST inhibitory circuits are key to modulate this process disinhibiting PCs.

VISUAL EXPERIENCE DIFFERENTIALLY AFFECTS THE ORGANIZATION OF CORTICAL FEEDBACK ORIGINATING FROM SUPERFICIAL AND DEEP LAYERS IN THE MOUSE VISUAL CORTEX

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Radhika Rajan, Rodrigo Ferreira Dias, Margarida Baeta, Leopoldo Petreanu
Champalimaud Foundation, Champalimaud Research, Lisbon, Portugal

Perception emerges from the activity of a series of hierarchically organized cortical areas interconnected via ascending feedforward projections and descending feedback projections. Feedback connections from higher visual area lateral-medial area (LM) to primary visual cortex (V1) target retinotopically matched locations and their organization is dependent on the tuning properties of the axons. Neurons in multiple cortical layers send feedback to lower areas. Projections with different laminar origins might play distinct roles in cortical computation. Unveiling the role played by different feedback streams requires comparing their functional organization and how it depends on visual experience. Using laminar-specific driver mouse lines and simultaneous dual-colour 2-photon calcium imaging we measured the functional organization of LM axons arising specifically from Layer 5 (L5) or Layer 2/3 (L2/3) in V1 and how it depends on visual experience. We find that irrespective of visual experience, feedback axons from both L5 and L2/3 are retinotopically matched with their targets in V1. Feedback from L5 relays far more distal information to the V1 inputs compared to feedback from L2/3, predominantly from locations lying along the axis of optic flow from forward locomotion. Visual experience results in increased innervation from horizontally tuned L5, but not L2/3 inputs, relaying information from distal locations lying along the axis of optic flow. Our results suggest that feedback connections originating in the two layers play different roles in cortical computation, with L5 playing a more prominent role in shaping V1 activity depending on learned visual statistics than L2/3.

CHANDELIER CELLS PROVIDE DIVERSE INPUTS TO CORTICAL NETWORKS IN-VIVO

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Filipe Machado Ferreira, Winnie Wefelmeyer, Dylan Myers-Joseph, Juan Burrone, Adil Khan
King's College London, Mrc Centre For Developmental Neurobiology, London, United Kingdom

Chandelier cells are GABAergic interneurons which receive inputs from diverse brain regions and synapse onto hundreds of nearby excitatory pyramidal cells, precisely targeting their axon initial segments (AIS). They can thus exert a powerful control over the output of a cortical network, and have been suggested to play a key role in organising information processing across brain regions. However, the impact of chandelier cell activity on their local network is poorly understood. Here we used an all-optical approach to both activate and measure the activity of chandelier cells and their postsynaptic partners in the primary visual cortex (V1) and somatosensory cortex (S1) in mice. Network activity was measured using chronic two-photon calcium imaging of neural populations in layer 2/3 while we simultaneously activated chandelier cells using single cell-targeted two-photon optogenetics. Chandelier cells in V1 and S1 were largely unresponsive to visual and whisker stimulation respectively. However, stimulus evoked responses of putative pyramidal cells were modulated by chandelier cell activation. This modulation was heterogeneous across cells and included both facilitation and suppression of responses over distinct timescales. We measured the influence of the same identified chandelier cells longitudinally on the local network in pups over a developmental period (P14-P40) during which the postsynaptic effect of GABA released at the AIS has been postulated to change in polarity. Preliminary results indicate a dynamic and heterogeneous influence of chandelier cells in the developing cortex.

MODULATION OF THE CORTICAL STATE BY SEROTONERGIC (5-HT) RECEPTORS: A STUDY COMBINING OPTOGENETIC TOOLS AND MULTI-CHANNEL ELECTRODE RECORDINGS IN MOUSE VISUAL CORTEX

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Serotonin (5-HT) modulates sensory cortical drive by controlling the balance between responses to external inputs and ongoing internal activity. In the visual cortex various 5-HT receptor types that activate different signaling pathways are localized in distinct cell compartments, expressed in non-overlapping populations of interneurons, but widely co-expressed in pyramidal cells. Our previous study, considering 5-HT effects at the level of neuronal populations, showed that activation of the depolarizing 5-HT2A receptor leads to divisive suppression of the gain of visual evoked responses, while the inhibitory 5-HT1A receptor triggers divisive suppression of ongoing activity. However, the interplay of these receptor types and the exact mechanisms by which 5-HT modulates visual cortical circuitries at single cell levels is not fully understood. Here, using optogenetics we stimulated specific 5-HT receptors expressed selectively in either pyramidal or GABAergic cells and recorded single cell activity in the visual cortex of mice using multi-channel silicon probes. Our results indicate that selective activation of the 5-HT2A receptor in pyramidal cells leads to an increase in ongoing activity at the cortical network level. In conjunction with our previous study, these new results hint at polysynaptic mechanisms involved in the overall modulation of activity in the visual cortex. Altogether our findings suggest that 5-HT receptors orchestrate a fine-tuned change of the cortical state that influences the scaling between internal broadcasts and external sensory drive.

INTERACTION BETWEEN INFORMATION STREAMS IN VISUAL PROCESSING THROUGH INTERAREAL LAYER 1 INHIBITORY CIRCUITS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Yann Zerlaut, Marcel De Brito Van Velze, Alberto Bacci, Nelson Rebola
ICM - Institut du Cerveau | Paris Brain Institute, Sorbonne Université - Cnrs - Inserm, Paris, France

In the mouse, the anatomically-separated collicular and geniculate pathways carry distinct spatio-temporal features of a visual scene to the cortex. How such information streams then interact within the cortex and what are the cellular and circuit mechanisms behind this process is still unknown. The Layer 1 circuit of NDNF-positive (neuron-derived neurotrophic factor, L1-NDNF+) interneurons is a particularly good candidate to mediate interactions between information streams. This population is indeed strongly innervated by areas from concurrent pathways (e.g. in the geniculate-recipient primary visual cortex, L1-NDNF+ neurons receive inputs from the collicular streams via latero-posterior thalamic projections) and potently inhibit dendritic integration in the Layer 2/3 network below. In the present study, we investigate multi-pathway integration in the superficial layers of the visual cortex by building a two area spiking network model interconnected by L1-NDNF+ interneuronal circuits. We analyse the conditions, in terms of Layer 1 and Layer 2/3 network connectivity, leading to either a boosting (via disinhibition) or suppressive (via inhibition) effect on stimulus integration following L1-NDNF+ recruitment. We then address this question experimentally using visual stimulation and calcium imaging in the visual cortex of awake behaving mice. Our work suggests that interareal Layer 1 cortical circuits might be a key element of multi-pathway integration in visual processing.

SPECIALIZED CAUSAL ROLES OF CORTICAL BASAL DENDRITES

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

L. Federico Rossi[1], Anyi Liu[2], Naureen Ghani[3], Charu Reddy[2], Kenneth Harris[4], Matteo Carandini[2]
[1]University College London, Wolfson Institute For Biomedical Research, London, United Kingdom, [2]University College London, Institute Of Ophthalmology, London, United Kingdom, [3]University College London, Sainsbury Wellcome Center, London, United Kingdom, [4]University College London, Institute Of Neurology, London, United Kingdom

[Aims] Neurons in layer 2/3 of primary visual cortex (V1) receive most excitatory connections from presynaptic neurons that have similar preferences for stimulus orientation and are located in an elongated region. We asked how pruning the branches of the dendritic tree extending towards different retinotopic territories might affect a neuron's visual tuning. [Methods] We first used two-photon imaging to record the orientation tuning and retinotopy of V1 neurons, reconstructed their dendritic arbors from structural z-stacks, and estimated the visual position of each dendritic segment along the retinotopic map of V1. We then recorded again from the same neurons after 2-photon pruning of the 'parallel' dendrites which extended co-axially with the neuron's preferred orientation, or the 'orthogonal' dendrites, which extended orthogonally. [Results] Parallel pruning drastically reduced responses to all stimuli,significantly decreased orientation selectivity and occasionally shifted preferred orientation. By contrast, orthogonal pruning only caused a mild reduction in response amplitude. In both cases, changes increased progressively with the pruning of a greater dendritic length. [Conclusions] These results demonstrate a specialized role of different basal dendrites in cortex. This specialization may be explained by parallel dendrites extending towards, and receiving more of, the appropriate co-tuned inputs, potentially providing a morphological substrate to orientation selectivity. To test this hypothesis we are currently combining dendritic pruning with synaptic imaging of glutamatergic transmission to reveal the synaptic organization of inputs on these specialized dendrites, and causally test their role.

We constantly update our internal model of the world using information received via our sensory organs. Coherent representations are central to this process that relies on integration of the different types of sensory input. Here we have used a combination of in vivo and in vitro methods in the mouse to explore the possibility that cross-modal connectivity between primary sensory cortices might be mediate this process. Firstly, we find that whisker stimulation suppresses visually driven activity in the primary visual cortex (V1). Using brain-wide retrograde and anterograde trans-synaptic anatomical tracing followed by serial two-photon tomography and deep-learning based 3D detection of labeled cells, we find a direct cortico-cortical (CC) pathway between the barrel field of the primary somatosensory cortex and V1. Secondly, we show that excitatory L6 CC cells are the main source for direct projections to V1 and using opthophysiological experiments reveal fast-spiking interneuron-mediated feedforward inhibition of L2/3 pyramidal cells in V1. Strikingly, the anatomical location of recipient neurons in V1 corresponds to the area in the visual field that overlaps with the external world space where whiskers perform tactile exploration. Hence, our data reveal a functional convergence between somatosensory and visual information streams that overlap in somato-visual space and highlight a role for multisensory integration in primary sensory cortices.

DIFFERENTIAL SYNAPTIC PROPERTIES OF LONG-RANGE INPUTS CONTACTING L1 INTERNEURONS IN THE PRIMARY VISUAL CORTEX

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Marie Martinez
ICM, Icm, Paris, France

In the visual system, the processing of visual information is strongly influenced by the behavioral relevance of the stimulus, the animal's internal brain state, as well as the presence of other sensory modalities. These contextual signals are conveyed to primary cortical sensory areas by multiple pathways including thalamic and intra-cortical feedback projections that strongly innervate layer 1 (L1). Thus, by integrating bottom-up sensory input with top-down information, L1 is a key hub structure underlying contextual encoding of sensory information. Yet, the functional architecture of L1 circuits is still poorly defined. Through an optogenetic approach, we dissect the synaptic and connectivity properties of long-range, top-down projections carrying contextual signals to L1 microcircuits in the primary visual cortex. We expressed the light-sensitive opsin channelrhodopsin2 (ChR2) in different associative visual areas (V2L and V2M) and lateral posterior (LP) nucleus of thalamus and recorded from L1 interneurons (L1-INs) while stimulating ChR2-positive axons. At the cellular level, we found that both V2L and V2M inputs preferentially target VIP-negative, NDNF-positive interneurons. Surprisingly, functional synaptic properties were quite heterogeneous across inputs. We found that the NMDA/AMPA ratio was much higher when the stimulated glutamatergic fibers originated from V2M, intermediate for LP and smallest for V2L. Preliminary current clamp recordings suggest that the different proportion of synaptic NMDARs results in pathway-specific integration properties of the multiple top-down inputs contacting L1-INs. In conclusion, we provide anatomical and functional evidence for the existence of L1 microcircuits suggesting differential engagement of L1-INs by long-range inputs in V1.

EFFECTS OF AROUSAL ON VISUAL SPATIAL SELECTIVITY ACROSS NETWORK, CELLULAR AND SUBTHRESHOLD LEVELS IN MOUSE VISUAL CORTEX

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Stefano Coletta, Joseph Del Rosario, Kayla Peelman, Alejandra Del Castillo Valerio, Bilal Haider
Georgia Institute of Technology, Biomedical Engineering, Atlanta, United States of America

Sensory processing depends upon multiple behavioral factors (Vinck et al., 2015; Stringer et al., 2019; Neske et al., 2019). In primary visual cortex (V1) of head-fixed mice, increased arousal during locomotion leads to membrane potential (Vm) depolarization and increased spiking. There remain open questions regarding arousal's effects on vision in the absence of locomotion, and effects on visual spatial selectivity across subthreshold and spiking levels. Here, we performed silicon probe and whole-cell patch-clamp recordings in awake, head-fixed, stationary mice while monitoring spontaneous behavior with high-speed video. We showed brief (0.1s) vertical bars (9° wide) throughout the visual field, and measured effects of pupil size and facial motion energy on V1 spatial responses. In some recordings, we optogenetically identified parvalbumin (PV) and somatostatin (SOM) interneurons. We found that even in stationary mice, changes in pupil size and facial movement correlated with electrophysiological brain state, and both exerted clear effects on visual spatial responses. With increasing arousal, local field potential (LFP) responses were smaller in the center of the receptive field (RF). In contrast, RS neurons (n = 1150) showed increased spiking at the center of the RF, as did PV/FS neurons (n=315), and SOM neurons (n=20). Across cell types, increased arousal generally improved the signal to noise ratio (SNR) of center versus surround visual responses. In excitatory neurons (n=35), subthreshold responses, SNR, spiking, and spatial selectivity generally increased. These findings suggest that even in stationary mice, increased arousal recruits cortical circuits to increase visual SNR without diminishing spatial selectivity.

Spatial modulation of dark versus bright stimulus responses in the mouse visual system.
A fundamental task of the visual system is to respond to both increases and decreases of luminance with action potentials (ON and OFF responses). OFF responses are stronger, faster, and more salient than ON responses in primary visual cortex (V1) of both cats and primates, but in ferrets and mice, ON responses can be stronger, weaker, or balanced in comparison to OFF responses. These discrepancies could arise from differences in species, experimental techniques, or stimulus properties, particularly retinotopic location in the visual field, as has been speculated; however, the role of retinotopy for ON/OFF dominance has not been systematically tested across multiple scales of neural activity within species. Here, we measured OFF versus ON responses across large portions of visual space with silicon probe and whole-cell patch-clamp recordings in mouse V1 and lateral geniculate nucleus (LGN). We found that OFF responses dominated in the central visual field, whereas ON and OFF responses were more balanced in the periphery. These findings were consistent across local field potential (LFP), spikes, and subthreshold membrane potential in V1, and were aligned with spatial biases in ON and OFF responses in LGN. Our findings reveal that retinotopy may provide a common organizing principle for spatial modulation of OFF versus ON processing in mammalian visual systems.

Structural Correlates of CA2 and CA3 Pyramidal Cell Activity in Freely-Moving Mice.
Plasticity within hippocampal circuits is essential for memory functions. The hippocampal CA2/CA3 region is thought to be able to rapidly store incoming information by plastic modifications of synaptic weights within its recurrent network. High-frequency spike-bursts are believed to be essential for this process, by serving as triggers for synaptic plasticity. Given the diversity of CA2/CA3 pyramidal neurons, it is currently unknown whether and how burst activity, assessed during natural behavior, relates to principal cell heterogeneity. To explore this issue, we juxtacellularly recorded the activity of single CA2/CA3 neurons from freely-moving male mice, exploring a familiar environment. In line with previous work, we found that spatial and temporal activity patterns of pyramidal neurons correlated with their topographical position. Morphometric analysis

revealed that neurons with a higher proportion of distal dendritic length displayed a higher tendency to fire spike-bursts. We propose that the dendritic architecture of pyramidal neurons might determine burst-firing by setting the relative amount of distal excitatory inputs from the entorhinal cortex. High-frequency spike-bursts are thought to serve fundamental computational roles within neural circuits. Within hippocampal circuits, spike-bursts are believed to serve as potent instructive signals, which increase the efficiency of information transfer and induce rapid modifications of synaptic efficacies. In the present study, by juxtacellularly recording and labeling single CA2/CA3 neurons in freely-moving mice, we explored whether and how burst propensity relates to pyramidal cell heterogeneity. We provide evidence that, within the CA2/CA3 region, neurons with higher proportion of distal dendritic length display a higher tendency to fire spike-bursts. Thus, the relative amount of entorhinal inputs, arriving onto the distal dendrites, might determine the burst propensity of individual CA2/CA3 neurons during natural behavior.

Interspike interval analysis and spikelets in presubicular head-direction cells.
Head-direction (HD) neurons are thought to provide the mammalian brain with an internal sense of direction. These cells, which selectively increase their firing when the animal's head points in a specific direction, use the spike rate to encode HD with a high signal-to-noise ratio. In the present work, we analyzed spike train features of presubicular HD cells recorded juxtacellularly in passively rotated rats. We found that HD neurons could be classified into two groups on the basis of their propensity to fire spikes at short interspike intervals. "Bursty" neurons displayed distinct spike waveforms and were weakly but significantly more modulated by HD compared with "nonbursty" cells. In a subset of HD neurons, we observed the occurrence of spikelets, small-amplitude "spike-like" events, whose HD tuning was highly correlated to that of the co-recorded juxtacellular spikes. Bursty and nonbursty HD cells, as well as spikelets, were also observed in freely moving animals during natural behavior. We speculate that spike bursts and spikelets might contribute to presubicular HD coding by enhancing its accuracy and transmission reliability to downstream targets. NEW & NOTEWORTHY We provide evidence that presubicular head-direction (HD) cells can be classified into two classes (bursty and nonbursty) on the basis of their propensity to fire spikes at short interspike intervals. Bursty cells displayed distinct electrophysiological properties and stronger directional tuning compared with nonbursty neurons. We also provide evidence for the occurrence of spikelets in a subset of HD cells. These electrophysiological features (spike bursts and spikelets) might contribute to the precision and robustness of the presubicular HD code.

Manipulating Hippocampal Place Cell Activity by Single-Cell Stimulation in Freely Moving Mice.
Learning critically depends on the ability to rapidly form and store non-overlapping representations of the external world. In line with their postulated role in episodic memory, hippocampal place cells can undergo a rapid reorganization of their firing fields upon contextual manipulations. To explore the mechanisms underlying such global remapping, we juxtacellularly stimulated 42 hippocampal neurons in freely moving mice during spatial exploration. We found that evoking spike trains in silent neurons was sufficient for creating place fields, while in place cells, juxtacellular stimulation induced a rapid remapping of their place fields to the stimulus location. The occurrence of complex spikes was most predictive of place field plasticity. Our data thus indicate that plasticity-inducing stimuli are able to rapidly bias place cell activity, simultaneously suppressing existing place fields. We propose that such competitive place field dynamics could support the orthogonalization of the hippocampal map during global remapping.

29487125: Coletta S, Frey M, Nasr K, Preston-Ferrer P, Burgalossi A
Testing the Efficacy of Single-Cell Stimulation in Biasing Presubicular Head Direction Activity.
To support navigation, the firing of head direction (HD) neurons must be tightly anchored to the external space. Indeed, inputs from external landmarks can rapidly reset the preferred direction of HD cells. Landmark stimuli have often been simulated as excitatory inputs from "visual cells" (encoding landmark information) to the HD attractor network; when excitatory visual inputs are sufficiently strong, preferred directions switch abruptly to the landmark location. In the present work, we tested whether mimicking such inputs via juxtacellular stimulation would be sufficient for shifting the tuning of individual presubicular HD cells recorded in passively rotated male rats. We recorded 81 HD cells in a cue-rich environment, and evoked spikes trains outside of their preferred direction (distance range, 11-178°). We found that HD tuning was remarkably resistant to activity manipulations. Even strong stimulations, which induced seconds-long spike trains, failed to induce a detectable shift in directional tuning. HD tuning curves before and after stimulation remained highly correlated, indicating that postsynaptic activation alone is insufficient for modifying HD output. Our data are thus consistent with the predicted stability of an HD attractor network when anchored to external landmarks. A small spiking bias at the stimulus direction could only be observed in a visually deprived environment in which both average firing rates and directional tuning

were markedly reduced. Based on this evidence, we speculate that, when attractor dynamics become unstable (e.g., under disorientation), the output of HD neurons could be more efficiently controlled by strong biasing stimuli. The activity of head direction (HD) cells is thought to provide the mammalian brain with an internal sense of direction. To support navigation, the firing of HD neurons must be anchored to external landmarks, a process thought to be supported by associative plasticity within the HD system. Here, we investigated these plasticity mechanisms by juxtacellular stimulation of single HD neurons in awake rats. We found that HD coding is strongly resistant to external manipulations of spiking activity. Only in a visually deprived environment was juxtacellular stimulation able to induce a small activity bias in single presubicular neurons. We propose that juxtacellular stimulation can bias HD tuning only when competing anchoring inputs are reduced or not available.

Anatomical organization of presubicular head-direction circuits.
Neurons coding for head-direction are crucial for spatial navigation. Here we explored the cellular basis of head-direction coding in the rat dorsal presubiculum (PreS). We found that layer2 is composed of two principal cell populations (calbindin-positive and calbindin-negative neurons) which targeted the contralateral PreS and retrosplenial cortex, respectively. Layer3 pyramidal neurons projected to the medial entorhinal cortex (MEC). By juxtacellularly recording PreS neurons in awake rats during passive-rotation, we found that head-direction responses were preferentially contributed by layer3 pyramidal cells, whose long-range axons branched within layer3 of the MEC. In contrast, layer2 neurons displayed distinct spike-shapes, were not modulated by head-direction but rhythmically-entrained by theta-oscillations. Fast-spiking interneurons showed only weak directionality and theta-rhythmicity, but were significantly modulated by angular velocity. Our data thus indicate that PreS neurons differentially contribute to head-direction coding, and point to a cell-type- and layer-specific routing of directional and non-directional information to downstream cortical targets.

CONNECTIVITY AND FUNCTION OF CHANDELIER CELLS IN MOUSE PRIMARY VISUAL CORTEX

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Koen Seignette[1], Nora Jamann[2], Ralph Porneso[1], Maaike Van Der Aa[1], Leander De Kraker[1], Chris Van Der Togt[1,3], Emma Ruimschotel[1], Paul Neering[1], Matthew Self[3], Maarten Kole[2], Christiaan Levelt[1]

Chandelier cells (ChCs) are a unique subtype of GABAergic cells that exclusively target the axon initial segment of pyramidal neurons (PyNs). Although ChCs were first identified decades ago, their function remains a mystery. Here, we studied the connectivity, plasticity and function of ChCs in mouse primary visual cortex (V1). We performed two-photon calcium imaging in mice performing a behavioral task in a virtual tunnel. We find that in our task, PyNs can be clustered in visual and non-visual cells and that ChC responses align well with those of non-visual cells. We further employed viral tracing, histology and electrophysiology to study their connectivity with PyNs. This revealed that ChCs receive extensive feedback inputs, matching their functional properties. Using opto- and chemogenetics we are currently testing the hypothesis that ChCs preferentially target visual neurons, thus separating feedforward and feedback information streams in the cortical network.

A parameter-free statistical test for neuronal responsiveness.
Neurophysiological studies depend on a reliable quantification of whether and when a neuron responds to stimulation. Simple methods to determine responsiveness require arbitrary parameter choices, such as binning size, while more advanced model-based methods require fitting and hyperparameter tuning. These parameter choices can change the results, which invites bad statistical practice and reduces the replicability. New recording techniques that yield increasingly large numbers of cells would benefit from a test for cell-inclusion that requires no manual curation. Here, we present the parameter-free ZETA-test, which outperforms t-tests, ANOVAs, and renewal-process-based methods by including more cells at a similar false-positive rate. We show that our procedure works across brain regions and recording techniques, including calcium imaging and Neuropixels data. Furthermore, in illustration of the method, we show in mouse visual cortex that (1) visuomotor-mismatch and spatial location are encoded by different neuronal subpopulations and (2) optogenetic stimulation of VIP cells leads to early inhibition and subsequent disinhibition.

Thalamic inhibition regulates critical-period plasticity in visual cortex and thalamus.
During critical periods of development, experience shapes cortical circuits, resulting in the acquisition of functions used throughout life. The classic example of critical-period plasticity is ocular dominance (OD) plasticity, which optimizes binocular vision but can reduce the responsiveness of the primary visual cortex (V1) to an eye providing low-grade visual input. The onset of the critical period of OD plasticity involves the maturation of inhibitory synapses within V1, specifically those containing the GABA receptor α1 subunit. Here we show that thalamic relay neurons in mouse dorsolateral geniculate nucleus (dLGN) also undergo OD plasticity. This process depends on thalamic α1-containing synapses and is required for consolidation of the OD shift in V1 during long-term deprivation. Our findings demonstrate that thalamic inhibitory circuits play a central role in the regulation of the critical period. This has far-reaching consequences for the interpretation of studies investigating the molecular and cellular mechanisms regulating critical periods of brain development.

FAMILIARITY-EVOKED THETA OSCILLATIONS IN THE MOUSE VISUAL CORTEX

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Yu Tang, Mang Gao, Alexander Chubykin
Purdue University, Biological Sciences, West Lafayette, United States of America

Recognizing familiarity and novelty in the environment is critical for animal survival. Surprisingly, very little is known about how animals distinguish familiar from novel stimuli. We have recently discovered persistent stimulus-triggered theta oscillations in the visual cortex of mice, which are specific to the familiarity and spatial frequency features of the stimulus. These oscillations are dependent on the cholinergic muscarinic receptors for both induction and expression. Familiarity-evoked oscillations lead to the decrease in suprathreshold responses to the non-preferred directions of the drifting sinusoidal gratings and to the improved direction selectivity in V1 neurons. We then used optogenetics to directly measure the synaptic strength of the light-triggered EPSCs in V1 neurons in head-fixed mice. We discovered the weakening of the thalamocortical projections coinciding with the strengthening of the intracortical projections in V1 following visual experience and emergence of the familiarity-evoked theta oscillations. Finally, we have discovered theta oscillations in the higher visual areas (HVAs) which are synchronized with the theta oscillations in V1 following visual experience. This synchronization varies between different HVAs and depends on the properties of the visual stimuli.

FUNCTION-SPECIFIC CORTICOFUGAL CONNECTIVITY PROMOTES THE PLASTICITY OF OPTOKINETIC REFLEX

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Jiashu Liu[1], Yingtian He[1], Baohua Liu[1,2]
[1]University of Toronto, Cell And Systems Biology, Toronto, Canada, [2]University of Toronto Mississauga, Biology, Mississauga, Canada

The visual cortex sends massive corticofugal projection to the brainstem, by which the cortex can modulate the brainstem driven innate behaviors. One example is the optokinetic reflex (OKR), an involuntary eye movement to stabilize retinal images. Recent study showed that the corticofugal projection enabled the visual cortex to potentiate OKR to make up the loss of other ocular behaviors. Despite its importance, the underlying mechanisms remain unclear. We used an interdisciplinary approach to explore the biological substrate and mechanisms of this cortical function. Anatomically, we found that corticofugal neurons innervating the brainstem OKR circuit primarily came from anterior V1 and posterior higher visual areas, and synapsed on one brainstem population. Moreover, behavioral tests showed that above cortical areas and brainstem population were required for the cortical modulation of OKR. Next, with calcium imaging we discovered that those corticofugal neurons shared similar functional properties to their postsynaptic target in the brainstem. Interestingly, following OKR potentiation cortical activity evoked by temporal-nasal motion was boosted only in the neurons preferring temporal-nasal direction. Finally, modelling showed that the direction specific connectivity and activity potentiation of corticofugal neurons provided an efficient way to supply extra cortical innervation in support of OKR potentiation. Altogether, our results suggest that the corticofugal projection and its brainstem partner form a distinct pathway through which visual cortex sends functional relevant information to the brainstem.

RECAPITULATING THE EVOLUTIONARY TRANSFORMATION OF VISUAL CORTEX ARCHITECTURE IN A TABLETOP EXPERIMENT

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Julian Vogel[1,2], Jonas Franz[3], Manuel Schottdorf[4], Shy Shoham[5], Walter Stühmer[1], Fred Wolf[2,6,7]
[1]Max-Planck-Institut für Multidisziplinäre Naturwissenschaften, Optogenetics, Göttingen, Germany, [2]Georg-August-Universität Göttingen, Goettingen Campus Institute For Dynamics Of Biological Networks, Göttingen, Germany, [3]Institute of Neuropathology, University Medical Center Göttingen, Göttingen, Germany, [4]Princeton University, Princeton Neuroscience Institute, Princeton, United States of America, [5]NYU Langone Health, Department Of Neuroscience And Physiology, New York, United States of America, [6]Max Planck Institute for Dynamics and Self-Organization, Nonlinear Dynamics, Göttingen, Germany, [7]Georg-August-Universität Göttingen, Bernstein Center For Computational Neuroscience, Göttingen, Germany

In the visual cortex of primates and carnivores orientation selective neurons are organized into functional domains that are arranged around so called pinwheels. This structure most likely emerged from a prior rodent-like salt-and-pepper layout. We designed a synthetic biology approach in which we implemented evolutionary transition scenarios by switching between different wiring schemes for thalamic afferents. We used neuronal interface technology to connect a computational model of the retino-thalamic pathway to an in-vitro model of cortical input layer 4 (L4). The latter contained channelrhodopsin expressing principal neurons, either as a primary culture of cortical neurons or an acute brain slice. The two stages were connected via optogenetic holographic stimulation emulating thalamo-cortical synaptic input to L4. We recorded neural activity either with a multielectrode array or by calcium imaging. In the feed-forward model orientation selection in L4 is a result of convergent thalamic input. We implemented such a feed-forward scheme in our system with variable size of orientation domains. We then explored the consequences of scaling the size of orientation domains down to the size of single neurons. Furthermore, we implemented a random wiring scheme. We found that the fraction of orientation selective neurons only weakly decreased with shrinking domain size and even for random thalamo-cortical connections a considerable level of orientation selectivity was maintained. In this case the arrangement of orientation selective cells resembled a sparse salt-and-pepper layout. Our results indicate that evolutionary scaling of orientation domain sizes can induce a self-organized transition to and from a salt-and-pepper layout.

TO LOOK OR NOT TO LOOK? : A NEURAL NETWORK ROUTING VISUAL DISTRACTIONS INTO BEHAVIOR

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Dimitris Mariatos[1], Kuisong Song[1], Peng Cui[1], Joao Campagnolo[1], Iakovos Lazaridis[2], Konstantinos Meletis[1], Arvind Kumar[3], Andreas Kardamakis[1]

Responding to peripheral visual events during ongoing behavior is critical for survival. Identifying and controlling the neural circuits that route pop-up visual input during planned behavior is important for understanding the versatility of visuospatial behavior. Here, we designed a paradigm in which animals navigate a predicted trajectory and their movement can be interrupted by (1) presenting visual distractors optically projected at random points in space and time or (2) by selective optogenetic stimulation of projection neurons in the intermediate layer of the superior colliculus (SCi) targeting the contralateral gigantocellularis(c.Gi) in the brainstem. We found that both modes are sufficient to interrupt guided navigation with movement patterns reminiscent of natural visual distraction trials. To quantify and assess similarities between the two cases, we employed machine vision techniques to track animal movements, estimated multi-scale postural motifs, and clustered them to achieve unsupervised and systematic categorizations of animal motion. This analysis revealed similar basic motifs, suggesting the involvement of SCi projecting neurons in mediating visual distraction (which we are currently monitoring in vivo). Using transsynaptic circuit mapping, we found that these neurons receive monosynaptic inputs from retinal ganglion cells (RGCs) bypassing the superficial layer by a large extent. Whole-cell recordings showed that there is a weak functional connectivity between SCi projection neurons and channelrhodopsin-expressing RGCs. We propose that the RGC->SCi->c.Gi network is the neural hardware which routes visual distractions into task-dependent behavior.

COORDINATED ACTIVITY OF TWO CELL-TYPE SPECIFIC CIRCUITS AND THEIR ROLE IN GUIDING BEHAVIORS – INSIGHTS FROM THE MICE SUPERIOR COLLICULUS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Anna Chrzanowska[1,2], Bram Nuttin[1,2], Micheline Grillet[1,3], Arnau Sans Dublanc[1,2], Vicenç Gomez[1,4], Chaimae Ouriaghli Taouil[1], Gabriel Montaldo[1], Alan Urban[1,2,3], Karl Farrow[1,2]

Neuronal cell types are arranged in brain wide circuits to guide behavior. Using the mice superior colliculus as a model, it has been demonstrated that optogenetic activation of different genetically targetable collicular cell types leads to various defensive behaviors (passive or active avoidance), engaging distinct but overlapping brain-wide dynamics. However, the optogenetic approach doesn't ideally represent the activation going on in the brain in response to natural stimuli. The aim of this study is to shed light on how cell-type specific processing pathways enable behavioral execution in response to salient, ecologically relevant stimuli. To do that, we focused on two collicular cell types – wide- and narrow-field neurons, and their responses to visual stimuli that mimic predators (e.g., sweeping and looming discs). Freely-moving experiments in combination with chemogenetic inhibition of these neuronal populations resulted in a similar incapability of animals to react to potentially dangerous visual stimuli. This suggests the existence of common processing nodes of those two cell-type specific circuits, where the information about threat encounter converge. We are currently performing experiments to determine whether this is happening locally at the level of the superior colliculus, or globally via recruitment of a set of processing hubs in the brain. We map the local and global activity using high-density Neuropixels probes recordings and functional ultrasound imaging (fUSI), respectively. This work stresses the importance of cell types as functional building blocks in the brain and provides insight into how their coordinated activity can guide behavior.

CELL-TYPE-SPECIFIC CONTRIBUTIONS TO VISUOMOTOR TRANSFORMATIONS IN THE SUPERIOR COLLICULUS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Bram Nuttin[1,2], Anna Chrzanowska[1,2], Arnau Sans Dublanc[1,2], Vicenç Gomez[1,3], Norma Kühn[1,2], Karl Farrow[1,2]
[1]VIB, Neuro-electronics Research Flanders (nerf), Leuven, Belgium, [2]KU Leuven, Department Of Biology & Leuven Brain Institute, Leuven, Belgium, [3]University of Barcelona, Faculty Of Biology, Barcelona, Spain

How does an animal select which action to take when facing a sudden threat? In mice, most visual inputs are sent directly from the retina to a midbrain structure known as the superior colliculus. In the colliculus, a set of genetically-distinct cell types have been identified that are involved in driving defensive behaviors. However, it remains unclear how these cell types underly the transformation from visual inputs to behavioral actions. In this study, we characterize the organization of visual and behavior representations throughout the superior colliculus and uncover how different cell types contribute to that organization. By presenting threatening and non-threatening visual stimuli while doing electrophysiology recording in the colliculus, we observe a transformation from stimulus-specific encoding to threat encoding along collicular depth. Furthermore, by chemogenetically inhibiting collicular cell types in freely-moving experiments, we find two cell types -- GRP and NTSR1 neurons -- that are both required for visually-evoked defensive behaviors. This suggests that both cell types affect the processing of visual threats to trigger defensive behaviors. Therefore, we are now performing electrophysiology experiments combined with chemogenetic inhibition and optogenetic tagging to find out the role of both cell types in processing visual threats. Taken together, these experiments allow us to uncover the cell-type specific mechanisms underlying the transformation from visual threat to a defensive action in the superior colliculus, thereby hinting towards the importance of cell-type specific populations in the implementation of visuo-motor transformations across the brain.

A GENETIC SCREEN OF VISUAL PROJECTIONS AND RETINA ORGANIZATION IN ADULT MICE

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Amin Benadjal[1], Abby Jones[2], Bryony Hawgood[2], Robin Vigouroux[3], Alfonso Reimúndez Dubra[3], Jacqueline White[2], Alain Chédotal[3]
[1]Institut de la Vision, Department Of Development, Paris, France, [2]The Jackson Laboratory, Center For Biometric Analysis, Bar Harbor, United States of America, [3]Institut De La Vision, Department Of Development, Paris, France

In the mouse, over 30 subtypes of retinal ganglion cells project to at least 40 brain nuclei. The genetic program controlling visual system wiring during development is still largely unknown. To date, a screen for genes affecting the guidance of visual projections has never been performed in mammals. To identify new molecules controlling the development and plasticity of the visual system, we are performing a reverse genetic screen using single-gene knockout mouse lines produced by the JAX Knockout Mouse Phenotyping Program (KOMP2). Visual projections are labeled via intraocular injection of the axonal tracer cholera-toxin subunit B, conjugated to various fluorescent Alexa-dyes. For each line, four mice (two males and two females) are injected, along with age, sex and genetic background matched control animals. Brains are collected and cleared using iDISCO+. To study the topography of visual projections and detect axon targeting defects, cleared brains are imaged in 3D using light-sheet fluorescence microscopy. In parallel, we use the EyeDISCO protocol and TOPRO-3 nuclear staining to study the organization of the retina. We have already been able to image more than 250 lines, corresponding to about 800 brains and 800 eyes. We are developing AI-based analytic pipelines to quantify visual system connectivity in mutant mice. We are also testing various reprocessing strategies to perform secondary screens for axon guidance defects. This project will contribute to our understanding of the neuronal basis of the parallel processing of visual inputs and how circuits involved in image-forming vision or motion detection are established during development.

EARLY VISUAL DEPRIVATION PROMOTES ASTROCYTE REACTIVITY IN THE VISUAL THALAMUS

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Pablo Castellano-Ruiz, Lorenzo Puche-Aroca, Rafael Susín, Guillermina López-Bendito
Instituto de Neurociencias de Alicante, Universidad Miguel Hernandez - Cisc, Alicante, Spain

Sensory circuits development is a process that requires peripherally driven sensory signals. The loss of sensory input during the formation of these systems leads to structural and functional changes in stations along the circuit, as the thalamus and cortex. In the visual system, the removal of the eyes at postnatal stages (P3) leads to several changes in the dorsolateral geniculate nucleus (dLGN), the first order visual thalamic nucleus. Among them, postnatal bienucleation causes a decrease in the size of the nucleus which is explained by an increased cell death. Conversely, we observed a specific response in the non-neuronal population in the dLGN. The number of reactive astrocytes (GFAP+) was significantly increased at P6. BrdU labeling showed that reactive astrocytes were not proliferating in the bilateral enucleated mice but that they either become reactive in situ or had migrated from another source. Experiments from single-cell RNA-sequencing will be performed to determine the cell-populations and genes modified in the thalamus following postnatal enucleated condition. We have recently shown that thalamic astrocytes can be converted into specific sensory neurons. Since reactive astrocytes seem to switch to an immature stage and are better predisposed to change their identity into neurons, these experiments in early postnatal deprived mice are setting the scene for astrocyte-to-neuron reprogramming in sensory-deprived models.

SIGNIFICANCE OF OPTIC FLOW INFORMATION FOR VISUAL COURSE CONTROL IN FREELY FLYING FLIES

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Maria-Bianca Leonte, Alexander Borst
Max Planck Institute of Neurobiology, Circuits - Computation - Models, Martinsried, Germany

Counteracting involuntary course deviations during flight requires detection of self-motion. In dipteran flies, such as *Drosophila melanogaster*, this information is provided by mechanosensory receptors, located at the base of the halters, as well as by the visual system. In the latter, local motion information is encoded by four sets of directionally-selective T4 (ON-pathway) and T5 cells (OFF-pathway) per column, one for each of the four cardinal direction (right, left, up, down). According to their directional preference, T4 and T5 cells project to four anatomically defined layers of the lobula plate, where they provide synaptic input to large-field course-control neurons. Blocking the synaptic output from T4 and T5 cells renders flies completely blind to visual motion (Bahl et al, 2013; Schilling and Borst, 2015). In our previous study (Leonte et al, 2021), we have shown that in free flight, such motion-blind flies reveal a reduced straightness of inter-saccadic flight segments and are unable to compensate for aerodynamic asymmetries caused by wing damage. The goal of the current study is to investigate free flight performance in flies where visual motion information is not completely blocked but still present for certain directions. To this end, we silence the synaptic output of specific subtypes of T4/T5 cells and then assess the straightness of their inter-saccadic flight segments as recorded in a free flight arena. With this approach, we hope to determine whether flies are still able to correctly infer their self-motion when certain vector components used to compute the optic flow are lacking.

DYNAMIC AND STATE-DEPENDENT SWITCHING OF BEHAVIOUR IN RESPONSE TO COMPETING VISUAL STIMULI IN DROSOPHILA

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Roshan Kumar Satapathy
Institute of Science and Technology Austria, Neuroethology, Klosterneuburg, Austria

Sensorimotor circuits have classically been studied using defined stimuli that map onto reproducible behavioural responses. However, the numerous features in a complex natural environment would inevitably drive multiple dedicated circuits, generating a combination of competing motor commands. In order to cope with such a scenario, sensorimotor transformations should be selectively modulated depending on the goals and internal state of the animal. Here we developed a novel behavioural paradigm to study how the fruit fly processes competing visual stimuli to generate coherent behaviour. We take advantage of optomotor response and courtship tracking in fruit flies, two distinct visually-guided innate behaviours that can be elicited reliably in our experimental setup. We report that male flies suppress optomotor response to global visual motion while engaged in courtship tracking of female flies. Next, we recapitulate this experiment in virtual reality where the female fly is replaced with a dark dot while the global motion stimulus stays the same. In this setting, males switch between tracking and optomotor response and the probability and dynamics of this switching is governed by the relative strengths of the stimuli determined by their respective saliencies. Our findings show that fruit flies dynamically modulate innate responses to stimuli that are irrelevant to the task that they are engaged in, providing support for attention-like mechanisms in the fly brain. Currently, we are investigating the neuronal mechanism of the switching dynamics by targetedly disrupting octopaminergic and tyraminergic neuromodulatory inputs.

NEUROMECHANICAL SIMULATION OF ZEBRAFISH VISUOMOTOR COORDINATION

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Xiangxiao Liu[1], Matt Loring[2], Luca Zunino[1], Alexandre Bernardino[3], Auke Ijspeert[1], Eva Naumann[2]
[1]École polytechnique fédérale de Lausanne, Biorob, School Of Engineering, Lausanne, Switzerland, [2]Duke University, School Of Medicine, Durham, United States of America, [3]the University of Lisbon, Instituto Superior Técnico, Lisbon, Portugal

Abstract: Background and Aim: Zebrafish larvae has gained attention in neuroscience due to its optical accessibility and quantifiable behaviors. While scientists have elucidated the neural mechanisms underlying a variety of visually driven behaviors, such as prey-, escape-, optokinetic-, and optomotor responses (OMR), few studies have explored neuromechanical simulations of both the visuomotor circuits and the body, in order to investigate how sensory-driven behavior depends on neural circuits. Method: Recent advances in the understanding of the neural function and new simulation technologies have made this a feasible goal. We constructed software simulations that reproduce body, water interactions, neural circuits, and the closed-loop visual environments, replicating the experimental settings for live zebrafish behavioral recordings. Results: We implemented a neural network based on real recorded neurons of live zebrafish in a fish-like simulated body that allowed predictions for behavioral responses to different types of stimuli. Our model not only replicates several OMR behaviors reported in the literature, but also predicts novel behaviors to new stimuli that the animal is not confronted within nature (e.g., different stimuli for left and right eyes). Conclusion: Via iterations between simulation, prediction, and experimental validation we incrementally refined the functional elements and connectivity underlying the zebrafish visuomotor
circuits.

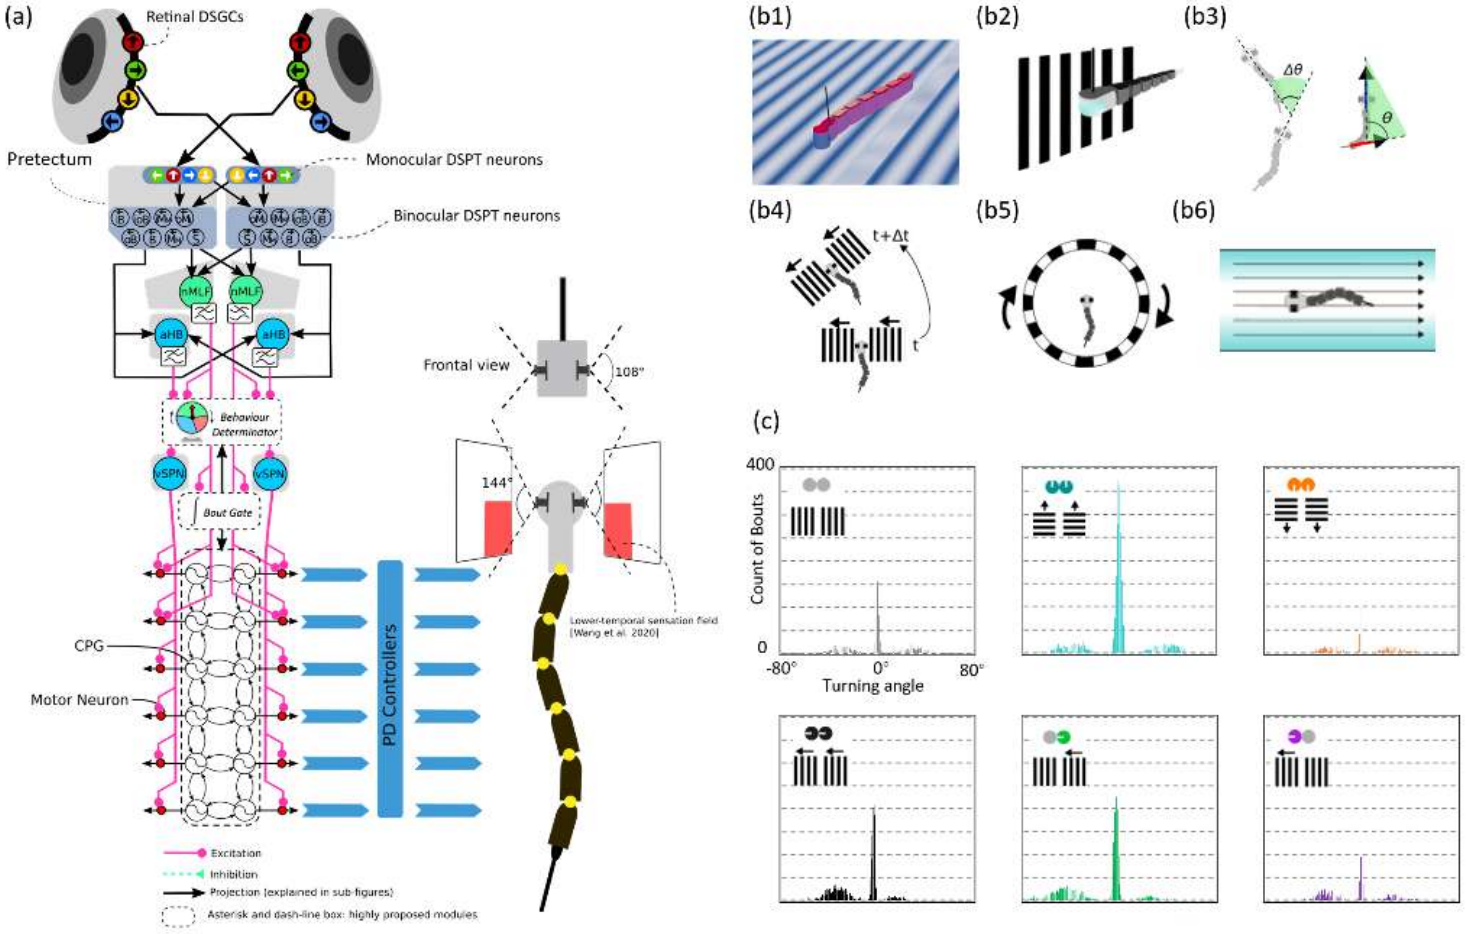

Figure 1: (a) Integrated neural network. (b1) fish body in the simulation. (b2) to (b6) Different visual stimulations that are used to verify the integrated neural mechanism. DEEP LEARNING OF BRAIN SPACETIME TO PREDICT OUTCOME OF VISION RESTORATION THERAPY USING NON-INVASIVE BRAIN STIMULATION

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Zheng Wu[1], Andreas Nürnberger[2], Bernhard A. Sabel[1]
[1]Institute of medical psychology, Medical faculty, Otto-von-guericke University Of Magdeburg, Magdeburg, Germany, [2]Data and Knowledge Engineering Group, Faculty of Computer Science, Otto-von-guericke University Magdeburg, Magdeburg, Germany

Background: Vision loss following optic nerve damage does not only impair visual field function in patients, but it also alter Brain Spacetime. As we showed repeatedly, non-invasive transcranial alternating current stimulation (tACS) can enhance residual visual capacity of the brain, however treatment efficacy varies considerably between subjects and the treatment outcomes remains unpredictable. **Methods**: We applied deep neural networks including FFNN, CNN, bidirectional LSTM and Transformer to the task of tACS induced visual recovery outcome. For 20 patients with optic nerve damage, EEG data and visual field information were collected from each subject while performing a visual discrimination task before receiving ACS treatment. EEG data were then processed and decomposed into different frequency bands to build functional brain network per trial in each frequency band on the msec. scale (Brain Spacetime). Node centralities were extracted and then fed into deep neural networks. After receiving tACS treatment, the visual field was evaluated again for each subject to calculate recovery of vision. **Results**: The bidirectional LSTM and FFNN model exhibited similar power of prediction compared to CNN and Transformer. Even so, the bidirectional LSTM model reflected higher accuracy in almost every frequency band compared to FFNN. In contrast, FFNN model had a higher accuracy only in the beta band. The CNN and Transformer were unable to reliably predict outcome. **Conclusions**: AI-based deep neural networks may provide useful information of future therapy outcome to patients before tACS treatment starts which may be of clinical benefit.

Interhemispheric Cortical Network Connectivity Reorganization Predicts Vision Impairment in Stroke.
Stroke is one of the main causes of disability in human beings, and when the occipital lobe is affected, this leads to partial vision loss (homonymous hemianopia). To understand brain mechanisms of vision loss and recovery, graph theory-based brain functional connectivity network (FCN) analysis was recently introduced. However, few brain network studies exist that have studied if the strength of the damaged FCN can predict the extent of functional impairment. We now characterized the brain FCN using deep neural network analysis to describe multiscale brain networks and explore their corresponding physiological patterns. In a group of 24 patients and 24 controls, Bi-directional long short-term memory (Bi-LSTM) was evaluated to reveal the cortical network pattern learning efficiency compared with other traditional algorithms. Bi-LSTM achieved the best balanced-overall accuracy of 73% with sensitivity of 70% and specificity and 75% in the low alpha band. This demonstrates that bi-directional learning can capture the brain network feature representation of both hemispheres. It shows that brain damage leads to reorganized FCN patterns with a greater number of functional connections of intermediate density in the high alpha band. Future studies should explore how this understanding of brain FCN can be used for clinical diagnostics and rehabilitation.

Reorganization of Brain Functional Connectivity Network and Vision Restoration Following Combined tACS-tDCS Treatment After Occipital Stroke.
Non-invasive brain stimulation (NIBS) is already known to improve visual field functions in patients with optic nerve damage and partially restores the organization of brain functional connectivity networks (FCNs). However, because little is known if NIBS is effective also following brain damage, we now studied the correlation between visual field recovery and FCN reorganization in patients with stroke of the central visual pathway. In a controlled, exploratory trial, 24 patients with hemianopia were randomly assigned to one of three brain stimulation groups: transcranial direct current stimulation (tDCS)/transcranial alternating current stimulation (tACS) (ACDC); sham tDCS/tACS (AC); sham tDCS/sham tACS (Sham),

which were compared to age-matched controls (= 24). Resting-state electroencephalogram (EEG) was collected at baseline, after 10 days stimulation and at 2 months follow-up. EEG recordings were analyzed for FCN measures using graph theory parameters, and FCN small worldness of the network and long pairwise coherence parameter alterations were then correlated with visual field performance. ACDC enhanced alpha-band FCN strength in the superior occipital lobe of the lesioned hemisphere at follow-up. A negative correlation (= -0.80) was found between the intact visual field size and characteristic path length (CPL) after ACDC with a trend of decreased alpha-band centrality of the intact middle occipital cortex. ACDC also significantly decreased delta band coherence between the lesion and the intact occipital lobe, and coherence was enhanced between occipital and temporal lobe of the intact hemisphere in the low beta band. Responders showed significantly higher strength in the low alpha band at follow-up in the intact lingual and calcarine cortex and in the superior occipital region of the lesioned hemisphere. While ACDC decreases delta band coherence between intact and damaged occipital brain areas indicating inhibition of low-frequency neural oscillations, ACDC increases FCN connectivity between the occipital and temporal lobe in the intact hemisphere. When taken together with the lower global clustering coefficient in responders, these findings suggest that FCN reorganization (here induced by NIBS) is adaptive in stroke. It leads to greater efficiency of neural processing, where the FCN requires fewer connections for visual processing.

Spacetime in the brain: rapid brain network reorganization in visual processing and recovery.

Functional connectivity networks (FCN) are the physiological basis of brain synchronization to integrating neural activity. They are not rigid but can reorganize under pathological conditions or during mental or behavioral states. However, because mental acts can be very fast, like the blink of an eye, we now used the visual system as a model to explore rapid FCN reorganization and its functional impact in normal, abnormal and post treatment vision. EEG-recordings were time-locked to visual stimulus presentation; graph analysis of neurophysiological oscillations were used to characterize millisecond FCN dynamics in healthy subjects and in patients with optic nerve damage before and after neuromodulation with alternating currents stimulation and were correlated with visual performance. We showed that rapid and transient FCN synchronization patterns in humans can evolve and dissolve in millisecond speed during visual processing. This rapid FCN reorganization is functionally relevant because disruption and recovery after treatment in optic nerve patients correlated with impaired and recovered visual performance, respectively. Because FCN hub and node interactions can evolve and dissolve in millisecond speed to manage spatial and temporal neural synchronization during visual processing and recovery, we propose "Brain Spacetime" as a fundamental principle of the human mind not only in visual cognition but also in vision restoration.

Disturbed connectivity of EEG functional networks in alcoholism: a graph-theoretic analysis.

Generally, an alcoholic's brain shows explicit damage. However, in cognitive tasks, the correlation between the topological structural changes of the brain networks and the brain damage is still unclear. Scalp electrodes and synchronization likelihood (SL) were applied to the constructions of the EGG functional networks of 28 alcoholics and 28 healthy volunteers. The graph-theoretic analysis showed that in cognitive tasks, compared with the healthy control group, the brain networks of alcoholics had smaller clustering coefficients in β1 bands, shorter characteristic path lengths, increased global efficiency, but similar small-world properties. The abnormal topological structure of the alcoholics may be related to the local-function brain damage and the compensation mechanism adopted to complete tasks. This conclusion provides a new perspective for alcohol-related brain damage.

Eccentricity Effects on the Efficiency of Attentional Networks: Evidence From a Modified Attention Network Test.

The effects of eccentricity on the attentional modulation of visual discrimination have been widely studied; however, the substrate of this complex phenomenon is poorly understood. Here, we provided a measure of the effects of eccentricity on three attentional networks: alerting, orienting, and executive attention. Participants (N = 63) were tested with a modified attention network test that included an additional eccentricity variation; this test allowed us to investigate the efficiency of the attentional networks at near and far eccentricities. Compared with targets at the near eccentricity, targets at the far eccentricity generally elicited significantly longer reaction times. We also found the far eccentricity was associated with smaller orienting effect scores and larger executive control scores than the near eccentricity. Interestingly, at the near eccentricity, executive control scores were larger when the spatial information was neutral (no cue, center cue, and double cue), but at the far eccentricity, the scores were larger when the spatial information was valid (spatial cue). We propose that the allocation of attentional resources differed among these cue conditions and influenced the interference caused by conflicting information.

ALPHA ACTIVITY CHANGE DURING IMPLICIT VISUAL STATISTICAL LEARNING

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Szabolcs Sáringer, András Benyhe, Ágnes Fehér, Péter Kaposvári
University of Szeged Albert Szent-Györgyi Medical School, Department Of Physiology, Szeged, Hungary

Introduction Statistical learning (SL) is a cognitive function during which environmental regularities are learned. This phenomenon helps the sensory system to make predictions, thus facilitating stimulus processing. SL has been demonstrated and studied across multiple modalities, but little is known about its neural background. In this study we examined the EEG correlates of implicit, visual SL. Materials and methods Sixty-four channel EEG was recorded on 22 healthy, right-handed volunteers with correct or corrected-to-normal vision (female: 13, mean age: 25.1y). Each participant was presented with a stream of visual stimuli, where eight images formed associative pairs and the remaining eight images were control stimuli. To keep the learning implicit while also maintaining their attention, participants were asked to perform a parallel detection task. Results Based on the literature, we compared the power of low-frequency activity across conditions. Using cluster-based statistics, a significant difference was found in the time-frequency window of 0-400 ms and 8-12 Hz. This difference was predominantly present in the frontal channels and it was mainly caused by a power reduction related to predictable stimuli. Discussion Our results are in line with previous studies, claiming that low-frequency activity is modulated during SL paradigms. We found that the predictability arising from paired stimuli was traceable by decreased alpha-band activity. The early presence of this power change implies dissimilarity during the visual processing of predictable and unpredictable stimuli.

SONOGENETIC THERAPY FOR VISUAL RESTORATION

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Ignacio Alcala[1], Sara Cadoni[1], Charlie Demené[2], Julie Dégardin[1], Matthieu Provansal[1], Fabrice Arcizet[1], Grégory Gauvain[1], Botond Roska[3], José-Alain Sahel[1], Mickael Tanter[2], Serge Picaud[1]
[1]Sorbonne-Université, INSERM, CNRS, Institut De La Vision, Paris, France, [2]ESPCI Paris, PSL Research University, Physics For Medicine Paris, Inserm U1273, Cnrs, Paris, France, [3]Institute of Molecular and Clinical Ophtalmology Basel, Basel, Basel, Switzerland

In recent work, we showed that sonogenetic therapy possesses high spatiotemporal resolution when stimulating the visual cortex (VC) with ultrasounds following the expression of the MscL mechanosensitive ionic channel in cortical neurons. Here we investigated if sonogenetic activation of the VC can generate visual perception using an associative learning test in mice. **Methods:** MscL was expressed by AAV injection in the mouse VC. Mice under water restriction and head-fixed were first taught to associate water delivery with visual light stimulation (LS). Water was delivered 500ms after the LS. Ultrasounds stimulations (US) were then applied using an ultrasound transducer on a cranial window above the VC. **Results:** Injected and non-injected mice increased their licking behavior between the LS and the water delivery from 23% the first day up to 76% the fourth day. Then, LS was replaced by US. The injected mice (n=9) efficacy of US induced response (66%) was close to their LS induced response (65%). Non-injected mice (n=7) efficacy of US induced response (34%) was far from their LS induced (89%). Latency of the first lick was 285.3 ± 12.4 ms (n=15) following LS whereas it decreased to 193.2 ± 12.8 ms (n=9) for US in injected animals. This shorter latency was consistent with direct cortical stimulation. **Conclusion:** We demonstrated that injected mice perceived US in the visual cortex as LS. These results are encouraging for the application of sonogenetics as a novel strategy to restore vision at a cortical level in blind patients with optic nerve atrophy.

A TWO-WAY LUMINANCE GAIN CONTROL IN THE FLY BRAIN ENSURES LUMINANCE INVARIANCE IN DYNAMIC VISION

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Madhura Ketkar[1], Shuai Shao[2,3], Julijana Gjorgijeva[2,4], Marion Silies[1]
[1]Johannes Gutenberg University of Mainz, Institute Of Developmental Biology And Neurobiology (idn), Mainz, Germany, [2]Max Planck institute for Brain Research, Computation In Neural Circuits Group, Frankfurt am Main, Germany, [3]Radboud University, Department Of Neurophysiology, Nijmegen, Netherlands, [4]Technical University of Munich, School Of Life Sciences, Freising, Germany

Aim*:* For visual perception to be unaffected by viewing conditions, animals must adapt their sensitivity to changing visual statistics, such as mean illumination. Consistently, photoreceptors in many species control their luminance gain and encode relative changes in luminance, termed contrast. However, this early gain control is insufficient for luminance-invariant contrast estimation in dynamic conditions. Sudden transitions to dim or bright environment would lead to an erroneous, reduced or enhanced perception of contrasts, thus imposing a two-way challenge on contrast estimation. Yet, visual behaviors are luminance invariant, and we aim to understand how the brains achieve such invariance. **Methods:** We combine fly behavior, *in vivo* two-photon calcium imaging and computational modelling approaches. **Results:** In fruit flies, a distinct visual pathway preserves luminance information past photoreceptors and enhances contrast estimation in sudden dim light. Here, we show that the pathway implements a generalized gain correction to tackle the two-way contrast coding deficits. When blocking the output of the luminance-sensitive interneurons, the flies underestimate large contrasts in sudden dim light and overestimate smaller contrasts in sudden bright light. Furthermore, the gain correction improves visibility of very dim stimuli at all contrasts. We formulated an algorithmic model that captures the data with high accuracy and explains how the gain correction is implemented in these widely differing scenarios. **Conclusion:** Our work demonstrates how post-receptor gain correction is key to perceptually relevant vision. Since visual systems of all behaving animals face similar challenges, the corrective gain control might be a universal strategy of visual systems.

NON-LINEAR CHROMATIC PROCESSING IN THE DROSOPHILA OPTIC LOBE

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Matthias Christenson[1], Alvaro Sanz[2], Rudy Behnia[2]
[1]Columbia University, Neuroscience, New York, United States of America, [2]Columbia University, Neuroscience, new york, United States of America

Color is an important visual percept that guides various animal behaviors, such as mating and foraging. In order to compute color, the brain compares the relative activation of different wavelength-specific photoreceptors through color opponent signals. This phenomenon has been observed across the animal kingdom, sometimes as early as in photoreceptor terminals themselves. However, how opponent responses are transformed into higher-order chromatic representations such as hue or saturation remains poorly understood. We use the well-defined brain of the fruit fly Drosophila melanogaster to understand how the brain transforms photoreceptor signals into color percepts. The fruit fly retina contains four types of cone-like photoreceptors, which we and others have previously shown to inhibit each other at the axonal level, giving rise to linear color opponent signals. It is unclear how these signals are further transformed in the fly brain. Postsynaptically, color information is relayed to a set of trans-medullary neurons implicated in color-dependent behaviors. However, the responses of these neurons to chromatic visual stimuli has not been reported. We devised a visual stimulus that allows us to map the responses of these neurons across color space and intensities. We find that chromatic information is non-linearly processed by different trans-medullary neural populations to extract specific features of the chromatic space of the animal. We formalize these transformations using simple mathematical models and, we use connectomic data to show how these nonlinearities arise in a biologically constrained model. Here, we define the neural circuit mechanisms that allow for the computation of higher-order chromatic representations.

Textures are useful visual stimuli for studying the neural underpinnings of object recognition. Textures are sufficiently complex to largely match the statistical properties of natural images, and, unlike natural images, they can be precisely parameterized and synthetized. Here, we studied the cortical processing of textures in mice, asking first whether mice could perceptually discriminate visual textures, and then whether the underlying neural architectures shared similarities with those found in primates. We found that mice could distinguish between types of textures, and between textures and spectrally matched stimuli (scrambles) lacking higher-order statistical features characteristic of textures. Mesoscale calcium imaging revealed that the primary visual cortex (V1) and the secondary ventral visual area (LM), but not other higher visual areas, were differentially activated by textures, relative to scrambles, with a stronger texture selectivity in LM than in V1. Similarly, 2-photon imaging recordings, examined with a regressive model, showed that cell responses in LM were better predicted by the higher-order statistics of textures than in V1. Furthermore, at the population level, textures clustered in activity subspaces that were more separable in LM than in V1, with the distance between clusters significantly correlated with the discrimination performance of the mice. In summary, our results demonstrate texture vision in the mouse with a neural substrate indicating preserved hierarchical coding principles across mammalian species for the processing of naturalistic stimuli.

REPRESENTATION OF PREY-RELATED VARIABLES IN MOUSE V1 DURING PREY CAPTURE BEHAVIOR

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Drago Guggiana Nilo, Matthew Mccann, Tobias Bonhoeffer, Mark Hübener
Max Planck Institute for Biological Intelligence (in foundation), Synapses - Circuits - Plasticity, Martinsried, Germany

Neurons in the mouse primary visual cortex (V1) are traditionally described using classical response properties, such as direction/orientation selectivity. These properties are measured by showing moving gratings to a head-fixed animal while recording the ensuing neural responses. This approach is in stark contrast to what mice see and do in nature, where they experience much more complex visual scenes while engaging in behaviors such as foraging and hunting. It is unclear how V1 cells respond during such behaviors. Here, using hunting as a naturalistic behavior, we show that V1 neurons encode a number of hunting-related variables, such as distance and angle to prey. To acquire such data, we combined video tracking of mice hunting live crickets in an open arena and calcium imaging using miniature microscopes. This allowed us to characterize the tuning of hundreds of V1 cells to several behaviorally-relevant variables. We observed that many neurons showed selective tuning to at least one of such variables. At the population level, however, decoding analyses showed that only a subset of these variables can be decoded. These included previously reported quantities, like mouse speed, but also hunting-relevant variables, such as prey distance. Our results therefore show that, despite the “early” positioning of V1 in the visual pathway, its cells can show complex response patterns to scenes that differ greatly from moving gratings. This highlights the importance of recording neuronal responses in freely-moving animals performing ethologically relevant behaviors, as these responses are a step towards understanding how the brain controls complex behaviors.

SELECTIVE BIDIRECTIONAL MODULATION OF RECIPROCATING NEURONS DURING HIERARCHICAL INTERACTIONS IN THE MOUSE VISUAL CORTEX

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Flora Vasile, Camille Mazo, Leopoldo Petreanu
Champalimaud Foundation, Champalimaud Research, Lisbon, Portugal

Visual perception arises from a set of hierarchically organised cortical areas, interconnected by ascending and descending projections. While the integration of feedforward inputs is thought to give rise to the increasingly complex visual representations of higher-order neurons, the function of descending inputs is less understood. Recent ex-vivo measurements showed that cortico-cortical projections selectively connect with reciprocating neurons in their target areas, suggesting that they mediate recurrent inter-area computations such as learning and predictive coding. However, whether hierarchical interactions selectively engage with reciprocating neurons in vivo remains unknown. Here we use in vivo 2-photon imaging, optogenetic stimulation and viral retrograde tracers to measure how interactions between the primary visual cortex (V1) and the posteromedial higher visual area (PM) depend on the projection type of the target neurons. Photostimulation of PM-to-V1 feedback axons resulted in a larger reduction of the responses of layer 2/3 neurons to gratings in cells projecting back to PM than in neighbouring ones projecting elsewhere. Similarly, a larger proportion of the PM neurons projecting back to V1 were modulated by V1-to-PM feedforward afferents photostimulation than non-V1 projecting neurons, by showing either an enhancement or a reduction of their visual responses. These results show that both ascending and descending projections in visual cortex selectively modulate reciprocating neurons during visual processing. The bidirectional selective modulation of reciprocating neurons by cortico-cortical projections challenges the classical view of feedforward cortical computation while supporting models of hierarchical computation involving selective recurrent interactions across visual processing stages.

A BIOPHYSICAL ACCOUNT OF MULTIPLICATION BY A SINGLE NEURON

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Birte Zuidinga, Lukas Groschner, Jonatan Malis, Alexander Borst
Max Planck Institute of Neurobiology, Circuits - Computation - Models, Martinsried, Germany

Nonlinear, multiplication-like operations carried out by individual nerve cells greatly enhance the computational power of a neural system, but our understanding of their biophysical implementation is scant. Here we pursue this problem in the *Drosophila melanogaster* ON motion vision circuit, in which we record the membrane potentials of direction-selective T4 neurons and of their columnar input elements in response to visual and pharmacological stimuli *in vivo*. Our electrophysiological measurements and conductance-based simulations provide evidence for a passive supralinear interaction between two distinct types of synapse on T4 dendrites. We show that this multiplication-like nonlinearity arises from the coincidence of cholinergic excitation and release from glutamatergic inhibition. The latter depends on the expression of the glutamate-gated chloride channel GluClα in T4 neurons, which sharpens the directional tuning of the cells and shapes the optomotor behaviour of the animals. Interacting pairs of shunting inhibitory and excitatory synapses have long been postulated as an analogue approximation of a multiplication.

WHITE MATTER DYNAMICS DEPENDS ON RECOVERY FROM RETINAL LESIONS AND VISUAL STIMULATION IN CATS.

POSTER SESSION 04 - SECTION: VISUAL SYSTEM, FROM RETINA TO CORTEX

Anna Kozak[1], Michał Wieteska[2], Michał Fiedorowicz[3], Bartosz Kossowski[1], Marco Ninghetto[1], Lutgarde Arckens[4], Ulf Eysel[5], Kalina Burnat[1]
[1]Nencki Institute of Experimental Biology PAS, Laboratory Of Brain Imaging Lobi, Warsaw, Poland, [2]Warsaw University of Technology, Institute Of Radioelectronics And Multimedia Technology, Warsaw, Poland, [3]Mossakowski Medical Research Institute, Polish Academy of Sciences, Small Animal Magnetic Resonance Imaging Laboratory, Warsaw, Poland, [4]Leuven Brain Institute, KU Leuven, Department Of Biology, Leuven, Belgium, [5]Ruhr-Universität Bochum, Department Of Neurophysiology Faculty Of Medicine, Bochum, Germany

Aims: Temporal assessment of the recovery from binocular central retinal lesions (RL) using simultaneous behavioral and MRI white matter morphology analysis.
Methods: 3 groups of cats participated: *control trained (CT, n=5); retinal lesioned naive (RLN, n=8); retinal lesioned and trained (RLT, n=4).* Behavioral training started 2 weeks after lesion in RLTrained cats, in CT after first scan, and lasted for 3 months. Visual stimulation was based on accelerated discrimination training from a previous study (Burnat et al, 2017). Longitudinal diffusion MRI protocol was applied and 5 scans till 3 months post lesion survival time were acquired (7T Bruker MRI BioSpec). Whole brain and regional analysis was performed (dLGN, Hippocampus, Areas 17/18, 20ab, PMLS, A1, A2, AEV).
Results: RL induced fractional anisotropy (FA) growth up to 5 weeks post-lesion followed by the continuous FA drop of up to 13 weeks post-lesion. In the RLT cats the pattern was similar, showing an increase of FA from 9 weeks post-lesion. CT cats showed continuous growth of FA from 5 weeks post-lesion. Individual FA levels correlated with behavioral performance and or difficulty of the task. Individual Fixel Based Analysis of diffusion data revealed differences in fiber cross section (FC), fiber density (FD) and fiber density and cross-section (FCD), between RLN and CT animals, and in FD and FC between RLN and RLT cats.
Conclusions: Visual stimulation applied shortly after retinal lesions has a longitudinal effect on white matter structure.

White matter hyperintensities (WMH) of presumed vascular origin is a common accompaniment of ageing, not only in dementia patients, but also in healthy population. The presence and progression of WMH in the brain have been widely associated to general cognitive impairment and all types of dementia, especially vascular cognitive impairment (VCI). Understand the effect of cerebrovascular damages in brain functioning could help in early diagnosis of different dementia subtypes. The aim of this investigation was to focus the research on the identification of specific electrophysiological signatures related to WMH total volume in the brain. Our data base consists in 350 cognitively healthy participants. All of them underwent a neuropsychological evaluation, MRI assessment (T1 and Flair), and MEG recordings (ten minutes of eyes closed resting state). WMH volume quantification was performed with an automatic detection toolbox, LST (SPM12). We used a completely data-driven approach to evaluate the relationship between power spectrum and the WMH total volume. Our result shows a general slowness pattern related with the severity of the white matter damage, as have been previously reported in the literature. Nevertheless, different patterns were found depending on the volume and etiology of the WMH: age-related or vascular disease. The high incidence and contribution to cognitive impairment of WMH, added to their treatable conditions and the lack of standardized results in the filed provides special importance to the study of robust biomarkers related with cerebrovascular pathologies in old population.

SPECTRAL PHASOR ANALYSIS FOR QUANTITATION OF AGE- AND DISEASE-RELATED PROTEIN MISFOLDING USING THE AMYLOID DYES BSB AND MCAAD-3

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Anastasiia Stepanchuk[1], Megan Morgan[1], Peter Stys[1], Jeffrey Joseph[1,2], Tammaryn Lashley[3,4]
[1]University of Calgary, Department Of Clinical Neurosciences, Hotchkiss Brain Institute, Calgary, Canada, [2]Alberta Health Services, Department Of Pathology And Laboratory Medicine, Calgary, Canada, [3]UCL Queen Square Institute of Neurology, Department Of Neurodegenerative Disease, London, United Kingdom, [4]UCL Queen Square Institute of Neurology, Department Of Clinical And Movement Neuroscience, Queen Square Brain Bank For Neurological Disorders, London, United Kingdom

Aims: This study examines the differences in protein aggregation related to ageing and Alzheimer's disease (AD). The aim of the project is to detect distinct types of amyloid assemblies (particularly ones that are not readily visualized using conventional techniques) and associate the specific types of protein deposits in the human hippocampus with signs of cognitive decline. Methods: Formalin-fixed, paraffin-embedded sections of human hippocampi were stained with conformationally sensitive amyloid dyes BSB and MCAAD-3 and imaged using spectral confocal microscopy. The same sections were then stained with anti-amyloid beta and anti-tau antibodies. Both the greater tissue parenchyma and the obvious protein aggregates were analyzed and quantitated across cases using the spectral phasor approach. Results: Using the varying emission spectra of the two probes, we were able to demonstrate different emission signatures between morphologically similar amyloid plaques across different regions and layers of the hippocampus. Moreover, we found a unique spectral signature of the greater tissue parenchyma across all cases in the AD cohort, where no plaques or tangles were present. Conclusions: Our novel method of staining, imaging and analysis suggested remarkable conformational heterogeneity of both age- and disease-related protein deposits in the hippocampus. The sensitivity of our method outperformed conventional immunohistochemistry with the detected spectral differences between the greater parenchyma of cognitively normal and AD cases indicating a subtle yet widespread proteopathy associated with disease. This subtle spectral change in AD was not present in cognitively unaffected cases exhibiting benign age-related amyloid deposition.

Complex Photophysical Properties of K114 Make for a Versatile Fluorescent Probe for Amyloid Detection.
Protein aggregation is a hallmark of Alzheimer's disease (AD) and many other neurodegenerative disorders. Small organic fluorophores such as Congo Red preferentially bind to cross-β-sheet-rich deposits and have been used to label amyloid plaques and tau tangles in histological samples. However, distinguishing between different conformations of protein aggregates is not trivial. Using silkworm and spider silks (prototypical amyloids) and transgenic AD mouse (5XFAD) and human AD brain samples, we report how spectral confocal microscopy allowed for improved detection and differentiation of protein aggregates based on the unexpected photophysical behavior of the amyloid-specific dye K114. The pH and excitation power had pronounced effects on the emission spectrum and intensity of amyloid-bound K114 fluorescence. When bound to β-sheet-rich assemblies, the emission spectrum of K114 was governed by the local pH of the binding pockets much more than by the pH of the mounting medium, likely due to ionization of titratable phenols. Unexpectedly, exposure to high excitation power caused a permanent increase in fluorescence intensity and a spectral blue-shift. These light-induced fluorescence changes were dependent in a complex manner on laser power, exposure time, pH, and amyloid type examined. The above-mentioned phenomena were observed in silk fibers and Alzheimer brain sections from mouse and human, indicating that this may be a general characteristic of K114 when bound to tightly aggregated macromolecules. Potential mechanisms are discussed, likely involving photoinduced electron transfer. Our findings illustrate how the complex photophysical behavior of amyloid-bound K114 can be exploited for improved detection and differentiation of protein aggregates.

34751140: Stepanchuk AA, Barber PA, Lashley T, Joseph JT, Stys PK
Quantitative detection of grey and white matter amyloid pathology using a combination of K114 and CRANAD-3 fluorescence.
Alzheimer's disease (AD) is a neurodegenerative disease that exacts a huge toll on the patient, the healthcare system and society in general. Abundance and morphology of protein aggregates such as amyloid β plaques and tau tangles, along with cortical atrophy and gliosis are used as measures to assess the changes in the brain induced by the disease. Not all of these parameters have a direct correlation with cognitive decline. Studies have shown that only particular protein conformers can be the main drivers of disease progression, and conventional approaches are unable to distinguish different conformations of disease-relevant proteins.
Neurobiol Dis, 2021; 161
34499422: Stepanchuk AA, Joseph JT, Stys PK
Spectral photokinetic conversion of the fluorescent probes BSB and K114 for improved detection of amyloid assemblies.
Cross-β-sheet-rich protein fibrils are infamous for their accumulation in the brains of patients diagnosed with a number of neurodegenerative diseases, including Alzheimer's disease (AD). Disease-relevant fibrils are a result of deviation of the proteins from their native structure to a misfolded state resulting in aggregation and formation of fibrils. In this study, we explored the phenomenon of light-induced fluorescence enhancement of amyloid assemblies stained with two amyloid probes (BSB and K114) using Bombyx mori silk and human AD brain sections. The photoconversion effect, accompanied by an increase in fluorescence intensity and spectral blue-shift, was highly dependent on the chemical structures of the dyes, pH, presence of glycerol and the type of amyloid. The degree of intensity and spectral change over time in response to high laser exposure were quantified and analyzed using custom-written analysis tools. Our findings provide further insight into possible mechanisms of amyloid-mediated photoconversion kinetics of K114 and BSB, and may provide more insight into the molecular nature of various amyloid assemblies.

Early detection of prion protein aggregation with a fluorescent pentameric oligothiophene probe using spectral confocal microscopy.
Misfolding of the prion protein (PrP) and templating of its pathological conformation onto cognate proteins causes a number of lethal disorders of central nervous system in humans and animals, such as Creutzfeldt-Jacob disease, chronic wasting disease and bovine spongiform encephalopathy. Structural rearrangement of PrP into PrP promotes aggregation of misfolded proteins into β-sheet-rich fibrils, which can be visualized by conformationally sensitive fluorescent probes. Early detection of prion misfolding and deposition might provide useful insights into its pathophysiology. Pentameric formyl thiophene acetic acid (pFTAA) is a novel amyloid probe that was shown to sensitively detect various misfolded proteins, including PrP. Here, we compared sensitivity of pFTAA staining and spectral microscopy with conventional methods of prion detection in mouse brains infected with mouse-adapted 22L prions. pFTAA bound to prion deposits in mouse brain sections exhibited a red-shifted fluorescence emission spectrum, which quantitatively increased with disease progression. Small prion deposits were detected as early as 50 days post-inoculation, well before appearance of clinical signs. Moreover, we detected significant spectral shifts in the greater brain parenchyma as early as 25 days post-inoculation, rivaling the most sensitive conventional method (real-time quaking-induced conversion). These results showcase the potential of pFTAA staining combined with spectral imaging for screening of prion-infected tissue. Not only does this method have comparable sensitivity to established techniques, it is faster and technically simpler. Finally, this readout provides valuable information about the spatial distribution of prion aggregates across tissue in the earliest stages of infection, potentially providing valuable pathophysiological insight into prion transmission.

IMAGING THE BRAIN ACROSS THE LIFESPAN: A RAT MODEL OF HEALTHY AGEING

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Antonio Cerdán-Cerdá, Patricia Martínez-Tazo, Mohamed Selim, Santiago Canals, Silvia De Rubeis
Instituto de Neurociencias de Alicante CSIC-UMH, Cellular And Systems Neurobiology, San Juan de Alicante, Spain

Across the lifespan, the brain is subject to dynamic structural changes which have a deep impact on its healthy and pathological evolution [1]. Recently, magnetic resonance imaging (MRI) in humans uncovered region- and sex-specific trajectories of microstructural integrity decline, suggesting prolonged neoteny in the female brain [2]. Animal models can dissect the neurobiological substrates driving maturation and senescence of the brain and inform on the mechanism underlying sex dimorphism in ageing. **Aims:** 1) To validate a model of healthy ageing in rats, replicating region- and sex-specific trajectories found in humans. 2) To dissect the neurobiological underpinning of the observed trajectories by using advanced MRI biomarkers and immunohistochemistry. **Methods:** We applied a diffusion MRI protocol to a cohort of 28 Wistar rats (14 females) longitudinally from 1 month to 4 months to extract indices of microstructural integrity. 12 rats (6 females) were sacrificed at different time points and processed for immunohistochemistry (GFAP, Iba-1 and myelin basic protein). **Results:** The analysis of MRI biomarkers highlighted region-specific patterns of maturation ($p<0.05$; Time*Region) which follow a quadratic curve for increasing age, with a trend toward difference in the maturation peak in males versus females ($p<0.07$; see figure). Myelin staining intensity varies quadratically with age ($p<0.01$) in a region-specific way. **Conclusions:** Our rat model faithfully reproduces brain-ageing patterns seen in humans, and points to myelin as an important driver of region-specific trajectories of evolution across the lifespan. MRI can provide biomarkers of structural brain development and deterioration in a longitudinal and non-invasive

manner.

Diffusion-weighted MRI in neurodegenerative and psychiatric animal models: Experimental strategies and main outcomes. Preclinical MRI approaches constitute a key tool to study a wide variety of neurological and psychiatric illnesses, allowing a more direct investigation of the disorder substrate and, at the same time, the possibility of back-translating such findings to human subjects. However, the lack of consensus on the optimal experimental scheme used to acquire the data has led to relatively high heterogeneity in the choice of protocols, which can potentially impact the comparison between results obtained by different groups, even using the same animal model. This is especially true for diffusion-weighted MRI data, where certain experimental choices can impact not only on the accuracy and precision of the extracted biomarkers, but also on their biological meaning. With this in mind, we extensively examined preclinical imaging studies that used diffusion-weighted MRI to investigate neurodegenerative, neurodevelopmental and psychiatric disorders in rodent models. In this review, we discuss the main findings for each preclinical model, with a special focus on the analysis and comparison of the different acquisition strategies used across studies and their impact on the heterogeneity of the findings.

Olfaction is governed by olfactory mucosal cells (OM) located in the upper nasal cavity. Impaired olfaction is a common, early sign of neurodegenerative diseases, including Alzheimer's disease (AD). The OM cells are at the forefront of exposure to inhaled air and are thus exposed to a myriad of particles present in ambient air. Recent studies correlate living in highly polluted cities with cognitive impairment and neurodegenerative disease risk, including AD. In this study, we investigated how exposure to air pollution particles affects the OM cell transcriptome. The specific aims were to: 1) Find key molecular mechanisms affected by air pollutant exposure in OM cells; 2) Evaluate differential responses in patient-derived OM cells of cognitively healthy individuals and AD patients. We used a unique, recently developed air-liquid-interface exposure system that mimics real-world traffic-derived air pollutant exposure. Primary OM cells from AD patients and age-matched healthy controls were subjected to exposure to either clean air or to diluted emissions from a heavy-duty diesel engine without aftertreatment for 3 days. After treatment, miRNA and mRNA expression analyses were performed. We found approximately 500 differentially expressed mRNA following exposure, some of which were differentially expressed between healthy and AD cells. Pathway analyses revealed that these genes are involved in the oxidative stress response. This study provides new information on the adverse effects of air pollutant exposure in OM cells and identifies possible biomarkers. It also provides molecular insight into the link between diesel exhaust exposure and AD.

Early detection of Alzheimer's Disease (AD) is vital for developing effective treatments. Neuroimaging can detect early brain changes, such as hippocampal atrophy in Mild Cognitive Impairment (MCI), a prodromal state of AD. Machine learning can utilise the many features from high-dimensional neuroimaging data, but many cases are required. While large, public datasets of MCI/AD exist for Magnetic Resonance Imaging (MRI), eg "ADNI", comparable datasets are lacking for Magnetoencephalography (MEG). MEG offers advantages in its millisecond resolution, potentially revealing physiological changes in brain oscillations or connectivity before structural changes are evident with MRI (and unconfounded by vascular changes in functional MRI). Here we describe the "BioFIND" dataset of 324 individuals, approximately half MCI and half controls, who have at least 2 mins of resting-state MEG, plus a T1 structural MRI, from one of two sites (Cambridge and Madrid). To our knowledge, this is the largest publically available MEG dataset for dementia research, available in BIDS format on DPUK platform: https://portal.dementiasplatform.uk/Apply. Initial analyses using Multi-kernel Learning (MKL) of Support Vector Machines (SVM) show that MEG sensor covariance adds complimentary information for MCI classification beyond grey-matter volume from structural MRI. Future possible analyses include source space, measures of functional connectivity (e.g, amplitude or phase), dynamic as well as static connectivity, more advanced classifiers (e.g, deep learning); future plans include adding new participants from ongoing projects, and follow-up diagnoses and other biomarkers where available.

Alzheimer's disease (AD), marked by extracellular amyloid-beta (Aβ) plaque accumulation leads to progressive memory and cognitive function loss. Resting-state (RS) functional connectivity (FC), an emerging biomarker of AD, measures only correlative inter-regional relationships. Here, we investigate changes in directed/causal information flow inferred from RS-fMRI measurements in a transgenic rat model (TgF344-AD) of AD at the pre-plaque stage. RS-fMRI data (9.4T Bruker Biospec, 1000 volumes, TR=0.6s) were acquired in anesthetized 4(N=15)- and 6(N=13)-month old TgF344-AD (TG) rats and wild type (WT) littermates (N=11). Preprocessed voxel-level data were parcellated into 126 grey-matter parcels. Normalized directed transfer entropy (NDTE), an information-theoretic approximation of Granger causality, was used to infer directed information flows between region-pairs. Predictive cross-validated accuracy of NDTE and FC to classify genotypes at each age was compared. Salient connections in NDTE's predictive accuracy were identified and their median NDTE was compared between genotypes using Wilcoxon ranksum test. NDTE and FC distinguished WT and TG rats better than chance at 4-months; only NDTE did it at 6-months with 80% accuracy. NDTE accurately classified the two ages only in the TG group implying changes with age predominantly occur in the TG. The most salient connections in NDTE's genotypes classification at both ages were from the forebrain to the cortex. Interestingly, median NDTE for these connections was higher in the TG at 4-months but lower at 6-months. Early impact of AD on basal forebrain, an important modulator of RS networks, could result in altered information flow from it as this study demonstrates.

Effective connectivity extracts clinically relevant prognostic information from resting state activity in stroke.
Recent resting-state functional MRI studies in stroke patients have identified two robust biomarkers of acute brain dysfunction: a reduction of inter-hemispheric functional connectivity between homotopic regions of the same network, and an abnormal increase of ipsi-lesional functional connectivity between task-negative and task-positive resting-state networks. Whole-brain computational modelling studies, at the individual subject level, using undirected effective connectivity derived from empirically measured functional connectivity, have shown a reduction of measures of integration and segregation in stroke as compared to healthy brains. Here we employ a novel method, first, to infer whole-brain directional effective connectivity from zero-lagged and lagged covariance matrices, then, to compare it to empirically measured functional connectivity for predicting stroke versus healthy status, and patient performance (zero, one, multiple deficits) across neuropsychological tests. We also investigated the accuracy of functional connectivity versus model effective connectivity in predicting the long-term outcome from acute measures. Both functional and effective connectivity predicted healthy from stroke individuals significantly better than the chance-level; however, accuracy for the effective connectivity was significantly higher than for functional connectivity at 1- to 2-week, 3-month and 1-year post-stroke. Predictive functional connections mainly included those reported in previous studies (within-network inter-hemispheric and between task-positive and -negative networks intra-hemispherically). Predictive effective connections included additional between-network links. Effective connectivity was a better predictor than functional connectivity of the number of behavioural domains in which patients suffered deficits, both at 2-week and 1-year post-onset of stroke. Interestingly, patient deficits at 1-year time-point were better predicted by effective connectivity values at 2 weeks rather than at 1-year time-point. Our results thus demonstrate that the second-order statistics of functional MRI resting-state activity at an early stage of stroke, derived from a whole-brain effective connectivity, estimated in a model fitted to reproduce the propagation of neuronal activity, has pertinent information for clinical prognosis.

Resting-State Co-activation Patterns as Promising Candidates for Prediction of Alzheimer's Disease in Aged Mice.
Alzheimer's disease (AD), a neurodegenerative disorder marked by accumulation of extracellular amyloid-β (Aβ) plaques leads to progressive loss of memory and cognitive function. Resting-state fMRI (RS-fMRI) studies have provided links between these two observations in terms of disruption of default mode and task-positive resting-state networks (RSNs). Important insights underlying these disruptions were recently obtained by investigating dynamic fluctuations in RS-fMRI signals in old TG2576 mice (a mouse model of amyloidosis) using a set of quasi-periodic patterns (QPP). QPPs represent repeating spatiotemporal patterns of neural activity of predefined temporal length. In this article, we used an alternative methodology of co-activation patterns (CAPs) that represent instantaneous and transient brain configurations that are likely contributors to the emergence of commonly observed RSNs and QPPs. We followed a recently published approach for obtaining CAPs that divided all time frames, instead of those corresponding to supra-threshold activations of a seed region as done traditionally, to extract CAPs from RS-fMRI recordings in 10 TG2576 female mice and eight wild type littermates at 18 months of age. Subsequently, we matched the CAPs from the two groups using the Hungarian method and compared the temporal (duration, occurrence rate) and the spatial (lateralization of significantly co-activated and co-deactivated voxels) properties of matched CAPs. We found robust differences in the spatial components of matched CAPs. Finally, we used supervised learning to train a classifier using either the temporal or the spatial component of CAPs to distinguish the transgenic mice from the WT. We found that while duration and occurrence rates of all CAPs performed the classification with significantly higher accuracy than the chance-level, blood oxygen level-dependent (BOLD) signals of significantly activated voxels from individual CAPs turned out to be a significantly better predictive feature demonstrating a near-perfect classification accuracy. Our results demonstrate resting-state co-activation patterns are a promising candidate in the development of a diagnostic, and potentially, prognostic RS-fMRI biomarker of AD.

Cell-Intrinsic Control of Interneuron Migration Drives Cortical Morphogenesis.
Interneurons navigate along multiple tangential paths to settle into appropriate cortical layers. They undergo a saltatory migration paced by intermittent nuclear jumps whose regulation relies on interplay between extracellular cues and genetic-encoded information. It remains unclear how cycles of pause and movement are coordinated at the molecular level. Post-translational modification of proteins contributes to cell migration regulation. The present study uncovers that carboxypeptidase 1, which promotes post-translational protein deglutamylation, controls the pausing of migrating cortical interneurons. Moreover, we demonstrate that pausing during migration attenuates movement simultaneity at the population level, thereby controlling the flow of interneurons invading the cortex. Interfering with the regulation of pausing not only affects the size of the cortical interneuron cohort but also impairs the generation of age-matched projection neurons of the upper layers.

Decreased integration and information capacity in stroke measured by whole brain models of resting state activity.
While several studies have shown that focal lesions affect the communication between structurally normal regions of the brain, and that these changes may correlate with behavioural deficits, their impact on brain's information processing capacity is currently unknown. Here we test the hypothesis that focal lesions decrease the brain's information processing capacity, of which changes in functional connectivity may be a measurable correlate. To measure processing capacity, we turned to whole brain computational modelling to estimate the integration and segregation of information in brain networks. First, we measured functional connectivity between different brain areas with resting state functional magnetic resonance imaging in healthy subjects (n = 26), and subjects who had suffered a cortical stroke (n = 36). We then used a whole-brain network model that coupled average excitatory activities of local regions via anatomical connectivity. Model parameters were optimized in each healthy or stroke participant to maximize correlation between model and empirical functional connectivity, so that the model's effective connectivity was a veridical representation of healthy or lesioned brain networks. Subsequently, we calculated two model-based measures: 'integration', a graph theoretical measure obtained from functional connectivity, which measures the connectedness of brain networks, and 'information capacity', an information theoretical measure that cannot be obtained empirically, representative of the segregative ability of brain networks to encode distinct stimuli. We found that both measures were decreased in stroke patients, as compared to healthy controls, particularly at the level of resting-state networks. Furthermore, we found that these measures, especially information capacity, correlate with measures of behavioural impairment and the segregation of resting-state networks empirically measured. This study shows that focal

lesions affect the brain's ability to represent stimuli and task states, and that information capacity measured through whole brain models is a theory-driven measure of processing capacity that could be used as a biomarker of injury for outcome prediction or target for rehabilitation intervention.

Hippocampal Sharp-Wave Ripples Influence Selective Activation of the Default Mode Network.
The default mode network (DMN) is a commonly observed resting-state network (RSN) that includes medial temporal, parietal, and prefrontal regions involved in episodic memory [1-3]. The behavioral relevance of endogenous DMN activity remains elusive, despite an emerging literature correlating resting fMRI fluctuations with memory performance [4, 5]-particularly in DMN regions [6-8]. Mechanistic support for the DMN's role in memory consolidation might come from investigation of large deflections (sharp-waves) in the hippocampal local field potential that co-occur with high-frequency (>80 Hz) oscillations called ripples-both during sleep [9, 10] and awake deliberative periods [11-13]. Ripples are ideally suited for memory consolidation [14, 15], since the reactivation of hippocampal place cell ensembles occurs during ripples [16-19]. Moreover, the number of ripples after learning predicts subsequent memory performance in rodents [20-22] and humans [23], whereas electrical stimulation of the hippocampus after learning interferes with memory consolidation [24-26]. A recent study in macaques showed diffuse fMRI neocortical activation and subcortical deactivation specifically after ripples [27]. Yet it is unclear whether ripples and other hippocampal neural events influence endogenous fluctuations in specific RSNs-like the DMN-unitarily. Here, we examine fMRI datasets from anesthetized monkeys with simultaneous hippocampal electrophysiology recordings, where we observe a dramatic increase in the DMN fMRI signal following ripples, but not following other hippocampal electrophysiological events. Crucially, we find increases in ongoing DMN activity after ripples, but not in other RSNs. Our results relate endogenous DMN fluctuations to hippocampal ripples, thereby linking network-level resting fMRI fluctuations with behaviorally relevant circuit-level neural dynamics.

Computational modeling of resting-state activity demonstrates markers of normalcy in children with prenatal or perinatal stroke.
Children who sustain a prenatal or perinatal brain injury in the form of a stroke develop remarkably normal cognitive functions in certain areas, with a particular strength in language skills. A dominant explanation for this is that brain regions from the contralesional hemisphere "take over" their functions, whereas the damaged areas and other ipsilesional regions play much less of a role. However, it is difficult to tease apart whether changes in neural activity after early brain injury are due to damage caused by the lesion or by processes related to postinjury reorganization. We sought to differentiate between these two causes by investigating the functional connectivity (FC) of brain areas during the resting state in human children with early brain injury using a computational model. We simulated a large-scale network consisting of realistic models of local brain areas coupled through anatomical connectivity information of healthy and injured participants. We then compared the resulting simulated FC values of healthy and injured participants with the empirical ones. We found that the empirical connectivity values, especially of the damaged areas, correlated better with simulated values of a healthy brain than those of an injured brain. This result indicates that the structural damage caused by an early brain injury is unlikely to have an adverse and sustained impact on the functional connections, albeit during the resting state, of damaged areas. Therefore, these areas could continue to play a role in the development of near-normal function in certain domains such as language in these children.

Brain state dependent postinhibitory rebound in entorhinal cortex interneurons.
Postinhibitory rebound (PIR) is believed to play an important role in the genesis and maintenance of biological rhythms. While it has been demonstrated during several in vitro studies, in vivo evidence for PIR remains scarce. Here, we report that PIR can be observed in the dorsomedial entorhinal cortex of anesthetized rats, mostly between putatively connected GABAergic interneurons, and that it is more prevalent during the theta (4-6 Hz) oscillation state than the slow (0.5-2 Hz) oscillation state. Functional inhibition was also found to be brain state and postsynaptic cell type dependent but that alone could not explain this brain state dependence of PIR. A theoretical analysis, using two Fitzhugh-Nagumo neurons coupled to an external periodic drive, predicted that the modulation of a faster spiking rate by the slower periodic drive could account for the brain state dependence of PIR. Model predictions were verified experimentally. We conclude that PIR is cell type and brain state dependent and propose that this could impact network synchrony and rhythmogenesis.

Characterisation of cortical activity in response to deep brain stimulation of ventral-lateral nucleus: modelling and experiment.

FENS Forum 2022
9-13 July 2022 | Paris, France

Motivated by its success as a therapeutic treatment in other neurological disorders, most notably Parkinson's disease, Deep Brain Stimulation (DBS) is currently being trialled in a number of patients with drug unresponsive epilepsies. However, the mechanisms by which DBS interferes with neuronal activity linked to the disorder are not well understood. Furthermore, there is a need to identify optimized values of parameters (for example in amplitude/frequency space) of the stimulation protocol with which one aims to achieve the desired outcome. In this paper we characterise the system response to stimulation, to gain an understanding of the role different brain regions play in generating the output observed in EEG. We perform a number of experiments in healthy rats, where the ventral-lateral thalamic nucleus is stimulated using a train of square-waves with different frequency and amplitudes. The response to stimulation in the motor cortex is recorded and the drive-response relationship over frequency/amplitude space is considered. Subsequently, we compare the experimental data with simulations of a mean-field model, finding good agreement between the output of the model and the experimental data--both in the time and frequency domains--when considering a transition to oscillatory activity in the cortex as the frequency of stimulation is increased. Overall, our study suggests that mean-field models can appropriately characterise the stimulus-response relationship of DBS in healthy animals. In this way, it constitutes a first step towards the goal of developing a closed-loop feedback control protocol for suppressing epileptic activity, by adaptively adjusting the stimulation protocol in response to EEG activity.

THE APOLIPOPROTEIN E GENOTYPE INFLUENCE ON GLOBAL AMYLOID BETA ACCUMULATION IN NON-DEMENTED ELDERLY

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Maha Wybitul[1], Anton Gietl[1], Nicolas Langer[2], Christoph Hock[1], Valerie Treyer[1]
[1]University of Zurich, Institute For Regenerative Medicine, Schlieren, Switzerland, [2]University of Zurich, Department Of Psychology, Zurich, Switzerland

The Apolipoprotein E (ApoE) gene is the most important genetic risk factor for Alzheimer's disease (AD) and may act as disease progression modifier. Research has demonstrated the association between the ApoE e4 allele and elevated amyloid beta (Aβ) burden when measured cross-sectionally. However, whether the e4 allele contributes to earlier Aβ accumulation onset or persistent higher accumulation over time is still unclear. Additionally, a genotype effect might be dependent on the accumulation phase. The current project, therefore, investigated ApoE genotype's effect on Aβ accumulation as measured by amyloid positron emission tomography (PET) imaging. Data of 540 non-demented elderly that received PET scans at three or more timepoints were obtained from ADNI and AIBL cohorts. Amyloid values were extracted via centiloid method and analyzed using linear mixed regression considering Aβ baseline status, ApoE genotype, age, gender, and diagnosis. Overall, the sample showed an increase in Aβ over time. ApoE genotype had a direct effect on Aβ load and displayed an indirect relationship with Aβ accumulation via interactions with Aβ baseline status and age. To assess differences in amyloid load trajectories the sample was divided into amyloid baseline positive and negative participants. Within each subgroup, cluster analysis then identified Aβ decrease, stabilization, and increase clusters. Further investigations within these trajectory clusters suggest that the ApoE genotype effect might be group dependent. The three-way interaction of ApoE, amyloid baseline status, and accumulation might explain previous contradictory literature. The trajectories of decreaser, stable, and increaser groups give insights into the complexity of AD's progression.

Recent genetic and neuropathological studies have implicated microglia cells to have a causal role in the pathogenesis of Alzheimer's disease (AD). Triggering receptor expressed on myeloid cells 2 (TREM2) is one of the most studied microglial receptors in the context of AD because carriers of its rare variant have an increased risk of disease development. TREM2 is involved in the regulation of myeloid cell number, amyloid β (Aβ) binding, phagocytosis, and inflammatory response. Its ectodomain is processed by a disintegrin and metalloprotease enzymes ADAM10 and ADAM17, and the fragment released in CSF and blood is referred to as soluble TREM2 (sTREM2). We aimed to compare CSF and plasma concentrations of sTREM2 in AD, mild cognitive impairment (MCI), and samples of cognitively normal controls, and to correlate them with the core CSF biomarkers of AD (levels of $A\beta_{1-42}$, total tau [t-tau], and tau phosphorylated at epitope 181 [p-tau181]). Concentrations of sTREM2 were measured in 127 AD, 79 MCI, and 36 control CSF samples and 99 AD, 37 MCI, and 10 control plasma samples using ELISA. The sTREM2 levels in CSF were significantly different among the groups, whereas differences in plasma levels did not reach significance. These results are congruent with previous reports showing elevated sTREM2 levels in CSF of AD subjects. We concluded that the CSF sTREM2 level, but not plasma sTREM2, is a promising biomarker of microglial activation in AD. Role of Microglial Cells in Alzheimer's Disease Tau Propagation.
Uncontrolled immune response in the brain contributes to the progression of all neurodegenerative disease, including Alzheimer's disease (AD). Recent investigations have documented the prion-like features of tau protein and the involvement of microglial changes with tau pathology. While it is still unclear what sequence of events is causal, it is likely that tau seeding potential and microglial contribution to tau propagation act together, and are essential for the development and progression of degenerative changes. Based on available evidence, targeting tau seeds and controlling some signaling pathways in a complex inflammation process could represent a possible new therapeutic approach for treating neurodegenerative diseases. Recent findings propose novel diagnostic assays and markers that may be used together with standard methods to complete and improve the diagnosis and classification of these diseases. In conclusion, a novel perspective on microglia-tau relations reveals new issues to investigate and imposes different approaches for developing therapeutic strategies for AD.

The Association of Essential Metals with APOE Genotype in Alzheimer's Disease.
The major confirmed genetic risk factor for late-onset, sporadic Alzheimer's disease (AD) is variant ε4 of apolipoprotein E gene (APOE). It is proposed that ApoE, a protein involved in transport of cholesterol to neurons can cause neurodegeneration in AD through interaction with metals. Previous studies mostly associated copper, iron, zinc, and calcium with ApoE4-mediated toxicity.

Blood-brain barrier and innate immunity in the pathogenesis of Alzheimer's disease.
The pathogenesis of Alzheimer's disease (AD) is only partly understood. This is the probable reason why significant efforts to treat or prevent AD have been unsuccessful. In fact, as of April 2019, there have been 2094 studies registered for AD on the clinicaltrials.gov U.S. National Library of Science web page, of which only a few are still ongoing. In AD, abnormal accumulation of amyloid and tau proteins in the brain are thought to begin 10-20 years before the onset of overt symptoms, suggesting that interventions designed to prevent pathological amyloid and tau accumulation may be more effective than attempting to reverse a pathology once it is established. However, to be successful, such early interventions need to be selectively administered to individuals who will likely develop the disease long before the symptoms occur. Therefore, it is critical to identify early biomarkers that are strongly predictive of AD. Currently, patients are diagnosed on the basis of a variety of clinical scales, neuropsychological tests, imaging and laboratory modalities, but definitive diagnosis can be made only by postmortem assessment of underlying neuropathology. People suffering from AD thus may be misdiagnosed clinically with other primary causes of dementia, and vice versa, thereby also reducing the power of clinical trials. The amyloid cascade hypothesis fits well for the familial cases of AD with known mutations, but is not sufficient to explain sporadic, late-onset AD (LOAD) that accounts for over 95% of all cases. Since the earliest descriptions of AD there have been neuropathological features described other than amyloid plaques (AP) and neurofibrillary tangles (NFT), most notably gliosis and neuroinflammation. However, it is only recently that genetic and experimental studies have implicated microglial dysfunction as a causal factor for AD, as opposed to a merely biological response of its accumulation around AP. Additionally, many studies have suggested the importance of changes in blood-brain barrier (BBB) permeability in the pathogenesis of AD. Here we suggest how these less investigated aspects of the disease that have gained increased attention in recent years may contribute mechanistically to the development of lesions and symptoms of AD.

Understanding Emotions: Origins and Roles of the Amygdala.
Emotions arise from activations of specialized neuronal populations in several parts of the cerebral cortex, notably the anterior cingulate, insula, ventromedial prefrontal, and subcortical structures, such as the amygdala, ventral striatum, putamen, caudate nucleus, and ventral tegmental area. Feelings are conscious, emotional experiences of these activations that contribute to neuronal networks mediating thoughts, language, and behavior, thus enhancing the ability to predict, learn, and reappraise stimuli and situations in the environment based on previous experiences. Contemporary theories of emotion converge around the key role of the amygdala as the central subcortical emotional brain structure that constantly evaluates and integrates a variety of sensory information from the surroundings and assigns them appropriate values of emotional dimensions, such as valence, intensity, and approachability. The amygdala participates in the regulation of autonomic and endocrine functions, decision-making and adaptations of instinctive and motivational behaviors to changes in the environment through implicit associative learning, changes in short- and long-term synaptic plasticity, and activation of the fight-or-flight response via efferent projections from its central nucleus to cortical and subcortical structures.

SEXUALLY DIMORPHIC NEURODEGENERATION AND NEUROINFLAMMATION IN THE HUMAN OLFACTORY BULB IN ALZHEIMER'S DISEASE.

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Alicia Flores-Cuadrado[1], Daniel Saiz-Sanchez[1], Mohedano-Moriano[2], Lucian[1], Ruiz-Aguilera[1], Martinez-Marcos[1], Isabel Ubeda-Banon[1]
[1]UNIV. CASTILLA-LA MANCHA, Facultad De Medicina De Ciudad Real, CIUDAD REAL, Spain, [2]FACULTAD DE CIENCIAS DE LA SALUD, Ciencias MÉdicas, TALAVERA DE LA REINA, Spain

Alzheimer's disease (AD) is the most prevalent neurodegenerative disease and mainly diagnosed in females, calling attention to understand sexual dimorphisms. Neurofibrillary tangles of tau and amyloid-β plaques have been described early and preferentially in the olfactory bulb and resonance analysis have reported a reduction in this area. However, whether this diminution is due to loss of neurons or glial cells is unknown. Microglial and astroglial density has been also described in AD, but not in the olfactory bulb. Therefore, the present report aims at describing neural and glial changes in the olfactory bulb using unbiased-stereological methods with specific neural (Neu-N), microglial (Iba-1) and astroglial (GFAP) markers in AD and non-diseased cases (NAD). 58 clinically diagnosed individuals were used (AD= 34 and NAD= 24). These samples from donors were provided by the IDIBAPS, BIOBANC-MUR, BTCIEN and Biobanco Vasco, integrated in the Spanish National Biobanks. Stereological quantification was performed using Stereo Investigator and ImageJ softwares and proteins were quantified by Western-blot (WB). No differences were observed in volume and GFAP. Neurodegeneration was higher in AD males' cases based on stereology, whereas in females by Western-blot. Microgliosis was increased in AD and focused on females. These data constitute the first demonstration of sex differences in neurodegeneration using specific neural markers and confirm the microgliosis in the human olfactory bulb in AD. Sponsored by the UCLM/ERDF (2021-GRIN-31233), Spanish Ministries of Economy and Competitiveness/ERDF (SAF2016-75768-R) and Science and Innovation (PID2019-108659RB-I00) to AMM and Autonomous Government of Castilla- La Mancha/ERDF (SBPLY/17/180501/000430) to AMM and DSS.

Astrogliosis and sexually dimorphic neurodegeneration and microgliosis in the olfactory bulb in Parkinson's disease.
Hyposmia is prodromal, and male sex is a risk marker for an enhanced likelihood ratio of Parkinson's disease. The literature regarding olfactory bulb volume reduction is controversial, although the olfactory bulb has been largely reported as an early and preferential site for α-synucleinopathy. These pathological deposits have been correlated with neural loss in Nissl-stained material. However, microgliosis has rarely been studied, and astrogliosis has been virtually neglected. In the present report, α-synucleinopathy (α-synuclein), neurodegeneration (Neu-N), astrogliosis (GFAP), and microgliosis (Iba-1) were quantified, using specific markers and stereological methods. Disease, sex, age, disease duration, and post-mortem interval were considered variables for statistical analysis. No volumetric changes have been identified regarding disease or sex. α-Synucleinopathy was present throughout the OB, mainly concentrated on anterior olfactory nucleus. Neurodegeneration (reduction in Neu-N-positive cells) was statistically significant in the diseased group. Astrogliosis (increased GFAP labeling) and microgliosis (increased Iba-1 labeling) were significantly enhanced in the Parkinson's disease group. When analyzed per sex, neurodegeneration and microgliosis differences are only present in men. These data constitute the demonstration of sex differences in neurodegeneration using specific neural markers, enhanced astrogliosis and increased microgliosis, also linked to male sex, in the human olfactory bulb in Parkinson's disease.

Neuropsychiatric disorders are prevalent diseases whose causes and mechanisms involve cellular, genetic and synaptic alterations that remain elusive. In this context, translating experimental findings to the clinic represents a major challenge. We propose to use high-throughput neurohistological methods to overcome this limitation. We developed a next- generation neurohistopathology pipeline to perform a systematic multiscale analysis of brain pathology in postmortem human brains and identify the cellular, molecular and circuit underpinnings of neurodegenerative and psychiatric disorders. We adapted tissue clearing and labeling techniques, combined with light-sheet microscopy and advanced image-processing tools, to map cell types, gene expression, synaptic connectivity and neuronal circuits in large samples of diseased and non-diseased archival human brains. We combined this approach with whole brain histological mapping of cellular and molecular markers from tissue sections and high-resolution imaging of subcellular structures in pathological hot spots. We demonstrated the validity of this approach in Alzheimer's disease and frontotemporal dementia. Overall, the multimodal mapping of the human brain offers promising avenues for investigating the mechanisms of brain disorders, identifying new biomarkers and devising novel preventive and therapeutic interventions.

APP accumulates with presynaptic proteins around amyloid plaques: A role for presynaptic mechanisms in Alzheimer's disease?
In Alzheimer's disease (AD), the distribution of the amyloid precursor protein (APP) and its fragments other than amyloid beta, has not been fully characterized. Here, we investigate the distribution of APP and its fragments in human AD brain samples and in mouse models of AD in reference to its proteases, synaptic proteins, and histopathological features characteristic of the AD brain, by combining an extensive set of histological and analytical tools. We report that the prominent somatic distribution of APP observed in control patients remarkably vanishes in human AD patients to the benefit of dense accumulations of extra-somatic APP, which surround dense-core amyloid plaques enriched in APP-Nter. These features are accentuated in patients with familial forms of the disease. Importantly, APP accumulations are enriched in phosphorylated tau and presynaptic proteins whereas they are depleted of post-synaptic proteins suggesting that the extra-somatic accumulations of APP are of presynaptic origin. Ultrastructural analyses unveil that APP concentrates in autophagosomes and in multivesicular bodies together with presynaptic vesicle proteins. Altogether, alteration of APP distribution and its accumulation together with presynaptic proteins around dense-core amyloid plaques is a key histopathological feature in AD, lending support to the notion that presynaptic failure is a strong physiopathological component of AD.

Distinctive alteration of presynaptic proteins in the outer molecular layer of the dentate gyrus in Alzheimer's disease.
Synaptic degeneration has been reported as one of the best pathological correlates of cognitive deficits in Alzheimer's disease. However, the location of these synaptic alterations within hippocampal sub-regions, the vulnerability of the presynaptic versus postsynaptic compartments, and the biological mechanisms for these impairments remain unknown. Here, we performed immunofluorescence labelling of different synaptic proteins in fixed and paraffin-embedded human hippocampal sections and report reduced levels of several presynaptic proteins of the neurotransmitter release machinery (complexin-1, syntaxin-1A, synaptotagmin-1 and synaptogyrin-1) in Alzheimer's disease cases. The deficit was restricted to the outer molecular layer of the dentate gyrus, whereas other hippocampal sub-fields were preserved. Interestingly, standard markers of postsynaptic densities (SH3 and multiple ankyrin repeat domains protein 2) and dendrites (microtubule-associated

protein 2) were unaltered, as well as the relative number of granule cells in the dentate gyrus, indicating that the deficit is preferentially presynaptic. Notably, staining for the axonal components, myelin basic protein, SMI-312 and Tau, was unaffected, suggesting that the local presynaptic impairment does not result from axonal loss or alterations of structural proteins of axons. There was no correlation between the reduction in presynaptic proteins in the outer molecular layer and the extent of the amyloid load or of the dystrophic neurites expressing phosphorylated forms of Tau. Altogether, this study highlights the distinctive vulnerability of the outer molecular layer of the dentate gyrus and supports the notion of presynaptic failure in Alzheimer's disease.

Presenilin-mediated cleavage of APP regulates synaptotagmin-7 and presynaptic plasticity.
Mutations of the intramembrane protease presenilin (PS) or of its main substrate, the amyloid precursor protein (APP), cause early-onset form of Alzheimer disease. PS and APP interact with proteins of the neurotransmitter release machinery without identified functional consequences. Here we report that genetic deletion of PS markedly decreases the presynaptic levels of the Ca sensor synaptotagmin-7 (Syt7) leading to impaired synaptic facilitation and replenishment of synaptic vesicles. The regulation of Syt7 expression by PS occurs post-transcriptionally and depends on γ-secretase proteolytic activity. It requires the substrate APP as revealed by the combined genetic invalidation of APP and PS1, and in particular the APP-Cterminal fragments which interact with Syt7 and accumulate in synaptic terminals under pharmacological or genetic inhibition of γ-secretase. Thus, we uncover a role of PS in presynaptic mechanisms, through APP cleavage and regulation of Syt7, that highlights aberrant synaptic vesicle processing as a possible new pathway in AD.

Non-specific Detection of a Major Western Blotting Band in Human Brain Homogenates by a Multitude of Amyloid Precursor Protein Antibodies.
The use of human post-mortem brain material is of great value when investigating which pathological mechanisms occur in human brain, and to avoid translational problems which have for example been evident when translating animal research into Alzheimer disease (AD) clinical trials. The amyloid β (Aβ)-peptide, its amyloid precursor protein (APP) and the intermediate APP-c-terminal fragments (APP-CTFs) are all important players in AD pathogenesis. In order to elucidate which APP CTF that are the most common in brain tissue of different species and developmental stages, and whether there are any differences in these fragments between AD and control brain, we investigated the occurrence of these fragments using different APP c-terminal antibodies. We noticed that whereas the conventional APP-CTFα and CTFβ fragments were most prominent in rat and mouse brain tissue, the major western blotting band detected in human, macaque and guinea pig was of approximately 20 kDa in size, possibly corresponding to the newly discovered APP-CTFη. However, this band was also intensely stained with a total protein stain, as well as by several other antibodies. The staining intensity of the 20 kDa band by the APP antibodies varied considerably between samples and correlated with the staining intensity of this band by the total protein stain. This could potentially be due to non-specific binding of the antibodies to another protein of this size. In-gel digestion and mass spectrometry confirmed that small amounts of APP were present in this band, but many other proteins were identified as well. The major hit of the mass spectrometry analysis was myelin basic protein (MBP) and a myelin removal protocol removed proportionally more of the 20 kDa APP band than the full-length APP and APP-CTFα/β bands. However, the signal could not be immunodepleted with an MBP antibody. In summary, we report on a potentially non-specific western blotting band of approximately 20 kDa and call for precaution when analyzing proteins of this size in human brain tissue.

Mesencephalic dopamine neurons interfacing the shell of nucleus accumbens and the dorsolateral striatum in the rat.
Parallel corticostriatonigral circuits have been proposed that separately process motor, cognitive, and emotional-motivational information. Functional integration requires that interactions exist between neurons participating in these circuits. This makes it imperative to study the complex anatomical substrate underlying corticostriatonigral circuits. It has previously been proposed that dopaminergic neurons in the ventral mesencephalon may play a role in this circuit interaction. Therefore, we studied in rats convergence of basal ganglia circuits by depositing an anterograde neuroanatomical tracer into the ventral striatum together with a retrograde fluorescent tracer ipsilaterally in the dorsolateral striatum. In the mesencephalon, using confocal microscopy, we looked for possible appositions of anterogradely labeled fibers and retrogradely labeled neurons, "enhancing" the latter via intracellular injection of Lucifer Yellow. Tyrosine hydroxylase (TH) immunofluorescence served to identify dopaminergic neurons. In neurophysiological experiments, we combined orthodromic stimulation in the medial ventral

striatum with recording from ventral mesencephalic neurons characterized by antidromic stimulation from the dorsal striatum. We observed terminal fields of anterogradely labeled fibers that overlap populations of retrogradely labeled nigrostriatal cell bodies in the substantia nigra pars compacta and lateral ventral tegmental area (VTA), with numerous close appositions between boutons of anterogradely labeled fibers and nigrostriatal, TH-immunopositive neurons. Neurophysiological stimulation in the medial ventral striatum caused inhibition of dopaminergic nigrostriatal neurons projecting to the ventrolateral striatal territory. Responding nigrostriatal neurons were located in the medial substantia nigra and adjacent VTA. Our results strongly suggest a functional link between ventromedial, emotional-motivational striatum, and the sensorimotor dorsal striatum via dopaminergic nigrostriatal neurons.

MITOCHONDRIAL CA2+ DYNAMICS, OLFACTION AND ALZHEIMER'S DISEASE

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Nelly Redolfi[1], Greotti Elisa[2], Diana Pendin[2], Cristina Fasolato[1], Paola Pizzo[1]

Aim: Alzheimer's disease (AD) is one of the main causes of cognitive decline and the leading cause of dementia in elderly population. AD can be divided in Sporadic (SAD) and Familial (FAD) depending on the absence or presence of autosomal dominant inheritance. Both forms present common clinical features, including neuronal loss and brain amyloid-β (Aβ) deposition. FAD is caused by autosomal mutations in Aβ precursor protein (APP), presenilin-1 (PS1) and presenilin-2 (PS2) genes and is characterized by early onset of symptoms. Based on the assumptions that: i) altered sense of smell is one of the early clinical symptoms of AD, ii) mitochondrial Ca2+ handling is altered in AD and iii) mitochondrial Ca2+ mobilization is involved in the olfactory signalling and in odor memory, we aim to investigate mitochondrial Ca2+ dynamics impairment as a potential mechanism underpinning early olfactory impairment in AD. Methodology: In an established murine model of FAD, we will firstly ascertain at which age Aβ plaque deposition occurs in the olfactory areas. To establish the capability of discriminating odours, animals will perform the habituation/dishabituation test before and after plaque deposition. Additionally, we will investigate cytosolic and mitochondrial Ca2+ dynamics along the olfactory pathway at the early stage of the olfactory defect by 2P-microscope imaging. Results and Conclusions: Preliminary data show that 6-month-old AD mice present olfactory defects respect to controls. Finding the relationship between mitochondrial Ca2+ dynamics and olfactory dysfunctions in AD, possibly identifying a cause-effect relationship, would represent a progression in the comprehension of the AD pathogenesis.

Evidence suggests that lightly myelinated cortical regions are more vulnerable to aging and Alzheimer's disease (AD). However, it is unknown whether blood AD markers, such as amyloid-b fragment 1-42 ($A\beta_{1-42}$) and neurofilament light chain (NfL), are associated with changes in intracortical myelin content in cognitively normal older adults, and whether these myelin changes may eventually moderate patterns of resting state functional connectivity (rs-FC). One hundred and thirty-three cognitively normal older adults participated in the study. Plasma $A\beta_{1-42}$ and NfL levels were assessed with ultra-sensitive single-molecule array (Simoa) assays, and the ratio T1-weigthed/T2-weighted (T1w/T2w) was employed as a proxy of intracortical myelination. Using cortical surface-based multiple linear regression analyses, we examined: i) whether plasma AD markers were associated with intracortical myelin content at different cortical depths, and ii) whether the relationship between intracortical myelin content and rs-FC was moderated by plasma $A\beta_{1-42}$ and NfL levels. Results showed that decreased plasma $A\beta_{1-42}$ and increased NfL levels were associated with reductions of myelin content in the temporo-parietal-occipital regions and insular cortex, respectively. These associations were most evident in the inner cortical layers. Plasma NfL levels, but not $A\beta_{1-42}$, moderated functional coordination between insula and medial orbitofrontal cortex, presumably due to impaired neural synchronization associated with myelin deficits in the insular cortex. Together, these findings have revealed that plasma levels of $A\beta_{1-42}$ and NfL are able to track intracortical myelin deficits in cognitively normal older adults, which may contribute to identify vulnerability to AD at the earliest stage among the aged population.

Alzheimer's disease, the most prevalent form of dementia in Europe, is clinically defined by a progressive loss of cognitive functions, but microstructural alterations are known to take place years before pathology is detectable [1]. Early detection of such alterations has therefore high priority. Diffusion-weighted magnetic resonance imaging (dw-MRI) allows characterizing microstructural integrity *in vivo*, revealing increased diffusivity in humans with Alzheimer [3]. Mice models are fundamental to investigate the pathological mechanisms and test interventions. One of the most established models is the APP/PSEN1 mice, known to develop amyloid plaques in parietal cortex and hippocampus from 6 months of age. However, its potential to show similar radiological patterns as found in human disease is unexplored. **Aims:** To use dw-MRI to measure axial diffusivity, an index of microstructural integrity, in the APP/PSEN1 mice, and compare it with controls. **Methods:** We applied a dw-MRI protocol to a cohort of 9 wild type C75BL/6 mice and 5 APP/PSEN1 mice to measure axial diffusivity in parietal cortex and hippocampus. ANOVA with post-hoc t-test was employed to test significant effects of region-of-interest and group. **Results:** ANOVA revealed significant interaction between region-of-interest and group ($F(1,2)=6.280, p=0.028$). Axial diffusivity was significantly increased ($p<0.05$,1-tail; see figure) in the hippocampus in APP/PSEN1 mice compared to control. This biomarker is sensitive to compromised microstructural integrity.
Conclusions: This preliminary study confirms the utility of the model to recapitulate salient radiological features of human Alzheimer's disease. Current work is looking at advanced dw-MRI biomarkers to detect alteration in the glia and neuron morphology.

Demyelination is an early event in Alzheimer's disease (AD) previous to neurodegeneration. Demyelination has been identified at the hippocampal formation and the fornix. Specifically, fornix demyelination appears in pre-symptomatic carriers of familial AD mutations, and also in clinically normal older adults with elevated Aβ burden and is associated with accelerated memory decline. The fornix commissure is the connection between both hippocampi and it has been shown that is implicated in recognition memory. We aimed to study the specific demyelination of this connection. In a pilot study, we have assessed demyelination by immunohistochemistry in 10 APP/PS1 mice as a model of AD and 10 wild-type mice as controls from the same colony. We also recruited 10 AD patients, 10 mild cognitive impairment (MCI) patients, and 10 non-demented age-matched controls. We performed 3T nuclear magnetic resonance to analyze by diffusion-tensor imaging the hippocampal commissure of the recruited patients. Also, electroencephalography in the resting state with closed eyes by EEG recordings was performed in all subjects. In AD mice, we observed significant demyelination in the hippocampal commissure compared to controls. In the AD and MCI patients, our preliminary results suggest differences in fractional anisotropy and the apparent diffusion coefficient compared to controls, as well as changes in the interhemispheric phase coherence between the temporal electrodes in the 8-13 Hz frequency band.

IMAGING COMMON PROTEIN SIGNATURES OF SINGLE CELL-PROTEOPATHY INTERACTIONS ACROSS HUMAN ALZHEIMER'S DISEASE TISSUE USING MULTIPLEXED BEAM IMAGING

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Bryan Cannon, Kausalia Vijayragavan, Dmitry Tebaykin, Dunja Mrdjen, Jp Oliveria, Noah Greenwald, Alex Baranski, Mike Angelo, Tom Montine, Sean Bendall
Stanford University, Pathology, Stanford, United States of America

Identifying cell-based and regional phenotypes in human brain tissue is a necessary task to understand neurodegenerative pathologies in Alzheimer's disease. Using MIBI (multiplexed ion-beam imaging) we have simultaneously quantified tissue-level expression of 40 different targets encoding a deep set of neurological phenotypes with nanometer scale spatial resolution. To localize protein expression to specific cells or tissue restricted regions, we use a combination of single cell and single object segmentation methods. Applying this technique to multiple MIBI scans of archival human hippocampus cross-sections, we are able to identify the spatial distribution and expression heterogeneity of glial, neuronal, and endothelial cell types and proteopathies in both cognitively healthy and diseased human brain. Using off-the-shelf and in-house developed computational strategies we are able to isolate unique protein-disease trends in traditional hippocampal neuroanatomy, particularly identifying tau-tangle targeting by microglia in severe Alzheimer's within the CA1 region. Additional work using cross-sample clustering algorithms derived common areas of disease and healthy tissue independent of AD severity. Identification of neurons able to survive in these proteopathy-associated regions may lead to additional work testing the functional significance of the descriptive work outlined here. We believe this will be a straight forward approach to discretize and select features for multiplexed imaging technologies as applied to human brain tissue in both degenerative and non-degenerative contexts.

B cells in rheumatoid arthritis synovial tissues encode focused antibody repertoires that include antibodies that stimulate macrophage TNF-α production.
Rheumatoid arthritis (RA) is characterized by the production of anti-citrullinated protein antibodies (ACPAs). To gain insights into the relationship between ACPA-expressing B cells in peripheral blood (PB) and synovial tissue (ST), we sequenced the B cell repertoire in paired PB and ST samples from five individuals with established, ACPA+ RA. Bioinformatics analysis of paired heavy- and light-chain sequences revealed clonally-related family members shared between PB and ST. ST-derived antibody repertoires exhibited reduced diversity and increased normalized clonal family size compared to PB-derived repertoires. Functional characterization showed that seven recombinant antibodies (rAbs) expressed from subject-derived sequences from both compartments bound citrullinated antigens and immune complexes (ICs) formed using one ST-derived rAb stimulated macrophage TNF-α production. Our findings demonstrate B cell trafficking between PB and ST in subjects with RA and ST repertoires include B cells that encode ACPA capable of forming ICs that stimulate cellular responses implicated in RA pathogenesis.
Clin Immunol, 2020; 212

ALZHEIMER'S DISEASE GENETIC RISK FACTOR APOE4 IS ASSOCIATED WITH ATTENUATED AUDITORY RESPONSES

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Emma Ducos[1], Felix Schneefeld[2], Kinga Igloi[2], Luc Arnal[1]
[1]Institut Pasteur, Institut De L'audition, Paris, France, [2]Université de Genève, Faculté De Médecine, Genève, Switzerland

Recent studies have suggested that prodromal stages of Alzheimer's Disease (AD) are accompanied with central auditory system dysfunction, which may be used as early indicators of disease onset and progression. In AD patients of 60 years old and more, atypical patterns of oscillatory entrainment to repetitive sound transients have been reported and suggested as potential neuromarkers of AD. Whether such alterations of auditory functions relate to genetic risk factor of AD (APOE4) at an early age (<30) is unknown. We used EEG recordings to measure auditory responses to repetitive sounds (1 second click trains presented at various frequencies (10-250Hz) in 32 young neurotypical participants). To test whether auditory responsivity is affected by AD risk factor, we compared auditory brain responses from seventeen APOE3 (age mean=21.6, sd=1.8) and fifteen APOE4 carriers (age mean=23.6, sd=4.9). Comparing the magnitude of auditory event related potentials (ERPs) we observed that APOE4 carriers exhibit slightly attenuated P2 and P3 ERP responses as compared to APOE3 carriers. Focusing on Auditory Steady State Response (ASSR) power across frequencies (10-90Hz), we observed that APOE3 carriers exhibit reliably larger neural entrainment than APOE4 carriers (Cohens' d = 0.8, 'large' effect size). This difference was sustained across the peristimulus time course and did vary across stimulus frequencies. Overall, these results suggest that central auditory differences can be detected very early in at-risk populations. Studying these signals could help identify early AD pathology and provide an entry point for therapeutic interventions against neurodegeneration.

SILENT EPILEPTIC ACTIVITIES: THE MISSING LINK BETWEEN ALZHEIMER'S DISEASE, DISRUPTED SLEEP AND DYSFUNCTIONAL MEMORY CONSOLIDATION?

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Anna B. Szabo[1,2], Jonathan Curot[2,3], Marie Denuelle[2,3], Rachel Debs[3], Emmanuel J. Barbeau[2], Béatrice Lemesle[3], Fleur Gerard[2,3], Patrice Péran[4], Jérémie Pariente[3,4], Lionel Dahan[1], Luc Valton[2,3]
[1]Centre de Recherches sur la Cognition Animale (CRCA) Centre de Biologie Intégrative (CBI), Université Paul Sabatier, Cnrs, Toulouse, France, [2]Centre de Recherche Cerveau & Cognition , UMR 5549, Université Paul Sabatier, Cnrs, Toulouse Cedex, France, [3]Département de Neurologie, Hôpital Purpan, Centre Hospitalier Universitaire De Toulouse, Toulouse, France, [4]Toulouse NeuroImaging Center, Université Paul Sabatier, Inserm, Toulouse, France

Alzheimer's disease (AD) and epileptic activities (EA) were linked through the very first descriptions of AD a century ago and the interest toward this comorbidity exponentially increased in the past decades. These investigations revealed that EA accelerate AD progression, however, given that they are mostly subclinical and occur predominantly during sleep, they may remain undetected and could potentially disrupt sleep-related memory consolidation – although this assumption has not been tested in AD. Moreover, previous clinical studies on this subject focused on non-REM sleep, but preclinical research hints that EA in AD models drastically increase during REM sleep – therefore, consolidation processes could be disrupted both at the systemic and synaptic levels. Here we present the results of a monocentric case-control study exploring the prevalence, the structural and genetic underpinnings and the consequences of subclinical EA in AD during sleep, and particularly REM sleep, in a cohort of mild-to moderate stage AD patients and age-matched controls. These objectives were investigated using neuroimaging methods, genetic testing and a full-night video-EEG, as well as a comprehensive neuropsychological test battery evaluating visual, declarative and episodic memory before the video-EEG and consolidation efficiency directly afterwards. Our study details the distribution of AD-related EA during sleep and is the first to report on the potential memory consolidation deficits they could induce in AD. Finally, these results could have implications from bench to bedside as they pinpoint important divergences between AD models and clinical observations and could potentially lead to improvements in future patient care as well.

ANTE-MORTEM MAGNETIC RESONANCE IMAGING GREY-WHITE MATTER CONTRAST REGIONAL SIGNATURES OF ALZHEIMER'S DISEASE NEUROPATHOLOGY

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Francisco Almeida[1], Ana Coelho[1], Miguel Quintas-Neves[1], Merilee Teylan[2], Charles Mock[2], Walter Kukull[2], John Crary[3], Tiago Gil Oliveira[1]
[1]University of Minho, Life And Health Sciences Research Institute (icvs), Braga, Portugal, [2]National Alzheimer's Coordinating Center, University of Washington, Seattle, Washington, Department Of Epidemiology, Washington, United States of America, [3]Neuropathology Brain Bank & Research Core, Department Of Pathology, Nash Family Department Of Neuroscience, Department Of Artificial Intelligence & Human Health, Friedman Brain Institute, Ronald M. Loeb Center For Alzheimer's Disease, Icahn School Of Medicine At Mount Sinai, New York, United States of America

Introduction: Grey matter (GM), white matter (WM) contrast (GWC) in T1-weighted MRI has been shown to decrease with age in healthy populations and cognitive impairment in clinical Alzheimer's Disease (AD). However, the neuropathological determinants of this signal remain unknown. Here, we aimed to study whether GWC is associated with AD neuropathology and longitudinal hippocampal atrophy. **Methods:** 157 patients with neuropathological, clinical data and ante-mortem MRI were selected from the National Alzheimer's Coordinating Center database. Cortical volume and GWC (WM/GM intensity) in T1/MRI were obtained with Freesurfer 6.0. Hippocampal volume was divided into anterior, intermediate and posterior regions using a lab-based algorithm. Correlational analysis was conducted for GWC with age, and GWC residuals after linear regression with age for volume, BRAAK stage (neurofibrillary tangles), CERAD score (neuritic plaque density) and Cognitive Dementia Rating Sum-of-Boxes (CDR-SB). APOE genotypes were compared using one-way-ANOVA. **Results:** GWC was negatively correlated with age in widespread brain areas ($p < 0.05$, FDR), but only the entorhinal cortex showed a positive correlation between volume and GWC. There were no significant correlations between GWC and BRAAK stage, CERAD score, CDR-SB or differences according to APOE genotype. Entorhinal GWC correlated positively only with the posterior hippocampal volume in BRAAK III-IV ($p = 0.031$; $R = 0.34$). **Conclusion:** GWC is highly modulated by age, but not by classical AD neuropathology, APOE genotype or dementia severity in this cohort. Entorhinal GWC correlates with entorhinal and posterior hippocampal volume, suggesting it might reflect an early pathophysiological process distinct from classical AD neuropathology.

INFLUENCE OF WHITE MATTER HYPERINTENSITIES OF VASCULAR ORIGIN ON BRAIN FUNCTIONAL CONNECTIVITY MEASURED WITH MEG

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Lucia Torres-Simon[1], Lucía Hernández Orozco[1], Alberto Del Cerro[1], Pablo Cuesta[2], Brenda Chino[3], Sandra Doval[1], Miguel Yus[4], Ricardo Bruña[2], Fernando Maestu[5]
[1]Complutense university of Madrid, Experimental Psychology, Madrid, Spain, [2]Complutense University of Madrid, Radiology, Rehabilitation And Physiotherapy, Madrid, Spain, [3]Autonomous University of Barcelona, Institute Of Neuroscience, Barcelona, Spain, [4]Hospital Clinico San Carlos, Radiology, Madrid, Spain, [5]Complutense University of Madrid, Experimental Psychology, Madrid, Spain

White matter hyperintensities (WMH) of presumed vascular origin is a common accompaniment of ageing, not only in dementia patients, but also in healthy population. In fact, they are present on neuroimaging in practically every individual over 60 years old and its prevalence increases with age. The clinical importance of WMH have been widely reported in the literature. The presence and progression of WMH on the brain have been associated to general cognitive impairment and all types of dementia, especially vascular cognitive impairment (VCI). The aim of this investigation was to focus the research on the identification of specific functional connectivity signatures related to WMH total volume in the brain. 350 cognitively healthy participants were recruited for the present study (aged from 50 to 87). All of them underwent a neuropsychological evaluation, MRI assessment (T1 and Flair), and MEG recordings (ten minutes of eyes closed resting state). WMH volume quantification was performed with an automatic detection toolbox, LST (SPM12). We used a completely data-driven approach to evaluate the relationship between functional connectivity (FC) and the WMH total volume. Interestingly, a dual pattern of FC emerged depending on the WMH volume, probably related to the underlying etiology: aged-related or vascular disease. Early identification and classification of dementia pathogenesis is a crucially important goal for the search for more effective management approaches. These findings could help to understand and try to palliate the contribution of WMH to particular symptoms in mixed dementias, and most subtypes of VCI.

TEMPORAL AND SPECTRAL ERPS BIOMARKERS IN EARLY STAGES OF DEMENTIA

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Alberto Vergani[1,2], Michael Lassi[1,2], Alberto Mazzoni[1,2]
[1]Sant'Anna School of Advanced Studies, Department Of Excellence In Robotics And Ai, Pisa, Italy, [2]Sant'Anna School of Advanced Studies, The Biorobotics Institute, Pisa, Italy

AIM. Improving early dementia diagnosis thanks to EEG using as neural marker Event Related Potentials (ERPs) features associated to a visual recognition task. METHODS. The study involved 93 subjects: 43 SCD (Subjective Cognitive Decline), 38 MCI (Mild Cognitive Impairment) and 12 controls. Patients' condition was assessed with standard clinical procedures. ERPs were decomposed in time-windowed neurocognitive processes associated to visual recognition, i.e, expectation, stimulus encoding, decision and post-decision. For each latent processes and for standard frequency bands, ERPs topographical maps were compared across subjects' groups and response correctness. RESULTS. ERPs topographies varied significantly according to groups during expectation (right occipital, parietal and centro-parietal ROIs), decision (right temporo-parietal, left centro-parieto-frontal ROIs) and post-decision (right/left occipital, right parieto-occipital and left centro-frontal ROIs). The main difference was in the abnormal amplitude and latency of late positive potential as it is associated with cognitive decline. The correctness of the answer affected the ERPs topographies during the encoding period (right central and occipito-parietal ROIs), coherently with the hypothesis that subjects accuracy may depend by initial phases of visual information processing. Spectral topographies displayed a group effect for alpha band (left parietal ROIs), while the correctness was dominant for delta band (left frontal, centro-fronto-parietal ROIs). CONCLUSIONS. These results highlighted ERPs temporal segments and spectral bands that might act as features to differentiate healthy, SCD and MCI condition. A support vector machine based on these signatures was tested and validated in blind, highlighting the possibility to include ERPs biomarkers during the early diagnosis of dementia.

CAN WE SEE ALZHEIMER THROUGH EYE?

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Aygun Badalova
University College London, Neuroscience, London, United Kingdom

Introduction One of the most common and prevalent neurodegenerative disorders are Alzheimer's and Dementia which are considered significant causes of mortality and morbidity in today's society particularly among the elderly population.(Erkkinen, Kim et al. 2018)The etiologic and pathophysiologic factors of neuro-degenerative disorders are still complicated and unrecognized. In last decade, the overall mortality rate for deaths cause by dementia and Alzheimer's disease has been generally increasing year-on-year. One of concerning statistics reported by Office for National Statistics , which indicates approximately 52% of increase in amount of people who diagnosed with dementia. Indeed, it is very threatening statistics in deaths of any health condition. From statistical point of view such huge increase on these disorders make and urgent need to understand the mechanisms behind the onset and progression of these heterogeneous diseases (Fig 1). Currently diagnosing Alzheimer's disease is also challenging due to lack of biomarkers. One of the pathological factors of Alzheimer's disease include the accumulation of proteins such as hyper phosphorylated tau and amyloid protein in hippocampal areas of the brain. The detection of these pathological biomarkers are conducted either by performing cerebrospinal fluid analysis, brain imaging or post-mortem brain tissues under microscope. However, these methods are not easily accessible and largely available due to different reasons. These include challenges in collecting certain samples, lack of post-mortem tissues and high-cost of experiment.(Guidoboni, Sacco et al. 2020)

EEG MICROSTATE TOPOGRAPHIES DISCRIMINATE SUBJECTIVE COGNITIVE DECLINE AND MILD COGNITIVE IMPAIRMENT

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Michael Lassi[1,2], Alberto Vergani[1,2], Alberto Mazzoni[1,2]
[1]Sant'Anna School of Advanced Studies, The Biorobotics Institute, Pisa, Italy, [2]Sant'Anna School of Advanced Studies, Department Of Excellence In Robotics And Ai, Pisa, Italy

AIMS: Alzheimer’s disease (AD) neurodegeneration may begin up to decades earlier than the appearance of the first symptoms of cognitive decline. In order to prevent irreversible neuronal damage due to dementia, early diagnosis of AD is necessary. Prodromic signs of AD have been usually studied in mild cognitive impairment (MCI), the initial stage of clinical cognitive decline. However, subjective cognitive decline (SCD) is the first pre-clinical sign of possible AD and it has been shown to lead to an increased risk of AD itself. METHODS: To gain insights into the route to AD, we investigated whether it is possible to discriminate between SCD and MCI conditions by recording resting-state electroencephalographic (EEG) signals on a cohort of 81 patients (46 SCD, 35 MCI). For each subject, four microstates that best clustered EEG signal topographies were extracted. We characterized each microstate's topography by introducing a set of features, namely theta angle, gradient, and curvature. RESULTS: A classifier trained on these features reached a cross-validated accuracy of 74.8% (F1-score 74.1%, ROC-AUC 0.88) in discriminating between SCD and MCI and it highlighted differences between the two groups in all microstates topographies. With this work, we show that resting-state EEG signals can possibly be used as a low-cost and non-invasive pre-clinical dementia onset marker. CONCLUSIONS: The proposed topographical features could be employed in future works to gain insights on the specific pathways leading to the pathogenesis of AD, as EEG microstates have been previously related to underlying resting-state networks generating EEG rhythms.

Aims: Alzheimer's disease dementia (ADD), Parkinson's disease dementia (PDD), and dementia with Lewy body (DLB) are the most common types of dementia. One of the essential questions in the last years is what electrophysiological differences among these groups of dementia are. EEG Event-related oscillations (EROs) are one of the core methodologies that could show the differences among dementia groups. The present study aimed to investigate the EEG-EROs during the cognitive tasks in patients with ADD, PDD, and DLB. **Methods:** EEG recordings of 20 ADD, 20 PDD, and 17 DLB patients and matched 20 healthy controls (HC) were performed during the auditory and visual oddball paradigms. Event-related power spectrum and phase-locking were analyzed for the theta (4-7 Hz) frequency band. Repeated measures of ANOVA were used for statistical analysis ($p<0.05$). **Results:** There were significant differences among groups for both event-related theta power and phase-locking in the auditory task ($p<0.0001$). All dementia groups had decreased theta power and phase-locking compared to HC. PDD patients had lower theta power than ADD patients ($p<0.005$). Similarly, groups showed significant differences for both event-related theta power and phase-locking in the visual task ($p<0.0001$). All dementia groups had reduced theta phase-locking compared to HC. PDD and DLB patients had lower theta power than HC ($p<0.0001$) and ADD patients ($p<0.005$). **Conclusions:** The present study showed decreased event-related theta responses during auditory and visual cognitive tasks in patients with dementia. The decrease of the event-related theta power is more severe in PDD and DLB patients.

Telling functional networks apart using ranked network features stability.
Over the past few years, it has become standard to describe brain anatomical and functional organisation in terms of complex networks, wherein single brain regions or modules and their connections are respectively identified with network nodes and the links connecting them. Often, the goal of a given study is not that of modelling brain activity but, more basically, to discriminate between experimental conditions or populations, thus to find a way to compute differences between them. This in turn involves two important aspects: defining discriminative features and quantifying differences between them. Here we show that the ranked dynamical stability of network features, from links or nodes to higher-level network properties, discriminates well between healthy brain activity and various pathological conditions. These easily computable properties, which constitute local but topographically aspecific aspects of brain activity, greatly simplify inter-network comparisons and spare the need for network pruning. Our results are discussed in terms of microstate stability. Some implications for functional brain activity are discussed.

Resting State Alpha Electroencephalographic Rhythms Are Affected by Sex in Cognitively Unimpaired Seniors and Patients with Alzheimer's Disease and Amnesic Mild Cognitive Impairment: A Retrospective and Exploratory Study.
In the present retrospective and exploratory study, we tested the hypothesis that sex may affect cortical sources of resting

state eyes-closed electroencephalographic (rsEEG) rhythms recorded in normal elderly (Nold) seniors and patients with Alzheimer's disease and mild cognitive impairment (ADMCI). Datasets in 69 ADMCI and 57 Nold individuals were taken from an international archive. The rsEEG rhythms were investigated at individual delta, theta, and alpha frequency bands and fixed beta (14-30 Hz) and gamma (30-40 Hz) bands. Each group was stratified into matched females and males. The sex factor affected the magnitude of rsEEG source activities in the Nold seniors. Compared with the males, the females were characterized by greater alpha source activities in all cortical regions. Similarly, the parietal, temporal, and occipital alpha source activities were greater in the ADMCI-females than the males. Notably, the present sex effects did not depend on core genetic (APOE4), neuropathological (Aβ42/phospho-tau ratio in the cerebrospinal fluid), structural neurodegenerative and cerebrovascular (MRI) variables characterizing sporadic AD-related processes in ADMCI seniors. These results suggest the sex factor may significantly affect neurophysiological brain neural oscillatory synchronization mechanisms underpinning the generation of dominant rsEEG alpha rhythms to regulate cortical arousal during quiet vigilance.

Are there consistent abnormalities in event-related EEG oscillations in patients with Alzheimer's disease compared to other diseases belonging to dementia?
Cerebrospinal and structural-molecular neuroimaging in-vivo biomarkers are recommended for diagnostic purposes in Alzheimer's disease (AD) and other dementias; however, they do not explain the effects of AD neuropathology on neurophysiological mechanisms underpinning cognitive processes. Here, an Expert Panel from the Electrophysiology Professional Interest Area of the Alzheimer's Association reviewed the field literature and reached consensus on the event-related electroencephalographic oscillations (EROs) that show consistent abnormalities in patients with significant cognitive deficits due to Alzheimer's, Parkinson's (PD), Lewy body (LBD), and cerebrovascular diseases. Converging evidence from oddball paradigms showed that, as compared to cognitively unimpaired (CU) older adults, AD patients had lower amplitude in widespread delta (>4 Hz) and theta (4-7 Hz) phase-locked EROs as a function of disease severity. Similar effects were also observed in PD, LBD, and/or cerebrovascular cognitive impairment patients. Non-phase-locked alpha (8-12 Hz) and beta (13-30 Hz) oscillations were abnormally reduced (event-related desynchronization, ERD) in AD patients relative to CU. However, studies on patients with other dementias remain lacking. Delta and theta phase-locked EROs during oddball tasks may be useful neurophysiological biomarkers of cognitive systems at work in heuristic and intervention clinical trials performed in AD patients, but more research is needed regarding their potential role for other dementias.
Psychophysiology, 2022; 59

Abnormalities in auditory and visual cognitive processes are differentiated with theta responses in patients with Parkinson's disease with and without dementia.
The research on the abnormalities of event-related oscillations in Parkinson's disease (PD) was mostly studied with cognitively normal patients. The present study aims to show the adverse effects of cognitive decline in PD patients via the EEG-Brain Oscillations approach by comparing the electrophysiological responses in two modalities, i.e. auditory, and visual in which PD group show deficit. We conducted a study in which we analyzed event-related theta power and phase-locking during auditory and visual oddball paradigm. Cognitively normal PD (PDCN) patients (N = 15), PD with mild cognitive impairment (PDMCI) patients (N = 22), PD dementia (PDD) patients (N = 11) and healthy controls (HC) (N = 17) were included in the study. Neuropsychological assessments were applied to all participants. There was a gradual decrease in scores of neuropsychological tests (HC, PDCN, PDMCI, PDD, respectively). Most of the neuropsychological test scores of the participants were highly correlated with the theta power and theta phase locking values, especially over frontal-central areas. HC had higher theta phase-locking and power in comparison to PDMCI and PDD. The differentiation between HC and PDCN was specific to frontal-central areas. Theta power and theta phase-locking were decreased overall locations in PDMCI and PDD both during visual and auditory oddball paradigms compared with PDCN. The results indicate that theta responses in PD patients decreased gradually as the cognitive decline increased. We can conclude that complex abnormalities in their neurotransmitter and neuronal signal systems that occur with the progression of the disease could be responsible for these results.

Impairment in recognition of emotional facial expressions in Alzheimer's disease is represented by EEG theta and alpha responses.
Behavioral studies have shown that the recognition of facial expressions may be impaired in patients with Alzheimer's disease (AD). The identification and recognition of a facial expression might be represented by event-related brain oscillations. The present study aims to analyze EEG event-related oscillations and determine the electrophysiological

indicators of impaired facial expression recognition in AD patients. EEGs of 30 healthy controls and 30 AD patients were recorded during their perception of three different facial expressions (angry, happy, neutral). Event-related power spectrum and phase locking were analyzed in the theta (4-7) and alpha (8-13 Hz) frequency bands with the EEGLAB open toolbox. There was a significant facial Expression × Group interaction ($p < 0.05$) for the theta power spectrum; the healthy control group had higher theta power than the AD group during the perception of angry facial expressions ($p < 0.05$). There was a significant hemisphere difference between the two groups ($p < 0.05$). There was a right hemisphere alpha power dominance in healthy subjects. However, AD patients did not have this alpha power asymmetry. The present study, for the first time in the literature, presents the electrophysiological indicators of impaired recognition of facial expression in AD patients. The current study could be a basis for future studies that will analyze emotional processing in different kinds of dementia patients, and this study may have provided indicators of electrophysiological correlates of behavioral problems observed in clinical practice.
Psychophysiology, 2019; 56

Theta and alpha oscillatory responses differentiate between six-to seven-year-old children and adults during successful visual and auditory memory encoding.
The healthy maturation of the brain is one of the intriguing topics that need to be investigated to understand human brain and child development. The present study aimed to investigate the development of memory processes both for auditory and visual memory using electroencephalography (EEG)-Brain Dynamics methodologies. Sixteen healthy children between the ages of 6 and 7 years and eighteen healthy young adults (age: 21.32 ± 3.28 years) were included in the study. EEG was recorded from 18 channels during the visual and auditory memory paradigms. Two different subtests of the WISC-IV IQ test were applied to all children. Event-related theta (4-7 Hz), alpha (8-13 Hz) power and phase-locking were analyzed. The young adults had higher memory performance than the children for both auditory and visual paradigms. The children had increased theta phase-locking and left alpha power in response to the remembered objects in comparison to the forgotten objects. The young adults had higher theta and alpha phase-locking than the children over the frontal and central locations ($p < 0.05$), and the children had higher parietal-occipital alpha phase-locking than the young adults. There was an increase in alpha power in children, whereas young adults had decreased post-stimulus alpha power in response to memory paradigms. The present study showed that frontocentral theta and alpha phase-locking had an essential role in brain maturation and successful memory performance. Event-related theta and alpha responses could be one of the important indicators of the mature and healthy brain, and these responses could change depending on the maturation state and age.
Brain Res, 2020; 1747

31938578: Yıldırım E, Güntekin B, Hanoğlu L, Algun C
EEG alpha activity increased in response to transcutaneous electrical nervous stimulation in young healthy subjects but not in the healthy elderly.
Transcutaneous Electrical Nerve Stimulation (TENS) is used not only in the treatment of pain but also in the examination of sensory functions. With aging, there is decreased sensitivity to somatosensory stimuli. It is essential to examine the effect of TENS application on the sensory functions in the brain by recording the spontaneous electroencephalogram (EEG) activity and the effect of aging on the sensory functions of the brain during the application. The present study aimed to investigate the effect of the application of TENS on the brain's electrical activity and the effect of aging on the sensory functions of the brain during application of TENS. A total of 15 young (24.2 ± 3.59) and 14 elderly (65.64 ± 4.92) subjects were included in the study. Spontaneous EEG was recorded from 32 channels during TENS application. Power spectrum analysis was performed by Fast Fourier Transform in the alpha frequency band (8-13 Hz) for all subjects. Repeated measures of analysis of variance was used for statistical analysis (< 0.05). Young subjects had increased alpha power during the TENS application and had gradually increased alpha power by increasing the current intensity of TENS (= 0.035). Young subjects had higher alpha power than elderly subjects in the occipital and parietal locations (= 0.073). We can, therefore, conclude that TENS indicated increased alpha activity in young subjects. Young subjects had higher alpha activity than elderly subjects in the occipital and somatosensory areas. To our knowledge, the present study is one of the first studies examining the effect of TENS on spontaneous EEG in healthy subjects. Based on the results of the present study, TENS may be used as an objective method for the examination of sensory impairments, and in the evaluative efficiency of the treatment of pain conditions.

THE INTERACTION OF REMINISCENCE THERAPY PLUS WALKING INTERVENTIONS ON COGNITIVE PERFORMANCE AND WELL-BEING OF OLDER ADULTS WITH EARLY STAGE DEMENTIA OF ALZHEIMER TYPE.

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Carmen Pocknell, Cassandra Dinius, Seán Commins, Richard Roche
Maynooth University, Psychology Department, Maynooth, Ireland

The population of older adults (60+) is increasing, leading to a pronounced growth of age-related disorders, including Alzheimer's Disease. Therefore, it is a major health challenge to develop treatments and improve quality of life by providing communities with evidence-based programmes. Walking presents cognitive and psychological benefits and can minimise age-related loss in memory-related regions of the brain, notably structural and functional changes to the pre-frontal cortex and hippocampus for older adults and people with Alzheimer's Disease. Reminiscence Therapy (RT) has been shown to produce psychological and cognitive benefits, including improved memory, for older adults with dementia. We used a Public and Patient Involvement (PPI) approach to investigate potential cognitive, and/or well-being benefits when combining these two interventions in a sample of older adults with Alzheimer's Disease. The intervenion group, facilitated by a researcher, were guided through a series of weekly historical walking tours of their local community over a period of four weeks. We compared this group, who walked and were encouraged to recall stories about the locations, with a control group who reminisced using only photos of the same sites. Cognitive measurements (including the MOCA, EAMI Memory Interview and Holden Communication Scale) and well-being measures (CASP-19 questionnaire, Satisfaction With Life Scale SWLS) were also administered. Changes in pre- and post-intervention measures of cognition and well-being will be discussed in the context of potential benefits and future studies. Walking, combined with RT, may represent an inexpensive, accessible, easily implemented and non-invasive therapy for older adults living with Alzheimer's Disease.

MEDITATION: A POTENTIAL THERAPY TARGETING AMYGDALA FOR THE PREVENTION & REVERSAL OF ALZHEIMER'S DISEASE

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Nikita Sharma
Maharishi Aurobindo Subharti College & Hospital of Naturopathy & Yogic Sciences, Swami Vivekanand Subharti University, Department Of Postgraduate Studies, Meerut, India

INTRODUCTION – The most common yet undefeatable, age-associated neurodegenerative disease Alzheimer's Disease (AD) can be prevented with the help of accessible, fruitful, easily learnable & customized practice of meditation whose competence has stood the test of time stanning over 5,000 years. Its role in AD has not been well established indicating a target component or region of the brain. **AIM** – This review aims to highlight the clinical correlation of amygdalar atrophy & activation in AD & the role of meditation in amygdalar deactivation resulting in impedance of cognitive decline. **METHODS** – A review of relevant data from publicly accessible research databases on neurosciences was performed. **RESULTS** – Limbic system component amygdala responsible for processing & memorizing emotional reactions resulting in regulation of social & behavioural responses is found to be influenced in AD. Morphologically, alteration in volume of amygdala results progression of mild cognitive impairment to AD which can be seen as structural shrinkage, distortion, neuronal loss & widespread gliosis. There are numerous researches attesting the positive associations between meditation & regulated amygdalar activity, which plays the vital role in learning & processing of emotional memory. They also acknowledge the ability of meditation to improve neuronal connectivity with prefrontal cortex which is responsible for inducing happiness, reducing fear & anxiety via amygdalar deactivation. **CONCLUSION** – This review presents worthy trappings of meditation in attenuating evolution of AD while impeding cognitive decline & reducing risk factors accompanying AD.

MOTOR IMAGERY PRESERVATION IN AMYOTROPHIC LATERAL SCLEROSIS: RESULTS FROM A BRAIN-COMPUTER INTERFACE TRIAL

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Rossella Spataro[1,2], Alessia Geraci[2], Lavinia Guccione[2], Vincenzo La Bella[2]
[1]IRCCS Centro Neurolesi Bonino Pulejo, Presidio Pisani, Palermo, Italy, [2]University of Palermo, Department Of Biomedicine, Neurosciences And Advanced Diagnostics, PALERMO, Italy

Aims Patients with amyotrophic lateral sclerosis (ALS) experience progressive motor disability, which causes gradual loss of independence. Motor Imagery (MI)-based Brain-computer interface (BCI) represents a promising approach for controlling exoskeletons, orthosis, and other devices targeted to restore motor function and autonomy. However, the preservation of MI ability in ALS patients is controversial. This study aimed to assess MI in an ALS cohort compared to a group of healthy subjects. Methods We included twenty-six ALS patients (M/F=1.9; disease duration: 28.9±22.6 months; ALSFRS-R: 34.84±7.24) and thirteen healthy controls (M/F=1.6). Age at examination and education were not different between the two groups (Age: ALS, 65.9 + 6.9 years *vs* Controls, 64.4 ± 5.12 years, p=0.5; Education: ALS, 9.7±4.3 years *vs* Controls, 11.3 ± 4.5, p= 0.3). Written informed consent was obtained. The RecoveriX© system (g.tec, Austria) was used for EEG data recording and real-time processing. All subjects participated in an MI-BCI + FES paradigm. The system measured the accuracy in accomplishing the mental task. Correlation between age, education, disease duration, ALSFRS-R, neuropsychological variables and BCI performance has been explored. Results MI-BCI accuracy was not significantly different between ALS patients and healthy controls (p=0.23). This value did not correlate with ALSFRS-R total score (p= 0.9) and upper limbs score (p= 0.9), ECAS total score (p=0.2) and specific scores (p= 0.4), education (p=0.2), and disease' duration (p= 0.8). Conclusions ALS at the intermediate stage does not affect the patients' MI ability. MI BCIs might be adopted for advanced applications to improve autonomy in this devastating disease.

BIASED AGONISTS OF MUSCARINIC RECEPTORS

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Alena Randakova[1], Dominik Nelic[1], Nikolai Chetverikov[1], Jan Jakubík[1], John Boulos[2]
[1]Institute of Physiology, Czech Academy of Sciences, Neurochemistry, Prague, Czech Republic, [2]Barry University, Chemistry And Physics, Miami Shores, United States of America

The disruption of muscarinic signalling is frequently involved in various pathophysiological conditions, including neuropathic pain, neurological and psychiatric disorders, e.g., Alzheimer's disease or schizophrenia. To target these particular conditions, selective modulation of individual muscarinic subtypes to avoid undesired side effects is necessary. High homology of the orthosteric binding site among all muscarinic subtypes makes a finding of orthosteric agonists that bind selectively to individual muscarinic subtypes virtually unattainable. Selective targeting at a particular G-protein mediated signalling pathway by biased agonists, via agonist-specific conformation, can be the way to achieve functional selectivity among individual subtypes of muscarinic receptors. Specifically, the binding of an agonist to one or a subset of functional hot spots within the binding site results in activation of a subset of signalling pathways and thus in ligand-mediated signalling bias. An agonist relatively small in size has a greater chance to bind to a smaller number of functional hot spots than a larger agonist. We demonstrate that newly developed tetrahydropyridin based muscarinic agonists activate only a subset of signalling pathways. They display agonist-specific activation profiles of individual G-protein isoforms, that differ among subtypes. Our results prove that selective activation of individual subtypes of muscarinic receptors by biased agonists can be achieved.

IDENTIFICATION OF INFECTIOUS AGENTS IN POSTMORTEM BRAIN TISSUE OF PATIENTS WITH ALZHEIMER'S DISEASE

POSTER SESSION 04 - SECTION: ALZHEIMER'S DISEASE AND NEURODEGENERATION

Johana Gomez[1], Wildeman Zapata[2], Juan Zapata[3], Carlos Villegas[1], Ana Mesa[4]
[1]University of Antioquia, Medicine School, medellin, Colombia, [2]Cooperative University of Colombia, Medicine School, Medellin, Colombia, [3]R&D division, Viriom Inc., Gaithersburg, United States of America, [4]University of Antioquia, Antioquia, medellin, Colombia

Background: Currently, there are established genetic and environmental risk factors for Alzheimer's disease (AD). Infectious agents are considered as possible causes of AD since some of them have been detected (ADN or structural components) in the brain tissue of patients suffering from this type of dementia. The aim of this study was to look for and identify infectious agents in *postmortem* brain tissues of patients with AD. **Methods:** Neuropathological changes were studied in fixed brain tissues from patients with a diagnosis of sporadic AD (SAD = 9), familial AD (FAD = 12), and brain samples of healthy individuals (n = 9). In addition, the clinical and demographic characteristics were analyzed. Microarrays, multiplex PCR, panfungal PCR, and immunohistochemistry were used to search for infectious agents in froxen tissue. **Results:** All cases with AD showed high degree of deterioration, according to scales of neuropathological diagnosis. Infectious agents were identified in two brain samples from cases with FAD (Herpes simplex virus type 1or 2, Human herpes virus type 3) and one case from control group was positive to environmental bacteria. **Conclusions:** Although the hypothesis of an infectious origin of AD has been proposed, our results did not confirm direct involvement of infectious microorganism to AD etiology despite the use of different techniques used for the detection of infectious agents. It is possible that infectious agents, in early stages of AD, induce an exacerbated immune response that affects brain tissue, although further studies are needed to confirm this hypothesis.

THE VPAC2 RECEPTOR MEDIATES RESILIENCE TO STRESS IN FEMALE, BUT NOT MALE MICE

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Briana Chen[1], Abhishek Shah[1], Grace Shin[2], Holly Hunsberger[3], Christine Denny[4]
[1]Columbia University, Neurobiology & Behavior, New York, United States of America, [2]Boston University, School Of Medicine, Boston, United States of America, [3]Rosalind Franklin University of Medicine and Science / The Chicago Medical School, Center For Neurodegenerative Diseases And Therapeutics, North Chicago, United States of America, [4]Columbia University Irving Medical Center, Psychiatry, New York, United States of America

Aims: The neuropeptide pituitary adenylate cyclase activating peptide (PACAP) has been implicated in the pathophysiology of post-traumatic stress disorder (PTSD). Although PACAP binds to the vasoactive intestinal peptide receptor 2 (VPAC2) it is still unknown whether VPAC2 is involved in the psychopathology of stress-induced psychiatric disease. Here, we hypothesized that administration of the pharmacological agonist of VPAC2, Bay 55-9837, could prevent a variety of stress-induced fear, behavioral despair, and anxiety-like behaviors. Methods: A single injection of saline, (*R,S*)-ketamine, or Bay 55-9837 was administered before or after contextual fear conditioning (CFC) stress in male and female 129S6/SvEv mice. Drug efficacy was assayed using the forced swim test (FST), elevated plus maze (EPM), open field (OF), novelty-suppressed feeding (NSF), contextual fear discrimination (CFD), and Piezo sleep boxes. Brain-wide VPAC2 expression was assayed using immunohistochemistry. Results: Activating VPAC2 prior to stress attenuated learned fear, reduced behavioral despair, suppressed hyponeophagia, and facilitated CFD in female, but not male mice. Prophylactic Bay 55-9837 protected against stress-induced changes in sleep/wake cycles in female mice. Bay 55-9837 administration after stress reduced behavioral despair and hyponeophagia in both sexes. CFD learning upregulated VPAC2 expression in hippocampal CA3 and the agranular insular cortex. Conclusions: Our data indicate that activating the VPAC2 receptor suppresses fear behavior and facilitates CFD learning in female, but not male mice. These results show that VPAC2 critically modulates fear learning and retrieval in a sex-specific manner. Overall, our findings suggest that VPAC2 may be a novel, female-specific target for preventing and treating stress-induced psychiatric disorders.

Hippocampal neurogenesis confers stress resilience by inhibiting the ventral dentate gyrus.
Adult neurogenesis in the dentate gyrus of the hippocampus is highly regulated by environmental influences, and functionally implicated in behavioural responses to stress and antidepressants. However, how adult-born neurons regulate dentate gyrus information processing to protect from stress-induced anxiety-like behaviour is unknown. Here we show in mice that neurogenesis confers resilience to chronic stress by inhibiting the activity of mature granule cells in the ventral dentate gyrus (vDG), a subregion that is implicated in mood regulation. We found that chemogenetic inhibition of adult-born neurons in the vDG promotes susceptibility to social defeat stress, whereas increasing neurogenesis confers resilience to chronic stress. By using in vivo calcium imaging to record neuronal activity from large cell populations in the vDG, we show that increased neurogenesis results in a decrease in the activity of stress-responsive cells that are active preferentially during attacks or while mice explore anxiogenic environments. These effects on dentate gyrus activity are necessary and sufficient for stress resilience, as direct silencing of the vDG confers resilience whereas excitation promotes susceptibility. Our results suggest that the activity of the vDG may be a key factor in determining individual levels of vulnerability to stress and related psychiatric disorders.

Artificially Enhancing and Suppressing Hippocampus-Mediated Memories.
Emerging evidence indicates that distinct hippocampal domains differentially drive cognition and emotion [1, 2]; dorsal regions encode spatial, temporal, and contextual information [3-5], whereas ventral regions regulate stress responses [6], anxiety-related behaviors [7, 8], and emotional states [8-10]. Although previous studies demonstrate that optically manipulating cells in the dorsal hippocampus can drive the behavioral expression of positive and negative memories, it is

unknown whether changes in cellular activity in the ventral hippocampus can drive such behaviors [11-14]. Investigating the extent to which distinct hippocampal memories across the longitudinal axis modulate behavior could aid in the understanding of stress-related psychiatric disorders known to affect emotion, memory, and cognition [15]. Here, we asked whether tagging and stimulating cells along the dorsoventral axis of the hippocampus could acutely, chronically, and differentially promote context-specific behaviors. Acute reactivation of both dorsal and ventral hippocampus cells that were previously active during memory formation drove freezing behavior, place avoidance, and place preference. Moreover, chronic stimulation of dorsal or ventral hippocampal fear memories produced a context-specific reduction or enhancement of fear responses, respectively, thus demonstrating bi-directional and context-specific modulation of memories along the longitudinal axis of the hippocampus. Fear memory suppression was associated with a reduction in hippocampal cells active during retrieval, while fear memory enhancement was associated with an increase in basolateral amygdala activity. Together, our data demonstrate that discrete sets of cells throughout the hippocampus provide key nodes sufficient to bi-directionally reprogram both the neural and behavioral expression of memory.

Prophylactic efficacy of 5-HTR agonists against stress.
Enhancing stress resilience could protect against stress-induced psychiatric disorders in at-risk populations. We and others have previously reported that (R,S)-ketamine acts as a prophylactic against stress when administered 1 week before stress. While we have shown that the selective 5-hydroxytryptamine (5-HT) (serotonin) reuptake inhibitor (SSRI) fluoxetine (Flx) is ineffective as a prophylactic, we hypothesized that other serotonergic compounds such as serotonin 4 receptor (5-HTR) agonists could act as prophylactics. We tested if three 5-HTR agonists with varying affinity could protect against stress in two mouse strains by utilizing chronic corticosterone (CORT) administration or contextual fear conditioning (CFC). Mice were administered saline, (R,S)-ketamine, Flx, RS-67,333, prucalopride, or PF-04995274 at varying doses, and then 1 week later were subjected to chronic CORT or CFC. In C57BL/6N mice, chronic Flx administration attenuated CORT-induced weight changes and increased open-arm entries in the elevated plus maze (EPM). Chronic RS-67,333 administration attenuated CORT-mediated weight changes and protected against depressive- and anxiety-like behavior. In 129S6/SvEv mice, RS-67,333 attenuated learned fear in male, but not female mice. RS-67,333 was ineffective against stress-induced depressive-like behavior in the forced swim test (FST), but prevented anxiety-like behavior in both sexes. Prucalopride and PF-04995274 attenuated learned fear and decreased stress-induced depressive-like behavior. Electrophysiological recordings following (R,S)-ketamine or prucalopride administration revealed that both drugs alter AMPA receptor-mediated synaptic transmission in CA3. These data show that in addition to (R,S)-ketamine, 5-HTR agonists are also effective prophylactics against stress, suggesting that the 5-HTR may be a novel target for prophylactic drug development.

Sex-specific neurobiological actions of prophylactic (R,S)-ketamine, (2R,6R)-hydroxynorketamine, and (2S,6S)-hydroxynorketamine.
Enhancing stress resilience in at-risk populations could significantly reduce the incidence of stress-related psychiatric disorders. We have previously reported that the administration of (R,S)-ketamine prevents stress-induced depressive-like behavior in male mice, perhaps by altering α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPAR)-mediated transmission in hippocampal CA3. However, it is still unknown whether metabolites of (R,S)-ketamine can be prophylactic in both sexes. We administered (R,S)-ketamine or its metabolites (2R,6R)-hydroxynorketamine ((2R,6R)-HNK) and (2S,6S)-hydroxynorketamine ((2S,6S)-HNK) at various doses 1 week before one of a number of stressors in male and female 129S6/SvEv mice. Patch clamp electrophysiology was used to determine the effect of prophylactic drug administration on glutamatergic activity in CA3. To examine the interaction between ovarian hormones and stress resilience, female mice also underwent ovariectomy (OVX) surgery and a hormone replacement protocol prior to drug administration. (2S,6S)-HNK and (2R,6R)-HNK protected against distinct stress-induced behaviors in both sexes, with (2S,6S)-HNK attenuating learned fear in male mice, and (2R,6R)-HNK preventing stress-induced depressive-like behavior in both sexes. (R,S)-ketamine and (2R,6R)-HNK, but not (2S,6S)-HNK, attenuated large-amplitude AMPAR-mediated bursts in hippocampal CA3. All three compounds reduced N-methyl-D-aspartate receptor (NMDAR)-mediated currents 1 week after administration. Furthermore, ovarian-derived hormones were necessary for and sufficient to restore (R,S)-ketamine- and (2R,6R)-HNK-mediated prophylaxis in female mice. Our data provide further evidence that resilience-enhancing prophylactics may alter AMPAR-mediated glutamatergic transmission in CA3. Moreover, we show that prophylactics against stress-induced depressive-like behavior can be developed in a sex-specific manner and demonstrate that ovarian hormones are necessary for the prophylactic efficacy of (R,S)-ketamine and (2R,6R)-HNK in female mice.

Behavioral and neurobiological effects of GnRH agonist treatment in mice-potential implications for puberty suppression in transgender individuals.
In the United States, ~1.4 million individuals identify as transgender. Many transgender adolescents experience gender dysphoria related to incongruence between their gender identity and sex assigned at birth. This dysphoria may worsen as puberty progresses. Puberty suppression by gonadotropin-releasing hormone agonists (GnRHa), such as leuprolide, can help alleviate gender dysphoria and provide additional time before irreversible changes in secondary sex characteristics may be initiated through feminizing or masculinizing hormone therapy congruent with the adolescent's gender experience. However, the effects of GnRH agonists on brain function and mental health are not well understood. Here, we investigated the effects of leuprolide on reproductive function, social and affective behavior, cognition, and brain activity in a rodent model. Six-week-old male and female C57BL/6J mice were injected daily with saline or leuprolide (20 µg) for 6 weeks and tested in several behavioral assays. We found that leuprolide increases hyperlocomotion, changes social preference, and increases neuroendocrine stress responses in male mice, while the same treatment increases hyponeophagia and despair-like behavior in females. Neuronal hyperactivity was found in the dentate gyrus (DG) of leuprolide-treated females, but not males, consistent with the elevation in hyponeophagia and despair-like behavior in females. These data show for the first time that GnRH agonist treatment after puberty onset exerts sex-specific effects on social- and affective behavior, stress regulation, and neural activity. Investigating the behavioral and neurobiological effects of GnRH agonists in mice will be important to better guide the investigation of potential consequences of this treatment for youth experiencing gender dysphoria.

Propranolol Decreases Fear Expression by Modulating Fear Memory Traces.
Posttraumatic stress disorder can develop after a traumatic event and results in heightened, inappropriate fear and anxiety. Although approximately 8% of the U.S. population is affected by posttraumatic stress disorder, only two drugs have been approved by the Food and Drug Administration to treat it, both with limited efficacy. Propranolol, a nonselective β-adrenergic antagonist, has shown efficacy in decreasing exaggerated fear, and there has been renewed interest in using it to treat fear disorders.

Fluoroethylnormemantine, A Novel Derivative of Memantine, Facilitates Extinction Learning Without Sensorimotor Deficits.
Memantine, a noncompetitive N-methyl-D-aspartate receptor antagonist, has been approved for use in Alzheimer's disease, but an increasing number of studies have investigated its utility for neuropsychiatric disorders. Here, we characterized a novel compound, fluoroethylnormemtantine (FENM), which was derived from memantine with an extra Fluor in an optimized position for in vivo biomarker labeling. We sought to determine if FENM produced similar behavioral effects as memantine and/or if FENM has beneficial effects against fear, avoidance, and behavioral despair.

A NOVEL ENDOCANNABINOID HYDROLASE FAAH INHIBITOR AS A POTENTIAL ANTIDEPRESSANT INDUCES GENE EXPRESSION CHANGES IN NUCLEUS ACCUMBENS IN A BALB/C MICE ACUTE STRESS MODEL

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Carlos Medina-Saldivar, Sergio R. Cruz-Visalaya, Grace E. Pardo, Juan Manuel Iglesias-Pedraz, Luis Fernando Pacheco-Otarola
Universidad Andina del Cusco, Laboratorio De Investigación En Neurociencias, Cusco, Peru

Fatty acid amide hydrolase (FAAH) inhibitors have shown antidepressant effects by increasing the bioavailability of anandamide in the central nervous system. We aim to study the new macamide MCH1 (from *Lepidium meyenii*), which shows FAAH inhibitory activity in-vitro. For this purpose, we compared the expression pattern in nucleus accumbens of mice groups receiving 3, 10 and 30 mg/kg i.p. of MCH1 versus vehicle and fluoxetine (FLX) littermates. We used mice exposed to the acute stress model. Real-time polymerase chain reaction (RT-qPCR) analysis shows changes in *Faah, Cnr1, Drn1* and *Drn2* expression levels in MCH1 and FLX groups, compared to the vehicle group. Statistical analysis showed that MCH1 30 mg/kg group had a significant 2.9-fold increase in *Faah* expression compared to vehicle ($p = 0.0352$). Nonetheless, there was no significant difference in expression level in *the Cnr1* gene compared to the group receiving 3 mg/kg MCH1 and the vehicle ($p = 0.8949$). However, we observed that the groups receiving 10 and 30 mg/kg MCH1 and FLX increased the *Cnr1* expression up to 4.3-fold more than the vehicle group ($p = 0.0063$). Moreover, comparing expression levels of *Drd1* and *Drd2* between vehicles and all MCH1 groups shows no statistical difference. Furthermore, we observe a dose-dependent increasing trend of *Drd1* and *Drd2* expression between MCH1 groups. Finally, FLX group shown significant increase in *Drd1* expression compared to 3 mg/kg MCH1 group ($p = 0.0371$) and in *Drd2* expression compared to 3 mg/kg ($p = 0.0027$) and 10 mg/kg ($p = 0.0101$) MCH1 group

Bipolar disorder (BD) is a psychiatric condition characterized by depressive and manic episodes affecting 2% of the world population. Lithium (Li) is the first-line long-term treatment for mood stabilization. Induced pluripotent stem cell (iPSC) modeling of BD using dentate gyrus (DG)-like neurons derived from Li responsive (LR) and Li non-responsive (NR) patients showed neuronal hyperexcitability. Li treatment reversed hyperexcitability on LR neurons indicating that DG neuronal hyperexcitability correlates with patient clinical information and drug response. In this study, we searched for the molecular mechanisms causing hyperexcitability and Li resistance using a combination of cellular techniques, RNA sequencing and electrophysiology. We observed that valproic acid (VPA), a drug used to treat NR patients decreased hyperexcitability in NR neurons. These neurons showed a decrease in Wnt/β-catenin signaling pathway activity and expression of *LEF1* gene that was reversed by VPA treatment. In addition, decreasing *LEF1* expression in control neurons using shRNA caused hyperexcitability. These results indicate that hyperexcitability in NR neurons is related to changes in LEF1 and in Wnt/β-catenin pathway, potentially modulated by VPA treatment. While *LEF1* expression is similar in NR, LR and control neural progenitors, its expression is progressively downregulated over time during neuronal differentiation. The Wnt/β-catenin pathway is essential for hippocampal embryonic development and adult neurogenesis and it was observed that BD patients have consistently smaller volumes of the hippocampus and DG in imaging studies. Our results suggest that Wnt/β-catenin pathway is implicated in hyperexcitability, drug resistance and differentiation of hippocampal DG neurons in an iPSC model of BD.

EARLY LIFE ADVERSITY PERTURBS MITOSTASIS AND DRIVES INFLAMMAGING IN THE RAT HIPPOCAMPUS

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Pratik Chaudhari[1], Aastha Singla[2], Sashaina Fanibunda[1,3], Kowshik Kukkemane[1], Praachi Tiwari[2], Shital Suryavanshi[1], Ullas Kolthur-Seetharam[1], Carmen Sandi[4], Ashok Vaidya[3], Vidita Vaidya[1]

Early life stressors result in life-long alterations in anxiety and depression-like behaviour, and accelerate neuronal aging. However, the molecular and cellular changes evoked by early adversity that contribute to these phenotype is not delineated. Neurodegenerative disorders are associated with mitochondrial dysfunction and inflammation, and early adversity is also known to enhance neurodegenerative changes in the process of aging. The primary thrust of our project was to gain insights into the contribution of perturbed mitochondrial metabolism and inflammation within limbic neurocircuits in mediating the accelerated aging that has been suggested to be one of the sequelae of early adversity. Using a rodent model of early adversity, maternal separation (MS) which is reported to enhance adult anxiety and depression-like behaviour, accelerate aging, and perturb neuroendocrine stress responses that endure across the life span, we addressed whether this was accompanied by perturbed mitostasis and peripheral/central inflammatory changes. We provide novel information that a history of MS is associated with a robust dysregulation in mitostasis, with a decline noted in mitochondrial biogenesis and enhanced mitophagy, accompanied by an inflammatory state evoked in the hippocampus and prefrontal cortex, which emerges in an age-dependent manner. This is accompanied by impaired mitochondrial function and morphology in middle-aged animals subjected to MS. The changes in the brain are also associated with robust peripheral inflammatory changes, which appear to precede the neuroinflammation. Studies are under way to assess the influence of interventional strategies that may serve to reverse the mitochondrial and inflammatory changes that we observe following early adversity.

Chronic postnatal chemogenetic activation of forebrain excitatory neurons evokes persistent changes in mood behavior. Early adversity is a risk factor for the development of adult psychopathology. Common across multiple rodent models of early adversity is increased signaling via forebrain Gq-coupled neurotransmitter receptors. We addressed whether enhanced Gq-mediated signaling in forebrain excitatory neurons during postnatal life can evoke persistent mood-related behavioral changes. Excitatory hM3Dq DREADD-mediated chemogenetic activation of forebrain excitatory neurons during postnatal life (P2-14), but not in juvenile or adult windows, increased anxiety-, despair-, and schizophrenia-like behavior in adulthood. This was accompanied by an enhanced metabolic rate of cortical and hippocampal glutamatergic and GABAergic neurons. Furthermore, we observed reduced activity and plasticity-associated marker expression, and perturbed excitatory/inhibitory currents in the hippocampus. These results indicate that Gq-signaling-mediated activation of forebrain excitatory neurons during the critical postnatal window is sufficient to program altered mood-related behavior, as well as functional changes in forebrain glutamate and GABA systems, recapitulating aspects of the consequences of early adversity.

Acute Chemogenetic Activation of CamKIIα-Positive Forebrain Excitatory Neurons Regulates Anxiety-Like Behaviour in Mice. Anxiety disorders are amongst the most prevalent mental health disorders. Several lines of evidence have implicated cortical regions such as the medial prefrontal cortex, orbitofrontal cortex, and insular cortex along with the hippocampus in the top-down modulation of anxiety-like behaviour in animal models. Both rodent models of anxiety, as well as treatment with anxiolytic drugs, result in the concomitant activation of multiple forebrain regions. Here, we sought to examine the effects of chemogenetic activation or inhibition of forebrain principal neurons on anxiety and despair-like behaviour. We acutely activated or inhibited Ca/calmodulin-dependent protein kinase II α (CamKIIα)-positive forebrain excitatory neurons using the

hM3Dq or the hM4Di Designer Receptor Exclusively Activated by Designer Drug (DREADD) respectively. Circuit activation was confirmed via an increase in expression of the immediate early gene, c-Fos, within both the hippocampus and the neocortex. We then examined the influence of DREADD-mediated activation of forebrain excitatory neurons on behavioural tests for anxiety and despair-like behaviour. Our results indicate that acute hM3Dq DREADD activation of forebrain excitatory neurons resulted in a significant decline in anxiety-like behaviour on the open field, light-dark avoidance, and the elevated plus maze test. In contrast, hM3Dq DREADD activation of forebrain excitatory neurons did not alter despair-like behaviour on either the tail suspension or forced swim tests. Acute hM4Di DREADD inhibition of CamKIIα-positive forebrain excitatory neurons did not modify either anxiety or despair-like behaviour. Taken together, our results demonstrate that chemogenetic activation of excitatory neurons in the forebrain decreases anxiety-like behaviour in mice.

Chronic hM4Di-DREADD-Mediated Chemogenetic Inhibition of Forebrain Excitatory Neurons in Postnatal or Juvenile Life Does Not Alter Adult Mood-Related Behavior.
G-protein-coupled receptors (GPCRs) coupled to G signaling, in particular downstream of monoaminergic neurotransmission, are posited to play a key role during developmental epochs (postnatal and juvenile) in shaping the emergence of adult anxiodepressive behaviors and sensorimotor gating. To address the role of G signaling in these developmental windows, we used a CaMKIIα-tTA::TRE hM4Di bigenic mouse line to express the hM4Di-DREADD (designer receptor exclusively activated by designer drugs) in forebrain excitatory neurons and enhanced G signaling via chronic administration of the DREADD agonist, clozapine--oxide (CNO) in the postnatal window (postnatal days 2-14) or the juvenile window (postnatal days 28-40). We confirmed that the expression of the HA-tagged hM4Di-DREADD was restricted to CaMKIIα-positive neurons in the forebrain, and that the administration of CNO in postnatal or juvenile windows evoked inhibition in forebrain circuits of the hippocampus and cortex, as indicated by a decline in expression of the neuronal activity marker c-Fos. hM4Di-DREADD-mediated inhibition of CaMKIIα-positive forebrain excitatory neurons in postnatal or juvenile life did not impact the weight profile of mouse pups, and also did not influence the normal ontogeny of sensory reflexes. Further, postnatal or juvenile hM4Di-DREADD-mediated inhibition of CaMKIIα-positive forebrain excitatory neurons did not alter anxiety- or despair-like behaviors in adulthood and did not impact sensorimotor gating. Collectively, these results indicate that chemogenetic induction of G signaling in CaMKIIα-positive forebrain excitatory neurons in postnatal and juvenile temporal windows does not appear to impinge on the programming of anxiodepressive behaviors in adulthood.

Hemidesmosomal linker proteins regulate cell motility, invasion and tumorigenicity in oral squamous cell carcinoma derived cells.
BPAG1e and Plectin are hemidesmosomal linker proteins which anchor intermediate filament proteins to the cell surface through β4 integrin. Recent reports indicate that these proteins play a role in various cellular processes apart from their known anchoring function. However, the available literature is inconsistent. Further, the previous study from our laboratory suggested that Keratin8/18 pair promotes cell motility and tumor progression by deregulating β4 integrin signaling in oral squamous cell carcinoma (OSCC) derived cells. Based on these findings, we hypothesized that linker proteins may have a role in neoplastic progression of OSCC. Downregulation of hemidesmosomal linker proteins in OSCC derived cells resulted in reduced cell migration accompanied by alterations in actin organization. Further, decreased MMP9 activity led to reduced cell invasion in linker proteins knockdown cells. Moreover, loss of these proteins resulted in reduced tumorigenic potential. SWATH analysis demonstrated upregulation of N-Myc downstream regulated gene 1 (NDRG1) in linker proteins downregulated cells as compared to vector control cells. Further, the defects in phenotype upon linker proteins ablation were rescued upon loss of NDRG1 in linker proteins knockdown background. These data together indicate that hemidesmosomal linker proteins regulate cell motility, invasion and tumorigenicity possibly through NDRG1 in OSCC derived cells.

Aberrant expression of vimentin predisposes oral premalignant lesion derived cells towards transformation.
We have previously reported the aberrant expression of vimentin in human oral premalignant lesions and a 4-Nitroquinoline 1-oxide (4NQO) model of rat lingual carcinogenesis. Hence, we wanted to understand whether the expression of vimentin in early stage contributes to the process of transformation.

Effect of biologically synthesised silver nanoparticles on Staphylococcus aureus biofilm quenching and prevention of biofilm formation.

The development of green experimental processes for the synthesis of nanoparticles is a need in the field of nanotechnology. In the present study, the authors reported rapid synthesis of silver nanoparticles using fresh leaves extract of Cymbopogan citratus (lemongrass) with increased stability. The synthesised silver nanoparticles were found to be stable for several months. UV-visible spectrophotometric analysis was carried out to assess the synthesis of silver nanoparticles. The synthesised silver nanoparticles were further characterised by using nanoparticle tracking analyser (NTA), transmission electron microscope (TEM) and energy-dispersive x-ray spectra (EDX). The NTA results showed that the mean size was found to be 32 nm. Silver nanoparticles with controlled size and shape were observed under TEM micrograph. The EDX of the nanoparticles confirmed the presence of elemental silver. These silver nanoparticles showed enhanced quorum quenching activity against Staphylococcus aureus biofilm and prevention of biofilm formation which can be seen under inverted microscope (40X). In the near future, silver nanoparticles synthesised using green methods may be used in the treatment of infections caused by a highly antibiotic resistant biofilm.

Multifaceted role of keratins in epithelial cell differentiation and transformation.
Keratins, the epithelial-predominant members of the intermediate filament superfamily, are expressed in a pairwise, tissuespecific and differentiation-dependent manner. There are 28 type I and 26 type II keratins, which share a common structure comprising a central coiled coil α-helical rod domain flanked by two nonhelical head and tail domains. These domains harbor sites for major posttranslational modifications like phosphorylation and glycosylation, which govern keratin function and dynamics. Apart from providing structural support, keratins regulate various signaling machinery involved in cell growth, motility, apoptosis etc. However, tissue-specific functions of keratins in relation to cell proliferation and differentiation are still emerging. Altered keratin expression pattern during and after malignant transformation is reported to modulate different signaling pathways involved in tumor progression in a context-dependent fashion. The current review focuses on the literature related to the role of keratins in the regulation of cell proliferation, differentiation and transformation in different types of epithelia.

Versatile hemidesmosomal linker proteins: structure and function.
Hemidesmosomes are anchoring junctions which connect basal epidermal cells to the extracellular matrix. In complex epithelia like skin, hemidesmosomes are composed of transmembrane proteins like α6β4 integrin, BP180, CD151 and cytoplasmic proteins like BPAG1e and plectin. BPAG1e and plectin are plakin family cytolinker proteins which anchor intermediate filament proteins i.e. keratins to the hemidesmosomal transmembrane proteins. Mutations in BPAG1e and plectin lead to severe skin blistering disorders. Recent reports indicate that these hemidesmosomal linker proteins play a role in various cellular processes like cell motility and cytoskeleton dynamics apart from their known anchoring function. In this review, we will discuss their role in structural and signaling functions.

SPHINGOMYELIN SYNTHASES IN DEPRESSION AND ANTIDEPRESSANT TREATMENT

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Roberto Damián Bilbao Canalejas, Claudia Von Zimmermann, Tanja Richter-Schmidinger, Bernd Lenz, Johannes Kornhuber, Christiane Mühle
Universitätsklinikum Erlangen, Friedrich-Alexander University Erlangen-Nürnberg (FAU, Department Of Psychiatry And Psychotherapy, Erlangen, Germany

Major depressive disorder is a severe and common psychiatric disease. Recent studies in mice have revealed that pharmacological inhibition of sphingomyelin synthases (SMS) induces neurogenesis and rapidly improves depression-like behaviour by activating autophagy. However, whether these effects are due to the inhibition of one or both SMS isoforms (SMS1 and SMS2) remains unknown. We aim to elucidate the involvement of SMS1 and SMS2 in depression and to identify their role in the autophagy-dependent antidepressant effect. Therefore, we have compared the activity and expression of SMS under human healthy and pathological conditions. Our first data indicate a sex-independent higher expression of SMS genes in peripheral blood cells from patients with a current major depressive episode (n=129) compared to healthy controls (n=60). In addition, an increase of SMS enzyme activity was observed in female but not male depressed patients compared to controls. To study the specific roles of SMS isoforms on autophagy, we downregulated SMS1 or SMS2 with siRNAs in H4 cells. The *in vitro* studies showed that downregulation of SMS1 (but not SMS2) leads to an accumulation of the autophagic marker LC3B-II in the presence of bafilomycin A1 compared to control cells, indicating an increased autophagic flux. Moreover, the expression of several autophagy related genes (*SQSTM1*/p62, *ULK1*, *PIK3C3*) is increased specifically after SMS1 downregulation. Overall, our results fit with the hypothesis of increased SMS activity in depression and with a specific involvement of SMS1 in autophagy induction, thereby suggesting a potential pharmacological target for the design of fast-acting antidepressants.

Aims: Depression is a devastating mood disorder that causes profound disability worldwide. Despite the growing number of antidepressant medications available, treatment options for depression are limited. Therefore, it is imperative to understand the etiology and pathophysiology of depression to discover novel therapeutic targets of action. Here, we explore how endoplasmic reticulum (ER) stress might play an important role in the pathophysiology of depression and how the antidepressant ketamine actions involve ER pathways
Methods: We generated a mouse model of ER stress in serotonin (5-HT) neurons using the stressor tunicamycin (200 µg/µl). We examined ER/UPR pathway markers by Western blot, neuroplasticity gene expression (BDNF, TrkB, VEGF, Neuritin, PSD95, and Zif268) by in situ hybridization, 5-HT release by microdialysis, and behavioral depressive-like phenotype. Ketamine (10 mg/kg, i.p.) was used to reverse the ER stress-induced depressive mouse model.
Results: Tunicamycin-induced ER stress in 5-HT neurons left a time-dependent increase in GRP78 and CHOP protein levels. In addition, increased phosphorylation of eIF2α and eEF2 was found, suggesting activation of PERK pathway. Tunicamycin-treated mice exhibited an anxious/depressive phenotype, reduced 5-HT release in the medial prefrontal cortex, and changes in neuroplasticity gene expression in 5-HT projection areas. A single dose of ketamine reversed the depressive phenotype 30 minutes later, which is associated with reduced levels of phosphorylated eIF2α and recovery of BDNF expression.
Conclusions: The results strongly indicate that ER stress and UPR may represent cellular pathogenic mechanisms in the development of mood disorders and that eIF2α pathway is central for the antidepressant activity of ketamine.

Up and Down γ-Synuclein Transcription in Dopamine Neurons Translates into Changes in Dopamine Neurotransmission and Behavioral Performance in Mice.
The synuclein family consists of α-, β-, and γ-Synuclein (α-Syn, β-Syn, and γ-Syn) expressed in the neurons and concentrated in synaptic terminals. While α-Syn is at the center of interest due to its implication in the pathogenesis of Parkinson's disease (PD) and other synucleinopathies, limited information exists on the other members. The current study aimed at investigating the biological role of γ-Syn controlling the midbrain dopamine (DA) function. We generated two different mouse models with: (i) γ-Syn overexpression induced by an adeno-associated viral vector and (ii) γ-Syn knockdown induced by a ligand-conjugated antisense oligonucleotide, in order to modify the endogenous γ-Syn transcription levels in midbrain DA neurons. The progressive overexpression of γ-Syn decreased DA neurotransmission in the nigrostriatal and mesocortical pathways. In parallel, mice evoked motor deficits in the rotarod and impaired cognitive performance as assessed by novel object recognition, passive avoidance, and Morris water maze tests. Conversely, acute γ-Syn knockdown selectively in DA neurons facilitated forebrain DA neurotransmission. Importantly, modifications in γ-Syn expression did not induce the loss of DA neurons or changes in α-Syn expression. Collectively, our data strongly suggest that DA release/re-uptake processes in the nigrostriatal and mesocortical pathways are partially dependent on substantia nigra pars compacta /ventral tegmental area (SNc/VTA) γ-Syn transcription levels, and are linked to modulation of DA transporter function, similar to α-Syn.

Dual 5-HT3 and 5-HT6 Receptor Antagonist FPPQ Normalizes Phencyclidine-Induced Disruption of Brain Oscillatory Activity

in Rats.
Schizophrenia is a severe mental disorder featuring psychotic, depressive, and cognitive alterations. Current antipsychotic drugs preferentially target dopamine D2-R and/or serotonergic 5-HT2A/1A-R. They partly alleviate psychotic symptoms but fail to treat negative symptoms and cognitive deficits. Here we report on the putative antipsychotic activity of (1-[(3-fluorophenyl)sulfonyl]-4-(piperazin-1-yl)-1H-pyrrolo[3,2-c]quinoline dihydrochloride) (FPPQ), a dual serotonin 5-HT3-R/5-HT6-R antagonist endowed with pro-cognitive properties. FPPQ fully reversed phencyclidine-induced decrease of low-frequency oscillations in the medial prefrontal cortex of anaesthetized rats, a fingerprint of antipsychotic activity. This effect was mimicked by the combined administration of the 5-HT3-R and 5-HT6-R antagonists ondansetron and SB-399 885, respectively, but not by either drug alone. In freely moving rats, FPPQ countered phencyclidine-induced hyperlocomotion and augmentation of gamma and high-frequency oscillations in medial prefrontal cortex, dorsal hippocampus, and nucleus accumbens. Overall, this supports that simultaneous blockade of 5-HT3R and 5-HT6-R-like that induced by FPPQ-can be a new target in antipsychotic drug development.

Intracerebral Administration of a Ligand-ASO Conjugate Selectively Reduces α-Synuclein Accumulation in Monoamine Neurons of Double Mutant Human A30P*A53T*α-Synuclein Transgenic Mice.
α-Synuclein (α-Syn) protein is involved in the pathogenesis of Parkinson's disease (PD). Point mutations and multiplications of the α-Syn, which encodes the gene, are correlated with early-onset PD, therefore the reduction in a-Syn synthesis could be a potential therapy for PD if delivered to the key affected neurons. Several experimental strategies for PD have been developed in recent years using oligonucleotide therapeutics. However, some of them have failed or even caused neuronal toxicity. One limiting step in the success of oligonucleotide-based therapeutics is their delivery to the brain compartment, and once there, to selected neuronal populations. Previously, we developed an indatraline-conjugated antisense oligonucleotide (IND-1233-ASO), that selectively reduces α-Syn synthesis in midbrain monoamine neurons of mice, and nonhuman primates. Here, we extended these observations using a transgenic male mouse strain carrying both A30P and A53T mutant human α-Syn (A30P*A53T*α-Syn). We found that A30P*A53T*α-Syn mice at 4-5 months of age showed 3.5-fold increases in human α-Syn expression in dopamine (DA) and norepinephrine (NE) neurons of the substantia nigra pars compacta (SNc) and locus coeruleus (LC), respectively, compared with mouse α-Syn levels. In parallel, transgenic mice exhibited altered nigrostriatal DA neurotransmission, motor alterations, and an anxiety-like phenotype. Intracerebroventricular IND-1233-ASO administration (100 µg/day, 28 days) prevented the α-Syn synthesis and accumulation in the SNc and LC, and recovered DA neurotransmission, although it did not reverse the behavioral phenotype. Therefore, the present therapeutic strategy based on a conjugated ASO could be used for the selective inhibition of α-Syn expression in PD-vulnerable monoamine neurons, showing the benefit of the optimization of ASO molecules as a disease modifying therapy for PD and related α-synucleinopathies.

Involvement of NMDA receptors containing the GluN2C subunit in the psychotomimetic and antidepressant-like effects of ketamine.
Acute ketamine administration evokes rapid and sustained antidepressant effects in treatment-resistant patients. However, ketamine also produces transient perceptual disturbances similarly to those evoked by other non-competitive NMDA-R antagonists like phencyclidine (PCP). Although the brain networks involved in both ketamine actions are not fully understood, PCP and ketamine activate thalamo-cortical networks after NMDA-R blockade in GABAergic neurons of the reticular thalamic nucleus (RtN). Given the involvement of thalamo-cortical networks in processing sensory information, these networks may underlie psychotomimetic action. Since the GluN2C subunit is densely expressed in the thalamus, including the RtN, we examined the dependence of psychotomimetic and antidepressant-like actions of ketamine on the presence of GluN2C subunits, using wild-type and GluN2C knockout (GluN2CKO) mice. Likewise, since few studies have investigated ketamine's effects in females, we used mice of both sexes. GluN2C deletion dramatically reduced stereotyped (circling) behavior induced by ketamine in male and female mice, while the antidepressant-like effect was fully preserved in both genotypes and sexes. Despite ketamine appeared to induce similar effects in both sexes, some neurobiological differences were observed between male and female mice regarding c-fos expression in thalamic nuclei and cerebellum, and glutamate surge in prefrontal cortex.

In conclusion, the GluN2C subunit may discriminate between antidepressant-like and psychotomimetic actions of ketamine. Further, the abundant presence of GluN2C subunits in the cerebellum and the improved motor coordination of GluN2CKO mice after ketamine treatment suggest the involvement of cerebellar NMDA-Rs in some behavioral actions of ketamine.

Anti-α-synuclein ASO delivered to monoamine neurons prevents α-synuclein accumulation in a Parkinson's disease-like mouse model and in monkeys.

Progressive neuronal death in monoaminergic nuclei and widespread accumulation of α-synuclein are neuropathological hallmarks of Parkinson's disease (PD). Given that α-synuclein may be an early mediator of the pathological cascade that ultimately leads to neurodegeneration, decreased α-synuclein synthesis will abate neurotoxicity if delivered to the key affected neurons.

COMBINING PRENATAL AND POSTNATAL STRESS PARADIGMS IN MICE FOR A HIGHLY TRANSLATIONAL MODEL OF DEVELOPMENTAL STRESS EXPOSURE

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Sowmya Narayan
Max Planck Institue for Psychiatry, Research Group Neurobiology Of Stress Resilience, Munich, Germany

Early life adversity leads to a higher risk of mood disorders in adulthood, and a growing body of research also implicates the fetal environment's crucial impact on health outcome; however, the biological mechanisms underlying the susceptibility to these disorders due to developmental stress are not yet fully understood. These can be characterized through behavioral assessment and transcriptional profiling in the adult brain following developmental stress exposure. Here we begin this endeavor by assessing the complex social and anxiety-related behavior in adult mice that were exposed to developmental stress. Developmental stress was modeled by a combination of maternal corticosterone (CORT) injections during late pregnancy and a limited nesting and bedding paradigm (ELS) during postnatal days 2-9. Behavioral testing of both sexes in early adulthood (2 months old) revealed higher prevalence of anxious behavior than controls during individual and social assessments, and increased likelihood of taking on a subordinate role in a semi-naturalistic social setting. Furthermore, these phenotypes are present at a more elevated degree in combined treatment CORT+ELS mice than mice that experienced only the prenatal or only the postnatal stressor. As this combination of stress treatments in the mouse is translationally relevant to stress exposure during the human gestational and neurodevelopmental period, we intend to use this model to study the transcriptional response to stress across brain regions moving forward. Through a full characterization of the developmental stress transcription profile in males and females, we hope to unveil more possible targets for early interventions in mood disorders like anxiety and depression.

Neuropathic pain is a chronic pathological condition caused by an injury or disease of the somatosensory system. Almost 30% of patients with chronic pain develop a major depressive disorder (MDD) during their lifespan. The dopaminergic (DA) neurons of the ventral tegmental area (VTA), part of the mesolimbic DA system, are involved in a variety of functions, such as motivation and reward; hence, alterations in this system have been reported in chronic pain and MDD. The lateral habenula (LHb), another key region in mood regulation sends projections to the VTA with a minor direct excitatory and a major indirect inhibitory pathway. Our hypothesis is that VTA DA neurons and more particularly the ones receiving inputs from the LHb can be altered in the comorbidity of chronic pain and MDD. By performing single-cell recording of optogenetically identified VTA DA neurons in anesthetized mice, we studied the basal activity of VTA DA neurons and their response to electrical stimulation of the LHb in a mouse model of neuropathic pain-induced depressive-like behaviors. Our data demonstrated that the tonic activity of VTA DA neurons is increased in animals displaying chronic pain and depressive-like behaviours. Moreover, this increased activity is observed only in VTA DA neurons located contralateral to the paw where the peripheral nerve injury was performed. Finally, the proportion of inhibited neurons by LHb stimulation seems to decrease in neuropathic versus control mice.

Background. Depression is a chronic psychiatric disease of multifactorial etiology whose complete pathophysiology understanding remains elusive. Stress and comorbidity with other inflammatory pathologies are risk factors of psychiatric diseases. Epidemiological evidence points out that periodontitis, as a source of low-grade chronic inflammation, could be associated with depression, but the underlying mechanisms have not been fully elucidated yet. **Aims.** We developed a combined model of periodontitis and Chronic Mild Stress (CMS) -previously described in Martinez et al., 2019 - to study the role of the sphingosine-1 phosphate (S1P) pathway in the microglial activation through the S1PR3 receptor during the neuroinflammatory response. **Methods.** Quantitative and morphological studies of microglia in prefrontal cortex slices stained by fluorescence immunohistochemistry against the ionized calcium-binding adapter molecule 1 (IBA1) as well as biochemical analysis via western blotting and RT-qPCR were performed. **Results.** In this study, we observed a significant increase in the microglial population across the prefrontal cortex in the periodontitis, CMS, and the combined model groups compared to control. Moreover, there was a change in their morphology and size that can be related to their reactivity status. S1PR3 receptor expression in the frontal cortex increased after CMS exposure and could modulate the activation of microglia during neuroinflammation and lead to the liberation of pro-inflammatory cytokines. **Conclusion.** Thus, our results indicate that the model causes an increase in the number of microglia cells and a shift in their activation state that could leads to neuroinflammation throught overexpresion of S1PR3.

Toll-like receptor 4 agonist and antagonist lipopolysaccharides modify innate immune response in rat brain circumventricular organs.
The circumventricular organs (CVOs) are blood-brain-barrier missing structures whose activation through lipopolysaccharide (LPS) is a starting point for TLR-driven (Toll-like receptors) neuroinflammation. The aim of this study was to evaluate in the CVO area postrema (AP), subfornical organ (SFO), and median eminence (ME), the inflammatory response to two TLR4 agonists: LPS from Escherichia coli (EC-LPS), the strongest endotoxin molecule described, and LPS from Porphyromonas gingivalis (PG-LPS), a pathogenic bacteria present in the periodontium related to neuroinflammation in neurodegenerative/psychiatric diseases. The response to LPS from the cyanobacteria Rhodobacter sphaeroides (RS-LPS), a TLR4 antagonist with an interesting anti-inflammatory potential, was also assessed.

Depletion of brain perivascular macrophages regulates acute restraint stress-induced neuroinflammation and oxidative/nitrosative stress in rat frontal cortex.
The central nervous system can respond to peripheral immune stimuli through the activation of the neurovascular unit. One of the cellular types implicated are perivascular macrophages (PVMs), hematopoietic-derived brain-resident cells located in the perivascular space. PVMs have been implicated in the immune surveillance and in the regulation of the accumulation/trafficking of macromolecules in brain-blood interfaces. Recent studies suggested that the role of PVMs could vary depending on the nature and duration of the immune challenge applied. Here, we investigate the role of PVMs in stress-induced neuroinflammation and oxidative/nitrosative consequences. The basal phagocytic activity of PVMs was exploited to selectively deplete them by ICV injection of liposomes encapsulating the pro-apoptotic drug clodronate. Acute restraint stress-induced neuroinflammation and oxidative/nitrosative stress in rat brain frontal cortex samples were assessed by western blot

and RT-PCR analyses. The depletion of PVMs: (1) decreased tumor necrosis-α levels (2) prevented the Janus kinase/signal transducers and activators of transcription pathway and increased interleukin-6 receptor protein-expression in stress conditions; (3) prevented the stress-induced Toll-like receptor 4/Myeloid differentiation primary response 88 protein signaling pathway; (4) down-regulated the pro-inflammatory nuclear factor κB/cyclooxygenase-2 pathway; (5) prevented stress-induced lipid peroxidation and the concomitant increase of the endogenous antioxidant mediators nuclear factor (erythroid-derived 2)-like 2, glutathione reductase 1 and Parkinsonism-associated deglycase mRNA expression. Our results point to PVMs as regulators of stress-induced neuroinflammation and oxidative/nitrosative stress. Much more scientific effort is still needed to evaluate whether their selective manipulation is promising as a therapeutic strategy for the treatment of stress-related neuropsychopathologies.

THE BLOOD-BRAIN BARRIER PERMEABILITY IN A PRECLINICAL IN VIVO MODEL OF PERIODONTITIS AND DEPRESSION: A STEP FORWARD IN THE UNDERSTANDING OF INFLAMMATORY MECHANISMS

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Marina Muñoz-López[1], Javier Robledo-Montaña[1], María Martinez[2], Leire Virto[2], Borja García-Bueno[1], Juan Carlos Leza[1], Elena Figuero[2], David Martín-Hernández[1]
[1]Universidad Complutense de Madrid (UCM), Farmacología Y Toxicología, MADRID, Spain, [2]Universidad Complutense de Madrid (UCM), Etep (etiology And Therapy Of Periodontal And Peri-implant Diseases) Research Group (ucm), Universidad Complutense De Madrid Ucm., MADRID, Spain

Background. Depression is a mental illness in which inflammation may play an important role. On the other hand, periodontitis is an inflammatory gum disease caused by an oral multispecies bacterial chronic infection. Despite many underlying aspects remaining unknown, some studies suggest comorbidity between these diseases and point to chronic inflammation as the common denominator. **Aims.** To unravel the potential mechanisms contributing to both pathologies in the frontal cortex of rats. **Methods.** We used a preclinical *in vivo* model of periodontitis and depression (Perio+CMS) (Martínez et al., 2021). The expression of proteins related to the permeability of the blood-brain barrier (BBB) and the sphingosine-1-phosphate (S1P) pathway was analyzed by Western Blot, RT-qPCR, and ELISA techniques. **Results.** The Perio+CMS model downregulated the expression of S1P receptor 1 (S1PR1), which could be involved through RAC1/2/3 signaling in the development and differentiation of endothelial cells to maintain the integrity of the BBB. Moreover, there was a decrease in the expression of some structural proteins (ZO-1, occludin) and an increase in molecules involved in immune trafficking (cell and leukocyte adhesion molecules - ICAM-1, VCAM-1 -, and matrix metalloproteinase 9 - MMP9). **Conclusions.** Thus, the described changes could indicate and increase in the BBB permeability, which may be associated with the induction and promotion of neuroinflammation. These processes could be relevant to the pathophysiology and comorbidity of periodontitis and depression. Moreover, they lay the ground for a better understanding of the interplay between chronic inflammatory diseases and the central nervous system.

Aims: Prevalence, symptoms, and treatment of depression suggest that major depressive disorders (MDD) present sex differences. Social stress-induced neurovascular pathology is associated with depressive symptoms in male mice; however, this association is unclear in females. **Methods**: Transcriptional profiling of genes associated with vascular integrity, permeability, angiogenesis, tight junctions, and blood-brain barrier (BBB) formation was performed in the brain of female mice following the 10-day chronic social defeat paradigm. Functional studies using adeno-associated viruses were conducted to confirm the causal role of the BBB in the establishment maladaptive stress behaviors. Endothelium transcriptomic and peripheral blood profiles were established to gain mechanistic insights and uncover novel biomarkers of MDD. **Results**: Chronic social stress promotes BBB alterations in the prefrontal cortex (PFC) of female mice. Targeted disruption of the BBB in this brain region induces anxiety- and depression-like behaviours. By comparing the endothelium cell-specific transcriptomic profiling of the mouse male and female PFC, we identify several pathways and genes involved in maladaptive stress responses and resilience to stress. Furthermore, we confirm that the BBB in the PFC of stressed female mice is leaky. Then, we identify circulating vascular biomarkers of chronic stress, such as soluble E-selectin. Similar changes in circulating soluble E-selectin, BBB gene expression and morphology can be found in blood serum and *postmortem* brain samples from women diagnosed with MDD. **Conclusions**: Altogether, we propose that BBB dysfunction plays an important role in modulating stress responses in female mice and possibly MDD.

Vascular and blood-brain barrier-related changes underlie stress responses and resilience in female mice and depression in human tissue.
Prevalence, symptoms, and treatment of depression suggest that major depressive disorders (MDD) present sex differences. Social stress-induced neurovascular pathology is associated with depressive symptoms in male mice; however, this association is unclear in females. Here, we report that chronic social and subchronic variable stress promotes blood-brain barrier (BBB) alterations in mood-related brain regions of female mice. Targeted disruption of the BBB in the female prefrontal cortex (PFC) induces anxiety- and depression-like behaviours. By comparing the endothelium cell-specific transcriptomic profiling of the mouse male and female PFC, we identify several pathways and genes involved in maladaptive stress responses and resilience to stress. Furthermore, we confirm that the BBB in the PFC of stressed female mice is leaky. Then, we identify circulating vascular biomarkers of chronic stress, such as soluble E-selectin. Similar changes in circulating soluble E-selectin, BBB gene expression and morphology can be found in blood serum and postmortem brain samples from women diagnosed with MDD. Altogether, we propose that BBB dysfunction plays an important role in modulating stress responses in female mice and possibly MDD.

Inflammation-driven brain and gut barrier dysfunction in stress and mood disorders.
Regulation of emotions is generally associated exclusively with the brain. However, there is evidence that peripheral systems

are also involved in mood, stress vulnerability vs. resilience, and emotion-related memory encoding. Prevalence of stress and mood disorders such as major depression, bipolar disorder, and post-traumatic stress disorder is increasing in our modern societies. Unfortunately, 30%-50% of individuals respond poorly to currently available treatments highlighting the need to further investigate emotion-related biology to gain mechanistic insights that could lead to innovative therapies. Here, we provide an overview of inflammation-related mechanisms involved in mood regulation and stress responses discovered using animal models. If clinical studies are available, we discuss translational value of these findings including limitations. Neuroimmune mechanisms of depression and maladaptive stress responses have been receiving increasing attention, and thus, the first part is centered on inflammation and dysregulation of brain and circulating cytokines in stress and mood disorders. Next, recent studies supporting a role for inflammation-driven leakiness of the blood-brain and gut barriers in emotion regulation and mood are highlighted. Stress-induced exacerbated inflammation fragilizes these barriers which become hyperpermeable through loss of integrity and altered biology. At the gut level, this could be associated with dysbiosis, an imbalance in microbial communities, and alteration of the gut-brain axis which is central to production of mood-related neurotransmitter serotonin. Novel therapeutic approaches such as anti-inflammatory drugs, the fast-acting antidepressant ketamine, and probiotics could directly act on the mechanisms described here improving mood disorder-associated symptomatology. Discovery of biomarkers has been a challenging quest in psychiatry, and we end by listing promising targets worth further investigation.

Molecular adaptations of the blood-brain barrier promote stress resilience vs. depression.
Preclinical and clinical studies suggest that inflammation and vascular dysfunction contribute to the pathogenesis of major depressive disorder (MDD). Chronic social stress alters blood-brain barrier (BBB) integrity through loss of tight junction protein claudin-5 (cldn5) in male mice, promoting passage of circulating proinflammatory cytokines and depression-like behaviors. This effect is prominent within the nucleus accumbens, a brain region associated with mood regulation; however, the mechanisms involved are unclear. Moreover, compensatory responses leading to proper behavioral strategies and active resilience are unknown. Here we identify active molecular changes within the BBB associated with stress resilience that might serve a protective role for the neurovasculature. We also confirm the relevance of such changes to human depression and antidepressant treatment. We show that permissive epigenetic regulation of expression and low endothelium expression of repressive cldn5-related transcription factor are associated with stress resilience. Region- and endothelial cell-specific whole transcriptomic analyses revealed molecular signatures associated with stress vulnerability vs. resilience. We identified proinflammatory TNFα/NFκB signaling and as mediators of stress susceptibility. Pharmacological inhibition of stress-induced increase in hdac1 activity rescued expression in the NAc and promoted resilience. Importantly, we confirmed changes in expression in the NAc of depressed patients without antidepressant treatment in line with CLDN5 loss. Conversely, many of these deleterious -related molecular changes were reduced in postmortem NAc from antidepressant-treated subjects. These findings reinforce the importance of considering stress-induced neurovascular pathology in depression and provide therapeutic targets to treat this mood disorder and promote resilience.

Neurobiology of resilience in depression: immune and vascular insights from human and animal studies.
Major depressive disorder (MDD) is a chronic and recurrent psychiatric condition characterized by depressed mood, social isolation and anhedonia. It will affect 20% of individuals with considerable economic impacts. Unfortunately, 30-50% of depressed individuals are resistant to current antidepressant treatments. MDD is twice as prevalent in women and associated symptoms are different. Depression's main environmental risk factor is chronic stress, and women report higher levels of stress in daily life. However, not every stressed individual becomes depressed, highlighting the need to identify biological determinants of stress vulnerability but also resilience. Based on a reverse translational approach, rodent models of depression were developed to study the mechanisms underlying susceptibility vs resilience. Indeed, a subpopulation of animals can display coping mechanisms and a set of biological alterations leading to stress resilience. The aetiology of MDD is multifactorial and involves several physiological systems. Exacerbation of endocrine and immune responses from both innate and adaptive systems are observed in depressed individuals and mice exhibiting depression-like behaviours. Increasing attention has been given to neurovascular health since higher prevalence of cardiovascular diseases is found in MDD patients and inflammatory conditions are associated with depression, treatment resistance and relapse. Here, we provide an overview of endocrine, immune and vascular changes associated with stress vulnerability vs. resilience in rodents and when available, in humans. Lack of treatment efficacy suggests that neuron-centric treatments do not address important causal biological factors and better understanding of stress-induced adaptations, including sex differences, could contribute

to develop novel therapeutic strategies including personalized medicine approaches.

BACKGROUND Depression is among the most common mental disorders and Treatment-Resistant Depression (TRD) is also prevalent. *Nardostachys Jatamansi* DC is a promising drug that is present in several Ayurvedic formulations for the complementary treatment of TRD. Investigating the variations in pathophysiological deformities in depression with the administration of the *Ayurvedic* drug by utilizing available neurophysiologic techniques will lead to a better understanding of the disease and its possible management with reduced side effects. **AIM** To evaluate the efficacy of Ayurvedic drug (*Nardostachys Jatamansi* DC.) in treating MDD on clinical improvement assessed by depression scores, cardiac autonomic functions measured by heart rate variability (HRV). **METHODS** In this randomized controlled double-blind study, patients of MDD being treated with Escitalopram were recruited into two groups and given either *Nardostachys Jatamansi* DC. powder or placebo as add-on therapy for 8 weeks. The assessment is based on clinical rating scales and cardiac autonomic functions measured by HRV. **RESULTS** 21 patients have been recruited till now with the majority showing an overall reduction of all rating scores after the completion of treatment. There is an increase in HRV parameters (SDNN, RMSSD, PNN50, Total power & HF nu) and a decrease in LF nu and LF/HF ratio. The unblinding will be done at the end of the study. **CONCLUSION** Cardiac autonomic dysfunction has been observed in depression and our preliminary findings support the same. After unblinding the groups, results may show the possible pathophysiology of the Ayurvedic drug in modulating HRV parameters in the effective management of MDD.

DOES PHYSICAL EXERCISE OFFER RESILIENCE IN A SOCIAL DEFEAT STRESS MOUSE MODEL?

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Julie Reis[1,2], Edna Soares[1,2], Carlos Fontes-Ribeiro[1,2], Frederico Pereira[1,2]
[1]Faculty of Medicine of the University of Coimbra, Coimbra Institute For Clinical And Biomedical Research (icbr), Coimbra, Portugal, [2]Faculty of Medicine of the University of Coimbra, Institute Of Pharmacology And Experimental Therapeutics, Coimbra, Portugal

Introduction: Several studies support the adoption of physical exercise (PE) as a non-pharmacological approach in depression and anxiety. However, the mechanism underlying the beneficial impact of PE remains poorly studied. **Aims:** To evaluate whether PE provides resilience in a Chronic Social Defeat Stress (CSDS) mice model. **Material & Methods**: Young-adult male C57BL/6 mice (7-8 weeks-old) were used, and four different groups were analyzed: (1) CSDS, (2) PE+CSDS, (3) PE, (4) Control. CSDS mice were subjected to bouts of social defeat by aggressive male CD-1 mice (10 min/day; 10 days). PE+CSDS mice group were subjected to a treadmill PE program prior to CSDS protocol. Mice emotional status (anxiety and depression-like behavior) was analyzed between 24 and 96h after CSDS protocol. Data are presented as mean ± standard deviation (SD). Groups (N=6-28) were compared using ANOVA or Kruskal-Wallis followed by post-hoc multiple comparison tests. Significance was assigned to differences with a $p<0.5$. **Results**: CSDS and PE+CSDS mice group showed social avoidance behavior to CD1. A cluster analysis revealed that a subset of CSDS mice showed a decrease in entries and in time spent in the open arms in the Elevated Plus Maze test. PE did not prevent the observed emotional changes. Other behaviors including exploratory, self-care and anhedonia were not changed by chronic stress and by PE. **Conclusions:** CSDS model induced social avoidance and changes in anxiety-like but not in depression-like behavior. However, PE failed to prevent this CSDS phenotype. **Funded by FCT POCI-01-0145-FEDER-030786**

Circulating Extracellular Vesicles: The Missing Link between Physical Exercise and Depression Management?
Depression is associated with an increased risk of aging-related diseases. It is also seemingly a common psychological reaction to pandemic outbreaks with forced quarantines and lockdowns. Thus, depression represents, now more than ever, a major global health burden with therapeutic management challenges. Clinical data highlights that physical exercise is gaining momentum as a non-pharmacological intervention in depressive disorders. Although it may contribute to the reduction of systemic inflammation associated with depression, the mechanisms underlying the beneficial physical exercise effects in emotional behavior remain to be elucidated. Current investigations indicate that a rapid release of extracellular vesicles into the circulation might be the signaling mediators of systemic adaptations to physical exercise. These biological entities are now well-established intercellular communicators, playing a major role in relevant physiological and pathophysiological functions, including brain cell-cell communication. We also reviewed emerging evidence correlating depression with modified circulating extracellular vesicle surfaces and cargo signatures (e.g., microRNAs and proteins), envisioned as potential biomarkers for diagnosis, efficient disease stratification and appropriate therapeutic management. Accordingly, the clinical data summarized in the present review prompted us to hypothesize that physical exercise-related circulating extracellular vesicles contribute to its antidepressant effects, particularly through the modulation of inflammation. This review sheds light on the triad "physical exercise-extracellular vesicles-depression" and suggests new avenues in this novel emerging field.

Single Low Dose of Cocaine-Structural Brain Injury Without Metabolic and Behavioral Changes.
Chronic cocaine use has been shown to lead to neurotoxicity in rodents and humans, being associated with high morbidity and mortality rates. However, recreational use, which may lead to addictive behavior, is often neglected. This occurs, in part, due to the belief that exposure to low doses of cocaine comes with no brain damage risk. Cocaine addicts have shown glucose metabolism changes related to dopamine brain activity and reduced volume of striatal gray matter. This work aims to evaluate the morphological brain changes underlying metabolic and locomotor behavioral outcome, in response to a single low dose of cocaine in a pre-clinical study. In this context, a Balb-c mouse model has been chosen, and animals were injected with a single dose of cocaine (0.5 mg/kg). Control animals were injected with saline. A behavioral test, positron emission tomography (PET) imaging, and anatomopathological studies were conducted with this low dose of cocaine, to study functional, metabolic, and morphological brain changes, respectively. Animals exposed to this cocaine dose showed similar open field activity and brain metabolic activity as compared with controls. However, histological analysis showed alterations in the prefrontal cortex and of mice exposed to cocaine. For the first time, it has been demonstrated that a single low dose of cocaine, which can cause no locomotor behavioral and brain metabolic changes, can induce structural damage. These brain changes must always be considered regardless of the dosage used. It is essential to alert the population even against the consumption of low doses of cocaine.

SLEEP DISTURBANCE AND CHANGES IN OSCILLATORY ACTIVITY IN A MOUSE MODEL OF DEPRESSION: EFFECTS OF SLEEP DEPRIVATION, KETAMINE AND CIRCADIAN CLOCK MODULATION.

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Wilf Gardner[1,2], Patrice Bourgin[1,3], Tsvetan Serchov[1,2,4]
[1]University of Strasbourg, Inci: Institut Des Neurosciences Cellulaires Et Intégratives, Strasbourg, France, [2]University of Strasbourg, Institute For Advanced Study (usias), Strasbourg, France, [3]University Hospital Strasbourg, Centre Des Troubles Du Sommeil (circsom), Strasbourg, France, [4]University of Freiburg, Department For Psychiatry And Psychotherapy, Faculty Of Medicine, Freiburg, Germany

Introduction Sleep disturbances are a critical feature of affective disorders with implications during treatment. The chronic despair mouse (CDM) is a recently established model in which repetitive forced swim stress (FST) produces long-lasting anhedonia- and despair-like phenotypes. In the current pilot study, sleep architecture and oscillatory activity was assessed in the CDM model, compared to non-depressive controls and following anti-depressant treatments (sleep deprivation, ketamine and circardian clockwork modulation via a ROR-α/γ agonist). Materials and methods C57BL/6 mice were surgically implanted with electrocorticography (ECoG) and electromyography (EMG) electrodes in order to assess sleep, plus a deep electrode in the medial pre-frontal cortex (mPFC). 48h recordings were conducted before and after the CDM protocol (five consecutive days 10-minute FST), then before and after 6h sleep deprivation (from light cycle onset), ROR agonist SR1078 (10mg/kg), ketamine (3mg/kg) or vehicle. Sleep assessment and spectral analysis were performed. Results CDM mice exhibited more fragmented sleep, with an increase in slow wave activity (SWA) during slow wave sleep (SWS) and a reduction in theta band oscillations during REM sleep. Sleep deprivation increased REM sleep, reduced SWS fragmentation and increased SWA immediately following treatment. Ketamine produced a sustained increase in mPFC SWA, while all treatments suppressed light cycle gamma-band activity in the mPFC. Conclusions CDM mice showed fragmented sleep, but without REM sleep changes typical of affective disorders. Suppression of gamma activity in the mPFC after all treatments suggests a potential common mechanism or marker of anti-depressant response

Lithium is the first-line treatment for bipolar disorder (BD). However, only 30% of patients respond satisfactorily to this medication. Therefore, the aim of this study is to find biomarkers that help predict clinical response to lithium in BD patients. Olfactory neural progenitors (ONP), cells with a neuronal linage, from patients who respond to lithium (LR), or not (NR) and healthy controls (HC) were cultured with or without lithium. Blood samples (PBMCs) extracted from these patients were used to search for peripheral biomarkers. Proteomic analysis obtained from both ONP and PBMCs showed that PKA signalling pathway was downregulated in cells derived from LR patients when compared to HC, but it was upregulated in LNR. In vitro lithium treatment restored PKA signalling pathway, but exclusively in cells derived from LR patients. PKA signalling pathway regulates cytoskeleton organization and indeed, 45 cytoskeleton-related proteins changed in NR. Moreover, ONP cells from LR and NR patients showed less points of adhesion to the substrate, that it was restored after lithium treatment. ONP cells from NR patients showed an increase in the cell size and morphologic alterations that were not restored by lithium. Changes in cytoskeleton proteins related to PKA signalling pathway and cell size/morphology could serve as differential biomarkers to predict the clinical response to lithium in BD.

The Role of the Locus Coeruleus in Pain and Associated Stress-Related Disorders.
The locus coeruleus (LC)-noradrenergic system is the main source of noradrenaline in the central nervous system and is involved intensively in modulating pain and stress-related disorders (e.g., major depressive disorder and anxiety) and in their comorbidity. However, the mechanisms involving the LC that underlie these effects have not been fully elucidated, in part owing to the technical difficulties inherent in exploring such a tiny nucleus. However, novel research tools are now available that have helped redefine the LC system, moving away from the traditional view of LC as a homogeneous structure that exerts a uniform influence on neural activity. Indeed, innovative techniques such as DREADDs (designer receptors exclusively activated by designer drugs) and optogenetics have demonstrated the functional heterogeneity of LC, and novel magnetic resonance imaging applications combined with pupillometry have opened the way to evaluate LC activity in vivo. This review aims to bring together the data available on the efferent activity of the LC-noradrenergic system in relation to pain and its comorbidity with anxiodepressive disorders. Acute pain triggers a robust LC stress response, producing spinal cord-

mediated endogenous analgesia while promoting aversion, vigilance, and threat detection through its ascending efferents. However, this protective biological system fails in chronic pain, and LC activity produces pain facilitation, anxiety, increased aversive memory, and behavioral despair, acting at the medulla, prefrontal cortex, and amygdala levels. Thus, the activation/deactivation of specific LC projections contributes to different behavioral outcomes in the shift from acute to chronic pain.
Biol Psychiatry, 2022; 91

Pain and depression comorbidity causes asymmetric plasticity in the locus coeruleus neurons.
There is strong comorbidity between chronic pain and depression, although the neural circuits and mechanisms underlying this association remain unclear. By combining immunohistochemistry, tracing studies and western blotting, with the use of different DREADDS (designer receptor exclusively activated by designer drugs) and behavioural approaches in a rat model of neuropathic pain (chronic constriction injury), we explore how this comorbidity arises. To this end, we evaluated the time-dependent plasticity of noradrenergic locus coeruleus neurons relative to the site of injury: ipsilateral (LCipsi) or contralateral (LCcontra) locus coeruleus at three different time points: short (2 days), mid (7 days) and long term (30-35 days from nerve injury). Nerve injury led to sensorial hypersensitivity from the onset of injury, whereas depressive-like behaviour was only evident following long-term pain. Global chemogenetic blockade of the LCipsi system alone increased short-term pain sensitivity while the blockade of the LCipsi or LCcontra relieved pain-induced depression. The asymmetric contribution of locus coeruleus modules was also evident as neuropathy develops. Hence, chemogenetic blockade of the LCipsi→spinal cord projection, increased pain-related behaviours in the short term. However, this lateralized circuit is not universal as the bilateral chemogenetic inactivation of the locus coeruleus-rostral anterior cingulate cortex pathway or the intra-rostral anterior cingulate cortex antagonism of alpha1- and alpha2-adrenoreceptors reversed long-term pain-induced depression. Furthermore, chemogenetic locus coeruleus to spinal cord activation, mainly through LCipsi, reduced sensorial hypersensitivity irrespective of the time post-injury. Our results indicate that asymmetric activation of specific locus coeruleus modules promotes early restorative analgesia, as well as late depressive-like behaviour in chronic pain and depression comorbidity.
Brain, 2022; 145
35025190: Camarena-Delgado C, Llorca-Torralba M, Suárez-Pereira I, Bravo L, López-Martín C, Garcia-Partida JA, Mico JA, Berrocoso E
Nerve injury induces transient locus coeruleus activation over time: role of the locus coeruleus-dorsal reticular nucleus pathway.
The transition from acute to chronic pain results in maladaptive brain remodeling, as characterized by sensorial hypersensitivity and the ensuing appearance of emotional disorders. Using the chronic constriction injury of the sciatic nerve as a model of neuropathic pain in male Sprague-Dawley rats, we identified time-dependent plasticity of locus coeruleus (LC) neurons related to the site of injury, ipsilateral (LCipsi) or contralateral (LCcontra) to the lesion, hypothesizing that the LC→dorsal reticular nucleus (DRt) pathway is involved in the pathological nociception associated with chronic pain. LCipsi inactivation with lidocaine increased cold allodynia 2 days after nerve injury but not later. However, similar blockade of LCcontra reduced cold allodynia 7 and 30 days after inducing neuropathy but not earlier. Furthermore, lidocaine blockade of the LCipsi or LCcontra reversed pain-induced depression 30 days after neuropathy. Long-term pain enhances phosphorylated cAMP-response element binding protein expression in the DRtcontra but not in the DRtipsi. Moreover, inactivation of the LCcontra→DRtcontra pathway using dual viral-mediated gene transfer of designer receptor exclusively activated by designer drugs produced consistent analgesia in evoked and spontaneous pain 30 days postinjury. This analgesia was similar to that produced by spinal activation of α2-adrenoreceptors. Furthermore, chemogenetic inactivation of the LCcontra→DRtcontra pathway induced depressive-like behaviour in naïve animals, but it did not modify long-term pain-induced depression. Overall, nerve damage activates the LCipsi, which temporally dampens the neuropathic phenotype. However, the ensuing activation of a LCcontra→DRtcontra facilitatory pain projection contributes to chronic pain, whereas global bilateral LC activation contributes to associated depressive-like phenotype.

Olfactory Neuroepithelium Cells from Cannabis Users Display Alterations to the Cytoskeleton and to Markers of Adhesion, Proliferation and Apoptosis.
Cannabis is the third most commonly used psychoactive substance of abuse, yet it also receives considerable attention as a potential therapeutic drug. Therefore, it is essential to fully understand the actions of cannabis in the human brain. The olfactory neuroepithelium (ON) is a peripheral nervous tissue that represents an interesting surrogate model to study the

effects of drugs in the brain, since it is closely related to the central nervous system, and sensory olfactory neurons are continually regenerated from populations of stem/progenitor cells that undergo neurogenesis throughout life. In this study, we used ON cells from chronic cannabis users and healthy control subjects to assess alterations in relevant cellular processes, and to identify changes in functional proteomic pathways due to cannabis consumption. The ON cells from cannabis users exhibited alterations in the expression of proteins that were related to the cytoskeleton, cell proliferation and cell death, as well as, changes in proteins implicated in cancer, gastrointestinal and neurodevelopmental pathologies. Subsequent studies showed cannabis provoked an increase in cell size and morphological alterations evident through β-Tubulin III staining, as well as, enhanced beta-actin expression and a decrease in the ability of ON cells to undergo cell attachment, suggesting abnormalities of the cytoskeleton and cell adhesion system. Furthermore, these cells proliferated more and underwent less cell death. Our results indicate that cannabis may alter key processes of the developing brain, some of which are similar to those reported in mental disorders like DiGeorge syndrome, schizophrenia and bipolar disorder.

Sustained escitalopram administration affects glucose metabolism in the rat brain.
Escitalopram is a selective serotonin reuptake inhibitor (SSRIs) antidepressant, drug that is currently used as first-line agents for the treatment of depression and it is also used in the treatment of other psychiatric disorders. The main goal of this study was to identify which brain areas are affected by escitalopram administration. This study was carried out on male Wistar rats that received escitalopram daily over 14 days and that were studied by 2-deoxy-2[F]fluoro-D-glucose ([F]FDG)-PET on the last day of treatment. Computed tomography (CT) images were acquired immediately before each PET scan and the main effects of drug administration were elucidated by Statistical Parametric Mapping. The results obtained indicated that repeated exposure to escitalopram increased metabolic activity in the retrosplenial and posterior cingulate cortices, while it decreased such activity in the ventral hippocampus, cerebellum, brainstem and midbrain regions, including the raphe nuclei and ventral tegmental area. Therefore, repeated exposure to escitalopram alters the activity of several brain areas closely related to the serotonergic system, and previously identified as key regions in the antidepressant effect induced by SSRIs. Furthermore, some of the changes found, such as the dampened metabolism in the ventral tegmental area, are similar to changes that have been described after treating with other fast-acting antidepressant approaches.

Induced Dipoles and Possible Modulation of Wireless Effects in Implanted Electrodes. Effects of Implanting Insulated Electrodes on an Animal Test to Screen Antidepressant Activity.
There is evidence that Deep Brain Stimulation (DBS) produces health benefits in patients even before initiating stimulation. Furthermore, DBS electrode insertion in rat infralimbic cortex (ILC) provokes antidepressant-like effects before stimulation, due to local inflammation and astrogliosis. Consequently, a significant effect of implanting electrodes is suspected. External fields, similar in magnitude to the brain's endogenous fields, induce electric dipoles in conducting materials, in turn influencing neural cell growth through wireless effects. To elucidate if such dipoles influence depressive-like behavior, without external stimulation, the comparative effect of conducting and insulated electrodes along with the glial response is studied in unstressed rats. Naïve and implanted rats with electrically insulated or uninsulated steel electrodes were evaluated in the modified forced swimming test and expression of ILC-glial markers was assessed. An antidepressant-like effect was observed with conducting but not with insulated electrodes. Gliosis was detected in both groups, but astroglial reactivity was larger near uninsulated electrodes. Thus, induced dipoles and antidepressant-like effects were only observed with conducting implants. Such correlation suggests that dipoles induced in electrodes by endogenous fields in turn induce neuron stimulation in a feedback loop between electrodes and neural system. Further research of the effects of unwired conducting implants could open new approaches to regulating neuronal function, and possibly treat neurological disorders.

Neuropathic pain increases spontaneous and noxious-evoked activity of locus coeruleus neurons.
The noradrenergic locus coeruleus nucleus is an important station in both the ascending and descending pain regulatory pathways. These neurons discharge in tonic and phasic modes in response to sensory stimuli. However, few studies have set out to characterize the electrophysiological response of the locus coeruleus to noxious stimuli in conditions of neuropathic pain. Thus, the effects of mechanical nociceptive stimulation of the sciatic nerve area on spontaneous (tonic) and sensory-evoked (phasic) locus coeruleus discharge were studied by extracellular recording in anesthetized rats seven, fourteen and twenty-eight days after chronic constriction injury. Minor significant electrophysiological changes were found seven and fourteen days after nerve injury. However, alterations to the spontaneous activity in both the ipsilateral and contralateral locus coeruleus were found twenty-eight days after nerve constriction, as witnessed by an increase of burst firing incidence and irregular firing patterns. Furthermore, noxious-evoked responses were exacerbated in the contralateral and ipsilateral nucleus

at twenty-eight days after injury, as were the responses evoked when stimulating the uninjured paw. In addition, mechanical stimulation of the hindpaw produced a significant sensitization of neuronal tonic activity after 28 days of neuropathy. In summary, long-term nerve injury led to higher spontaneous activity and exacerbated noxious-evoked responses in the locus coeruleus to stimulation of nerve-injured and even uninjured hindpaws, coinciding temporally with the development of depressive and anxiogenic-like behavior.

Monoamines as Drug Targets in Chronic Pain: Focusing on Neuropathic Pain.
Monoamines are involved in regulating the endogenous pain system and indeed, peripheral and central monoaminergic dysfunction has been demonstrated in certain types of pain, particularly in neuropathic pain. Accordingly, drugs that modulate the monaminergic system and that were originally designed to treat depression are now considered to be first line treatments for certain types of neuropathic pain (e.g., serotonin and noradrenaline (and also dopamine) reuptake inhibitors). The analgesia induced by these drugs seems to be mediated by inhibiting the reuptake of these monoamines, thereby reinforcing the descending inhibitory pain pathways. Hence, it is of particular interest to study the monoaminergic mechanisms involved in the development and maintenance of chronic pain. Other analgesic drugs may also be used in combination with monoamines to facilitate descending pain inhibition (e.g., gabapentinoids and opioids) and such combinations are often also used to alleviate certain types of chronic pain. By contrast, while NSAIDs are thought to influence the monoaminergic system, they just produce consistent analgesia in inflammatory pain. Thus, in this review we will provide preclinical and clinical evidence of the role of monoamines in the modulation of chronic pain, reviewing how this system is implicated in the analgesic mechanism of action of antidepressants, gabapentinoids, atypical opioids, NSAIDs and histaminergic drugs.

Pain in neuropsychiatry: Insights from animal models.
Pain is the most common symptom reported in clinical practice, meaning that it is associated with many pathologies as either the origin or a consequence of other illnesses. Furthermore, pain is a complex emotional and sensorial experience, as the correspondence between pain and body damage varies considerably. While these issues are widely acknowledged in clinical pain research, until recently they have not been extensively considered when exploring animal models, important tools for understanding pain pathophysiology. Interestingly, chronic pain is currently considered a risk factor to suffer psychiatric disorders, mainly stress-related disorders like anxiety and depression. Conversely, pain appears to be altered in many psychiatric disorders, such as depression, anxiety and schizophrenia. Thus, pain and psychiatric disorders have been linked in epidemiological and clinical terms, although the neurobiological mechanisms involved in this pathological bidirectional relationship remain unclear. Here we review the evidence obtained from animal models about the co-morbidity of pain and psychiatric disorders, placing special emphasis on the different dimensions of pain.

A POTENTIAL ROLE FOR THE STRESS-REGULATED MIR-708 IN AFFECTIVE DISORDERS

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Carlotta Gilardi, Helena Martins, Fridolin Gross, David Colameo, Reetu Daswani, Pierre-Luc Germain, Gerhard Schratt
ETH Zurich, Institute For Neuroscience, D-hest, Zurich, Switzerland

Defects in synaptic plasticity are frequently observed in Major Depressive Disorder (MDD) and Bipolar Disorder (BD). microRNAs (miRNAs) have been implicated in biological pathways regulating brain development and synaptic plasticity, suggesting that they could play a significant role in MDD and BD. miR-708 represents an interesting candidate miRNA, since both miR-708 and its host gene ODZ4/TENM4 are significantly associated with BD based on previous GWAS. Our results show that miR-708 is upregulated in the peripheral blood of healthy human subjects with high genetic predisposition to inherit MDD or BD (Genetic Risk, GR) or that suffered childhood maltreatment (Environmental Risk, ER), and of patients diagnosed with BD or MDD. Furthermore, miR-708 is upregulated in the hippocampus of juvenile rats that underwent social isolation, a model of chronic stress associated with anxiety and depression-like behavior. To investigate the functional impact of elevated miR-708 levels in the hippocampus, we delivered a miR-708-overexpression plasmid via stereotactic injection in adult mice. RNA sequencing of hippocampal RNA revealed differential expression of miR-708 targets involved in the regulation of synaptic transmission. Further bioinformatic analysis showed that the downregulated genes are mostly enriched in inhibitory interneurons, whereas upregulated genes are mostly enriched in glutamatergic neurons of the dentate gyrus and oligodendrocytes. An extensive behavioural characterization of miR-708 overexpressing mice in the context of anxiety, memory, depression, and sociability is currently ongoing. Taken together, our results indicate that stress-induced upregulation of miR-708 alters gene regulatory networks in the hippocampus, with potential implications for cognition and behavior.

The Ferret as a Model System for Neocortex Development and Evolution.
The neocortex is the largest part of the cerebral cortex and a key structure involved in human behavior and cognition. Comparison of neocortex development across mammals reveals that the proliferative capacity of neural stem and progenitor cells and the length of the neurogenic period are essential for regulating neocortex size and complexity, which in turn are thought to be instrumental for the increased cognitive abilities in humans. The domesticated ferret, , is an important animal model in neurodevelopment for its complex postnatal cortical folding, its long period of forebrain development and its accessibility to genetic manipulation . Here, we discuss the molecular, cellular, and histological features that make this small gyrencephalic carnivore a suitable animal model to study the physiological and pathological mechanisms for the development of an expanded neocortex. We particularly focus on the mechanisms of neural stem cell proliferation, neuronal differentiation, cortical folding, visual system development, and neurodevelopmental pathologies. We further discuss the technological advances that have enabled the genetic manipulation of the ferret . Finally, we compare the features of neocortex development in the ferret with those of other model organisms.

Neocortical Expansion Due to Increased Proliferation of Basal Progenitors Is Linked to Changes in Their Morphology.
The evolutionary expansion of the mammalian neocortex (Ncx) is thought to be linked to increased proliferative capacity of basal progenitors (BPs) and their neurogenic capacity. Here, by quantifying BP morphology in the developing Ncx of mouse, ferret, and human, we show that increased BP proliferative capacity is linked to an increase in BP process number. We identify human membrane-bound PALMDELPHIN (PALMD-Caax) as an underlying factor, and we show that it drives BP process growth and proliferation when expressed in developing mouse and ferret Ncx. Conversely, CRISPR/Cas9-mediated disruption of PALMD or its binding partner ADDUCIN-γ in fetal human Ncx reduces BP process numbers and proliferation. We further show that PALMD-induced processes enable BPs to receive pro-proliferative integrin-dependent signals. These findings provide a link between BP morphology and proliferation, suggesting that changes in BP morphology may have

contributed to the evolutionary expansion of the Ncx.

Human-specific induces hallmarks of neocortical expansion in developing ferret neocortex.
The evolutionary increase in size and complexity of the primate neocortex is thought to underlie the higher cognitive abilities of humans. is a human-specific gene that, based on its expression pattern in fetal human neocortex and progenitor effects in embryonic mouse neocortex, has been proposed to have a key function in the evolutionary expansion of the neocortex. Here, we study the effects of expression in the developing neocortex of the gyrencephalic ferret. In contrast to its effects in mouse, markedly increases proliferative basal radial glia, a progenitor cell type thought to be instrumental for neocortical expansion, and results in extension of the neurogenic period and an increase in upper-layer neurons. Consequently, the postnatal ferret neocortex exhibits increased neuron density in the upper cortical layers and expands in both the radial and tangential dimensions. Thus, human-specific can elicit hallmarks of neocortical expansion in the developing ferret neocortex.

2-BROMO-LSD: A NON-HALLUCINOGENIC LSD ANALOGUE WITH THERAPEUTIC POTENTIAL FOR MAJOR DEPRESSIVE DISORDER.

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Vern Lewis, Emily Arsenault, Fatimeh-Frouh Taghavi-Abkuh, Fatema El Sayegh, Argel Aguilar Valles
Carleton University, Neuroscience, Ottawa, Canada

Major depressive disorder (MDD) is the leading cause of disability worldwide. Current pharmacotherapy treatments, such as SSRI's and SNRI's, have long effective latencies, require chronic administration, and show an estimated 30% treatment resistance rate, necessitating the search for more effective, alternate treatments. Interest in psychedelic hallucinogens (e.g., lysergic acid diethylamide [LSD], psilocybin) has seen a resurgence due to their potential for the treatment of neuropsychiatric diseases, including anxiety and depressive disorders. However, psychedelics induce hallucinations which can last for hours, making efficient and cost-effective treatment difficult. Therefore, discovering non-hallucinogenic derivatives with antidepressant properties is of paramount importance. 2-Bromo-LSD (2BLSD, BETR-001) is an LSD derivative with 5-HT2A agonist activity that lacks hallucinogenic effects and has been safely used for cluster headache treatment. Here we examine the anti-depressant and neural plasticity-promoting activity of 2BLSD. Our findings demonstrate that 2BLSD reverses the depression-like behaviors following chronic variable stress in mice and promotes dendritic arbor complexity in cultured primary rat cortical neurons. These results show that 2BLSD may possess a therapeutic potential and represents a promising alternative to psychedelics in the treatment for MDD.

Transcriptomic signature of extinction learning in the brain of the fire-bellied toad, Bombina orientalis.
Insight into the molecular and cellular mechanisms of learning and memory from a diverse array of taxa contributes to our understanding of the evolution of these processes. The fire-bellied toad, Bombina orientalis, is a basal anuran amphibian model species who could help us describe shared and divergent characteristics of learning and memory mechanisms between amphibians and other vertebrates, and hence answer questions about the evolution of learning. Utilizing next generation sequencing techniques, we profiled gene expression patterns associated with the extinction of prey-catching conditioning in the brain of the fire-bellied toad. For this purpose, gene expression was at first compared between toads sacrificed after acquisition and extinction of the conditioned response. A second comparison was done between toads submitted to extinction following either short or long acquisition training, which results in toads displaying response extinction or resistance to extinction, respectively. We analyzed brain tissue transcription profiles common to both acquisition and extinction learning, or unique to extinction learning and resistance to extinction, and found significant overlap in gene expression related to molecular pathways involving neuronal plasticity (e.g. structural modification, transcription). However, extinction learning induced a unique GABAergic transcriptomic signal, which may be responsible for suppression of the original response memory. Further, when comparing extinction learning in short- and long-trained groups, short training engaged many pathways related to neuronal plasticity, as expected, but long training engaged molecular pathways related to the suppression of learning through epigenetic mediated transcriptional suppression and inhibitory neurotransmission. Overall, gene expression patterns associated with extinction learning in the fire-bellied toad were similar to those found in mammals submitted to extinction, although some divergent profiles highlighted potential differences in the mechanisms of learning and memory among tetrapods.

Temporal Profile of Brain Gene Expression After Prey Catching Conditioning in an Anuran Amphibian.
A key goal in modern neurobiology is to understand the mechanisms underlying learning and memory. To that end, it is essential to identify the patterns of gene expression and the temporal sequence of molecular events associated with learning and memory processes. It is also important to ascertain if and how these molecular events vary between organisms. In vertebrates, learning and memory processes are characterized by distinct phases of molecular activity involving gene transcription, structural change, and long-term maintenance of such structural change in the nervous system. Utilizing next

generation sequencing techniques, we profiled the temporal expression patterns of genes in the brain of the fire-bellied toad after prey catching conditioning. The fire-bellied toad is a basal tetrapod whose neural architecture and molecular pathways may help us understand the ancestral state of learning and memory mechanisms in tetrapods. Differential gene expression following conditioning revealed activity in molecular pathways related to immediate early genes (IEG), cytoskeletal modification, axon guidance activity, and apoptotic processes. Conditioning induced early IEG activity coinciding with transcriptional activity and neuron structural modification, followed by axon guidance and cell adhesion activity, and late neuronal pruning. While some of these gene expression patterns are similar to those found in mammals submitted to conditioning, some interesting divergent expression profiles were seen, and differential expression of some well-known learning-related mammalian genes is missing altogether. These results highlight the importance of using a comparative approach in the study of the mechanisms of leaning and memory and provide molecular resources for a novel vertebrate model in the relatively poorly studied Amphibia.

Behavioural evidence for a sleep-like quiescent state in a pulmonate mollusc, Lymnaea stagnalis (Linnaeus).
The objective of this study was to determine whether the great pond snail, Lymnaea stagnalis, expresses a sleep-like behavioural state. We found that snails spontaneously enter a relatively brief (22±1 min) quiescent state characterized by postural relaxation of the foot, mantle and tentacles, and cessation of radula rasping. Quiescence was reversed ('aroused') by appetitive (sucrose solution) and aversive (tactile) stimuli. Responsiveness to both stimuli was significantly lower in quiescent snails than in active snails. However, tactile stimuli evoked a more sustained defensive response in quiescent snails. Quiescence bouts were consolidated into 'clusters' over an infradian timescale and were only weakly affected by time of day. Clusters contained 7±0.5 bouts, lasted 13±1 h and were separated by long (37±4 h) intervals of almost continuous activity. Analysis of Kaplan-Meier survival curves revealed that the quiescent bout duration was described by an exponential probability distribution (time constant 15±1 min). Active bout duration was described by a bi-exponential probability distribution (time constants 62±4 and 592±48 min). We found no evidence for a 'sleep rebound' mechanism and quiescence expression appeared to be regulated through stochastic processes causing state transitions to resemble a Markovian random walk. We conclude that Lymnaea is a potentially valuable model system for studies of cellular function in sleep.

The detrimental effects of early life adversity (ELA) on brain development and mental health are well established. While studies have mainly identified neuorns as targets of ELA across species, knowledge about the role of NG2+ cells is still lacking. NG2+ cells are a particularly interesting subpopulation, comprising oligodendrocyte precursor cells, with unique properties, as they form synapses with neurons and respond to stress hormones. Using a mouse model of ELA, we performed molecular profiling in hippocampal NG2+ cells at early postnatal and adult stages. To further dissect the impact of glucocorticoids on ELA-induced transcriptional changes, we integrated our data with Chip-seq data on genomic binding sites of the glucocorticoid receptor (GR). The functional relevance of one candidate, Scn7a, was confirmed by electrophysiological recordings in hippocampal NG2+ cells. First, we have established a link between maternal behavior, activation of the offspring's stress response and heterogeneity in the outcome to ELA. We further showed that ELA targets the hippocampal NG2+ transcriptome with glucocorticoids being an important mediator of the ELA-induced molecular changes. ELA altered the NG2+ transcriptome and these transcriptional effects were linked on stress-induced glucocorticoids. The functional relevance of one ELA candidate gene, Scn7a, could be confirmed by an increase in the density of voltage-gated sodium (Nav) channel activated currents in hippocampal NG2+ cells. Our findings indicate that ELA specifically targets the transcriptional profile and electrophysiological properties of hippocampal NG2+ glia. Considering that Na_v channels are important for NG2+ cell-to-neuron communication, our findings establish novel insights into the pathophysiology of ELA.

Early life adversity targets the transcriptional signature of hippocampal NG2+ glia and affects voltage gated sodium (Na) channels properties.
The precise mechanisms underlying the detrimental effects of early life adversity (ELA) on adult mental health remain still elusive. To date, most studies have exclusively targeted neuronal populations and not considered neuron-glia crosstalk as a crucially important element for the integrity of stress-related brain function. Here, we have investigated the impact of ELA, in the form of a limited bedding and nesting material (LBN) paradigm, on a glial subpopulation with unique properties in brain homeostasis, the NG2+ cells. First, we have established a link between maternal behavior, activation of the offspring's stress response and heterogeneity in the outcome to LBN manipulation. We further showed that LBN targets the hippocampal NG2+ transcriptome with glucocorticoids being an important mediator of the LBN-induced molecular changes. LBN altered the NG2+ transcriptome and these transcriptional effects were correlated with glucocorticoids levels. The functional relevance of one LBN-induced candidate gene, , could be confirmed by an increase in the density of voltage-gated sodium (Na) channel activated currents in hippocampal NG2+ cells. remained upregulated until adulthood in LBN animals, which displayed impaired cognitive performance. Considering that Na channels are important for NG2+ cell-to-neuron communication, our

findings provide novel insights into the disruption of this process in LBN mice.

Dimethylarginine dimethylaminohydrolases (DDAH) metabolize asymmetric dimethylarginine (ADMA) the major endogenous inhibitor of nitric oxide synthase (NOS), thereby regulating NO availability. Altered NOS activity, and thus NO levels, are associated with affective disorders. Inline, altered ADMA levels were found in patients with major depression, bipolar disorder, and schizophrenia. Thus, the DDAH/ADMA pathway may play a role in the regulation of NO levels underlying pathology. To investigate the function of the DDAH/ADMA system in neuropathology, we employed a full knockout DDAH1 mice line (DDAH1-ko). We aimed to characterize its impact on mood-related and cognitive behavior and brain morphological and molecular features. DDAH1-ko mice were found to lack DDAH1 mRNA and protein as well as DDAH activity measured by conversion of ADMA to citrulline. DDAH1-ko mice showed a longer active exploration in a novel-object-recognition test and an altered response to an amphetamine challenge paradigm. Based on the decreased response to the psychostimulant, neurotransmitter content was measured and the tissue content of the dopamine metabolite DOPAC was found to be reduced in the caudoputamen and piriform cortex in DDAH1-ko. In contrast to our hypothesis, DDAH1-ko mice showed only minimal behavioral abnormalities compared to littermate wild-type controls. These findings may be explained by the existence of a compensatory mechanism, such as developmental or regulation of NO content through DDAH2 activity. Further research may also focus on the well-established gene-environment interactions in the etiology of neuropsychiatric disorders and thus combine the DDAH1-ko model with external stressors.

Role of the trace amine associated receptor 5 (TAAR5) in the sensorimotor functions.
Classical monoamines are well-known modulators of sensorimotor neural networks. However, the role of trace amines and their receptors in sensorimotor function remains unexplored. Using trace amine-associated receptor 5 knockout (TAAR5-KO) mice, that express beta-galactosidase mapping its localization, we observed TAAR5 expression in the Purkinje cells of the cerebellum and the medial vestibular nucleus, suggesting that TAAR5 might be involved in the vestibular and motor control. Accordingly, in various behavioral tests, TAAR5-KO mice demonstrated lower endurance, but better coordination and balance compared to wild-type controls. Furthermore, we found specific changes in striatal local field potentials and motor cortex electrocorticogram, such as a decrease in delta and an increase in theta oscillations of power spectra, respectively. The obtained data indicate that TAAR5 plays a considerable role in regulation postural stability, muscle force, balance, and motor coordination during active movements, likely via modulation of monoaminergic systems at different levels of sensorimotor control involving critical brain areas such as the brainstem, cerebellum, and forebrain.

Divergent Dimethylarginine Dimethylaminohydrolase Isoenzyme Expression in the Central Nervous System.
The endogenous methylated derivative of L-arginine, N,N-dimethyl-L-arginine (asymmetric dimethylarginine, ADMA), an independent risk factor in many diseases, inhibits the activity of nitric oxide synthases and, consequently, modulates the availability of nitric oxide. While most studies on the biological role of ADMA have focused on endothelial and inducible nitric oxide synthases modulation and its contribution to cardiovascular, metabolic, and renal diseases, a role in regulating neuronal nitric oxide synthases and pathologies of the central nervous system is less understood. The two isoforms of

dimethylarginine dimethylaminohydrolase (DDAH), DDAH1 and DDAH2, are thought to be the main enzymes responsible for ADMA catabolism. A current impediment is limited knowledge on specific tissue and cellular distribution of DDAH enzymes within the brain. In this study, we provide a detailed characterization of the regional and cellular distribution of DDAH1 and DDAH2 proteins in the adult murine and human brain. Immunohistochemical analysis showed a wide distribution of DDAH1, mapping to multiple cell types, while DDAH2 was detected in a limited number of brain regions and exclusively in neurons. Our results provide key information for the investigation of the pathophysiological roles of the ADMA/DDAH system in neuropsychiatric diseases and pave the way for the development of novel selective therapeutic approaches.

Increased dopamine transmission and adult neurogenesis in trace amine-associated receptor 5 (TAAR5) knockout mice.
Trace amine-associated receptors (TAARs) are a class of sensory G protein-coupled receptors that detect biogenic amines, products of decarboxylation of amino acids. The majority of TAARs (TAAR2-TAAR9) have been described mainly in the olfactory epithelium and considered to be olfactory receptors sensing innate odors. However, there is recent evidence that one of the members of this family, TAAR5, is expressed also in the limbic brain areas receiving projection from the olfactory system and involved in the regulation of emotions. In this study, we further characterized a mouse line lacking TAAR5 (TAAR5 knockout, TAAR5-KO mice) that express beta-galactosidase mapping TAAR5 expression. We found that in TAAR5-KO mice the number of dopamine neurons, the striatal levels of dopamine and its metabolites, as well as striatal levels of GDNF mRNA, are elevated indicating a potential increase in dopamine neuron proliferation. Furthermore, an analysis of TAAR5 beta-galactosidase expression revealed that TAAR5 is present in the major neurogenic areas of the brain such as the subventricular zone (SVZ), the subgranular zone (SGZ) and the less characterized potentially neurogenic zone surrounding the 3rd ventricle. Direct analysis of neurogenesis by using specific markers doublecortin (DCX) and proliferating cell nuclear antigen (PCNA) revealed at least 2-fold increase in the number of proliferating neurons in the SVZ and SGZ of TAAR5-KO mice, but no such markers were detected in mutant or control mice in the areas surrounding the 3rd ventricle. These observations indicate that TAAR5 involved not only in regulation of emotional status but also adult neurogenesis and dopamine transmission. Thus, future TAAR5 antagonists may exert not only antidepressant and/or anxiolytic action but may also provide new treatment opportunity for neurodegenerative disorders such as Parkinson's disease.

Minimal Age-Related Alterations in Behavioral and Hematological Parameters in Trace Amine-Associated Receptor 1 (TAAR1) Knockout Mice.
Since the discovery in 2001, the G protein-coupled trace amine-associated receptor 1 (TAAR1) has become an important focus of research targeted on evaluation of its role in the central nervous system (CNS). Meanwhile, impact of TAAR1 in the peripheral organs is less investigated. Expression of TAAR1 was demonstrated in different peripheral tissues: pancreatic β-cells, stomach, intestines, white blood cells (WBC), and thyroid. However, the role of TAAR1 in regulation of hematological parameters has not been investigated yet. In this study, we performed analysis of anxiety-related behaviors, a complete blood count (CBC), erythrocyte fragility, as well as FT3/FT4 thyroid hormones levels in adult and middle-aged TAAR1 knockout mice. Complete blood count analysis was performed on a Siemens Advia 2120i hematology analyzer and included more than 35 measured and calculated parameters. Erythrocyte fragility test evaluated spherocytosis pathologies of red blood cells (RBC). No significant alterations in essentially all these parameters were found in mice without TAAR1. However, comparative aging analysis has revealed a decreased neutrophils level in the middle-aged TAAR1 knockout mouse group. Minimal alterations in these parameters observed in TAAR1 knockout mice suggest that future TAAR1-based therapies should exert little hematological effect and thus will likely have a good safety profile.

32194374: Espinoza S, Sukhanov I, Efimova EV, Kozlova A, Antonova KA, Illiano P, Leo D, Merkulyeva N, Kalinina D, Musienko P, Rocchi A, Mus L, Sotnikova TD, Gainetdinov RR
Trace Amine-Associated Receptor 5 Provides Olfactory Input Into Limbic Brain Areas and Modulates Emotional Behaviors and Serotonin Transmission.
Trace amine-associated receptors (TAARs) are a class of G-protein-coupled receptors found in mammals. While TAAR1 is expressed in several brain regions, all the other TAARs have been described mainly in the olfactory epithelium and the glomerular layer of the olfactory bulb and are believed to serve as a new class of olfactory receptors sensing innate odors. However, there is evidence that TAAR5 could play a role also in the central nervous system. In this study, we characterized a mouse line lacking TAAR5 (TAAR5 knockout, TAAR5-KO) expressing beta-galactosidase mapping TAAR5 expression. We found that TAAR5 is expressed not only in the glomerular layer in the olfactory bulb but also in deeper layers projecting to the

limbic brain olfactory circuitry with prominent expression in numerous limbic brain regions, such as the anterior olfactory nucleus, the olfactory tubercle, the orbitofrontal cortex (OFC), the amygdala, the hippocampus, the piriform cortex, the entorhinal cortex, the nucleus accumbens, and the thalamic and hypothalamic nuclei. TAAR5-KO mice did not show gross developmental abnormalities but demonstrated less anxiety- and depressive-like behavior in several behavioral tests. TAAR5-KO mice also showed significant decreases in the tissue levels of serotonin and its metabolite in several brain areas and were more sensitive to the hypothermic action of serotonin 5-HT1A receptor agonist 8-hydroxy-2-(di--propilamino)tetralin (8-OH-DPAT). These observations indicate that TAAR5 is not just innate odor-sensing olfactory receptor but also serves to provide olfactory input into limbic brain areas to regulate emotional behaviors likely modulation of the serotonin system. Thus, anxiolytic and/or antidepressant action of future TAAR5 antagonists could be predicted. In general, "olfactory" TAAR-mediated brain circuitry may represent a previously unappreciated neurotransmitter system involved in the transmission of innate odors into emotional behavioral responses.

Haploinsufficiency of the intellectual disability gene SETD5 disturbs developmental gene expression and cognition.
SETD5 gene mutations have been identified as a frequent cause of idiopathic intellectual disability. Here we show that Setd5-haploinsufficient mice present developmental defects such as abnormal brain-to-body weight ratios and neural crest defect-associated phenotypes. Furthermore, Setd5-mutant mice show impairments in cognitive tasks, enhanced long-term potentiation, delayed ontogenetic profile of ultrasonic vocalization, and behavioral inflexibility. Behavioral issues are accompanied by abnormal expression of postsynaptic density proteins previously associated with cognition. Our data additionally indicate that Setd5 regulates RNA polymerase II dynamics and gene transcription via its interaction with the Hdac3 and Paf1 complexes, findings potentially explaining the gene expression defects observed in Setd5-haploinsufficient mice. Our results emphasize the decisive role of Setd5 in a biological pathway found to be disrupted in humans with intellectual disability and autism spectrum disorder.

OLFACTORY BULBECTOMY INDUCES TIME-DEPENDENT HYPERLOCOMOTION AND GLIOSIS IN THE MALE RAT

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Julio Cesar Morales Medina, Mario Alberto Bautista-Carro, Zaida Citlali García-Crispín
CINVESTAV, Centro De Investigacion En Reproduccion Animal, San Felipe Ixtacuixtla, Mexico

Background. Major depression disorder (MDD) induces a constellation of behavioral deficits including difficulties to adapt to novelty. A working hypothesis of MDD include astrocytic and microglia activation in the central nervous system. The prefrontal cortex (PFC) and hippocampus are two brain regions affected in MDD. Olfactory bulbectomy (OBX) is a well-known preclinical model of depression-related behavior in rodents. **Aims.** In the present study, we tested the hypothesis that OBX induce alterations to adapt to a novel environment as a result of gliosis in the PFC and hippocampus in a time-dependent manner in the rat. **Methods.** To test a possible lack of adaptation to novel places, we measured horizontal and vertical behaviors in the open field test (OFT). To determine whether OBX modulated astrocytic and/or microglial expression, we measured the number and morphology of glial fibrillary acidic protein and Iba1 in the PFC and hippocampus. All these measurements were done in three independent cohorts at three critical times after surgery: one, four and fifteen weeks. **Results.** OBX rats presented hyperlocomotion in the OFT at one and four weeks after surgery, interpreted as a failure of adaptation to novel environment. At four weeks after surgery, OBX rats displayed increased rearing and grooming, suggesting alterations in stress-coping behaviors. The number of astrocytes was increased in the PFC in OBX rats. **Conclusions.** The data from this preclinical animal model supports the immunological theory of MDD. These results add further support to the validity and usefulness of the OBX rat as a model of depression.

ASSESSING POSITIVE AND NEGATIVE VALENCE SYSTEMS TO REFINE ANIMAL MODELS OF BIPOLAR DISORDERS: THE EXAMPLE OF GBR 12909-INDUCED MANIC PHENOTYPE

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Mathilde Bigot[1,2], Éléonore Vicq[1], Pierre-Marie Lledo[1], Mariana Alonso[1], Chantal Henry[1,3]
[1]Institut Pasteur, Perception And Memory Unit, Paris, France, [2]Sorbonne Université, Collège Doctoral, Paris, France, [3]GHU Paris Psychiatrie & Neurosciences, Department Of Psychiatry, Paris, France

Bipolar disorders are defined by recurrences of depressive and manic episodes. The pathophysiology is still unknown, and translating clinical symptoms into behaviors explorable in animal models is challenging. Animal models of bipolar disorder do not exist because cyclicity of the disease is impossible to mimic, and it is therefore necessary to study mania and depression models separately. Beyond mood, emotional biases differentiate bipolar states in humans. Mania is associated with positive biases, *e.g.* emotional stimuli become more rewarding and less aversive, and the opposite for depression. We propose to assess behavioral hedonic responses to innately appetitive and aversive olfactory and gustatory cues in mice as proxies for the assigned emotional valence. A mania model is therefore supposed to exhibit positive hedonic bias. Using the GBR 12909 mania model, we observed the classical hyperactivity phenotype, along with low depressive-like but high anxiety-like behaviors. Unexpectedly, GBR 12909-treated mice exhibited strong negative hedonic biases. Consequently, the GBR 12909 model of mania might not be appropriate for studying emotional disturbances associated with mania states. We propose olfactory and gustatory preference tests as crucial assessment for positive and negative valence biases, necessary for precisely characterizing animal models of bipolar disorders.

THE HYPERACTIVE NATURE OF THE RODENT OLFACTORY BULBECTOMY MODEL: A SYSTEMATIC REVIEW AND META-ANALYSIS

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Alana Panzenhagen[1], Augusto Maffini[2], Roberto Almeida[3], Flávio Shansis[2], José Moreira[1]
[1]Universidade Federal do Rio Grande do Sul, Programa De Pós-graduação Em Ciências Biológicas: Bioquímica, Porto Alegre, Brazil, [2]Universidade do Vale do Taquari, Ciencias Medicas, Lajeado, Brazil, [3]Universidade Federal de Ouro Preto, Departamento De Ciencias Biologicas, Ouro Preto, Brazil

Major Depressive Disorder (MDD) is a highly impairing and prevalent psychiatric condition. The nature of the disorder makes it difficult to study it in vivo, which supports the use of animal models. One of the most widely used models in MDD research is the rodent model of olfactory bulbectomy (OBX), which should present core depressive-like behaviors like anhedonia or hopelessness. However, many studies also investigate its locomotor activity, which seems to be sometimes exacerbated due to olfactory bulb removal. Regardless of the reason, hyperactivity is seldom a symptom of patients with MDD, which could jeopardize OBX's translatability. To investigate the consistency of these findings, we conducted a systematic review and meta-analysis of the studies that evaluated the locomotor activity of OBX rats or mice in the open field apparat. The protocol for this study was registered on Prospero (CRD42020205536). Duplicates were removed, and records were independently screened by at least two reviewers. A third reviewer resolved the discrepancies. Inclusion criteria were: studies that included OBX rats or mice, a comparator control, and performed the open field test. A total of 305 articles were recruited from PubMed, 569 from Web of Science, and 239 from Scopus. After the duplicates were removed, 630 remained to be selected, and of these, 123 studies were included. After conducting a random-effects meta-analysis, we found an overall positive effect (z = 5,00, p-value < 0.01), indicating that the OBX indeed presents hyperactivity. This raises the question of whether OBX could be regarded as a satisfactory model for MDD.

Neurological impairment caused by Schistosoma mansoni systemic infection exhibits early features of idiopathic neurodegenerative disease.
Schistosomiasis, a neglected tropical disease caused by trematodes of the Schistosoma genus, affects over 250 million people around the world. This disease has been associated with learning and memory deficits in children, whereas reduced attention levels, impaired work capacity, and cognitive deficits have been observed in adults. Strongly correlated with poverty and lack of basic sanitary conditions, this chronic endemic infection is common in Africa, South America, and parts of Asia and contributes to inhibition of social development and low quality of life in affected areas. Nonetheless, studies on the mechanisms involved in the neurological impairment caused by schistosomiasis are scarce. Here, we used a murine model of infection with Schistosoma mansoni in which parasites do not invade the central nervous system to evaluate the consequences of systemic infection on neurologic function. We observed that systemic infection with S. mansoni led to astrocyte and microglia activation, expression of oxidative stress-induced transcription factor Nrf2, oxidative damage, Tau phosphorylation, and amyloid-β peptide accumulation in the prefrontal cortex of infected animals. We also found impairment in spatial learning and memory as evaluated by the Morris water maze task. Administration of anthelmintic (praziquantel) and antioxidant (N-acetylcysteine plus deferoxamine) treatments was effective in inhibiting most of these phenotypes, and the combination of both treatments had a synergistic effect to prevent such changes. These data demonstrate new perspectives toward the understanding of the pathology and possible therapeutic approaches to counteract long-term effects of systemic schistosomiasis on brain function.

Attention-deficit/hyperactivity disorder and brain metabolites from proton magnetic resonance spectroscopy: a systematic review and meta-analysis protocol.
Despite major advances in the study of the brain, investigations on neurochemistry in vivo still lack the solid ground of more established methods, such as structural and functional magnetic resonance imaging. Proton magnetic resonance spectroscopy (MRS) is a technique that might potentially fill in this gap. Nevertheless, studies using this approach feature great methodological heterogeneity, such as varying voxel of choice, differences on emphasized metabolites, and absence of a standardized unit. In this study, we present a methodology for creating a systematic review and meta-analysis for this kind of scientific evidence using the prototypical case of attention-deficit/hyperactivity disorder. Systematic review registration: International Prospective Register of Systematic Reviews (PROSPERO), CRD42018112418.

Effects of foetal and breastfeeding exposure to methylmercury (MeHg) and retinol palmitate (Vitamin A) in rats: Redox parameters and susceptibility to DNA damage in liver.
Methylmercury (MeHg) is known to be a chemical that poses a risk to public health. Exposure to MeHg and vitamin A (VitA) occurs through the ingestion of fish, present in the diet of most pregnant women. The absorption of these elements generates oxidative stress and can generate adaptations for future stressful events. Here, we assessed how exposure to VitA and/or MeHg during the fetal and breastfeeding period modulates the toxicity of MeHg reexposure in adulthood. We focus on redox systems and repairing DNA damage. Male rats (n = 50), were divided into 5 groups. Control received mineral oil; The VitA group received VitA during pregnancy, during breastfeeding and was exposed to MeHg in adulthood; VitA + MeHg received VitA and MeHg during pregnancy and breastfeeding and was exposed to MeHg in adulthood. The single exposure group (SE) was exposed to MeHg only in adulthood; and the MeHg group was pre-exposed to MeHg during pregnancy and breastfeeding and re-exposed to MeHg in adulthood. After treating the animals, we evaluated the redox status and the level of DNA damage in all rats. The results revealed that MeHg significantly decreased the activity of glutathione peroxidase (GPx) and sulfhydryl levels and increased the activity of superoxide dismutase (SOD), glutathione transferase, glutathione and carbonyl in all exposed groups. These results suggest that the second exposure to MeHg directly altered the effects of oxidation and that there were no specific effects associated with exposure during the fetal and breastfeeding periods. In addition, our findings indicate that MDA levels increased in MeHg and SE levels and no differences in MDA levels were observed between the VitA and MeHg + VitA groups. We also observed that animals pretreated exclusively with VitA showed residual damage similar to the control's DNA, while the other groups showed statistically higher levels of damage. In conclusion, low doses of MeHg and VitA during fetal and breastfeeding periods were unable to condition an adaptive response to subsequent exposure to MeHg in adulthood in relation to the observed levels of oxidative damage assessed after exposure.

Hepatic and neurobiological effects of foetal and breastfeeding and adulthood exposure to methylmercury in Wistar rats.
Methylmercury (MeHg) is an organic bioaccumulated mercury derivative that strongly affects the environment and represents a public health problem primarily to riparian communities in South America. Our objective was to investigate the hepatic and neurological effects of MeHg exposure during the phases foetal and breast-feeding and adult in Wistar rats. Wistar rats (n = 10) were divided into 3 groups. Control group received mineral oil; The simple exposure (SE) group was exposed only in adulthood (0.5 mg/kg/day); and double exposure (DE) was pre-exposed to MeHg 0.5 mg/kg/day during pregnancy and breastfeeding (±40 days) and re-exposed to MeHg for 45 days from day 100. After, we evaluated possible abnormalities. Behavioral and biochemical parameters in liver and occipital cortex (CO), markers of liver injury, redox and AKT/GSK3β/mTOR signaling pathway. Our results showed that both groups treated with MeHg presented significant alterations, such as decreased locomotion and exploration and impaired visuospatial perception. The rats exposed to MeHg showed severe liver damage and increased hepatic glycogen concentration. The MeHg groups showed significant impairment in redox balance and oxidative damage to liver macromolecules and CO. MeHg upregulated the AKT/GSK3β/mTOR pathway and the phosphorylated form of the Tau protein. In addition, we found a reduction in NeuN and GFAP immunocontent. These results represent the first approach to the hepatotoxic and neural effects of foetal and adult MeHg exposure.

Systematic review and meta-analysis of the behavioral effects of methylphenidate in the spontaneously hypertensive rat model of attention-deficit/hyperactivity disorder.
The spontaneously hypertensive rats (SHR) are the most widely used model for ADHD. While face and construct validity are consolidated, questions remain about the predictive validity of the SHR model. We aim at summarizing the evidence for the predictive validity of SHR by evaluating its ability to respond to methylphenidate (MPH), the most well documented treatment for ADHD. A systematic review was carried out to identify studies evaluating MPH effects on SHR behavior. Studies (n=36) were grouped into locomotion, attention, impulsivity or memory, and a meta-analysis was performed. Meta-regression, sensitivity, heterogeneity, and publication bias analyses were also conducted. MPH increased attentional and mnemonic performances in the SHR model and decreased impulsivity in a dose-dependent manner. However, MPH did not reduce hyperactivity in low and medium doses, while increased locomotor activity in high doses. Thus, since the paradoxical effect of stimulant in reducing hyperactivity was not observed in the SHR model, our study does not fully support the predictive validity of SHR, questioning their validity as an animal model for ADHD.

Evidence of sexual dimorphism of HTR1B gene on major adult ADHD comorbidities.
Attention-deficit/hyperactivity disorder (ADHD) is a very common psychiatric disorder across the life cycle and frequently presents comorbidities. Since ADHD is highly heritable, several studies have focused in the underlying genetic factors involved in its etiology. One of the major challenges in this search is the phenotypic heterogeneity, which could be partly attributable to the sexual dimorphism frequently seen in psychiatric disorders. Taking into account the well-known sexual dimorphic effect observed in serotonergic system characteristics, we differentially tested the influence of HTR1B SNPs (rs11568817, rs130058, rs6296 and rs13212041) on ADHD susceptibility and on its major comorbidities according to sex. The sample comprised 564 adults with ADHD diagnosed according to DSM-IV criteria and 635 controls. There was no association of any HTR1B SNPs tested in relation to ADHD susceptibility. As for the comorbidities evaluated, after correction for multiple tests, significant associations were observed for both rs11568817 and rs130058 with substance use disorders (P = 0.009 and P = 0.018, respectively) and for rs11568817 with nicotine dependence (P = 0.025) in men with ADHD. In women with ADHD, the same rs11568817 was associated with generalized anxiety disorder (P = 0.031). The observed effects of rs11568817 G allele presence conferring risk to either substance use disorders or generalized anxiety disorder according to sex, suggest an overall scenario where a higher transcriptional activity of HTR1B, resulting from the presence of this allele, is related to externalizing behaviors in men and internalizing behaviors in women. These results are consistent with and expand previous evidence of sexual dimorphism of the serotoninergic system.

TRANSCRIPTOME SEQUENCING REVEALS KEY GENES AND PATHWAYS IN THE DORSOMEDIAL PREFRONTAL CORTEX OF SUICIDE VICTIMS

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Fanni Dóra[1,2], Rashmi Kumari[2,3], Éva Renner[1,4], Miklós Palkovits[1,4], Árpád Dobolyi[2,3]
[1]Semmelweis University, Human Brain Tissue Bank, Budapest, Hungary, [2]Semmelweis University, Laboratory Of Neurobiology, Department Of Anatomy, Histology And Embryology, Budapest, Hungary, [3]Eötvös Loránd Research Network and Eötvös Loránd University, Department Of Physiology And Neurobiology, Budapest, Hungary, [4]Semmelweis University, Human Brain Tissue Bank And Microdissection Laboratory, Budapest, Hungary

Recent studies revealed that the default mode network (DMN) has an outstanding role in psychiatric disorders. However, expressional alterations related to depression and suicidal behavior have not been reported in the dorsomedial prefrontal cortex (DMPFC), a major component of the dorsal DMN. We used RNA sequencing in DMPFC samples to investigate the molecular changes in suicide victims without any medication for chronic depression as compared to controls. More than 1000 genes differed between the groups using log2FC >±1 and adjusted p-value <0.05 criteria. Particularly the important or intriguing 15 related genes were validated with RT-PCR. Gene set enrichment and protein-protein interaction (PPI) network analysis revealed that the cell surface receptor signaling pathway and synaptic signaling were over-represented in suicide victims suggesting that these processes are involved in suicidal behavior. One of the validated differentially expressed genes was the neuronal Ca(2+) -binding protein 2 (NECAB2). Since NECAB2 may have great importance in modulating glutamatergic functions, and previously had not been fully characterized for its role in mood disorders, we aimed to further characterize its distribution in different layers of the DMPFC by performing in situ hybridization and immunohistochemistry. The distributional data were compared with cell type-specific gene expressional data of the Allen Brain Atlas, based on which we suggest that NECAB2 is located mainly in layer II-IV and VI inhibitory neurons. Our results imply extensive gene expressional alterations in the DMPFC indicating that some of these genes may contribute to the altered mental state and behavior of suicide victims.

Trigeminal Aδ- and C-afferent supply of lamina I neurons in the trigeminocervical complex.
Nociceptive trigeminal afferents innervating craniofacial area, eg, facial skin and cranial meninges, project to a broad region in the medullary and upper cervical dorsal horn designated as the trigeminocervical complex. Lamina I neurons in the trigeminocervical complex integrate and relay peripheral inputs, thus playing a key role in both cranial nociception and primary headache syndromes. Because of the technically challenging nature of recording, the long-range trigeminal afferent inputs to the medullary and cervical lamina I neurons were not intensively studied so far. Therefore, we have developed an ex vivo brainstem-cervical cord preparation with attached trigeminal nerve for the visually guided whole-cell recordings from the medullary and cervical lamina I neurons. Two-thirds of recorded neurons generated intrinsic rhythmic discharges. The stimulation of the trigeminal nerve produced a complex effect; it interrupted the rhythmic discharge for hundreds of milliseconds but, if the neuron was silenced by a hyperpolarizing current injection, could elicit a discharge. The monosynaptic inputs from the trigeminal Aδ, high-threshold Aδ, low-threshold C, and C afferents were recorded in the medullary neurons, as well as in the cervical neurons located in the segments C1 to C2 and, to a lesser degree, in C3 to C4. This pattern of supply was consistent with our labelling experiments showing extensive cervical projections of trigeminal afferents. Excitatory inputs were mediated, although not exclusively, through AMPA/kainate and NMDA receptors, whereas inhibitory inputs through both GABA and glycine receptors. In conclusion, the trigeminocervical lamina I neurons receive a complex pattern of long-range monosynaptic and polysynaptic inputs from a variety of the trigeminal nociceptive afferents.

Neuronal activation in zebra finch parents associated with reintroduction of nestlings.
Recent studies of the brain mechanisms of parental behaviors have mainly focused on rodents. Using other vertebrate taxa, such as birds, can contribute to a more comprehensive, evolutionary view. In the present study, we investigated a passerine

songbird, the zebra finch (Taeniopygia guttata), with a biparental caring system. Parenting-related neuronal activation was induced by first temporarily removing the nestlings, and then, either reuniting the focal male or female parent with the nestlings (parental group) or not (control group). To identify activated neurons, the immediate early gene product, Fos protein, was labeled. Both parents showed an increased level of parental behavior following reunion with the nestlings, and no sexual dimorphism occurred in the neuronal activation pattern. Offspring-induced parental behavior-related neuronal activation was found in the preoptic, ventromedial (VMH), paraventricular hypothalamic nuclei, and in the bed nucleus of the stria terminalis. In addition, the number of Fos-immunoreactive (Fos-ir) neurons in the nucleus accumbens predicted the frequency of the feeding of the nestlings. No difference was found in Fos expression when the effect of isolation or the presence of the mate was examined. Thus, our study identified a number of nuclei involved in parental care in birds and suggests similar regulatory mechanisms in caring females and males. The activated brain regions show similarities to rodents, while a generally lower number of brain regions were activated in the zebra finch. Furthermore, future studies are necessary to establish the role of the apparently avian-specific neuronal activation in the VMH of zebra finch parents.

Brain Distribution and Sexually Dimorphic Expression of Amylin in Different Reproductive Stages of the Zebra Finch () Suggest Roles of the Neuropeptide in Song Learning and Social Behaviour.
The expression of the recently identified neuropeptide, amylin, is restricted in rodents to the postpartum preoptic area and may play a role in the control of parental behaviours and food intake. These processes are substantially different between bird and rodent parents as birds do not lactate but often show biparental care of the offspring. To establish the presence and role of amylin in the bird brain, in the present study, we investigated the distribution of amylin in brains of adult male and female zebra finches in three different reproductive stages (i.e. paired without young, incubating eggs or provisioning nestlings) and in unpaired control birds living in same sex flocks. Amylin mRNA was identified in the hypothalamus of zebra finch by RT-PCR, which was also used to produce probes for hybridisation. Subsequently, hybridisation histochemistry was performed in brain sections, and the labelling signal was quantified and compared between the groups. Amylin showed a much wider brain distribution than that of rodents. A strong and, in some regions, sexually dimorphic label was found in the striatum and several brain regions of the social behavioural network in both males and females. Many regions responsible for the learning of birdsong also contained amylin-positive neurons, and some regions showed sex differences reflecting the fact that vocalisation is sexually dimorphic in the zebra finch: only males sing. Area X (Ar.X), a striatal song centre present only in males, was labelled in paired but not unpaired male. Ar.X, another song centre, the lateral part of the magnocellular nucleus of the anterior nidopallium (lMAN) also contained amylin and had higher amylin label in paired, as opposed to unpaired birds. The wider distribution of amylin in birds as compared to rodents suggests a more general role of amylin in social or other behaviours in avian species than in mammals. Alternatively, parental care in birds may be a more complex behavioural trait involving a wider set of brain regions. The sex differences in song centres, and the changes with reproductive status suggest a participation of amylin in social behaviours and related changes in the singing of males.

Transcriptome Sequencing in the Preoptic Region of Rat Dams Reveals a Role of Androgen Receptor in the Control of Maternal Behavior.
(1) Background: Preoptic region of hypothalamus is responsible to control maternal behavior, which was hypothesized to be associated with gene expressional changes. (2) Methods: Transcriptome sequencing was first applied in the preoptic region of rat dams in comparison to a control group of mothers whose pups were taken away immediately after parturition and did not exhibit caring behavior 10 days later. (3) Results: Differentially expressed genes were found and validated by quantitative RT-PCR, among them NACHT and WD repeat domain containing 1 (Nwd1) is known to control androgen receptor (AR) protein levels. The distribution of Nwd1 mRNA and AR was similar in the preoptic area. Therefore, we focused on this steroid hormone receptor and found its reduced protein level in rat dams. To establish the function of AR in maternal behavior, its antagonist was administered intracerebroventricularly into mother rats and increased pup-directed behavior of the animals. (4) Conclusions: AR levels are suppressed in the preoptic area of mothers possibly mediated by altered Nwd1 expression in order to allow sustained high-level care for the pups. Thus, our study first implicated the AR in the control of maternal behaviors.

ALTERED CIRCADIAN CLOCK GENE EXPRESSION IN THE MPFC OF MOUSE MODEL OF DEPRESSION AND ITS MODULATION BY RAPID ANTIDEPRESSANT TREATMENTS

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Carole Marchese[1], Tsvetan Serchov[1], Chockalingam Ramanathan[2]
[1]INCI: Institut des Neurosciences Cellulaires et Intégratives, Cnrs, Strasbourg, France, [2]Institute of Physiology University of Freiburg, University Of Freiburg, Freiburg, Germany

Accumulating evidence correlates circadian dysregulation with major depressive disorder (MDD). Circadian clock oscilation in multiple brain regions are implicated in depression, and their manipulation can affect mood, suggesting potential role in MDD pathophysiology and treatment. To investigate this relationship, we have utilized the chronic despair mouse (CDM) model of depression, induced by 5 days of repeated swim stress, in combination with rapid antidepressant treatments (AD) (6h of sleep deprivation and low-dose ketamine) and circadian clock modulation by RORα/ɣ agonist (SR1078). Tissues from the medial prefrontal cortex (mPFC) and suprachiasmatic nucleus (SCN) of CDM, CDM-treated and naïve (control) mice, prepared at 6 different zeitgeber time points, were analysed via qRT-PCR for the oscillating mRNA expression of the canonical clock genes (CCGs) Bmal1, Per1/2, Cry1/2, Rev-ERBα and RORα. Compared to controls, CDM mice exhibited significant dysregulation of CCGs in the mPFC, including upregulation of positive regulatory loop, downregulation of negative circadian loop and altered acrophase. In contrast, the CCGs expression in the SCN was not significantly altered in CDM mice. AD and SR1078 treatments normalized abnormalities in CCG expression in the mPFC and differentially affected CCGs in the SCN. However, the SCN effects were not correlated with changes in the mPFC. Our results illustrate dysregulation of circadian clockwork in the mPFC, independent of the SCN, in a stress-induced model for depression. Changes of mPFC CCGs expression after treatment suggests for potential role of circadian clock in antidepressant mechanism, providing novel targets to develop circadian-based treatments.

PROGRESSIVE CHANGES IN NEURAL CIRCUITS ACTIVATION, BEHAVIOURAL PHENOTYPES AND MOLECULAR AND MICROBIAL PROFILES DURING DIFFERENT STAGES OF STRESS

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Anna Sancho Balsells[1,2,3,4], Xavier Xifró Collsamata[5], Jordi Alberch[1,2,3,4], Albert Giralt Torroella[1,2,3,4]

Major depression (MD) is a common, relapsing mental illness that affects millions of people worldwide. One of the most studied risk factors associated with MD is stress. Stress can provoke severe psychiatric disorders such as Major Depression (MD) when becomes insidiously chronic. Here, we want to assess which are the most key changes that transforms a stressful situation from adaptative to pathologic. To do so we performed in mice a multidimensional assessment including a comprehensive behavioral characterization, proteomics, metagenomics and an in-depth assessment of neural circuitry reorganization. We divided our mice into control non-stressed (NS), short-term stress (STS) and long-term stress mice (LTS). STS mice received only two days of stress whereas LTS mice underwent the chronic unpredictable mild stress protocol (CUMS) for 28 days. Results indicate that LTS induces much more severe depressive-like symptoms than STS as demonstrated in different behavioural tasks. Moreover, Mass Spectrometry studies reveal huge differences depending on the duration of the stress. The study of the microbiome in faeces also shows that the changes in the microbiota are mostly observed in LTS mice. Lastly, we identified the activation of different neural ensembles mostly in hippocampal subregions depending on the stress duration. In summary, our work suggests that there is a progression in the molecular, behavioural microbial and functional changes induced by stress. Furthermore, we identified key changes that could explain the transition from an adaptative stressful response to a pathological one. In summary, this work sheds light on the underlying mechanisms of stress-induced major depression.

Conditional BDNF Delivery from Astrocytes Rescues Memory Deficits, Spine Density, and Synaptic Properties in the 5xFAD Mouse Model of Alzheimer Disease.
It has been well documented that neurotrophins, including brain-derived neurotrophic factor (BDNF), are severely affected in Alzheimer's disease (AD), but their administration faces a myriad of technical challenges. Here we took advantage of the early astrogliosis observed in an amyloid mouse model of AD (5xFAD) and used it as an internal sensor to administer BDNF conditionally and locally. We first demonstrate the relevance of BDNF release from astrocytes by evaluating the effects of coculturing WT neurons and BDNF-deficient astrocytes. Next, we crossed 5xFAD mice with pGFAP:BDNF mice (only males were used) to create 5xFAD mice that overexpress BDNF when and where astrogliosis is initiated (5xF:pGB mice). We evaluated the behavioral phenotype of these mice. We first found that BDNF from astrocytes is crucial for dendrite outgrowth and spine number in cultured WT neurons. Double-mutant 5xF:pGB mice displayed improvements in cognitive tasks compared with 5xFAD littermates. In these mice, there was a rescue of BDNF/TrkB downstream signaling activity associated with an improvement of dendritic spine density and morphology. Clusters of synaptic markers, PSD-95 and synaptophysin, were also recovered in 5xF:pGB compared with 5xFAD mice as well as the number of presynaptic vesicles at excitatory synapses. Additionally, experimentally evoked LTP was increased in 5xF:pGB mice. The beneficial effects of conditional BDNF production and local delivery at the location of active neuropathology highlight the potential to use endogenous biomarkers with early onset, such as astrogliosis, as regulators of neurotrophic therapy in AD. Recent evidence places astrocytes as pivotal players during synaptic plasticity and memory processes. In the present work, we first provide evidence that astrocytes are essential for neuronal morphology via BDNF release. We then crossed transgenic mice (5xFAD mice) with the transgenic pGFAP-BDNF mice, which express BDNF under the GFAP promoter. The resultant double-mutant mice 5xF:pGB mice displayed a full rescue of hippocampal BDNF loss and related signaling compared with 5xFAD mice and a

significant and specific improvement in all the evaluated cognitive tasks. These improvements did not correlate with amelioration of β amyloid load or hippocampal adult neurogenesis rate but were accompanied by a dramatic recovery of structural and functional synaptic plasticity.

RTP801/REDD1 Is Involved in Neuroinflammation and Modulates Cognitive Dysfunction in Huntington's Disease.
RTP801/REDD1 is a stress-regulated protein whose levels are increased in several neurodegenerative diseases such as Parkinson's, Alzheimer's, and Huntington's diseases (HD). RTP801 downregulation ameliorates behavioral abnormalities in several mouse models of these disorders. In HD, RTP801 mediates mutant huntingtin (mhtt) toxicity in in vitro models and its levels are increased in human iPSCs, human postmortem putamen samples, and in striatal synaptosomes from mouse models of the disease. Here, we investigated the role of RTP801 in the hippocampal pathophysiology of HD. We found that RTP801 levels are increased in the hippocampus of HD patients in correlation with gliosis markers. Although RTP801 expression is not altered in the hippocampus of the R6/1 mouse model of HD, neuronal RTP801 silencing in the dorsal hippocampus with shRNA containing AAV particles ameliorates cognitive alterations. This recovery is associated with a partial rescue of synaptic markers and with a reduction in inflammatory events, especially microgliosis. Altogether, our results indicate that RTP801 could be a marker of hippocampal neuroinflammation in HD patients and a promising therapeutic target of the disease.

RTP801/REDD1 contributes to neuroinflammation severity and memory impairments in Alzheimer's disease.
RTP801/REDD1 is a stress-regulated protein whose upregulation is necessary and sufficient to trigger neuronal death. Its downregulation in Parkinson's and Huntington's disease models ameliorates the pathological phenotypes. In the context of Alzheimer's disease (AD), the coding gene for RTP801, DDIT4, is responsive to Aβ and modulates its cytotoxicity in vitro. Also, RTP801 mRNA levels are increased in AD patients' lymphocytes. However, the involvement of RTP801 in the pathophysiology of AD has not been yet tested. Here, we demonstrate that RTP801 levels are increased in postmortem hippocampal samples from AD patients. Interestingly, RTP801 protein levels correlated with both Braak and Thal stages of the disease and with GFAP expression. RTP801 levels are also upregulated in hippocampal synaptosomal fractions obtained from murine 5xFAD and rTg4510 mice models of the disease. A local RTP801 knockdown in the 5xFAD hippocampal neurons with shRNA-containing AAV particles ameliorates cognitive deficits in 7-month-old animals. Upon RTP801 silencing in the 5xFAD mice, no major changes were detected in hippocampal synaptic markers or spine density. Importantly, we found an unanticipated recovery of several gliosis hallmarks and inflammasome key proteins upon neuronal RTP801 downregulation in the 5xFAD mice. Altogether our results suggest that RTP801 could be a potential future target for theranostic studies since it could be a biomarker of neuroinflammation and neurotoxicity severity of the disease and, at the same time, a promising therapeutic target in the treatment of AD.

Pyk2 in the amygdala modulates chronic stress sequelae via PSD-95-related micro-structural changes.
Major depressive disorder (MDD) is a common disorder with a variety of symptoms including mood alterations, anhedonia, sleep and appetite disorders, and cognitive disturbances. Stressful life events are among the strongest risk factors for developing MDD. At the cellular level, chronic stress results in the modification of dendritic spine morphology and density. Here, we study the role of Pyk2 in the development of depressive-like symptoms induced by a model of chronic unpredictable mild stress (CUMS). Pyk2 is a non-receptor calcium-dependent protein-tyrosine kinase highly expressed in the forebrain principal neurons and involved in spine structure and density regulation. We show that Pyk2 knockout mice are less affected to anxiety-like and anhedonia-like phenotypes induced by the CUMS paradigm. Using region-specific knockout, we demonstrate that this phenotype is fully recapitulated by selective Pyk2 inactivation in the amygdala. We also show that in the absence of Pyk2 the spine alterations, PSD-95 clustering, and NMDA receptors changes induced by the CUMS paradigm are prevented. Our results reveal a possible role for Pyk2 in the response to stress and in synaptic markers expression and spine density regulation in the amygdala. We suggest that Pyk2 contributes to stress-induced responses through micro-structural changes and that its deficit may contribute to the resilience to chronic stress.

Astrocytic BDNF and TrkB regulate severity and neuronal activity in mouse models of temporal lobe epilepsy.
Astrocytes have emerged as crucial regulators of neuronal network activity, synapse formation, and underlying behavioral and cognitive processes. Despite some pathways have been identified, the communication between astrocytes and neurons remains to be completely elucidated. Unraveling this communication is crucial to design potential treatments for neurological disorders like temporal lobe epilepsy (TLE). The BDNF and TrkB molecules have emerged as very promising therapeutic targets. However, their modulation can be accompanied by several off-target effects such as excitotoxicity in case of uncontrolled upregulation or dementia, amnesia, and other memory disorders in case of downregulation. Here, we show that BDNF and TrkB from astrocytes modulate neuronal dysfunction in TLE models. First, conditional overexpression of BDNF from astrocytes worsened the phenotype in the lithium-pilocarpine mouse model. Our evidences pointed out to the astrocytic pro-BDNF isoform as a major player of this altered phenotype. Conversely, specific genetic deletion of BDNF in astrocytes prevented the increase in the number of firing neurons and the global firing rate in an in vitro model of TLE. Regarding to the TrkB, we generated mice with a genetic deletion of TrkB specifically in hippocampal neurons or astrocytes. Interestingly, both lines displayed neuroprotection in the lithium-pilocarpine model but only the mice with genetic deletion of TrkB in astrocytes showed significantly preserved spatial learning skills. These data identify the astrocytic BDNF and TrkB molecules as promising therapeutic targets for the treatment of TLE.

Human iPSC-Derived Hippocampal Spheroids: An Innovative Tool for Stratifying Alzheimer Disease Patient-Specific Cellular Phenotypes and Developing Therapies.
The hippocampus is important for memory formation and is severely affected in the brain with Alzheimer disease (AD). Our understanding of early pathogenic processes occurring in hippocampi in AD is limited due to tissue unavailability. Here, we report a chemical approach to rapidly generate free-floating hippocampal spheroids (HSs), from human induced pluripotent stem cells. When used to model AD, both APP and atypical PS1 variant HSs displayed increased Aβ42/Aβ40 peptide ratios and decreased synaptic protein levels, which are common features of AD. However, the two variants differed in tau hyperphosphorylation, protein aggregation, and protein network alterations. NeuroD1-mediated gene therapy in HSs-derived progenitors resulted in modulation of expression of numerous genes, including those involved in synaptic transmission. Thus, HSs can be harnessed to unravel the mechanisms underlying early pathogenic changes in the hippocampi of AD patients, and provide a robust platform for the development of therapeutic strategies targeting early stage AD.

Lack of Helios During Neural Development Induces Adult Schizophrenia-Like Behaviors Associated With Aberrant Levels of the TRIF-Recruiter Protein WDFY1.
The role of the WDFY1 protein has been studied as a TLR3/4 scaffold/recruiting protein in the immune system and in different oncogenic conditions. However, its function in brain remains poorly understood. We have found that in mice devoid of (He mice), a transcription factor specifically expressed during the development of the immune cells and the central nervous system, there is a permanent and sustained increase of gene expression in the striatum and hippocampus. Interestingly, we observed that WDFY1 protein levels were also increased in the hippocampus and dorsolateral prefrontal cortex of schizophrenic patients, but not in the hippocampus of Alzheimer's disease patients with an associated psychotic disorder. Accordingly, young He mice displayed several schizophrenic-like behaviors related to dysfunctions in the striatum and hippocampus. These changes were associated with an increase in spine density in medium spiny neurons (MSNs) and with a decrease in the number and size of PSD-95-positive clusters in the of the CA1. Moreover, these alterations in structural synaptic plasticity were associated with a strong reduction of neuronal NF-κB in the pyramidal layer of the CA1 in He mice. Altogether, our data indicate that alterations involving the molecular axis Helios-WDFY1 in neurons during the development of core brain regions could be relevant for the pathophysiology of neuropsychiatric disorders such as schizophrenia.

THE EFFECTS OF SIMVASTATIN ON EMOTIONAL PROCESSING AND INFLAMMATION IN HEALTHY VOLUNTEERS: AN EXPERIMENTAL MEDICINE STUDY

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Shona Waters, Riccardo De Giorgi, Alice Quinton, Philip Cowen, Catherine Harmer
University of Oxford, Psychiatry Department, Oxford, United Kingdom

Background: Simvastatin is commonly prescribed to lower cholesterol. Both simvastatin's anti-inflammatory effects and early clinical evidence suggest that it may be an ideal candidate for repurposing in the treatment of depression. Since emotional processing is an early marker of antidepressant response, understanding simvastatin's influence on emotional processing and inflammation could have significant translational value. *Aims*: To investigate the effects of simvastatin on emotional processing and an inflammatory marker in healthy volunteers. *Methods*: Healthy participants (N=53) were randomised to seven days of simvastatin (N=27) or placebo (N=26) in a double-blind fashion. Questionnaires measuring subjective rates of mood and anxiety, and a battery of tasks assessing emotional processing were then administered. Blood samples for the inflammatory marker C-reactive protein were collected before and after intervention. *Results*: Participants on simvastatin had more positively-valenced intrusions in the emotional recall task ($F_{1,51}$= 4.99, p= 0.03), but also an increase in anxiety scores ($F_{1,51}$= 5.37, p= 0.02) compared to controls. An exploratory analysis of female partcipants (N=27) showed the simvastatin subgroup misclassified fewer facial expressions as sad ($F_{1,25}$= 6.60, p= 0.02) compared to controls. No further statistically significant changes were observed. *Conclusions*: We found limited evidence that seven-day simvastatin use in healthy volunteers may induce a positive emotional bias whilst also being associated with an early increase in subjective anxiety. Similar dissociable effects are seen in acute antidepressant administration. This effect may be more evident in female subjects. Different sample populations and treatment lengths in further experimental medicine and clinical studies may clarify these findings.

MIR-135 AS A NEW TARGET FOR ANTIDEPRESSANT THERAPY: PRECLINICAL STUDY

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Rubén Pavia-Collado[1,2,3,4], Sharon Manashirov[3,4,5], Esther Ruiz-Bronchal[1,2], Irene Rodríguez-Navarro[1,2], Leticia Campa[1,2,3], Analia Bortolozzi[1,2,3]
[1]Institute of Biomedical Research of Barcelona, Neurosciences And Experimental Therapeutics, Barcelona, Spain, [2]August Pi i Sunyer Biomedical Research Institute (IDIBAPS), Systems Neuropharmacology, Barcelona, Spain, [3]Carlos III Health Institute, Biomedical Research Network Center In Mental Health, Madrid, Spain, [4]miCure Therapeutics, Ltd., Scientific Team, Tel-Aviv, Israel, [5]Max Planck Institute of Psychiatry, Stress Neurobiology And Neurogenetics, Munich, Germany

Aims: Major depressive disorder (MDD) is a major health problem worldwide. Most prescribed antidepressants show limited efficacy and delayed onset of action. Accumulating data support the association between MDD and changes in miRNA pathways. Indeed, low miR-135 levels were found in blood and postmortem brain tissue from depressed patients. *In vitro* and *in vivo* studies showed that miR-135 regulates both serotonin transporter (SERT) and 5-HT_{1A} receptor (5-HT_{1A}R) transcripts. The current study aimed to investigate the antidepressant-like effects of a synthetic miR-135 in a mouse model. **Methods:** We have designed a sertraline conjugated-synthetic miR-135 oligonucleotide (c-miR-135) to be accumulated in serotonin (5-HT) neurons after local infusion into dorsal raphe nucleus (DRN) or administered intranasally in mice. Histological and biochemical approaches and stress-related behavioral tests were performed to examine the potential antidepressant-like effects of c-miR-135. **Results:** Intranasal c-miR-135 administration resulted in its selective accumulation in raphe 5-HT neurons. This elicited a marked antidepressant-like effect in the tail suspension test but did not affect anxiety-like behaviors in the dark-light box. In parallel, c-miR-135 administration significantly decreased SERT and 5-HT_{1A}R protein levels in the DRN, without inducing the loss of TPH-positive neurons, astrogliosis, or microgliosis. Moreover, intranasal c-miR-135 administration modifies the extracellular 5-HT levels in the medial prefrontal cortex. Interestingly, a single dose of c-miR-135 reversed depressive-like behaviors in corticosterone-treated mice. **Conclusion:** These results suggest that miRNAs are useful as molecular targets to develop new therapeutic strategies for MDD. C-miR-135 evokes antidepressant-like responses by selectively targeting neuronal populations, opening a way for translational studies.

Up and Down γ-Synuclein Transcription in Dopamine Neurons Translates into Changes in Dopamine Neurotransmission and Behavioral Performance in Mice.
The synuclein family consists of α-, β-, and γ-Synuclein (α-Syn, β-Syn, and γ-Syn) expressed in the neurons and concentrated in synaptic terminals. While α-Syn is at the center of interest due to its implication in the pathogenesis of Parkinson's disease (PD) and other synucleinopathies, limited information exists on the other members. The current study aimed at investigating the biological role of γ-Syn controlling the midbrain dopamine (DA) function. We generated two different mouse models with: (i) γ-Syn overexpression induced by an adeno-associated viral vector and (ii) γ-Syn knockdown induced by a ligand-conjugated antisense oligonucleotide, in order to modify the endogenous γ-Syn transcription levels in midbrain DA neurons. The progressive overexpression of γ-Syn decreased DA neurotransmission in the nigrostriatal and mesocortical pathways. In parallel, mice evoked motor deficits in the rotarod and impaired cognitive performance as assessed by novel object recognition, passive avoidance, and Morris water maze tests. Conversely, acute γ-Syn knockdown selectively in DA neurons facilitated forebrain DA neurotransmission. Importantly, modifications in γ-Syn expression did not induce the loss of DA neurons or changes in α-Syn expression. Collectively, our data strongly suggest that DA release/re-uptake processes in the nigrostriatal and mesocortical pathways are partially dependent on substantia nigra pars compacta /ventral tegmental area (SNc/VTA) γ-Syn transcription levels, and are linked to modulation of DA transporter function, similar to α-Syn.

Intracerebral Administration of a Ligand-ASO Conjugate Selectively Reduces α-Synuclein Accumulation in Monoamine Neurons of Double Mutant Human A30P*A53T*α-Synuclein Transgenic Mice.
α-Synuclein (α-Syn) protein is involved in the pathogenesis of Parkinson's disease (PD). Point mutations and multiplications of the α-Syn, which encodes the gene, are correlated with early-onset PD, therefore the reduction in a-Syn synthesis could be a potential therapy for PD if delivered to the key affected neurons. Several experimental strategies for PD have been developed in recent years using oligonucleotide therapeutics. However, some of them have failed or even caused neuronal toxicity. One limiting step in the success of oligonucleotide-based therapeutics is their delivery to the brain compartment, and once there, to selected neuronal populations. Previously, we developed an indatraline-conjugated antisense oligonucleotide (IND-1233-ASO), that selectively reduces α-Syn synthesis in midbrain monoamine neurons of mice, and nonhuman primates. Here, we extended these observations using a transgenic male mouse strain carrying both A30P and A53T mutant human α-Syn (A30P*A53T*α-Syn). We found that A30P*A53T*α-Syn mice at 4-5 months of age showed 3.5-fold increases in human α-Syn expression in dopamine (DA) and norepinephrine (NE) neurons of the substantia nigra pars compacta (SNc) and locus coeruleus (LC), respectively, compared with mouse α-Syn levels. In parallel, transgenic mice exhibited altered nigrostriatal DA neurotransmission, motor alterations, and an anxiety-like phenotype. Intracerebroventricular IND-1233-ASO administration (100 µg/day, 28 days) prevented the α-Syn synthesis and accumulation in the SNc and LC, and recovered DA neurotransmission, although it did not reverse the behavioral phenotype. Therefore, the present therapeutic strategy based on a conjugated ASO could be used for the selective inhibition of α-Syn expression in PD-vulnerable monoamine neurons, showing the benefit of the optimization of ASO molecules as a disease modifying therapy for PD and related α-synucleinopathies.

Anti-α-synuclein ASO delivered to monoamine neurons prevents α-synuclein accumulation in a Parkinson's disease-like mouse model and in monkeys.
Progressive neuronal death in monoaminergic nuclei and widespread accumulation of α-synuclein are neuropathological hallmarks of Parkinson's disease (PD). Given that α-synuclein may be an early mediator of the pathological cascade that ultimately leads to neurodegeneration, decreased α-synuclein synthesis will abate neurotoxicity if delivered to the key affected neurons.
EBioMedicine, 2020; 59
29273501: Alarcón-Arís D, Recasens A, Galofré M, Carballo-Carbajal I, Zacchi N, Ruiz-Bronchal E, Pavia-Collado R, Chica R, Ferrés-Coy A, Santos M, Revilla R, Montefeltro A, Fariñas I, Artigas F, Vila M, Bortolozzi A
Selective α-Synuclein Knockdown in Monoamine Neurons by Intranasal Oligonucleotide Delivery: Potential Therapy for Parkinson's Disease.
Progressive neuronal death in brainstem nuclei and widespread accumulation of α-synuclein are neuropathological hallmarks of Parkinson's disease (PD). Reduction of α-synuclein levels is therefore a potential therapy for PD. However, because α-synuclein is essential for neuronal development and function, α-synuclein elimination would dramatically impact brain function. We previously developed conjugated small interfering RNA (siRNA) sequences that selectively target serotonin (5-HT) or norepinephrine (NE) neurons after intranasal administration. Here, we used this strategy to conjugate inhibitory oligonucleotides, siRNA and antisense oligonucleotide (ASO), with the triple monoamine reuptake inhibitor indatraline (IND), to selectively reduce α-synuclein expression in the brainstem monoamine nuclei of mice after intranasal delivery. Following internalization of the conjugated oligonucleotides in monoamine neurons, reduced levels of endogenous α-synuclein mRNA and protein were found in substantia nigra pars compacta (SNc), ventral tegmental area (VTA), dorsal raphe nucleus (DR), and locus coeruleus (LC). α-Synuclein knockdown by ~20%-40% did not cause monoaminergic neurodegeneration and enhanced forebrain dopamine (DA) and 5-HT release. Conversely, a modest human α-synuclein overexpression in DA neurons markedly reduced striatal DA release. These results indicate that α-synuclein negatively regulates monoamine neurotransmission and set the stage for the testing of non-viral inhibitory oligonucleotides as disease-modifying agents in α-synuclein models of PD.

ROLE OF ADULT HIPPOCAMPAL NEUROGENESIS IN THE ANTIDEPRESSANT EFFECTS OF LACTATE

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Anthony Carrard[1], Frédéric Cassé[1], Charline Carron[1], Sophie Burlet-Godinot[1], Nicolas Toni[1], Pierre Magistretti[2], Jean-Luc Martin[1]
[1]CHUV, Center For Psychiatric Neurosciences, Prilly, Switzerland, [2]KAUST, Biological And Environmental Sciences And Engineering, Thuwal, Saudi Arabia

Previous studies on the antidepressant effects of lactate have shown that chronic administration of lactate improved depressive-like behavior in different animal models (Carrard et al., 2018). The antidepressant effects of lactate are associated with changes in the expression of specific target genes among which Hes5 and p11 are involved in adult hippocampal neurogenesis. These findings led us to investigate the role of adult hippocampal neurogenesis in the antidepressant effects of lactate in the corticosterone model of depression. We found that chronic peripheral injection of lactate counteracted the decreased neural progenitor proliferation and survival induced by corticosterone. In contrast, chronic administration of pyruvate, the oxidized form of lactate, did not produce antidepressant effects and did not prevent the inhibition of neural progenitor proliferation and survival induced by corticosterone. Importantly, depletion of adult hippocampal neurogenesis by the antimitotic drug temozolomide suppressed the antidepressant effects of lactate on behavioral despair and anhedonia in animals chronically treated with corticosterone. *In vitro* studies on hippocampal stem cell cultures revealed that corticosterone decreased cell proliferation and increased ROS production. Consistent with our *in vivo* observations, lactate but not pyruvate suppressed the effect of corticosterone on ROS production and partially counteracted the effect of corticosterone on stem cell proliferation. Similarly to lactate, NADH prevented ROS production elicited by corticosterone and partially reversed the inhibition of stem cell proliferation induced by corticosterone. Together, these data suggest that conversion of lactate to pyruvate with the concomitant production of NADH is necessary for the neurogenic and antidepressant effects of lactate.

DIFFERENTIAL MODULATION OF ANTERIOR CINGULATE CORTEX SUBREGIONAL CONNECTIVITY BY INTRAVENOUS KETAMINE

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Laith Alexander[1], Peter Hawkins[2], Jennifer Evans[3], Carlos Zarate Jr.[3], Mitul Mehta[2]
[1]King's College London, Institute Of Psychiatry, Psychology And Neuroscience, London, United Kingdom, [2]King's College London, Centre For Neuroimaging Sciences, London, United Kingdom, [3]National Institute of Mental Health, Section On The Neurobiology And Treatment Of Mood Disorders, Bethesda, United States of America

The anterior cingulate cortex (ACC) is thought to be an important locus of ketamine's antidepressant action. Different subregions within the ACC appear to undergo differential changes in connectivity in response to ketamine but have yet to be directly compared. In a double-blind, randomised, placebo-controlled crossover trial, we used functional magnetic resonance imaging (fMRI) to compare changes in resting-state functional connectivity within the perigenual (pg)ACC, rostral subgenual (sg)ACC and caudal sgACC two days after intravenous treatment with ketamine or inactive placebo in a group of patients with treatment-resistant depression (TRD, n=29) *vs.* healthy controls (n=21). Intravenous ketamine (0.5mg/kg over 40mins) induced a robust antidepressant response two days after infusion, and differentially modulated functional connectivity across ACC subregions. The caudal sgACC showed reduced connectivity to key nodes of the default mode network (DMN) in participants with TRD. By contrast, rostral sgACC and pgACC showed increased connectivity to nodes of the DMN in TRD compared to healthy controls. However, these connectivity changes did not correlate with antidepressant responses as measured by the Hamilton Depression Rating Scale. Future work will explore whether functional connectivity changes within the ACC correlate with ketamine's action within specific symptom domains, such as improvements in reward processing or reductions in ruminative thinking.

The anterior cingulate cortex as a key locus of ketamine's antidepressant action.
The subdivisions of the anterior cingulate cortex (ACC) - including subgenual, perigenual and dorsal zones - are implicated in the etiology, pathogenesis and treatment of major depression. We review an emerging body of evidence which suggests that changes in ACC activity are critically important in mediating the antidepressant effects of ketamine, the prototypical member of an emerging class of rapidly acting antidepressants. Infusions of ketamine induce acute (over minutes) and post-acute (over hours to days) modulations in subgenual and perigenual activity, and importantly, these changes can correlate with antidepressant efficacy. The subgenual and dorsal zones of the ACC have been specifically implicated in ketamine's anti-anhedonic effects. We emphasize the synergistic relationship between neuroimaging studies in humans and brain manipulations in animals to understand the causal relationship between changes in brain activity and therapeutic efficacy. We conclude with circuit-based perspectives on ketamine's action: first, related to ACC function in a central network mediating affective pain, and second, related to its role as the anterior node of the default mode network.

Quantifying anhedonia-like symptoms in marmosets using appetitive Pavlovian conditioning.
Blunted reward responsivity is associated with anhedonia in humans and is a core feature of depression. This protocol describes how to train the common marmoset, , on an appetitive Pavlovian conditioning paradigm to measure behavioral and cardiovascular correlates of anticipatory and consummatory phases of reward processing. We describe how to use intracerebral infusions to manipulate brain regions whose activity is relevant to impaired reward processing in depression and how the paradigm can be used to test antidepressant efficacy. For complete details on the use and execution of this protocol, please refer to Alexander et al. (2019).

Over-activation of primate subgenual cingulate cortex enhances the cardiovascular, behavioral and neural responses to threat.

Stress-related disorders such as depression and anxiety are characterized by enhanced negative emotion and physiological dysfunction. Whilst elevated activity within area 25 of the subgenual anterior cingulate cortex (sgACC/25) has been implicated in these illnesses, it is unknown whether this over-activity is causal. By combining targeted intracerebral microinfusions with cardiovascular and behavioral monitoring in marmosets, we show that over-activation of sgACC/25 reduces vagal tone and heart rate variability, alters cortisol dynamics during stress and heightens reactivity to proximal and distal threat. F-FDG PET imaging shows these changes are accompanied by altered activity within a network of brain regions including the amygdala, hypothalamus and dorsolateral prefrontal cortex. Ketamine, shown to have rapid antidepressant effects, fails to reverse elevated arousal to distal threat contrary to the beneficial effects we have previously demonstrated on over-activation induced reward blunting, illustrating the symptom-specificity of its actions.

Ventromedial prefrontal area 14 provides opposing regulation of threat and reward-elicited responses in the common marmoset.
The ventromedial prefrontal cortex (vmPFC) is a key brain structure implicated in mood and anxiety disorders, based primarily on evidence from correlational neuroimaging studies. Composed of a number of brain regions with distinct architecture and connectivity, dissecting its functional heterogeneity will provide key insights into the symptomatology of these disorders. Focusing on area 14, lying on the medial and orbital surfaces of the gyrus rectus, this study addresses a key question of causality. Do changes in area 14 activity induce changes in threat- and reward-elicited responses within the nonhuman primate, the common marmoset, similar to that seen in mood and anxiety disorders? Area 14 overactivation was found to induce heightened responsivity to uncertain, low-imminence threat while blunting cardiovascular and behavioral anticipatory arousal to high-value food reward. Conversely, inactivation enhanced the arousal to high-value reward cues while dampening the acquisition of cardiovascular and behavioral responses to a Pavlovian threat cue. Basal cardiovascular activity, including heart rate variability and sympathovagal balance, which are dysfunctional in mood and anxiety disorders, are insensitive to alterations in area 14 activity as is the extinction of conditioned threat responses. The distinct pattern of dysregulation compared to neighboring region area 25 highlights the heterogeneity of function within vmPFC and reveals how the effects of area 14 overactivation on positive and negative reactivity mirror symptoms of anhedonia and anxiety that are so often comorbid in mood disorders.

A Focus on the Functions of Area 25.
Subcallosal area 25 is one of the least understood regions of the anterior cingulate cortex, but activity in this area is emerging as a crucial correlate of mood and affective disorder symptomatology. The cortical and subcortical connectivity of area 25 suggests it may act as an interface between the bioregulatory and emotional states that are aberrant in disorders such as depression. However, evidence for such a role is limited because of uncertainty over the functional homologue of area 25 in rodents, which hinders cross-species translation. This emphasizes the need for causal manipulations in monkeys in which area 25, and the prefrontal and cingulate regions in which it is embedded, resemble those of humans more than rodents. In this review, we consider physiological and behavioral evidence from non-pathological and pathological studies in humans and from manipulations of area 25 in monkeys and its putative homologue, the infralimbic cortex (IL), in rodents. We highlight the similarities between area 25 function in monkeys and IL function in rodents with respect to the regulation of reward-driven responses, but also the apparent inconsistencies in the regulation of threat responses, not only between the rodent and monkey literatures, but also within the rodent literature. Overall, we provide evidence for a causal role of area 25 in both the enhanced negative affect and decreased positive affect that is characteristic of affective disorders, and the cardiovascular and endocrine perturbations that accompany these mood changes. We end with a brief consideration of how future studies should be tailored to best translate these findings into the clinic.

Glutamate Within the Marmoset Anterior Hippocampus Interacts with Area 25 to Regulate the Behavioral and Cardiovascular Correlates of High-Trait Anxiety.
High-trait anxiety is a risk factor for the development of affective disorders and has been associated with decreased cardiovascular and behavioral responsivity to acute stressors in humans that may increase the risk of developing cardiovascular disease. Although human neuroimaging studies of high-trait anxiety reveals dysregulation in primate cingulate areas 25 and 32 and the anterior hippocampus (aHipp) and rodent studies reveal the importance of aHipp glutamatergic hypofunction, the causal involvement of aHipp glutamate and its interaction with these areas in the primate brain is unknown.

Accordingly, we correlated marmoset trait anxiety scores to their postmortem aHipp glutamate levels and showed that low glutamate in the right aHipp is associated with high-trait anxiety in marmosets. Moreover, pharmacologically increasing aHipp glutamate reduced anxiety levels in highly anxious marmosets in two uncertainty-based tests of anxiety: exposure to a human intruder with uncertain intent and unpredictable loud noise. In the human intruder test, increasing aHipp glutamate decreased anxiety by increasing approach to the intruder. In the unpredictable threat test, animals showed blunted behavioral and cardiovascular responsivity after control infusions, which was normalized by increasing aHipp glutamate. However, this aHipp-mediated anxiolytic effect was blocked by simultaneous pharmacological inactivation of area 25, but not area 32, areas which when inactivated independently reduced and had no effect on anxiety, respectively. These findings provide causal evidence in male and female primates that aHipp glutamatergic hypofunction and its regulation by area 25 contribute to the behavioral and cardiovascular symptoms of endogenous high-trait anxiety. High-trait anxiety predisposes sufferers to the development of anxiety and depression. Although neuroimaging of these disorders and rodent modeling implicate dysregulation in hippocampal glutamate and the subgenual/perigenual cingulate cortices (areas 25/32), the causal involvement of these structures in endogenous high-trait anxiety and their interaction are unknown. Here, we demonstrate that increased trait anxiety in marmoset monkeys correlates with reduced hippocampal glutamate and that increasing hippocampal glutamate release in high-trait-anxious monkeys normalizes the aberrant behavioral and cardiovascular responsivity to potential threats. This normalization was blocked by simultaneous inactivation of area 25, but not area 32. These findings provide casual evidence in primates that hippocampal glutamatergic hypofunction regulates endogenous high-trait anxiety and the hippocampal-area 25 circuit is a potential therapeutic target.

Fractionating Blunted Reward Processing Characteristic of Anhedonia by Over-Activating Primate Subgenual Anterior Cingulate Cortex.
Anhedonia is a core symptom of depression, but the underlying neurobiological mechanisms are unknown. Correlative neuroimaging studies implicate dysfunction within ventromedial prefrontal cortex, but the causal roles of specific subregions remain unidentified. We addressed these issues by combining intracerebral microinfusions with cardiovascular and behavioral monitoring in marmoset monkeys to show that over-activation of primate subgenual anterior cingulate cortex (sgACC, area 25) blunts appetitive anticipatory, but not consummatory, arousal, whereas manipulations of adjacent perigenual ACC (pgACC, area 32) have no effect. sgACC/25 over-activation also reduces the willingness to work for reward. F-FDG PET imaging reveals over-activation induced metabolic changes in circuits involved in reward processing and interoception. Ketamine treatment ameliorates the blunted anticipatory arousal and reverses associated metabolic changes. These results demonstrate a causal role for primate sgACC/25 over-activity in selective aspects of impaired reward processing translationally relevant to anhedonia, and ketamine's modulation of an affective network to exert its action.

Opposing roles of primate areas 25 and 32 and their putative rodent homologs in the regulation of negative emotion.
Disorders of dysregulated negative emotion such as depression and anxiety also feature increased cardiovascular mortality and decreased heart-rate variability (HRV). These disorders are correlated with dysfunction within areas 25 and 32 of the ventromedial prefrontal cortex (vmPFC), but a causal relationship between dysregulation of these areas and such symptoms has not been demonstrated. Furthermore, cross-species translation is limited by inconsistent findings between rodent fear extinction and human neuroimaging studies of negative emotion. To reconcile these literatures, we applied an investigative approach to the brain-body interactions at the core of negative emotional dysregulation. We show that, in marmoset monkeys (a nonhuman primate that has far greater vmPFC homology to humans than rodents), areas 25 and 32 have causal yet opposing roles in regulating the cardiovascular and behavioral correlates of negative emotion. In novel Pavlovian fear conditioning and extinction paradigms, pharmacological inactivation of area 25 decreased the autonomic and behavioral correlates of negative emotion expectation, whereas inactivation of area 32 increased them via generalization. Area 25 inactivation also increased resting HRV. These findings are inconsistent with current theories of rodent/primate prefrontal functional similarity, and provide insight into the role of these brain regions in affective disorders. They demonstrate that area 32 hypoactivity causes behavioral generalization relevant to anxiety, and that area 25 is a causal node governing the emotional and cardiovascular symptomatology relevant to anxiety and depression.

ALTERATIONS IN MICROGLIA AND THEIR LAG3 CHECKPOINT EXPRESSION IN THE HIPPOCAMPUS OF SUICIDAL BIPOLAR DISORDER PATIENTS

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Lior Naggan[1], Elad Robinson[2], Hagar Goldenberg[2], Ewa Kozela[3], Raz Yirmiya[2]

Bipolar disorder (BD) is a brain disorder characterized by extreme mood fluctuations between mania and depression. Previous studies implicated inflammatory processes, in general, and activation of brain microglia, in particular, in the pathophysiology of BD. Studies in our laboratory demonstrated that modulation of microglia in the hippocampus, mediated by the immune checkpoint molecule lymphocyte-activation gene 3 (LAG3), contributes to the development of depression and its associated brain processes in a mouse model of stress-induced depression. Therefore, in the present study we immunohistochemically stained postmortem hippocampal tissues collected from 15 BD patients and 12 healthy controls (HC) with antibodies to the specific microglia marker P2Y12 as well as to LAG3. Given that BD is associated with high rates of suicide attempts and death, which are more than 10-fold greater than in the general population, and that suicide is also associated with neuroinflammation and microglia activation, the BD group was further divided into a subgroup of suicide completers (BD-S; N=9) and another subgroup of death from other reasons (BD-NS, N=6). Overall, we found increased density of P2Y12-labeled microglia in the BD-S group, as compared with both the HC and BD-NS groups. In HC, 13.3% of all microglia expressed LAG-3 (in contrast with our previous findings in mice, in which most microglia express LAG-3). The percentage of LAG3-expressing microglia was significantly lower in BD-S than in both HC and BD-NS groups. These findings suggest that reduced LAG3 immune checkpoint inhibition contributes to microglia proliferation and suicide in BD.

Aims: Major depressive disorder (MDD) is a psychiatric disorder, that poses a high burden to society and is still difficult to treat. A recent study showed an association between GPR56/ADGRG1 mRNA, MDD and response to antidepressant treatment in blood and in brain. Among GPR56 transcript isoforms, the S4 isoform has recently been associated with microglial synaptic pruning, while microglia is already known as a central player in MDD. Therefore, we surmise that S4 is the specific isoform associated to MDD and antidepressant response. **Methods**: To test our hypothesis, an *in silico* analysis was first performed to identify the different proteins and transcript isoforms of GPR56. This analysis allowed to design endpoint PCR (PCR) and quantitative digital PCR (dPCR) primers. First, the level of S4 mRNA expression in blood leukocytes was analyzed by reverse transcription (RT) followed by PCR. Second, S4 was assessed by RT-dPCR in leukocytes from a cohort of 46 MDD patients including responders (n=31) and non-responders (n=17) to antidepressant treatment. **Results**: S4 isoform is expressed in leukocytes. The RT-dPCR analysis revealed significant differences between responders and non-responders. Considering that gene expression variations are modest in psychiatric disorders, RT-dPCR allowed a better precision of the measurements and thus offered the possibility to better distinguish small variations in expression levels. **Conclusions**: This study highlighted a link between one of the GPR56 transcript variants and response to antidepressant treatment. Furthermore, we may envisage a role of S4 in the pathophysiological mechanisms of MDD and the response to antidepressants via microglial activity.

The transient receptor potential ankyrin 1 (TRPA1) is a cation channel involved in pain and inflammation. Several studies have reported that TRPA1 receptor modulation could be strategies for the treatment of inflammatory diseases including itch, rheumatoid arthritis, and colitis. However, the role of the TRPA1 receptor in anxiety-like behavior and cognitive impairment caused by LPS has not been studied yet. Thus, we investigated the role of the TRPA1 receptor on LPS-induced anxiety behaviors and cognitive impairments with the TRPA1 knock-out (KO) animal model. Here, open field test (OFT), elevated plus maze (EPM), and social interaction test (SIT) were conducted to observe anxiety-like behaviors. TRPA1 KO mice did not show the anxiety-like behaviors induced by LPS administration. In addition, the memory function was evaluated by using novel object recognition test (NORT) and passive avoidance test (PAT). As a result, LPS-induced memory impairment did not appear in TRPA1 KO mice. Moreover, to investigate the role of TRPA1 in neurotransmitters levels, the concentrations of glutamate and GABA were measured in the prefrontal cortex (PFC) and hippocampus in the mouse brain. Repeated injection of LPS caused the increase in glutamate concentration and the decrease in GABA concentration in PFC. However, this alternation of the neurotransmitter did not appear in TRPA1 KO mice. In conclusion, TRPA1 might play an important role in LPS-induced cognitive and anxiety-like disorders by regulating the levels of glutamate and GABA in the PFC. Therefore, TRPA1 is expected to be a therapeutic target for anxiety and cognitive impairment.

Aim: Among the therapies for depression, restoration of immune functions is proposed to be beneficial. Therefore, we aimed to explore the antidepressant effects of the immunopotentiator thymosin alpha-1 (Tα1) and the underlying ERK and Bcl-2 pathway. **Methods:** C57 male mice were divided into 8 groups: Control, Tα1 (0.4 mg/kg), PD98059 (0.5 mg/kg), ABT-263 (1.5 mg/kg), stress, stress + Tα1, stress + Tα1 + PD98059, stress + Tα1 + ABT-263. PD98056 and ABT-263 are ERK and Bcl-2 inhibitors, respectively. Mice were exposed to chronic unpredictable mild stress (CUMS) for 10 weeks and treated (i.p.) for the last 3 weeks. Affective behaviors were assessed by sucrose preference and elevated plus test. Brain, meninges, spleen and thymus were collected and markers of lymphocytes, neurotransmitter, neuroplasticity and neuroinflammation were done using flow cytometry, HPLC, Western Blot, IHC and Elisa. **Results:** Main findings showed Tα1 treatment improved CUMS induced anhedonia and anxiety. Tα1 treatment recovered the function of central meningeal lymphocytes and hippocampal neuroinflammation, neurotransmitters as well neuroplasticity after stress, such as the increase in CD4/CD8 ratio, IL-4/INF-γ ratio, 5-HT/5-HIAA, PSD-95, DCX, PERK and Bcl-2/Bax ratio. Tα1 also restored peripheral lymphocytic CD4/CD8 and Th2/Th1 (CD4+IL-4+/CD4+IFN-γ+) ratio in spleen and thymus. Interestingly ERK and Bcl-2 inhibitors partly blocked the effect of Tα1 on the brain, spleen and thymus, suggesting that the actions of this immunopotentiator are via these pathways. **Conclusion:** Tα1 normalize stress-induced abnormities in affective behaviors, lymphocyte system, neuroinflammation, neurotransmitters and neuroplasticity through ERK and Bcl-2 pathway in adult male mice.

M1 ACETYLCHOLINE RECEPTOR IN SOMATOSTATIN INTERNEURONS MEDIATES CORTICAL EXCITATION/INHIBITION BALANCE AND ANTIDEPRESSANT RESPONSES

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Yale University, Department Of Psychiatry, New Haven, United States of America

Alterations in glutamatergic and GABAergic function in the medial prefrontal cortex (mPFC) are prevalent in individuals with Major Depressive Disorder (MDD), resulting in impaired excitation/inhibition (E/I) balance that compromises the integrity of signal transfer to limbic regions. Scopolamine, a non-selective muscarinic receptor antagonist, produces rapid antidepressant effects by initially targeting M1-type acetylcholine receptors (M1R) in somatostatin (SST) interneurons. We determined how M1R modulate the balance between GABA and glutamate signaling in mPFC by generating mice with conditional deletion of M1R (*M1$^{f/f}$Sst^{Cre+}*) only in SST interneurons. M1R deletion in SST cells resulted in baseline antidepressant- and anxiolytic-like responses in female mice, accompanied by disinhibition of SST interneurons and increased levels of proteins necessary for glutamatergic and GABAergic function in the mPFC. In contrast, male *M1$^{f/f}$Sst^{Cre+}* mice showed resilience to chronic stress that was positively correlated with levels of proteins relevant to glutamate and GABA signaling in the mPFC. Scopolamine-induced behavioral and molecular effects were absent in male and female mice lacking M1R in SST cells. Finally, chemogenetic inhibition of SST interneurons in the mPFC reversed the baseline decreases in stress-relevant behaviors in female *M1$^{f/f}$Sst^{Cre+}* mice. These findings suggest that restoring cortical plasticity and E/I balance via M1R blockade in SST interneurons could represent a promising strategy for antidepressant development. Support: NIMH (K99MH126098, R01MH105910, R01MH077681), NARSAD (29063).

EARLY LIFE MATERNAL ATTACHMENT GOVERNS MURINE EPIGENETIC ARCHITECTURE OF THE HIPPOCAMPUS AND MODIFIES ADULTHOOD NEUROCHEMISTRY AND SOCIAL BEHAVIOR

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Debpali Sur, Oryan Agranyoni, Elena Shmerkin, Michael Kirby, Raphael Avneri, Naamah Cohen, Brajesh Savita, Katerina Karandasheva, Elad Lax, Albert Pinhasov

Maternal care plays a crucial role in conditioning early epigenetic programming during postnatal brain development. Individual variations in predisposition for affective disorders may be exacerbated by alterations in early life maternal care. Stress is recognized as a vital factor that may affect maternal behavior, yet owing to high heterogeneity in stress response, the impact of maternal behavior tends to vary widely among individuals.
Our goal is to understand the connection between inborn stress vulnerability, maternal care, and early epigenetic programming using distinct mouse populations that exhibit opposite poles of the behavioral spectrum (social dominance [Dom] and submissiveness [Sub]).Dom mice are stress resilient; in contrast, Sub mice exhibit stress sensitivity, depressive-like behavior, systemic inflammation, and early aging. We demonstrated that Dom dams exhibit significantly higher maternal attachment towards their pups than Sub dams. Dom pups showed an elevated level of expression of hippocampal DNMT3a at postnatal day (PND) 7 and increased global 5-methylated cytosine (5mC) levels at PND 21. In cross-fostering experiments, Sub pups raised with Dom mothers showed elevated expression of DNMT3a and increased levels of 5mC at PND 21, and further displayed increased sociability and social dominance.Reduced representation bi-sulfite sequencing indicated significant hypermethylation of gene promoters connected with social behavior. Further, cross-fostered Sub mice displayed altered hippocampal monoamine levels, resembling neurochemical profile of Dom mice. Collectively, we speculate that epigenetic patterning sculpted by maternal care during early developmental stages shapes the diversity of gene expression patterns that may dictate lifelong stress sensitivity and social behavior.

Aims We followed-up suicide attempters and ideators with mood disorders. We analyzed the use of psychiatric drugs, and the change in suicidal ideation over time. **Methods** Among 800 suicidal ideators and attempters enrolled in Korean COhort for the Model Predicting A Suicide and Suicide related behavior (K-COMPASS), 639 participants evaluated as having bipolar disorder or major depressive disorder through Korean version of Mini-International Neuropsychiatric Interview were analyzed. Columbia-Suicide Severity Rating Scale and psychiatric drug use was assessed at the baseline, at 1, 3, 6, 9, 12, 18, 24, 30, 36, and 42 months. A linear mixed effect model was used to confirm the fixed effect of psychiatric drug use, type, and time on suicidal ideation intensity. **Results** Suicidal ideations of participants with mood disorders showed a tendency to decrease over time. Suicidal ideations were stronger during periods of psychiatric drug use than during periods of no use, but decreased more rapidly over time. Among psychiatric drugs, mood stabilizers showed a greater decrease in suicidal thoughts over time. On the other hand, in participants with bipolar disorders, there was a negative effect on the amount of change in suicidal ideation during the period of antidepressant use. **Conclusion** Psychiatric medications have a positive effect on the time-dependent reduction of suicidal thoughts in mood disorder patients. The use of antidepressants in patients with bipolar disorder can adversely affect suicidal

ACOUSTIC ANALYSIS OF SPEECH FOR SCREENING FOR SUICIDE RISK

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Sooyeon Min[1], Daun Shin[2], Hyunju Lee[1], Sang Jin Rhee[1], Yong Min Ahn[1]
[1]Seoul National University Hospital, Department Of Neuropsychiatry, Seoul, Korea, Republic of, [2]Seoul National University College of Medicine, Department Of Psychiatry And Behavioral Science, Seoul, Korea, Republic of

Aims: Assessment of a patient's risk of committing suicide is challenging for health professionals, as it depends largely on voluntary disclosure of the patient. This study aimed to examine the feasibility of using acoustic features as a biomarker for suicidality, independent of speech content. **Methods**: One-hundred patients diagnosed with mood disorder and 88 healthy subjects without psychiatric diagnosis were included in the study. All study participants underwent a semi-structured interview and completed self-report psychiatric questionnaires. Chi-square test and Student's t-test were used to compare baseline characteristics of suicidal (defined as Beck Scale for Suicidal Ideation ≥ 15) and non-suicidal groups. Several machine learning methods were evaluated for detecting suicidality. **Results**: Fifty-seven subjects were classified as being at high risk of suicide among 188 study participants. Suicidal and non-suicidal groups did not differ significantly in distribution of sex, income, and medical comorbidity. Compared to the non-suicidal group, the suicidal group was younger, had greater body mass index, was prescribed with higher dose of antipsychotics, and scored higher in all psychiatric scales such as Patient Health Questionnaire-9, Hamilton's Depression Rating Scale, Beck's Anxiety Inventory, except Barratt Impulsiveness Scale-11. Random Forest Classifier, using 21 acoustic features and two demographic variables, sex and age, correctly identified patients with high suicidality with the mean accuracy of 0.72 and an AUC of 0.69. **Conclusion:** Speech analysis using acoustic features is a promising approach for detection of suicide risk. A machine learning classifier using voice may eventually assist in identifying high-risk patients in clinical setting.

NETWORK ANALYSIS BETWEEN SUICIDE-RELATED SYMPTOMS AND SUICIDE ATTEMPT RISK IN PSYCHOTIC DISORDER AND MOOD DISORDER: A PROSPECTIVE COHORT STUDY.

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Yoojin Song[1], Jeong Hun Yang[1], Sang Jin Rhee[1], Hyung Keun Park[2], Yong Min Ahn[1]
[1]Seoul National University Hospital, Department Of Neuropsychiatry, Seoul, Korea, Republic of, [2]Asan Medical Center, Department Of Psychiatry, Seoul, Korea, Republic of

We followed-up suicide attempters and ideators with mood disorders over the age of 16 years. We followed up with various psychiatric scales. A network analysis was performed on the relationship between suicide attempts within 6 months and the scale. Among 800 suicidal ideators and attempters enrolled in Korean COhort for the Model Predicting A Suicide and Suicide related behavior (K-COMPASS), 639 participants evaluated as having mood disorder and 56 participants as having psychotic disorders through Korean version of Mini-International Neuropsychiatric Interview were analyzed. Psychiatric scales including the Columbia-Suicide Severity Rating Scale(C-SSRS), Young Mania Rating Scale (YMRS), Alcohol Use Disorders Identification Test (AUDIT), Stress Questionnaire for Korean National Health and Nutrition Examination Survey (KNHANES), Barratt Impulsiveness Scale (BIS), Early Trauma Inventory(ETI), Montgomery Asberg Depressiion Rating Scale(MADRS), Young Mania Rating Scale(YMRS), and Brief Psychiatric Rating Scale(BPRS). Partial correlation network analysis was performed to confirm the effect of psychiatric symptoms on suicidal attempt within 6 months. Participants with mood disorders and psychotic disorders were analyzed separately. In patients with psychotic disorder, various clinical measures such as YMRS, MADRS, PHQ, BAI, AUDIT, and C-SSRS significantly predicted suicide attempts during the follow-up period. On the other hand, in patients with mood disorders, only CSSRS, YMRS, and AUDIT predicted suicide attempts, and the correlation was lower. The correlation stability measured in both models was acceptable as 0.517 and 0.516, respectively. While psychiatric symptoms directly affect suicide attempts in patients with psychotic disorder, factors other than psychiatric symptoms may influence suicide attempts in mood disorder patients.

THIS ISN'T THE RHYTHM OF THE NIGHT: EFFECTS OF ACUTE DISRUPTION OF THE LIGHT-DARK CYCLE ON DEPRESSIVE SYMPTOMS IN MICE

POSTER SESSION 04 - SECTION: RISK FACTORS AND TREATMENT OF MOOD DISORDERS

Paula Berbegal-Sáez, Ines Gallego-Landin, Olga Valverde
Universitat Pompeu Fabra (UPF), Department Of Medicine And Life Sciences, Barcelona, Spain

Aims: Circadian rhythms are natural cyclical processes that internally regulate nearly all physiological activities. Since circadian disturbances are a core feature of depression and other mood disorders, we aimed to investigate whether environmental changes in the light-dark (LD) cycle can disrupt the inner clock and subsequently confer susceptibility to develop depressive and anxiety-like behaviors. **Methods:** We used C57BL/6 adult male mice housed under either a 12:12h LD cycle or an altered LD cycle with randomized light hours for 10 days. First, to validate the alteration of circadian machinery, we analyzed several clock-gene expressions at different time-points in brain areas related to mood control (i.e. medial prefrontal cortex (mPFC)) and circadian rhythms (i.e. suprachiasmatic nucleus (SCN)). Additionally, we evaluated the spontaneous locomotor activity considering it provides a measure of circadian fluctuations. Lastly, we performed a battery of tests to assess depression and anxiety-like behaviors. **Results:** Our model of altered LD cycle produces changes in locomotion schedule throughout the day with an increase in activity preceding the start of dark phase. Moreover, it attenuates the rhythmicity of clock-gene expressions in mPFC and subtly impairs their oscillations in SCN. Finally, acute exposure to irregular hours of light did not seem to induce anhedonia, anxiety nor despair-like behavior. **Conclusions:** Our findings suggest that temporary random changes in light-dark cycle may modify behavior's circadian rhythmicity. However, although we show molecular changes in mood-related brain areas, these light shifts are not enough to promote clear mood alterations in adult male mice.

CORTEX MOLECULAR SIGNATURES ANALYSIS OF A MOUSE MODEL OF KCNQ2-RELATED EPILEPTIC AND DEVELOPMENTAL ENCEPHALOPATHY.

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Lucile Brun[1], Morgane Terezol[1], Pauline Brochet[2], Claude Villard[3], Maya Belghazi[3], Nicolas Lenfant[1], Christophe Chevillard[2], Jean-Christophe Roux[1], Anaïs Baudot[1], Laurent Villard[1]
[1]Aix-Marseille Université, U1251 - Marseille Medical Genetics (mmg), Marseille, France, [2]Aix-Marseille Université, Tagc - Inserm U1090, Marseille, France, [3]Aix-Marseille Université, Institut De Neurophysiopathologie - Inserm U7051, Marseille, France

KCNQ2-related Epileptic and Developmental Encephalopathies (DEE) are rare and severe epileptic syndromes characterized by seizures in the first 3 months of life, abnormal interictal EEG, and a poor prognosis with severe motor and cognitive consequences. We produced the first knock-in model of the disease. As observed in patients, this model presents a progressive pathology with early epileptic seizures, remission of seizures after several weeks of life, and significant neurological deficits. To better understand the pathophysiology, we compared the proteome and the transcriptome of the prefrontal cortex of the *Kcnq2*-DEE mice at three stages: before seizure onset (P15), during the seizure susceptibility phase (P25-30), and after seizure arrest (P>100) and subsequently performed multi-omics integration. Our results show that SNARE proteins and proteins involved in mitochondrial metabolism are under-expressed in the KI compared to WT at the seizure susceptibility phase (P25-30). Abnormally expressed SNARE or mitochondrial proteins have been described in other types of epilepsy. These results reveal that physiological mechanisms important for neuronal activity are disrupted at early stages in the *KCNQ2*-DEE cortex and that the evolution towards remission of epileptic seizures could be accompanied by specific molecular signatures in the mutated cortex. Similar studies are underway using cortical neurons derived from patients' pluripotent stem cells. Through the integration of human and mouse omics data, we hope to contribute to a better understanding of the neuronal mechanisms at play in *KCNQ2*-DEE and to identify new therapeutic targets.

ELUCIDATING THE MECHANISMS LEADING TO EPILEPSY IN A DEPDC5 MOUSE MODEL

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Laurene Layus, Alexandre Bacq, Charlotte Deleuze, Marion Doladilhe, Eric Le Guern, Stephanie Baulac
Institut du Cerveau - Paris Brain Institute - ICM, Sorbonne Université, Inserm, Cnrs, Hôpital De La Pitié Salpêtrière, Paris, France

Focal cortical dysplasias (FCD) are cortical malformations causing pediatric refractory epilepsies, often requiring surgical resection to control seizures. FCD type II is characterized by a cortical dyslamination and the presence of dysmorphic neurons. Over the past years, both germline and somatic mutations have been found in FCD, in genes of the mTOR (mammalian target of rapamycin) pathway, in particular DEP domain-containing 5 protein (DEPDC5), a repressor of the amino-sensing branch of the mTORC1 (mTOR complex 1) pathway. It has recently been proven that a brain second hit inactivation of this gene causes constitutive activation of mTORC1 and FCDII associated with epilepsy (*Ribierre et al, 2018*). However, little is known on how a loss-of-function of DEPDC5 leads to epilepsy. To get further insights into the underlying pathophysiological mechanisms, we used a *Depdc5* knockout (KO) strain that combines a germline mutation and a neuron-specific deletion of the second allele (*Bacq et al., 2020*). This mouse model exhibits spontaneous epileptic seizures followed by a sudden unexpected death in epilepsy (SUDEP)-like event. We performed multi-electrode arrays (MEA) recordings in cortical brain slices in *Depdc5KO* mice and show hyperexcitability of the network. By performing bulk RNA sequencing on cortical lysates from Depdc5 adult mice, GSE analysis identified multiple dysregulated pathways such as mTOR signaling or mitochondrial functions that may underlie hyperexcitability and seizures, and pinpoint new therapeutic targets to treat children with FCD.

HEALTHY LIFE-STYLE APPROACHES TO ATTAIN DISEASE MODIFICATIONS IN ACQUIRED EPILEPSIES

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Valentina Kebede
Istituto Mario Negri IRCCS, Neuroscience, Milan, Italy

Healthy life-style was reported to improve neurological outcomes after acute brain injuries. In particular, physical activity might improve neurological deficits and reduce seizures in epilepsy. Our study investigates whether aerobic and regular physical exercise reduces the risk of developing epilepsy and disease severity following a focal brain lesion. C57BL66/N adult male mice were given free access to running wheels in their home cage for 3 weeks before being exposed to intra-amygdala kainate to induce a status epilepticus that leads to epilepsy development. Then, injured mice were allowed to run for 6 additional weeks, a time required for chronic epilepsy development. Control mice were similarly treated with kainate but left in their home cage in the absence of running wheels (sedentary mice). Sham mice were prepared as controls for post-mortem histological analysis. Data show that running mice develop status epilepticus of reduced severity (decreased number of spikes, $p<0.05$) vs sedentary mice. Moreover, running mice developed spontaneous seizures of reduced duration ($p<0.05$) vs sedentary mice while epilepsy incidence and seizures frequency were not modified. Nissl staining showed attenuation of hilar interneurons loss in the hippocampus of running mice vs sedentary mice. Data support the beneficial effects of physical activity to improve pathologic outcomes after epileptogenic brain lesions.

Microglia proliferation plays distinct roles in acquired epilepsy depending on disease stages.
Microgliosis occurs in animal models of acquired epilepsy and in patients. It includes cell proliferation that is associated with seizure frequency and decreased neuronal cells in human epilepsy. The role of microglia proliferation in the development of acquired epilepsy is unknown; thus, we examined its contribution to spontaneous seizure, neurodegeneration, and cognitive deficits in different disease phases.

CXCL1-CXCR1/2 signaling is induced in human temporal lobe epilepsy and contributes to seizures in a murine model of acquired epilepsy.
CXCL1, a functional murine orthologue of the human chemokine CXCL8 (IL-8), and its CXCR1 and CXCR2 receptors were investigated in a murine model of acquired epilepsy developing following status epilepticus (SE) induced by intra-amygdala kainate. CXCL8 and its receptors were also studied in human temporal lobe epilepsy (TLE). The functional involvement of the chemokine in seizure generation and neuronal cell loss was assessed in mice using reparixin (formerly referred to as repertaxin), a non-competitive allosteric inhibitor of CXCR1/2 receptors. We found a significant increase in hippocampal CXCL1 level within 24 h of SE onset that lasted for at least 1 week. No changes were measured in blood. In analogy with human TLE, immunohistochemistry in epileptic mice showed that CXCL1 and its two receptors were increased in hippocampal neuronal cells. Additional expression of these molecules was found in glia in human TLE. Mice were treated with reparixin or vehicle during SE and for additional 6 days thereafter, using subcutaneous osmotic minipumps. Drug-treated mice showed a faster SE decay, a reduced incidence of acute symptomatic seizures during 48 h post-SE, and a delayed time to spontaneous seizures onset compared to vehicle controls. Upon reparixin discontinuation, mice developed spontaneous seizures similar to vehicle mice, as shown by EEG monitoring at 14 days and 2.5 months post-SE. In the same epileptic mice, reparixin reduced neuronal cell loss in the hippocampus vs vehicle-injected mice, as assessed by Nissl staining at completion of EEG monitoring. Reparixin administration for 2 weeks in mice with established chronic seizures, reduced by 2-fold on average seizure number vs pre-treatment baseline, and this effect was reversible upon drug discontinuation. No significant changes in seizure number were measured in vehicle-injected epileptic mice that were EEG monitored in parallel. Data show that CXCL1-IL-8 signaling is activated in experimental and human epilepsy and contributes to acute and chronic seizures in

mice, therefore representing a potential new target to attain anti-ictogenic effects.

L-alpha-amino adipic acid provokes depression-like behaviour and a stress related increase in dendritic spine density in the pre-limbic cortex and hippocampus in rodents.
Astrocyte dysfunction is implicated in clinical depression. There is a paucity of animal models to assess the role of astrocytes in depression pathogenesis. Refinement of an existing model is described here. Administration of the astrocytic toxin L-alpha aminoadipic acid (L-AAA) to the pre-limbic cortex (PLC) was assessed in rats and mice in tests of anxiety and depression related behaviours. Delivery of L-AAA to the PLC of Wistar rats produced an increase in immobility in the forced swimming test (FST) and reduced exploration in the open field. Delivery to the CA3 subfield of the hippocampus produced a deficit in the novel object relocation task. Delivery of single or two successive doses of L-AAA to the PLC of C57Bl6/J mice was sufficient to induce an increase in immobility in the mouse tail suspension (TST) and FST independently of administration of anaesthetic agent or the surgical procedure. In both mice and rats, L-AAA produced a reduction in immunoreactivity of the astrocytic marker glial fibrillary acidic protein (GFAP) for up to 72 h. L-AAA provoked an increase in the density of apical and basal dendritic spines in mice exposed to the FST when compared to non-FST controls. In summary, L-AAA provokes a region-dependent change in behaviour, a reduction in GFAP immunoreactivity and FST-provoked increased in dendritic spine density in the PLC. This model may be further employed to assess the impact of astroglial integrity on the structural plasticity of neurons and the effect of antidepressant agents on L-AAA-related changes.

DEFICITS IN BRAIN ENERGY METABOLISM IN A MOUSE MODEL FOR GLUT1 DEFICIENCY SYNDROME

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Sophie Burlet-Godinot[1], Mariko Soya[1], Anthony Carrard[1], Maoxue Tang[2], Monani[2], Darryl De Vivo[2], Jean-Luc Martin[1], Pierre Magistretti[3]
[1]CHUV, Center For Psychiatric Neurosciences, Prilly, Switzerland, [2]Columbia University, Department Of Neurology, New York, United States of America, [3]KAUST, Biological And Environmental Sciences And Engineering, Thuwal, Saudi Arabia

Glucose transporter type 1 deficiency syndrome (Glut1DS), also called De Vivo disease, is caused by mutations in *SLC2A1* gene that encodes for glucose transporter type 1 (Glut1). In human, this mutation results in deficient glucose transport to the brain and generates early onset epilepsy, complex movement disorders and cognitive impairment. In order to assess the impact of Glut1 deficiency on brain energy metabolism, we measured glycogen, lactate, and glucose levels in the cerebral cortex and hippocampus of a male and female mouse model for Glut1DS (GLUT1 +/-). A significant decrease in glucose levels was already observed at 2 weeks both in the hippocampus and cerebral cortex of GLUT1 +/- mice compared to wild type (WT) animals (-29% and -42%, respectively) together with a significant reduction in glycogen (-30%) and lactate (-36.9% and -24.7%) levels. In 10-week old mice, similar decreases in glucose, glycogen and lactate hippocampal and cortical levels were observed in GLUT1 +/- compared to WT mice.These data show that Glut1 deficiency has an early and marked impact on brain energy metabolism not limited to glucose levels but extending to other important energy substrates including lactate and glycogen. As astrocytes store glycogen and release lactate, an important energy substrate for neurons and signaling molecule, these data suggest that Glut1DS may affect the metabolic cooperation between astrocytes and neurons. Further elucidation of the mechanisms underlying alterations in the astrocyte-neuron metabolic cooperation in GLUT1+/- mice should help to develop therapeutic targets for the treatment of De Vivo disease.

TWO CANDIDATE K-CL COTRANSPORTER 2 (KCC2) ENHANCERS PREVENT EPILEPTIFORM ACTIVITY IN VITRO AND IN VIVO

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Florian Donneger[1], Jeremy Besson[1], Adrien Zanin[1], Yoness Kadiri[1], Francine Chassoux[2], Bertrand Devaux[2], Vincent Navarro[3,4], Stéphane Clémenceau[5], Sabine Levi[6], Jean Christophe Poncer[1]
[1]INSERM-Sorbonne Université UMR-1270, Institut Du Fer à Moulin, Paris, France, [2]Centre Hospitalier Sainte Anne, Department Of Neurosurgery, Paris, France, [3]Hôpital de la Pitié-Salpêtrière, Service De Neurophysiologie Clinique, Paris, France, [4]Paris Brain Institute, ICM, Equipe "excitabilité Cellulaire Et Dynamiques Des Réseaux Neuronaux", Paris, France, [5]Centre Hospitalier Pitié Salpêtrière, Department Of Neurosurgery, Paris, France, [6]Inserm-Sorbonne Université UMR-1270, Institut Du Fer à Moulin, Paris, France

In neurons, the cation-chloride cotransporters (CCC) KCC2 and Na-K-Cl cotransporter 1 (NKCC1) control intraneuronal chloride homeostasis and, subsequently, the efficacy and polarity of gamma-aminobutyric acid (GABA) signaling. In many neurological disorders, including epilepsy, reduced KCC2 expression or function may result in depolarizing GABA signaling that may then contribute to pathological activities and seizures. Compensating for the dysregulation of CCC function in the pathology therefore appears as a promising therapeutic strategy. Various compounds derived from library screening were recently identified as candidate KCC2 enhancers. However, their mode of action in cortical neurons and their therapeutic potential in epilepsy remain unknown or even controversial. We first compared the mode of action of these two compounds in rat hippocampal neurons. We showed that both of them enhance KCC2 function and this effect was also accompanied by a direct modulation of GABA signaling. Single particle tracking experiments revealed that both compounds reduce the lateral diffusion of KCC2 in the plasma membrane. This effect was associated with enhanced KCC2 clustering with no change in total or plasmalemmal KCC2 expression. Both compounds effectively suppressed spontaneous, interictal-like discharges recorded in postoperative hippocampal tissue resected from intractable, mesial temporal lobe epilepsy patients. In addition, chronic administration of a Food and Drug Administration (FDA)-approved KCC2 enhancer reduced seizure occurrence by about 67% in a lithium-pilocarpine mouse model of temporal lobe epilepsy. Collectively, our data decipher the mode of action of two candidate KCC2 enhancers in hippocampal neurons and demonstrate for the first time their antiepileptic potential in pharmacoresistant epilepsy.

THE ABSENCE OF SV2A IN INTERNEURONS LEADS TO EPILEPSY

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Odile Bartholome[1], Virginie Neirinckx[1], Dominique Baiwir[2], Gabriel Mazzucchelli[2], Bernard Rogister[1]
[1]ULiège, Giga-neurosciences, Liège, Belgium, [2]ULiège, Giga-proteomics, Liège, Belgium

The SV2A protein is a glycoprotein present in the membranes of most synaptic vesicles whose physiological role remains unknown. However, it has been demonstrated that levetiracetam, an effective anti-epileptic drug, binds to SV2A. Moreover, SV2A expression is down-regulated in epileptic foci resected in humans with temporal lobe epilepsy, and *SV2A* full knock-out mice exhibited seizures around post-natal day 7 (P7) and die around P15. AIMS: This project aims to understand how SV2A protein may be involved in epilepsy. First, we wanted to test if the absence of SV2A could lead to seizures appearance after complete brain development. Next, we wished to unravel the sub-population of neurons responsible for seizures onset. METHODS: We induced recombination in Ubiquitin^{ERT2}:SV2A-cKO mice at P70 and observed the obtained phenotype. Next, we compared the phenotype of Dlx5,6:SV2A-cKO (targeting GABAergic interneurons) with Nex:SV2A-cKO (targeting glutamatergic neuron) mice. RESULTS: Ubiquitin^{ERT2}:SV2A-cKO mice recombinated at P70 presented seizures and died one to two months after while WT mice behaved normally. Then, we observed that Dlx5,6:SV2A-cKO mice exhibited lethal spontaneous seizure while Nex:SV2A-cKO had no evident phenotype. Furthermore, Dlx5,6:SV2A-cKO mice present a significant decreased of PV neuron density in the hippocampus. Mass spectrometry analysis revealed that Dlx and Nex:SV2A-cKO synaptosomes present the same modification compared to WT. CONCLUSIONS: Our results show that the absence of SV2A can lead to seizures after the complete brain development. We also observed that GABAergic neurons are sufficient to induce seizures in mice although they seem to bear the same molecular defect as glutamatergic neurons.

MODELLING MONOGENIC EPILEPSY IN HUMAN BRAIN SLICE CULTURES

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Faye Mcleod[1], Anna Dimtsi[1], David Lewis-Smith[2,3], Rhys Thomas[2,3], Gavin Clowry[1], Andrew Trevelyan[1]
[1]Newcastle University, Biosciences Institute, Newcastle upon Tyne, United Kingdom, [2]Newcastle University, Newcastle University Translational And Clinical Research Institute, Newcastle upon Tyne, United Kingdom, [3]Newcastle Upon Tyne Hospitals NHS Foundation Trust, Department Of Clinical Neurosciences, Newcastle upon Tyne, United Kingdom

Background Early infantile developmental and epileptic encephalopathies of genetic origin are devastating conditions, but the pathological mechanisms often remain obscure. A major obstacle is the difficulty of studying human cortical brain development, *in utero*. To date, no *in vitro* preparations, not even human cerebral organoids, have been developed that accurately reproduce the complex cellular networks found beyond the first trimester. **Methods** To address this, we established human brain slice cultures prepared from ethically sourced, 14-17 post conception week (pcw) brain tissue (www.hdbr.org). The gross anatomical structures of the marginal zone, cortical plate and subplate are maintained in these cultures for several months, while new synaptic networks form. **Results** We used this model system to examine variants in STXBP1, which encodes a critical presynaptic protein. Specifically, we induced STXBP1 haploinsufficiency, thereby mimicking a common genetic cause of developmental and epileptic encephalopathy. STXBP1 was enriched near spine-like structures and along putative axons of subplate neurons at 16-17 pcw. We achieved a ~50% reduction in STXBP1 expression, using a short hairpin RNA interference introduced by adeno-associated viral vectors, and quantified the effects using confocal microscopy and electrophysiological techniques. The induced STXBP1 haploinsufficiency had divergent effects upon glutamatergic and GABAergic synaptic number and function, without altering subplate neurite length and number. Furthermore, live imaging of synaptic vesicles with reduced STXBP1 levels revealed impaired spontaneous neurotransmitter release with slower release kinetics. **Conclusion** We provide a critical proof-of-principle for how to investigate the aetiology of monogenic epilepsy in prenatal neurodevelopment.

TBC1D24 INTERACTS WITH V-ATPASE AND REGULATES PH HOMEOSTASIS AND AUTOPHAGY IN NEURONS.

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Sara Pepe[1], Davide Aprile[1], Enrico Castroflorio[2], Anna Parsons[2], Tania Soares[2], Peter Oliver[2], Anna Fassio[1,3]
[1]University of Genoa, Department Of Experimental Medicine, Genoa, Italy, [2]MRC Harwell Institute, Harwell Campus, Oxfordshire, United Kingdom, [3]IRCCS, Ospedale Policlinico San Martino, Genoa, Italy

Background: *Tbc1d24* is a gene mutated in a spectrum of neurological disorders, from mild epilepsy to severe epileptic encephalopathy. TBC1D24 regulates neurite development, synaptic vesicle trafficking and synaptic function; yet the molecular mechanisms mediating these complex roles and their relationship to brain dysfunction are largely unknown. TBC1D24 is unique in containing conserved TBC and TLDc domains; importantly, TLDc proteins have been recently described as interactors of the essential v-ATPase proton pump. **Experimental approach:** First we evaluated the TBC1D24/v-ATPase interaction by immunoprecipitation experiments. Using *Tbc1d24* knockout mouse neurons, we investigated v-ATPase assembly by fractionation experiments, expression of endo-lysosomal and autophagic markers by Western blot and pH regulation by live cell imaging. **Key findings:** TBC1D24 interacts with the v-ATPase cytosolic domain. Loss of TBC1D24 leads to an increase in the cytosolic fraction of ATP6V1A and ATP6V1B2 V1 subunits, an alteration of intracellular organelles acidification and impairment of autophagic flux. This phenotype is accompanied by defects in neurite development, synaptic connectivity and an alteration in synaptic ultrastructure. **Conclusions:** We uncover a novel function for TBC1D24 as regulator of v-ATPase activity and suggest pH and autophagic dysregulation in neurons as key cellular mechanisms that underpin the synaptic defects and pathogenesis in *Tbc1d24* disorders.

Background:
Recently it has been reported that temporal lobe epilepsy (TLE) patients have increased brain amyloid beta (Aβ) expression, a neuropathological hallmark of Alzheimer's Disease (AD). Aβ accumulation might also explain the increased risk of developing epilepsy in AD. Since the low-density lipoprotein receptor-related protein 1 (LRP1) may be involved in Aβ clearance from the brain, we investigated LRP1 expression in the hippocampus of TLE and AD patients. **Methods:** Using immunohistochemistry, we studied the expression and cellular localization of LRP1 on hippocampal sections of autopsy controls (n=20), AD patients (n=12) and resected hippocampal tissue of age-matched TLE patients with hippocampal sclerosis (TLE-HS; n=14). **Results:** We demonstrated strong LRP1 expression at the abluminal side of brain capillaries in control specimens. Optical density analysis showed lower LRP1 expression in capillaries ($p<0.05$) and higher expression in astrocytes ($p<0.05$) in the dentate gyrus, CA1 and CA3 region of the hippocampus from AD and TLE-HS patients as compared to controls. **Conclusions:** Our results suggest that downregulation of LRP1 in brain endothelial cells could be involved in increased perivascular Aβ accumulation. In future studies we will investigate whether restoration of endothelial LRP1 expression can prevent or attenuate the development of epilepsy and/or accumulation of Aβ.

Leptin Receptor Expressing Neurons in the Substantia Nigra Regulate Locomotion, and in The Ventral Tegmental Area Motivation and Feeding.
Leptin is an anorexigenic hormone, important in the regulation of body weight. Leptin plays a role in food reward, feeding, locomotion and anxiety. Leptin receptors (LepR) are expressed in many brain areas, including the midbrain. In most studies that target the midbrain, either all LepR neurons of the midbrain or those of the ventral tegmental area (VTA) were targeted, but the role of substantia nigra (SN) LepR neurons has not been investigated. These studies have reported contradicting results regarding motivational behavior for food reward, feeding and locomotion. Since not all midbrain LepR mediated behaviors can be explained by LepR neurons in the VTA alone, we hypothesized that SN LepR neurons may provide further insight. We first characterized SN LepR and VTA LepR expression, which revealed LepR expression mainly on DA neurons. To further understand the role of midbrain LepR neurons in body weight regulation, we chemogenetically activated VTA LepR or SN LepR neurons in LepR-cre mice and tested for motivational behavior, feeding and locomotion. Activation of VTA LepR neurons in food restricted mice decreased motivation for food reward ($p=0.032$) and food intake ($p=0.020$), but not locomotion. In contrast, activation of SN LepR neurons in food restricted mice decreased locomotion ($p=0.025$), but not motivation for food reward or food intake. Our results provide evidence that VTA LepR and SN LepR neurons serve different functions, i.e. activation of VTA LepR neurons modulated motivation for food reward and feeding, while SN LepR neurons modulated locomotor activity.

ApoE4 disrupts interaction of sortilin with fatty acid-binding protein 7 essential to promote lipid signaling.
Sortilin is a neuronal receptor for apolipoprotein E (apoE). Sortilin-dependent uptake of lipidated apoE promotes conversion of polyunsaturated fatty acids (PUFA) into neuromodulators that induce anti-inflammatory gene expression in the brain. This neuroprotective pathway works with the apoE3 variant but is lost with the apoE4 variant, the main risk factor for Alzheimer's

disease (AD). Here, we elucidated steps in cellular handling of lipids through sortilin, and why they are disrupted by apoE4. Combining unbiased proteome screens with analyses in mouse models, we uncover interaction of sortilin with fatty acid-binding protein 7 (FABP7), the intracellular carrier for PUFA in the brain. In the presence of apoE3, sortilin promotes functional expression of FABP7 and its ability to elicit lipid-dependent gene transcription. By contrast, apoE4 binding blocks sortilin-mediated sorting, causing catabolism of FABP7 and impairing lipid signaling. Reduced FABP7 levels in the brain of AD patients expressing apoE4 substantiate the relevance of these interactions for neuronal lipid homeostasis. Taken together, we document interaction of sortilin with mediators of extracellular and intracellular lipid transport that provides a mechanistic explanation for loss of a neuroprotective lipid metabolism in AD.

Identification of Novel Neurocircuitry Through Which Leptin Targets Multiple Inputs to the Dopamine System to Reduce Food Reward Seeking.
Leptin reduces the motivation to obtain food by modulating activity of the mesolimbic dopamine (DA) system upon presentation of cues that predict a food reward. Although leptin directly reduces the activity of ventral tegmental area (VTA) DA neurons, the majority of leptin receptor (LepR)-expressing DA neurons do not project to the nucleus accumbens, the projection implicated in driving food reward seeking. Therefore, the precise locus of leptin action to modulate motivation for a food reward is unresolved.

Effects of GABA and Leptin Receptor-Expressing Neurons in the Lateral Hypothalamus on Feeding, Locomotion, and Thermogenesis.
The lateral hypothalamus (LH) is known for its role in feeding, and it also regulates other aspects of energy homeostasis. How genetically defined LH neuronal subpopulations mediate LH effects on energy homeostasis remains poorly understood. The behavioral effects of chemogenetically activating LH gamma-aminobutyric acid (GABA) and the more selective population of LH GABA neurons that coexpress the leptin receptor (LepR) were compared.

CHANGES OF GOLGI APPARATUS MORPHOLOGY IN EPILEPSY

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Anna Skupień-Jaroszek[1], Andrzej Szczepankiewicz[2], Andrzej Rysz[3], Joanna Dzwonek[1]
[1]Nencki Institute of Experimental Biology, Laboratory Of Cell Biophysics, Warsaw, Poland, [2]Nencki Institute of Experimental Biology, Laboratory Of Electron Microscopy, Warsaw, Poland, [3]Medical University, Department Of Neurological Surgery, Warsaw, Poland

The Golgi apparatus is a highly dynamic organelle, which has many essential functions in cellular mechanisms like lipid metabolism, protein secretion, intracellular signalling and regulation of cell division. The structure of the Golgi apparatus is mainly defined as a stack of disk-like membranes, called the cisternae. The Golgi is highly dynamic and can be fragmented into ministacks under both physiological and pathological conditions. Changes in Golgi structure in neurons were observed in several neurodegenerative disorders including Alzheimer's disease, amyotrophic lateral sclerosis or Parkinson's disease. On the other hand, Golgi apparatus fragmentation was also observed in hippocampal and neocortical neurons during hibernation in Syrian hamster. The role of changes in Golgi apparatus morphology in epilepsy is still poorly understood. In our study, using 3D reconstruction of Golgi apparatus, we have shown for the first time, that Golgi apparatus is fragmented in human brain of epileptic patients. Moreover, this phenomenon was also observed in rat brain upon kainic acid induced seizures. Our results indicate that kainic acid-induced seizures leads to Golgi dispersion in pyramidal and granule neurons. The structural changes of Golgi apparatus in dentate gyrus neurons were reversible and Golgi apparatus morphology returned to normal in 24 hours after KA treatment. These observations suggest that enhanced neuronal activity induces Golgi reorganization, that is not associated with cellular death, but can be rather involved in aberrant neuronal plasticity processes that underlie epilepsy.

CD44: a novel synaptic cell adhesion molecule regulating structural and functional plasticity of dendritic spines.
Synaptic cell adhesion molecules regulate signal transduction, synaptic function, and plasticity. However, their role in neuronal interactions with the extracellular matrix (ECM) is not well understood. Here we report that the CD44, a transmembrane receptor for hyaluronan, modulates synaptic plasticity. High-resolution ultrastructural analysis showed that CD44 was localized at mature synapses in the adult brain. The reduced expression of CD44 affected the synaptic excitatory transmission of primary hippocampal neurons, simultaneously modifying dendritic spine shape. The frequency of miniature excitatory postsynaptic currents decreased, accompanied by dendritic spine elongation and thinning. These structural and functional alterations went along with a decrease in the number of presynaptic Bassoon puncta, together with a reduction of PSD-95 levels at dendritic spines, suggesting a reduced number of functional synapses. Lack of CD44 also abrogated spine head enlargement upon neuronal stimulation. Moreover, our results indicate that CD44 contributes to proper dendritic spine shape and function by modulating the activity of actin cytoskeleton regulators, that is, Rho GTPases (RhoA, Rac1, and Cdc42). Thus CD44 appears to be a novel molecular player regulating functional and structural plasticity of dendritic spines.

Cleavage of Hyaluronan and CD44 Adhesion Molecule Regulate Astrocyte Morphology via Rac1 Signalling.
Communication of cells with their extracellular environment is crucial to fulfill their function in physiological and pathophysiological conditions. The literature data provide evidence that such a communication is also important in case of astrocytes. Mechanisms that contribute to the interaction between astrocytes and extracellular matrix (ECM) proteins are still poorly understood. Hyaluronan is the main component of ECM in the brain, where its major receptor protein CD44 is expressed by a subset of astrocytes. Considering the fact that functions of astrocytes are tightly coupled with changes in their morphology (e.g.: glutamate clearance in the synaptic cleft, migration, astrogliosis), we investigated the influence of hyaluronan cleavage by hyaluronidase, knockdown of CD44 by specific shRNA and CD44 overexpression on astrocyte morphology. Our results show that hyaluronidase treatment, as well as knockdown of CD44, in astrocytes result in a

"stellate"-like morphology, whereas overexpression of CD44 causes an increase in cell body size and changes the shape of astrocytes into flattened cells. Moreover, as a dynamic reorganization of the actin cytoskeleton is supposed to be responsible for morphological changes of cells, and this reorganization is controlled by small GTPases of the Rho family, we hypothesized that GTPase Rac1 acts as a downstream effector for hyaluronan and CD44 in astrocytes. We used FRET-based biosensor and a dominant negative mutant of Rac1 to investigate the involvement of Rac1 activity in hyaluronidase- and CD44-dependent morphological changes of astrocytes. Both, hyaluronidase treatment and knockdown of CD44, enhances Rac1 activity while overexpression of CD44 reduces the activity state in astrocytes. Furthermore, morphological changes were blocked by specific inhibition of Rac1 activity. These findings indicate for the first time that regulation of Rac1 activity is responsible for hyaluronidase and CD44-driven morphological changes of astrocytes.

CD44 regulates dendrite morphogenesis through Src tyrosine kinase-dependent positioning of the Golgi.
The acquisition of proper dendrite morphology is a crucial aspect of neuronal development towards the formation of a functional network. The role of the extracellular matrix and its cellular receptors in this process has remained enigmatic. We report that the CD44 adhesion molecule, the main hyaluronan receptor, is localized in dendrites and plays a crucial inhibitory role in dendritic tree arborization in vitro and in vivo. This novel function is exerted by the activation of Src tyrosine kinase, leading to the alteration of Golgi morphology. The mechanism operates during normal brain development, but its inhibition might have a protective influence on dendritic trees under toxic conditions, during which the silencing of CD44 expression prevents dendritic shortening induced by glutamate exposure. Overall, our results indicate a novel role for CD44 as an essential regulator of dendritic arbor complexity in both health and disease.

The interplay of seizures-induced axonal sprouting and transcription-dependent Bdnf repositioning in the model of temporal lobe epilepsy.
The Brain-Derived Neurotrophic Factor is one of the most important trophic proteins in the brain. The role of this growth factor in neuronal plasticity, in health and disease, has been extensively studied. However, mechanisms of epigenetic regulation of Bdnf gene expression in epilepsy are still elusive. In our previous work, using a rat model of neuronal activation upon kainate-induced seizures, we observed a repositioning of Bdnf alleles from the nuclear periphery towards the nuclear center. This change of Bdnf intranuclear position was associated with transcriptional gene activity. In the present study, using the same neuronal activation model, we analyzed the relation between the percentage of the Bdnf allele at the nuclear periphery and clinical and morphological traits of epilepsy. We observed that the decrease of the percentage of the Bdnf allele at the nuclear periphery correlates with stronger mossy fiber sprouting-an aberrant form of excitatory circuits formation. Moreover, using in vitro hippocampal cultures we showed that Bdnf repositioning is a consequence of transcriptional activity. Inhibition of RNA polymerase II activity in primary cultured neurons with Actinomycin D completely blocked Bdnf gene transcription and repositioning occurring after neuronal excitation. Interestingly, we observed that histone deacetylases inhibition with Trichostatin A induced a slight increase of Bdnf gene transcription and its repositioning even in the absence of neuronal excitation. Presented results provide novel insight into the role of BDNF in epileptogenesis. Moreover, they strengthen the statement that this particular gene is a good candidate to search for a new generation of antiepileptic therapies.

The M-current is a low-threshold K^+-current that determines neuronal excitability and contributes to dampening repetitive firing. M-channels assemble as tetramers of Kv7.2-7.3 subunits and are targets of neuromodulation. Mutations in the KCNQ2 gene encoding for Kv7.2 subunits are responsible for epilepsy and neurodevelopmental disorders, and a Kv7.2 dominant-negative mouse model displays hyperexcitability, unprovoked seizures and impaired cognition. Even though M-current dysfunction is a common epileptogenic mechanism, little is known about how M-currents are regulated. We have identified stargazin, a well-known regulator of AMPAR trafficking and gating, as a new interactor of Kv7.2 in the cortex. Here, we characterized Kv7.2-stargazin interaction and tested its functional relevance. Co-immunoprecipitation and proximity ligation (PLA) assays revealed that the stargazin-Kv7.2 interaction occurs in neurons, and stargazin co-expression with Kv7.2 potentiated Kv7.2-mediated currents without changing their voltage-dependence, while increasing Kv7.2 cell surface expression. Conversely, stargazin silencing in cultured cortical neurons decreased sensitivity to the M-channel specific blocker XE-991, and reduced the hyperpolarization induced by the M-channel activator retigabine, indicating decreased neuronal M-currents in the absence of stargazin. A variant of stargazin associated with intellectual disability failed to potentiate M-currents when co-expressed with Kv7.2. Additionally, a knock-in mouse model harbouring this stargazin variant showed decreased M-currents and medium after burst-hyperpolarization in pyramidal hippocampal neurons and enhanced susceptibility to pentylenetetrazol-induced seizures. Collectively, our data support a novel function for stargazin in regulating M-channel activity, and highlights that a disrupted stargazing/Kv7.2 interaction may have relevant impact in hyperexcitability disorders.

Aims: Abnormal activity of the mTOR signaling pathway leads to severe neurodevelopmental diseases (refractory epilepsy, autism, brain malformations...). These mTORopathies include Tuberous sclerosis complex (TSC) and focal cortical dysplasia (FCD). In FCDs, somatic mutations in *TSC1*, *TSC2* and the eponym *mTOR* gene were identified but the precise mechanisms linking mTOR dysregulation and epilepsy remain to be clarified. We previously reported that aberrant GluN2C-driven NMDA receptor (NMDAR) currents are involved in epileptogenesis caused by defects in the *TSC1* or *TSC2* genes. Whether this mechanism is a peculiarity of TSC genes or would expand to other mTORopathies remains undetermined. Methods: We use our previously characterized rat model of FCD created by *in utero* electroporation in neural progenitors of the dorsal telencephalon of expression vector encoding wild-type or mutant pathogenic mTOR. Activity of neuronal NMDARs was analyzed in acute brain slices in layer IV of somatosensory cortex at around P15 using whole-cell recordings and selective NMDARs inhibitors. Neuronal morphology was analyzed with biocytin labeling and 3D-reconstruction. Ex vivo extracellular recordings were performed to study epileptiform activity. Results: mTOR pathogenic mutation led to changes in neuronal morphology and intrinsic properties. Electroporated mutant but not wild-type neurons displayed increased NMDAR activity mostly sustained by GluN2C-mediated currents. Extracellular recordings revealed GluN2C-dependent spiking activity. Conclusion: Increased synaptic integration caused by slower kinetics of GluN2C-mediated currents might sustain hypersynchronous neuronal networks in FCDs. Broadening Glun2C-related pathogenesis to the mTORopathies spectrum would provide a unified mechanism underlying mTOR-related epileptogenesis and might lead to the design of Glun2C-targeting therapeutic strategies.

Focal malformations of cortical development (MCD) are important causes of severe pediatric drug-resistant epilepsies subjected to neurosurgery and associated with a spectrum of histological abnormalities. Here, we investigated the role of genetic postzygotic somatic mosaicism in MCD. We performed ultra-deep targeted gene sequencing on matched blood-brain samples of 120 patients with focal cortical dysplasia (FCD) or mild-MCD. We identified mTOR pathway hyperactivating somatic/germline/2-hit mutations in 54% of cases with FCD-II pathology. Somatic variant allele frequencies ranged between 0.4% and 34%, and correlated with the size of the lesion. By laser-capture-microdissection we demonstrated the somatic mutation enrichment in dysmorphic neurons and balloon cells, cytomegalic and mTOR hyperactive cells of neuronal and glial origin, thus suggesting that the mutation occurred in a common neuroglial progenitor. We also identified somatic loss-of-function mutations in the galactose transporter SLC35A2 (important for N-glycosylation) in 33% of mild-MCD cases, with mosaic rates between 12% and 43%. SLC35A2-cases showed white matter anomalies: heterotopic neurons and high-density clusters of oligodendroglial cells (a histological entity called MOGHE). By laser-capture-microdissection, we confirmed the mutation enrichment heterotopic neurons and oligodendrocytes from high-density clusters. Finally, in a cohort of 9 patients with confirmed somatic mutations in the brain tissue, we sequenced cell-free DNA from cerebrospinal fluid collected during neurosurgery and detected the somatic mutations at low mosaicism in 3/9 cases, providing a proof of concept for the presurgical genetic diagnosis in MCD. Our study shows that alterations in mTOR and N-glycosylation pathways are an important cause of a spectrum of focal epileptogenic MCDs.

Epilepsy is one of the most common neurological conditions, affecting ~50 million people worldwide. Brain insults can trigger pathogenic cellular events including cell death, chronic neuroinflammation, aberrant neurogenesis, and synaptic rewiring, which result in spontaneous seizures. These aberrant functions are usually the result of altered gene networks induced by the precipitating event; however, the full spectrum of such gene dysregulation remains unclear. MicroRNAs, a class of small non-coding RNAs involved in the regulation of gene expression at the post-transcriptional level, have previously been shown to regulate epileptogenic pathways. Nevertheless, how microRNAs shape the specific brain cells response to normal brain function and epilepsy-inciting events remains obscure. To address this, we generated transgenic mice that express a FLAG-tagged-Ago2 in neurons and microglia (using inducible Thy1 and CX3cr1 driven Cre-recombinase), allowing us to elute microRNAs from either neurons or microglia. By using the intra-amygdala kainic-acid technique, epileptogenesis was induced, and FLAG was immunoprecipitated from both lines followed by small RNA-Seq. As a result, the microRNA profiles of neurons and microglia and differential expression of microRNAs during epilepsy development were identified, allowing us to determine the role of specific microRNAs in epilepsy in specific cell types. This will be the most comprehensive *in vivo* map of microRNAs in adult mouse hippocampus, which will illuminate further the complex and nuanced role of microRNAs and individual cell types in epilepsy and in normal brain. Extrapolation of the contribution of specific cell types in epilepsy will facilitate the development of the most efficacious therapeutic targets.

Genome-wide analysis of DNA methylation in Hirschsprung enteric precursor cells: unraveling the epigenetic landscape of enteric nervous system development.
Hirschsprung disease (HSCR, OMIM 142623) is a rare congenital disorder that results from a failure to fully colonize the gut by enteric precursor cells (EPCs) derived from the neural crest. Such incomplete gut colonization is due to alterations in EPCs proliferation, survival, migration and/or differentiation during enteric nervous system (ENS) development. This complex process is regulated by a network of signaling pathways that is orchestrated by genetic and epigenetic factors, and therefore alterations at these levels can lead to the onset of neurocristopathies such as HSCR. The goal of this study is to broaden our knowledge of the role of epigenetic mechanisms in the disease context, specifically in DNA methylation. Therefore, with this aim, a Whole-Genome Bisulfite Sequencing assay has been performed using EPCs from HSCR patients and human controls. Clin Epigenetics, 2021; 13

RMRP, RMST, FTX and IPW: novel potential long non-coding RNAs in medullary thyroid cancer.
The relevant role of long non-coding RNAs (lncRNAs) in cancer is currently a matter of increasing interest. Medullary thyroid cancer (MTC) is a rare neuroendocrine tumor (2-5% of all thyroid cancer) derived from the parafollicular C-cells which secrete calcitonin. About 75% of all medullary thyroid cancers are believed to be sporadic medullary thyroid cancer (sMTC), whereas the remaining 25% correspond to inherited cancer syndromes known as Multiple Endocrine Neoplasia type 2 (MEN2). MEN2 syndrome, with autosomal dominant inheritance is caused by germline gain of function mutations in RET proto-oncogene. To date no lncRNA has been associated to MEN2 syndrome and only two articles have been published relating long non-coding RNA (lncRNA) to MTC: the first one linked MALAT1 with sMTC and, in the other, our group determined some new lncRNAs in a small group of sMTC cases in fresh tissue (RMST, FTX, IPW, PRNCR1, ADAMTS9-AS2 and RMRP). The aim of the current study is to validate such novel lncRNAs previously described by our group by using a larger cohort of patients, in

order to discern their potential role in the disease. Here we have tested three up-regulated (RMST, FTX, IPW) and one down-regulated (RMRP) lncRNAs in our samples (formalin fixed paraffin embedded tissues from twenty-one MEN2 and ten sMTC patients) by RT-qPCR analysis. The preliminary results reinforce the potential role of RMST, FTX, IPW and RMRP in the pathogenesis of MTC.

ChIP-Seq-Based Approach in Mouse Enteric Precursor Cells Reveals New Potential Genes with a Role in Enteric Nervous System Development and Hirschsprung Disease.
Hirschsprung disease (HSCR) is a neurocristopathy characterized by intestinal aganglionosis which is attributed to a failure in neural crest cell (NCC) development during the embryonic stage. The colonization of the intestine by NCCs is a process finely controlled by a wide and complex gene regulatory system. Several genes have been associated with HSCR, but many aspects still remain poorly understood. The present study is focused on deciphering the PAX6 interaction network during enteric nervous system (ENS) formation. A combined experimental and computational approach was performed to identify PAX6 direct targets, as well as gene networks shared among such targets as potential susceptibility factors for HSCR. As a result, genes related to PAX6 either directly (and) or indirectly (, , and) were identified as putative genes associated with HSCR. Interestingly, is involved in the RET/GDNF/GFRA1 signaling pathway, one of the main pathways implicated in the disease. Our findings represent a new contribution to advance in the knowledge of the genetic basis of HSCR. The investigation of the role of these genes could help to elucidate their implication in HSCR onset.

Identification of New Potential LncRNA Biomarkers in Hirschsprung Disease.
Hirschsprung disease (HSCR) is a neurocristopathy defined by intestinal aganglionosis due to alterations during the development of the Enteric Nervous System (ENS). A wide spectrum of molecules involved in different signaling pathways and mechanisms have been described in HSCR onset. Among them, epigenetic mechanisms are gaining increasing relevance. In an effort to better understand the epigenetic basis of HSCR, we have performed an analysis for the identification of long non-coding RNAs (lncRNAs) by qRT-PCR in enteric precursor cells (EPCs) from controls and HSCR patients. We aimed to test the presence of a set lncRNAs among 84 lncRNAs in human EPCs, which were previously related with crucial cellular processes for ENS development, as well as to identify the possible differences between HSCR patients and controls. As a result, we have determined a set of lncRNAs with positive expression in human EPCs that were screened for mutations using the exome data from our cohort of HSCR patients to identify possible variants related to this pathology. Interestingly, we identified three lncRNAs with different levels of their transcripts (, and) between HSCR patients and controls. We propose such lncRNAs as possible regulatory elements implicated in the onset of HSCR as well as potential biomarkers of this pathology.

Influencers on Thyroid Cancer Onset: Molecular Genetic Basis.
Thyroid cancer, a cancerous tumor or growth located within the thyroid gland, is the most common endocrine cancer. It is one of the few cancers whereby incidence rates have increased in recent years. It occurs in all age groups, from children through to seniors. Most studies are focused on dissecting its genetic basis, since our current knowledge of the genetic background of the different forms of thyroid cancer is far from complete, which poses a challenge for diagnosis and prognosis of the disease. In this review, we describe prevailing advances and update our understanding of the molecular genetics of thyroid cancer, focusing on the main genes related with the pathology, including the different noncoding RNAs associated with the disease.

What is new about the genetic background of Hirschsprung disease?
Hirschsprung disease (HSCR) is a rare congenital disorder caused by an incorrect enteric nervous system development due to a failure in migration, proliferation, differentiation and/or survival of enteric neural crest cells. HSCR is a complex genetic disease, where alterations at different molecular levels are required for the manifestation of the disease. In addition, a wide spectrum of mutations affecting many different genes cause HSCR, although the occurrence and severity of HSCR from many cases still remain unexplained. This review summarizes the current knowledge about molecular genetic basis of HSCR.
Clin Genet, 2020; 97

Epigenetic Mechanisms in Hirschsprung Disease.
Hirschsprung disease (HSCR, OMIM 142623) is due to a failure of enteric precursor cells derived from neural crest (EPCs) to proliferate, migrate, survive or differentiate during Enteric Nervous System (ENS) formation. This is a complex process which

requires a strict regulation that results in an ENS specific gene expression pattern. Alterations at this level lead to the onset of neurocristopathies such as HSCR. Gene expression is regulated by different mechanisms, such as DNA modifications (at the epigenetic level), transcriptional mechanisms (transcription factors, silencers, enhancers and repressors), postranscriptional mechanisms (3'UTR and ncRNA) and regulation of translation. All these mechanisms are finally implicated in cell signaling to determine the migration, proliferation, differentiation and survival processes for correct ENS development. In this review, we have performed an overview on the role of epigenetic mechanisms at transcriptional and posttranscriptional levels on these cellular events in neural crest cells (NCCs), ENS development, as well as in HSCR.

29290961: Torroglosa A, Villalba-Benito L, Fernández RM, Moya-Jiménez MJ, Antiñolo G, Borrego S
knock-down in enteric precursors reveals a possible mechanism by which this methyltransferase is involved in the enteric nervous system development and the onset of Hirschsprung disease.
Hirschsprung disease (HSCR, OMIM 142623) is a pathology that shows a lack of enteric ganglia along of the distal gastrointestinal tract. This aganglionosis is attributed to an abnormal proliferation, migration, differentiation and/or survival of enteric precursor cells (EPCs) derived from neural crest cells (NCCs) during the enteric nervous system (ENS) embryogenesis. DNMT3b methyltransferase is associated with NCCs development and has been shown to be implicated in ENS formation as well as in HSCR. In this study we have aimed to elucidate the specific mechanism underlying the DNMT3b role in such processes. We have performed the knockdown of expression (-KD) in enteric precursor cells (EPCs) to clarify its role on these cells . Moreover, we have analyzed several signaling pathways to determine the mechanisms responsible for the effect caused by -KD in EPCs. Our results seem to support that -KD promotes an increase EPCs proliferation that may be mediated by P53 and P21 activity, since both proteins were observed to be down-regulated in our -KD cultures. Moreover, we observed a down-regulation of and in HSCR patients. These results lead us to propose that DNMT3b could be involved in HSCR through P53 and P21 activity.

Overexpression of DNMT3b target genes during Enteric Nervous System development contribute to the onset of Hirschsprung disease.
Hirschsprung disease (HSCR) is attributed to a failure of neural crest cells (NCCs) to migrate, proliferate, differentiate and/or survive in the bowel wall during embryonic Enteric Nervous System (ENS) development. ENS formation is the result from a specific gene expression pattern regulated by epigenetic events, such DNA methylation by the DNA methyltransferases (DNMTs), among other mechanisms. Specifically, DNMT3b de novo methyltransferase is associated with NCCs development and has been shown to be implicated in ENS formation and in HSCR. Aiming to elucidate the specific mechanism underlying the DNMT3b role in such processes, we have performed a chromatin immunoprecipitation coupled with massively parallel sequencing analysis to identify the DNMT3B target genes in enteric precursor cells (EPCs) from mice. Moreover, the expression patterns of those target genes have been analyzed in human EPCs from HSCR patients in comparison with controls. Additionally, we have carried out a search of rare variants in those genes in a HSCR series. Through this approach we found 9 genes showing a significantly different expression level in both groups. Therefore, those genes may have a role in the proper human ENS formation and a failure in their expression pattern might contribute to this pathology.

[1]Institut du Cerveau - Paris Brain Institute - ICM, Sorbonne Université, Inserm, Cnrs, Hôpital De La Pitié Salpêtrière, Paris, France, [2]Service épilepsie et neurologie, Chu De Bordeaux, Bordeaux, France, [3]UCL Queen Square Institute of Neurology, Chalfont Centre For Epilepsy, Bucks, London, United Kingdom, [4]Université de Paris, service d'Anatomie Pathologique, Ap-hp, Hôpital Lariboisière, Dmu Dream, Umr 1141, Inserm, Paris, France, [5]American Memorial Hospital, Service de Pédiatrie, Chu Reims, Reims, France, [6]Epileptology Unit and Reference Center of Rare Epilepsies, Ap-hp, Pitié-salpêtrière Hospital, Paris, France, [7]EEG and Epilepsy Unit, Department Of Clinical Neurosciences, Geneva, Switzerland

Aims: Germline loss-of-function mutations in DEPDC5, and in its binding partners (NPRL2/3) of the mammalian target of rapamycin (mTOR) repressor GATOR1 complex, cause focal epilepsies and increase the risk of sudden unexpected death in epilepsy (SUDEP). Here, we asked whether DEPDC5 haploinsufficiency predisposes to primary cardiac defects that could contribute to SUDEP and therefore impact the clinical management of patients at high risk of SUDEP. **Methods:** Clinical cardiac investigations were performed in 16 patients with pathogenic variants in DEPDC5, NPRL2, or NPRL3. Two novel Depdc5 mouse strains, a human HA-tagged Depdc5 strain and a Depdc5 heterozygous knockout with a neuron-specific deletion of the second allele (Depdc5$^{c/-}$), were generated to investigate the role of Depdc5 in SUDEP and cardiac activity during seizures. **Results:** Holter, echocardiographic, and electrocardiographic (ECG) examinations provided no evidence for altered clinical cardiac function in the patient cohort, of whom 3 DEPDC5 patients succumbed to SUDEP and 6 had a family history of SUDEP. There was no cardiac injury at autopsy in a postmortem DEPDC5 SUDEP case. The HA-tagged Depdc5 mouse revealed expression of Depdc5 in the brain, heart, and lungs. Simultaneous electroencephalographic-ECG records on Depdc5$^{c/-}$ mice showed that spontaneous epileptic seizures resulting in a SUDEP-like event are not preceded by cardiac arrhythmia. **Conclusions:** Mouse and human data show neither structural nor functional cardiac damage that might underlie a primary contribution to SUDEP in the spectrum of DEPDC5-related epilepsies.

HETEROTOPIA SUBTYPE-SPECIFIC MORPHO-ELECTRIC AND CONNECTIVITY PROPERTIES UNDERLIE DISTINCT DYNAMICS OF EPILEPTIFORM ACTIVITY IN MURINE MODELS OF GREY MATTER HETEROTOPIA

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Jean-Christophe Vermoyal[1], Delphine Hardy[1], Lucas Goirand-Lopez[1], Lucas Silvagnoli[1], Antonin Vinck[1], Aurélien Fortoul[1], Fiona Francis[2,3,4], Silvia Cappello[5], Françoise Watrin[1], Thomas Marissal[1], Jean-Bernard Manent[1]
[1]INSERM - Aix-Marseille University, Inmed Umr-1249, Marseille, France, [2]Institut du Fer à Moulin, Cortical Development And Pathology, Paris, France, [3]Sorbonne Université, Sciences, Paris, France, [4]Inserm, U1270, Paris, France, [5]Max Planck Institute of Psychiatry, Developmental Neurobiology, Munich, Germany

Aims: Subcortical band heterotopia (SBH) and periventricular nodular heterotopia (PVNH) are two types of grey matter heterotopia (GMH) causing epilepsy. They present with misplaced neurons, either forming nodules lining the ventricles in PVNH, or forming bands in the white matter in SBH. Here, we compared epileptic circuitries in two murine models of SBH-like and PVNH-like malformations. **Methods**: We performed immunohistochemistry with cortical layer-specific markers to describe neuronal composition in heterotopia. We analyzed intrinsic electrophysiological and morphological properties of heterotopia neurons with whole-cell patch-clamp recordings and post-hoc neuronal reconstructions. We performed principal component analysis and clustering to identify morpho-electric signatures. We studied network excitability and dynamics of epileptiform activity with two-photon calcium imaging, and mapped microcircuits with laser scanning photostimulation of caged glutamate. **Results**: We show that SBH-like and PVNH-like malformations have distinct neuronal composition and histological properties, and are composed of neurons with peculiar morpho-electric properties. Among heterotopia models, we identified 3 morphotypes; two of them being mostly found in the SBH model, the other in the PVNH model. We also identified 2 model-specific electrotypes. In the two models, both the heterotopia and normotopic cortex contributed to epileptiform activity. The heterotopia was however recruited earlier than the normotopic cortex in the SBH model whereas no preference was found in the PVNH model. Last, we observed reciprocal functional connections between the heterotopia and normotopic cortex in the two GMH models. **Conclusions**: Our study will aid in our understanding of altered circuitry in cortical malformations causing epilepsy.

Aim: Focal cortical dysplasias (FCDs) are local malformations of the human neocortex and a leading cause of pharmacoresistant epilepsy. FCDs are characterized by local architectural disturbances of the neocortex and often feature a blurred gray-white matter boundary, indicating abnormal white matter myelination. We have recently shown that myelination is also compromised in the gray matter of FCD type IIa in the temporal lobe. In this study, we have analyzed the myelination pattern in FCD type IIa and IIb by focusing on the extratemporal cortical regions. Methods: We characterized the gray matter-associated myelination pathology of FCD IIa, FCD IIb and control specimens. We applied immunohistochemistry to visualize myelinated fibers and ultrastructural analyses of the myelin sheath. Furthermore, *in situ* hybridization was performed to analyze the density of myelinating oligodendrocytes (OLs) and PCR to determine the expression levels of myelin-associated transcripts. Results: We show that the proportion of myelinated gray matter is similar in FCD IIa, IIb and controls with myelinated fibers extending up to layer III. Electron microscopical analysis revealed that the myelin sheaths of layer V axons are significantly thinner in FCD IIa specimens than in controls. In addition, the density of OLs was reduced in FCD IIa, however, contrarily, we observed an increase of cells in FCD IIb. Similarly, the expression levels of myelin-associated transcripts were decreased in FCD IIa and increased in FCD IIb. Conclusion: The results indicate that the myelination pattern is disturbed in extratemporal FCD IIa and IIb cases, depending on the FCD type.

BRAIN REGION-SPECIFIC EPILEPTOGENESIS IN A CONDITIONAL MOUSE MODEL

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Jacqueline Bahr[1], Merle Harrer[1], Julia Schmierer[1], Henner Koch[2], Holger Lerche[1], Thomas Wuttke[1,3]
[1]University of Tuebingen, Germany, Hertie Institute For Clinical Brain Research, Tuebingen, Germany, [2]Aachen University, Universitätsklinikum Aachen, Aachen, Germany, [3]University of Tuebingen, Dept. Of Neurosurgery, Tuebingen, Germany

Genetic epilepsies show a large clinical features variability. Even when the same mutation occurs within a family, it often leads to a personal phenotype. This sparked the theory that a mutation induces a regional epileptogenic process which differs among patients causing distinct seizure types. A well-studied epilepsy gene is *SCN1A*, which encodes the voltage-gated sodium channel Na_V 1.1, expressed mainly in GABAergic interneurons throughout the central nervous system (CNS). Pathological variants cause Dravet syndrome (DS), a pharmacoresistant severe developmental and epileptic encephalopathy (DEE) with febrile seizures beginning in early childhood, high seizure frequency and delayed development. The early onset of this disorder suggests that factors in early brain development are crucial for phenotype formation. The most common genetic cause of Dravet syndrome is a loss-of-function (LOF) mutation in the *SCN1A* gene. This LOF leads to epilepsy through hyperexcitability of inhibitory neurons. In this work, a conditional LOF knock-in mouse line expressing a DS-causing mutation in the presence of Cre was used to study developmental and physiological aspects of epileptogenesis. This allowed us to turn on a specific genetic defect locally (in the S1 cortical area or in the hippocampus) and at defined time points (postnatal or adulthood). For this purpose, adeno-associated viruses encoding Cre recombinase were stereotaxically injected into the corresponding regions. We demonstrated that different types of seizures could be induced, which were dependent on both the area injected and the degree of maturation of the brain. Our results thus provide insight into the underlying mechanisms of epileptogenesis.

De Novo Pathogenic Variants in CACNA1E Cause Developmental and Epileptic Encephalopathy with Contractures, Macrocephaly, and Dyskinesias.
Developmental and epileptic encephalopathies (DEEs) are severe neurodevelopmental disorders often beginning in infancy or early childhood that are characterized by intractable seizures, abundant epileptiform activity on EEG, and developmental impairment or regression. CACNA1E is highly expressed in the central nervous system and encodes the α-subunit of the voltage-gated Ca2.3 channel, which conducts high voltage-activated R-type calcium currents that initiate synaptic transmission. Using next-generation sequencing techniques, we identified de novo CACNA1E variants in 30 individuals with DEE, characterized by refractory infantile-onset seizures, severe hypotonia, and profound developmental impairment, often with congenital contractures, macrocephaly, hyperkinetic movement disorders, and early death. Most of the 14, partially recurring, variants cluster within the cytoplasmic ends of all four S6 segments, which form the presumed Ca2.3 channel activation gate. Functional analysis of several S6 variants revealed consistent gain-of-function effects comprising facilitated voltage-dependent activation and slowed inactivation. Another variant located in the domain II S4-S5 linker results in facilitated activation and increased current density. Five participants achieved seizure freedom on the anti-epileptic drug topiramate, which blocks R-type calcium channels. We establish pathogenic variants in CACNA1E as a cause of DEEs and suggest facilitated R-type calcium currents as a disease mechanism for human epilepsy and developmental disorders.

Long-term adult human brain slice cultures as a model system to study human CNS circuitry and disease.
Most of our knowledge on human CNS circuitry and related disorders originates from model organisms. How well such data translate to the human CNS remains largely to be determined. Human brain slice cultures derived from neurosurgical resections may offer novel avenues to approach this translational gap. We now demonstrate robust preservation of the complex neuronal cytoarchitecture and electrophysiological properties of human pyramidal neurons in long-term brain slice cultures. Further experiments delineate the optimal conditions for efficient viral transduction of cultures, enabling 'high throughput' fluorescence-mediated 3D reconstruction of genetically targeted neurons at comparable quality to state-of-the-art biocytin fillings, and demonstrate feasibility of long term live cell imaging of human cells . This model system has implications toward a broad spectrum of translational studies, regarding the validation of data obtained in non-human model systems, for therapeutic screening and genetic dissection of human CNS circuitry.

CELL-TYPE SPECIFIC AND MOLECULAR CHARACTERIZATION OF DEPDC5-MEDIATED EPILEPSY

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Jacqunae Mays[1], James Okoh[1], Juan Oses-Prieto[2], Jin Park[1], Alma Burlingame[2], Jeannie Chin-Medina[1], Mauro Costa-Mattioli.[1]

Epilepsy affects over 60 million individuals worldwide and is characterized by unprovoked, recurrent seizures and cognitive deficits. Mutations in the DEP-domain-containing protein 5 (*DEPDC5)* gene are a major cause of focal epilepsy. Notably, over 60% of patients with *DEPDC5* mutations are nonresponsive to antiepileptic drugs. DEPDC5 negatively regulates mTORC1, a signaling network that integrates neuronal signals to promote cellular functions. However, the cell-types and molecular mechanism(s) by which DEPDC5-deficiency leads to abnormal, hypersynchronized activity in the brain remain elusive. Given that a) epilepsy is often characterized as a disorder caused by imbalance of excitatory and inhibitory inputs in the brain and b) a full understanding of the role of DEPDC5 in epilepsy requires its dissection at the cellular level, we generated mice lacking *Depdc5* in excitatory (*Depdc5* fb-KO) or inhibitory (*Depdc5 Gad2*-KO) neurons. Interestingly, both models exhibit hyperactive mTORC1 (and unchanged mTORC2 activity), seizures, and cognitive deficits. Importantly, *Depdc5* fb-KO (but not *Depdc5 Gad2*-KO) mice exhibit premature death and, thus, better recapitulate the sudden unexplained death in epilepsy (SUDEP) phenotype observed in patients with *DEPDC5* mutations. More importantly, the SUDEP, seizure and cognitive deficits in *Depdc5* fb-KO mice are fully suppressed by genetic (but not pharmacological) inhibition of mTORC1. Finally, using both phosphoproteomics and genomics, we began to decipher the mechanism by which loss of DEPDC5 leads to epilepsy. Our findings indicate that mTORC1 is the major driver of seizures and SUDEP associated with deficiency in DEPDC5. Moreover, new and selective mTORC1 inhibitors could represent effective therapies for *DEPDC5*-related disorders.

Therapeutic inhibition of mTORC2 rescues the behavioral and neurophysiological abnormalities associated with Pten-deficiency.
Dysregulation of the mammalian target of rapamycin (mTOR) signaling, which is mediated by two structurally and functionally distinct complexes, mTORC1 and mTORC2, has been implicated in several neurological disorders. Individuals carrying loss-of-function mutations in the phosphatase and tensin homolog (PTEN) gene, a negative regulator of mTOR signaling, are prone to developing macrocephaly, autism spectrum disorder (ASD), seizures and intellectual disability. It is generally believed that the neurological symptoms associated with loss of PTEN and other mTORopathies (for example, mutations in the tuberous sclerosis genes TSC1 or TSC2) are due to hyperactivation of mTORC1-mediated protein synthesis. Using molecular genetics, we unexpectedly found that genetic deletion of mTORC2 (but not mTORC1) activity prolonged lifespan, suppressed seizures, rescued ASD-like behaviors and long-term memory, and normalized metabolic changes in the brain of mice lacking Pten. In a more therapeutically oriented approach, we found that administration of an antisense oligonucleotide (ASO) targeting mTORC2's defining component Rictor specifically inhibits mTORC2 activity and reverses the behavioral and neurophysiological abnormalities in adolescent Pten-deficient mice. Collectively, our findings indicate that mTORC2 is the major driver underlying the neuropathophysiology associated with Pten-deficiency, and its therapeutic reduction could represent a promising and broadly effective translational therapy for neurological disorders where mTOR signaling is dysregulated.

mTORC2, but not mTORC1, is required for hippocampal mGluR-LTD and associated behaviors.
The mechanistic target of rapamycin complex 1 (mTORC1) has been reported to be necessary for metabotropic glutamate receptor-mediated long-term depression (mGluR-LTD). Here we found that mTORC1-deficient mice exhibit normal hippocampal mGluR-LTD and associated behaviors. Moreover, rapamycin blocks mGluR-LTD in mTORC1-deficient mice.

However, both rapamycin and mGluR activation regulate mTOR complex 2 (mTORC2) activity, and mTORC2-deficient mice show impaired mGluR-LTD and associated behaviors. Thus, mTORC2 is a major regulator of mGluR-LTD.

ATP6V1A, A KEY PLAYER FOR LYSOSOMAL FUNCTION AND AUTOPHAGY PROCESS, IS REQUIRED FOR NEURONAL DEVELOPMENT AND SYNAPTIC PLASTICITY

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Antonio Falace[1], Alessandro Esposito[2], Maria Cerullo[3], Sara Pepe[2], Katia Cortese[2], Valerio Conti[1], Fabio Benfenati[3,4], Renzo Guerrini[1], Anna Fassio[2,4]

ATP6V1A is a member of the vesicular-type adenosine triphosphate (v-ATPase), a ubiquitous multimeric complex that drive the transport of hydrogen ions upon ATP hydrolysis. In neurons, v-ATPase activity is also necessary for neurotransmitter loading into synaptic vesicles. Loss of function mutations in ATP6V1A have been described in patients with epileptic encephalopathy and metabolic disorders; downregulation of ATP6V1A have been recently reported has a hallmark of Alzheimer's disease. In fibroblasts derived from ATP6V1A patients we demonstrated defects in lysosomal homeostasis and autophagy. Yet the role of ATP6V1A in neuronal development and synaptic activity is largely unexplored. We modelled ATP6V1A loss by RNAi-knockdown in rat hippocampal neurons at different developmental stages. We evaluated the neuronal phenotypes by morphological analysis, immunolabelling with lysosomal, autophagy and synaptic markers and patch clamp recordings. Atp6v1a silencing resulted in impairment of neurite arborization and diminished number of glutamatergic synapses accompanied by a significant decrease in the frequency of miniature excitatory postsynaptic currents. These phenotypes were associated with lysosomal alterations and impaired autophagy. By challenging neurons with chemical LTP, we revealed that the autophagy boost followed by the upregulation of glutamatergic synapses were abolished in ATP6V1A silenced neurons compared to control neurons. The data suggest a pivotal role of ATP6V1A in the regulation of neuronal autophagy and in synaptic stabilization and plasticity.

Cortical malformations are associated with childhood-onset drug-resistant epilepsy for which surgery is the main therapeutic option to achieve seizure freedom. Focal cortical dysplasia type II (FCDII) is the most frequent cortical malformation among the epilepsy surgery population. FCDII is caused by brain somatic mTOR pathway-activating mutations that occured during neurodevelopment, which produce abnormal cytomegalic cells: dysmorphic neurons and balloon cells. Here we show by *in vitro* recordings of acute cortical slices from resected human FCDII cortex that epileptiform activity correlates with the density of mTOR-hyperactive dysmorphic neurons, supporting their pro-epileptogenic role. We discovered that human surgical FCDII brain tissues express molecular programs of cellular senescence, and further confirmed it at the protein and enzymatic levels, including p53/p16^{INK4A} expression and senescence-associated β-galactosidase activity, specifically in the abnormal cell types. In mTOR-hyperactive mouse models, cellular senescence hallmarks were also present alongside the production of a functional senescence-associated secretory phenotype (SASP). Administration of senolytic molecules that specifically eliminate senescent cells to an Mtor^{S2215F} FCDII mouse model, reduced both the density of dysmorphic-like neurons and the frequency of spontaneous seizures. Our results provide a proof-of-concept that targeting cellular senescence through senotherapy is an efficient approach to control seizures in a preclinical mouse model. These findings pave the way towards the development of ultra-precision medicine with the use of innovative therapeutic strategies selectively targeting mutated cells with a senescent phenotype, and possibly extend it to the spectrum of other 'mTORopathies'.

Gliosis is a prominent pathological finding in the epileptic brain. Recently, a growing number of studies suggest that microglia are not only involved in the inflammatory processes, but also monitor different functions of neurons. The somatic junction between microglia and neurons plays an important role in the latter. The morphology of microglia could refer to its function. In our study ramified, hypertrophic, dystrophic, amoeboid, and rod-shaped cells were distinguished. Six surgically removed epileptic cortices with type II focal cortical dysplasia (FCD) were compared to post-mortem control brains from the same cortical regions. Microglia were labeled with P2Y12 immunofluorescence, while neurons were marked with NeuN and their membrane with Kv2.1. The Kv2.1 potassium channel is part of the somatic junction. The densities of all microglia and the proportion of different features of morphologies were measured in layers 3, 5, and the white matter. Furthermore, in layer 3 the coverage of P2Y12-positive microglia were measured on neuronal somata. Our results show that although total density of microglia does not change in FCD compared to control, the proportion of dystrophic cells increases, primarily to the detriment of the ramified ones. In addition, mean microglial coverage is increased in FCD samples. Our results suggest that the functionality of microglia in FCD type II is impaired, causing the increase of dystrophic microglia. The somatic coverage may increase as compensation for the functional impairment. Our plan is the electron microscopic analysis of the microglia-neuron junction in FCD and further investigation of the brain macrophages.

Perisomatic innervation and neurochemical features of giant pyramidal neurons in both hemispheres of the human primary motor cortex.
Betz cells-the gigantopyramidal neurons found in high amount in the primary motor cortex-are among of the most characteristic neuronal cells. A part of them contains the calcium-binding protein parvalbumin (PV) in primates. However, less is known about these cells in the human motor cortex despite their important role in different neurological disorders. Therefore, the aim of our study was to investigate the neurochemical features and perisomatic input properties of Betz cells in control human samples with short post-mortem interval. We used different microscopic techniques to investigate the primary motor cortex of both hemispheres. The soma size and density, and expression of PV of the Betz cells were investigated. Furthermore, we used confocal fluorescent and electron microscopy to examine their perisomatic input. The soma size and density showed moderate variability among samples and hemispheres. Post-mortem interval and hemispherical localization did not influence these features. Around 70% of Betz cells expressed PV, but in less intensity than the cortical interneurons. Betz neurons receive dense perisomatic input, which are mostly VIAAT- (vesicular inhibitory amino acid transporter) and PV immunopositive. In the electron microscope, we found PV-immunolabelled terminals with asymmetric-like synaptic structure, too. Terminals with morphologically similar synaptic specialisation were also found among vGluT2- (vesicular glutamate transporter type 2) immunostained terminals contacting Betz cells. Our data suggest that Betz cells' morphological properties showed less variability among subjects and hemispheres than the density of them. Their neurochemical and perisomatic input characteristics support their role in execution of fast and precise movements.

Focal cortical dysplasia is the most common cause of drug-resistant epilepsy in the pediatric population and the second to third most common etiology in adults, creating a need for further investigation and development of new therapeutic strategies. Several genetic variants underlying malformations of cortical development and epilepsy have been identified, and a familial recessive loss of function in the gene *Cntnap2* was shown to give rise to cortical dysplasia with neurodevelopmental regression after onset of drug-resistant seizures, known as cortical dysplasia-focal epilepsy (CDFE) syndrome. Mice lacking functional *Cntnap2* expression show postnatal features akin to CDFE, such as hyperactivity and deficits in three core ASD behavioral domains, and develop spontaneous seizures around 6 months of age. Using continuous intracranial video-EEG, with bilateral recordings from hippocampus or hippocampus and cortex, after six months of age, we have identified the hippocampus as a potential origin for spontaneous recurrent seizures and an association between an increased number of interictal epileptiform discharges (IED) and seizures. Increased locomotor activity in the open field was still present in *Cntnap2* knock-out (KO) mice after seizure onset while the increase in self-grooming seen at 4-months was decreased after seizure onset. We found no differences in performance of memory tests, either short-term (object location task, after 20 minutes) or long-term (novel object recognition, 24 hours) between WT and *Cntnap2* KO mice at 4 months, while *Cntnap2* KO mice at 7-months, after seizure onset had a significantly decreased discrimination ratio.

Human stem cell-derived GABAergic neurons functionally integrate into human neuronal networks.
Gamma-aminobutyric acid (GABA)-releasing interneurons modulate neuronal network activity in the brain by inhibiting other neurons. The alteration or absence of these cells disrupts the balance between excitatory and inhibitory processes, leading to neurological disorders such as epilepsy. In this regard, cell-based therapy may be an alternative therapeutic approach. We generated light-sensitive human embryonic stem cell (hESC)-derived GABAergic interneurons (hdIN) and tested their functionality. After 35 days in vitro (DIV), hdINs showed electrophysiological properties and spontaneous synaptic currents comparable to mature neurons. In co-culture with human cortical neurons and after transplantation (AT) into human brain tissue resected from patients with drug-resistant epilepsy, light-activated channelrhodopsin-2 (ChR2) expressing hdINs induced postsynaptic currents in human neurons, strongly suggesting functional efferent synapse formation. These results provide a proof-of-concept that hESC-derived neurons can integrate and modulate the activity of a human host neuronal network. Therefore, this study supports the possibility of precise temporal control of network excitability by transplantation of light-sensitive interneurons.

Human Stem Cell-Derived GABAergic Interneurons Establish Efferent Synapses onto Host Neurons in Rat Epileptic Hippocampus and Inhibit Spontaneous Recurrent Seizures.
Epilepsy is a complex disorder affecting the central nervous system and is characterised by spontaneously recurring seizures (SRSs). Epileptic patients undergo symptomatic pharmacological treatments, however, in 30% of cases, they are ineffective, mostly in patients with temporal lobe epilepsy. Therefore, there is a need for developing novel treatment strategies. Transplantation of cells releasing γ-aminobutyric acid (GABA) could be used to counteract the imbalance between excitation and inhibition within epileptic neuronal networks. We generated GABAergic interneuron precursors from human embryonic stem cells (hESCs) and grafted them in the hippocampi of rats developing chronic SRSs after kainic acid-induced status epilepticus. Using whole-cell patch-clamp recordings, we characterised the maturation of the grafted cells into functional GABAergic interneurons in the host brain, and we confirmed the presence of functional inhibitory synaptic connections from grafted cells onto the host neurons. Moreover, optogenetic stimulation of grafted hESC-derived interneurons reduced the rate

of epileptiform discharges in vitro. We also observed decreased SRS frequency and total time spent in SRSs in these animals in vivo as compared to non-grafted controls. These data represent a proof-of-concept that hESC-derived GABAergic neurons can exert a therapeutic effect on epileptic animals presumably through establishing inhibitory synapses with host neurons.

Leaky Optoelectrical Fiber for Optogenetic Stimulation and Electrochemical Detection of Dopamine Exocytosis from Human Dopaminergic Neurons.
In Parkinson's disease, the degeneration of dopaminergic neurons in substantia nigra leads to a decrease in the physiological levels of dopamine in striatum. The existing dopaminergic therapies effectively alleviate the symptoms, albeit they do not revert the disease progression and result in significant adverse effects. Transplanting dopaminergic neurons derived from stem cells could restore dopamine levels without additional motor complications. However, the transplanted cells disperse in vivo and it is not possible to stimulate them on demand to modulate dopamine release to prevent dyskinesia. In order to address these issues, this paper presents a multifunctional leaky optoelectrical fiber for potential neuromodulation and as a cell substrate for application in combined optogenetic stem cell therapy. Pyrolytic carbon coated optical fibers are laser ablated to pattern micro-optical windows to permit light leakage over a large area. The pyrolytic carbon acts as an excellent electrode for the electrochemical detection of dopamine. Human neural stem cells are genetically modified to express the light sensitive opsin channelrhodopsin-2 and are differentiated into dopaminergic neurons on the leaky optoelectrical fiber. Finally, light leaking from the micro-optical windows is used to stimulate the dopaminergic neurons resulting in the release of dopamine that is detected in real-time using chronoamperometry.

MICROGLIA-SPECIFIC KNOCKDOWN OF CORE CLOCK GENE BMAL1 LEADS TO AN ALTERED BEHAVIOURAL PHENOTYPE AND INCREASED SUSCEPTIBILITY TO SEIZURES IN MICE

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Background: Despite technological advances, epilepsy remains an unsolved clinical issue. Brain inflammation, which is mostly mediated by microglial cells, is a known feature in epilepsy and contributor to the development of spontaneous seizures. Immunity and the inflammatory response is highly regulated by the circadian rhythm; i.e. the 24 hour internal clock governing physiological function via a series of autoregulatory transcriptional-translational feedback loops. Here we explored the impact of the microglial-specific core circadian gene (Bmal1) deletion on behavioural phenotype and seizure susceptibility in mice. **Methods:** Twenty male and female adult Bmal1-Cx3CR1Cre-ER mice bred inhouse were injected with either tamoxifen or vehicle daily (40 mg/kg; IP; 10 days) to induce microglial-specific Bmal1 deletion. Two weeks after recombination, mice underwent a battery of behavioural tests which was analysed via AnyMaze software. A separate cohort was implanted with electrodes for electroencephalographic (EEG) recordings and after recovery underwent the injection of a sub-convulsant dose of kainic acid (KA; IP; 15 mg/kg) to test seizure susceptibility. **Results:** Mice with Bmal1 microglial deletion (KO) displayed a hyperactive behavioural phenotype when compared to their littermate controls. Bmal1-KOs had an increased susceptibility to develop seizures and a significantly increased seizure severity measured by the total EEG power after KA administration at a dose that would not usually trigger seizures in naïve mice. **Conclusions**: Microglial-specific depletion of Bmal1 led to a disrupted behavioural and seizure phenotype in otherwise normal mice. Further studies using long-term EEG will allow to us understand how Bmal1 disruption contributes to the development of epilepsy.

Pediatric Intensive Care: Immunomodulation With Activated Protein C .

Sepsis is major cause of morbidity and mortality in the Pediatric Intensive Care Unit (PICU). PICU patients may develop transient immune deficiency during sepsis. Activated Protein C (APC) has significant anti-inflammatory and cytoprotective effects. Clinical trials of APC in adult sepsis initially showed improved outcome but recent trials showed no benefit in adults or children. We aimed to assess the effects of APC treatment on innate immune responses in children. We compared neutrophil and monocyte responses to lipopolysaccharide (LPS) with and without APC treatment in PICU patients at the time of evaluation for sepsis compared with healthy adults and age-matched pediatric controls. We used flow cytometry to examine cell activation (CD11b expression), function [intracellular reactive oxygen intermediate (ROI) release] and LPS recognition [Toll like Receptor 4 (TLR4) expression]. PICU patients had significantly decreased protein c levels and LPS responses compared with adult and pediatric controls for all parameters. APC reduced LPS-induced neutrophil PICU TLR4 and adult ROI (< 0.05). PICU non-survivors had increased LPS induced neutrophil and monocyte ROI production vs. survivors which was significantly reduced by APC. PICU patients demonstrate significantly reduced endotoxin reactivity which may predispose them to sepsis and alter effective antibacterial responses. APC reduces LPS-induced ROI production in adults and may have a role in treating severely compromised PICU patients especially given that newer APC forms are associated with decreased bleeding risk and enhanced anti-inflammatory effects.

Neonatal Encephalopathy: Need for Recognition of Multiple Etiologies for Optimal Management.
Neonatal encephalopathy (NE) is associated with high mortality and morbidity. Factors predisposing to NE can be antenatal, perinatal, or a combination of both. Antenatal maternal factors, familial factors, genetic predisposition, hypoxic ischemic encephalopathy, infections, placental abnormalities, thrombophilia, coagulation defects, and metabolic disorders all have been implicated in the pathogenesis of NE. At present, therapeutic hypothermia is the only treatment available, regardless of etiology. Recognizing the etiology of NE involved can also guide investigations such as metabolic and sepsis workups to ensure optimal management. Understanding the etiology of NE may allow the development of targeted adjunctive therapies related to the underlying mechanism and develop preventative strategies.

Altered inflammasome activation in neonatal encephalopathy persists in childhood.
Neonatal encephalopathy (NE) is characterized by altered neurological function in term infants and inflammation plays an important pathophysiological role. Inflammatory cytokines interleukin (IL)-1β, IL-1ra and IL-18 are activated by the nucleotide-binding and oligomerization domain (NOD)-, leucine-rich repeat domain (LRR)- and NOD-like receptor protein 3 (NLRP3) inflammasome; furthermore, we aimed to examine the role of the inflammasome multiprotein complex involved in proinflammatory responses from the newborn period to childhood in NE. Cytokine concentrations were measured by multiplex enzyme-linked immunosorbent assay (ELISA) in neonates and children with NE in the absence or presence of lipopolysaccharide (LPS) endotoxin. We then investigated expression of the NLRP3 inflammasome genes, NLRP3, IL-1β and

ASC by polymerase chain reaction (PCR). Serum samples from 40 NE patients at days 1 and 3 of the first week of life and in 37 patients at age 4-7 years were analysed. An increase in serum IL-1ra and IL-18 in neonates with NE on days 1 and 3 was observed compared to neonatal controls. IL-1ra in NE was decreased to normal levels at school age, whereas serum IL-18 in NE was even higher at school age compared to school age controls and NE in the first week of life. Percentage of LPS response was higher in newborns compared to school-age NE. NLRP3 and IL-1β gene expression were up-regulated in the presence of LPS in NE neonates and NLRP3 gene expression remained up-regulated at school age in NE patients compared to controls. Increased inflammasome activation in the first day of life in NE persists in childhood, and may increase the window for therapeutic intervention.

Newly regenerated axons via scaffolds promote sub-lesional reorganization and motor recovery with epidural electrical stimulation.
Here, we report the effect of newly regenerated axons via scaffolds on reorganization of spinal circuitry and restoration of motor functions with epidural electrical stimulation (EES). Motor recovery was evaluated for 7 weeks after spinal transection and following implantation with scaffolds seeded with neurotrophin producing Schwann cell and with rapamycin microspheres. Combined treatment with scaffolds and EES-enabled stepping led to functional improvement compared to groups with scaffold or EES, although, the number of axons across scaffolds was not different between groups. Re-transection through the scaffold at week 6 reduced EES-enabled stepping, still demonstrating better performance compared to the other groups. Greater synaptic reorganization in the presence of regenerated axons was found in group with combined therapy. These findings suggest that newly regenerated axons through cell-containing scaffolds with EES-enabled motor training reorganize the sub-lesional circuitry improving motor recovery, demonstrating that neuroregenerative and neuromodulatory therapies cumulatively enhancing motor function after complete SCI.

Altered Cytokine Endotoxin Responses in Neonatal Encephalopathy Predict MRI Outcomes.
Neonatal encephalopathy (NE) is associated with adverse neurodevelopmental outcome and is linked with systemic inflammation. Pro-inflammatory and anti-inflammatory cytokines are known to play a role in the pathology of NE by activating innate immune cells. Eighty-seven infants were enrolled including 53 infants with NE of whom 52 received therapeutic hypothermia (TH) and 34 term infant healthy controls (TC). Whole blood sampling was performed in the first 4 days of life, and a 14-spot ELISA Multiplex Cytokine Array was carried out on baseline samples or after stimulation with lipopolysaccharide (LPS) as an additional inflammatory stimulus. The cytokine medians were examined for differences between infants with NE and healthy TC; and then short-term outcomes of Sarnat stage, seizures, and MRI brain were examined within the NE group. The potential of LPS stimulation to predict abnormal MRI was explored using receiver operating characteristic (ROC) curves. At baseline, infants with NE had significantly higher levels of erythropoietin (Epo), interleukin (IL)-6, and IL-1ra and significantly lower vascular endothelial growth factor (VEGF) than had controls. All cytokines were increased after LPS stimulation in infants with NE with an excessive Epo and IL-1ra response than in controls. Infants with NE had lower IL-8, IL-2, IL-6, tumor necrosis factor (TNF)-α, granulocyte-macrophage colony-stimulating factor (GM-CSF), VEGF, and interferon (IFN)-γ than controls had following LPS. GM-CSF and IFN-γ, IL-1β, IL-1ra, and VEGF were higher on days 1-2 in NE infants with abnormal neuroimaging. GM-CSF, IFN-γ, and TNF-α levels with LPS stimulation were different upon stimulation between normal and abnormal neuroimaging. TNF-α is the only strong cytokine predictor both pre- and post-LPS stimulation of abnormal brain imaging. Altered cytokine responses are found in infants with NE vs. controls, and more significant differences are unmasked by the additional stimulus of LPS, which potentially improves the predictive power of these cytokines for the detection of abnormal MRIs. Infants with NE undergoing TH demonstrate both trained immunity and tolerance, and understanding these responses will facilitate adjunctive immunomodulatory treatments.

EARLY POSTNATAL TRANSPLANTATION OF HUMAN STEM CELL-DERIVED GABAERGIC INTERNEURONS IN CNTNAP2 KNOCK-OUT MICE

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Ana Gonzalez-Ramos, Fredrik Berglind, Kerstin Laurin, Diana Hatamian, Mohanad Hayatleh, Anja Vombergar, Marco Ledri, Merab Kokaia, My Andersson
Lund University, Epilepsy Centre, Clinical Sciences, Lund, Sweden

Focal cortical dysplasia (FCD) is a group of developmental malformations of the cortex manifesting as confined regions of pathology. We have explored a GABAergic cell-based replacement therapy in a mouse model of cortical dysplasia-focal epilepsy syndrome, Cntnap2-/- mice, targeting the hippocampus. Human embryonic stem cell (hESC)-derived interneurons (hdIN) were transplanted unilaterally to the dorsal hippocampus of postnatal day 2 (P2) Cntnap2-/- mice and behavioral tests assessing memory function, cognitive flexibility, anxiety, and locomotor activity were performed at 4- and 7-months of age, followed by 2 weeks of continuous video-EEG monitoring. Histological evaluation confirmed survival of hdINs at all time points studied, up to 9 months post-transplantation (PT), with hdINs migrating along the ipsi- and to the contralateral hippocampus and adjacent structures. However, cell-transplanted animals had increased IEDs and seizures compared to the sham- transplanted group, suggesting that hdIN transplantation does not prevent the development of epilepsy in this model, as hypothesized, but rather enhances it.

The Repressor Element 1 Silencing Transcription Factor (REST) is an epigenetic master regulator playing a crucial role in the nervous system. REST function was originally described in developmental stages, where it determines neuronal phenotype, however recent studies showed that REST participates in several processes also in the adult brain, including neuronal plasticity and epileptogenesis. In particular, whether REST prevents or promotes epileptogenesis is still debated. We here aim at tackling this issue through an *in vivo* characterization of transgenic murine lines where REST is deleted in specific cellular populations. First, we targeted the excitatory neuron population cloning the calcium/calmodulin-dependent protein kinase II (CaMKII) minimal promoter upstream of either the Cre recombinase or its inactive form. After assessing the specificity of promoter's expression, the transgenes were packaged in an innovative, engineered adeno-associated virus capsid (PHP.eB) able to cross the blood-brain and blood-cerebrospinal fluid barriers, and delivered in the lateral ventricles of 2-month-old $REST^{flox/flox}$ mice. We then characterized the cognitive phenotype (open field, novel object recognition, and social interaction tests) and the seizure propensity. We show that conditional REST knockout (REST-cKO) mice are more anxious, have short-term memory deficits, and are more social than control mice. On the other hand, behavioral evaluation of the susceptibility to epileptic seizures shows that REST-cKO mice are more resistant to chronic, but not acute, pentylenetetrazole (PTZ)-induced seizures, showing a milder phenotype. Overall, these data suggest that the absence of REST is sufficient to induce behavioral alterations and contributes to the progression of the epileptogenic process.

Protective role of mirtazapine in adult female Mecp2 mice and patients with Rett syndrome.
Rett syndrome (RTT), an X-linked neurodevelopmental rare disease mainly caused by MECP2-gene mutations, is a prototypic intellectual disability disorder. Reversibility of RTT-like phenotypes in an adult mouse model lacking the Mecp2-gene has given hope of treating the disease at any age. However, adult RTT patients still urge for new treatments. Given the relationship between RTT and monoamine deficiency, we investigated mirtazapine (MTZ), a noradrenergic and specific-serotonergic antidepressant, as a potential treatment.

Epilepsy, a neurological disorder that poses a major threat to public health and presents an enormous economic and social burden, is characterized by spontaneous recurrent seizures. Dysregulation of the mammalian target of rapamycin (mTOR), which functions via two distinct complexes named mTORC1 and mTORC2, has been causally linked to epilepsy. Currently, it is widely believed that hyperactivation of mTORC1, which is sensitive to the drug rapamycin, leads to abnormal network rhythmicity associated with epilepsy. Most of the evidence supporting the role for hyperactivation of mTORC1 in epilepsy relies on its chronic pharmacological inhibition with rapamycin. However, chronic rapamycin treatment, which reduces seizures in several epilepsy models, also inhibits mTORC2. We recently found that genetic inhibition of mTORC2, but not mTORC1, improved behavioral and neurophysiological deficits (including seizures) in mice lacking the mTOR upstream negative regulator, *Pten*. Thus, it remains unclear whether hyperactivation of mTORC1 or mTORC2 leads to abnormal synchronized neuronal firing during epilepsy. To dissect the role of mTOR complexes in epilepsy, we used molecular genetics to selectively silence the activity of either mTORC1 or mTORC2 in forebrain neurons. Starting with the kainic acid (KA) model of epilepsy, we found that selective genetic inhibition of mTORC1 increased acute seizures. Interestingly, we found that inhibition of mTORC2 reduced seizures not only in the KA model, but also in a wide range of epilepsy models. Taken together, these results suggest that mTORC2 is a central driver of seizures and inhibition of mTORC2 presents a novel and broadly applicable therapeutic target.

Prenatal High-Fat Diet Rescues Communication Deficits in Fmr1 Mutant Mice in a Sex-Specific Manner.
Using high-throughput analysis methods, the present study sought to determine the impact of prenatal high-fat dietary manipulations on isolation-induced ultrasonic vocalization production in both male and female Fmr1mutants on postnatal day 9. Prior to breeding, male FVB/129 Fmr1 wildtype and female Fmr1 heterozygous breeding pairs were assigned to 1 of 3 diet conditions: standard lab chow, omega-3 fatty acid-enriched chow, and a diet controlling for the fat increase. Prenatal exposure to omega-3 fatty acids improved reductions in the number of calls produced by Fmr1heterozygotes females. Moreover, diminished spectral purity in the female Fmr1homozygous mouse was rescued by exposure to both high-fat diets, although these effects were not seen in the male Fmr1knockout. Prenatal dietary fat manipulation also influenced several other aspects of vocalization production, such as the number of calls produced and their fundamental frequency, aside from effects due to loss of Fmr1.Specifically, in males, regardless of genotype, prenatal exposure to high omega-3s increased the average fundamental frequency of calls. These data support the need for future preclinical and clinical work elucidating the full potential of prenatal high-fat diets as a novel therapeutic alternative forFragile X syndrome.

Apical intercalated cell cluster: A distinct sensory regulator in the amygdala.
GABAergic neurons regulate different aspects of information processing in the amygdala. Among these are clusters of intercalated cells (ITCs), which have been implicated in fear-related behaviors. Although a few of the ITC clusters have been studied, the functional role of apical ITCs (apITCs) is unknown. Here, we combine monosynaptic rabies tracing with optogenetics and demonstrate that apITCs receive synaptic input from medial geniculate nucleus (MGm), posterior intralaminar nucleus (PIN), and medial dorsal nucleus of the thalamus and from a diverse range of cortical areas including temporal association, entorhinal, insular, piriform, and somatosensory cortex. Upon fear learning, PIN/MGm inputs are

strengthened, indicative of their involvement in fear behaviors. 3-D reconstruction of apITCs reveals local arborization and innervation of the dorsal striatum and lateral amygdala. We further show that apITCs provide sensory feedforward inhibition to LA principal cells, a putative mechanism for controlling plasticity during fear learning.

Dietary rescue of adult behavioral deficits in the Fmr1 knockout mouse.
The current study aimed to further address important questions regarding the therapeutic efficacy of omega-3 fatty acids for various behavioral and neuroimmune aspects of the Fmr1 phenotype. To address these questions, our experimental design utilized two different omega-3 fatty acid administration timepoints, compared to both standard laboratory chow controls ("Standard") and a diet controlling for the increase in fat content ("Control Fat"). In the first paradigm, post-weaning supplementation (after postnatal day 21) with the omega-3 fatty acid diet ("Omega-3") reversed deficits in startle threshold, but not deficits in prepulse inhibition, and the effect on startle threshold was not specific to the Omega-3 diet. However, post-weaning supplementation with both experimental diets also impaired acquisition of a fear response, recall of the fear memory and contextual fear conditioning compared to the Standard diet. The post-weaning Omega-3 diet reduced hippocampal expression of IL-6 and this reduction of IL-6 was significantly associated with diminished performance in the fear conditioning task. In the perinatal experimental paradigm, the Omega-3 diet attenuated hyperactivity and acquisition of a fear response. Additionally, perinatal exposure to the Control Fat diet (similar to a "Western" diet) further diminished nonsocial anxiety in the Fmr1 knockout. This study provides significant evidence that dietary fatty acids throughout the lifespan can significantly impact the behavioral and neuroimmune phenotype of the Fmr1 knockout model.

Deletion of ErbB4 Disrupts Synaptic Transmission and Long-Term Potentiation of Thalamic Input to Amygdalar Medial Paracapsular Intercalated Cells.
Identification of candidate risk genes and alteration in the expression of proteins involved in regulating inhibitory neuron function in various psychiatric disorders, support the notion that GABAergic neuron dysfunction plays an important role in disease etiology. Genetic variations in neuregulin and its receptor kinase ErbB4, expressed exclusively by GABAergic neurons in the CNS, have been linked with schizophrenia. In the amygdala, ErbB4 is highly expressed in GABAergic intercalated cell clusters (ITCs), which play a critical role in amygdala-dependent behaviors. It is however unknown whether ErbB4 deletion from ITCs affects their synaptic properties and function in amygdala circuitry. Here, we examined the impact of ErbB4 deletion on inhibitory and excitatory circuits recruiting medial paracapsular ITCs (mpITCs) using electrophysiological techniques. Ablation of ErbB4 in mpITCs suppressed NMDA receptor-mediated synaptic transmission at thalamo-mpITC synapses and enhanced thalamic driven GABAergic transmission onto mpITCs. Furthermore, long-term potentiation (LTP) at thalamo-mpITC synapses was compromised in ErbB4 mutant mice, indicating that ErbB4 activity is critical for LTP at these synapses. Together, our findings suggest that ErbB4 deletion from mpITCs disrupts excitation-inhibition balance and learning mechanisms in amygdala circuits.

A single early-life seizure results in long-term behavioral changes in the adult Fmr1 knockout mouse.
Fragile X syndrome (FXS) is the leading cause of inherited intellectual disability and a significant genetic contributor to Autism spectrum disorder. In addition to autistic-like phenotypes, individuals with FXS are subject to developing numerous comorbidities, one of the most prevalent being seizures. In the present study, we investigated how a single early-life seizure superimposed on a genetic condition impacts the autistic-like behavioral phenotype of the mouse. We induced status epilepticus (SE) on postnatal day (PD) 10 in Fmr1 wild type (WT) and knockout (KO) mice. We then tested the mice in a battery of behavioral tests during adulthood (PD90) to examine the long-term impact of an early-life seizure. Our findings replicated prior work that reported a single instance of SE results in behavioral deficits, including increases in repetitive behavior, enhanced hippocampal-dependent learning, and reduced sociability and prepulse inhibition ($p < 0.05$). We also observed genotypic differences characteristic of the FXS phenotype in Fmr1 KO mice, such as enhanced prepulse inhibition and repetitive behavior, hyperactivity, and reduced startle responses ($p < 0.05$). Superimposing a seizure on deletion of Fmr1 significantly impacted repetitive behavior in a nosepoke task. Specifically, a single early-life seizure increased consecutive nose poking behavior in the task in WT mice ($p < 0.05$), yet seizures did not exacerbate the elevated stereotypy observed in Fmr1 KO mice ($p > 0.05$). Overall, these findings help to elucidate how seizures in a critical period of development can impact long-term behavioral manifestations caused by underlying gene mutations in Fmr1. Utilizing double-hit models, such as superimposing seizures on the Fmr1 mutation, can help to enhance our understanding of comorbidities in disease models.

A single seizure selectively impairs hippocampal-dependent memory and is associated with alterations in PI3K/Akt/mTOR and FMRP signaling.
A single brief seizure before learning leads to spatial and contextual memory impairment in rodents without chronic epilepsy. These results suggest that memory can be impacted by seizure activity in the absence of epilepsy pathology. In this study, we investigated the types of memory affected by a seizure and the time course of impairment. We also examined alterations to mammalian target of rapamycin (mTOR) and fragile X mental retardation protein (FMRP) signaling, which modulate elements of the synapse and may underlie impairment.

NEURAL BASES OF THE BODILY SELF AS REVEALED BY ELECTRICAL BRAIN STIMULATION IN EPILEPTIC PATIENTS

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Zoé Dary
Aix-Marseille Université, Lnc, Marseille, France

Introduction: It's been proposed that the bodily self, involving pre-reflective awareness of the body, relies on several bodily experiences, such as self-location, body ownership, agency, first-person perspective, and the perceptual body image. Electrical brain stimulation in patients with pharmacoresistant epilepsy or tumour allows functional brain mapping with a high spatial resolution. The aim of this study is to identify the neural bases of the bodily self from electrical brain stimulation data. **Method:** We conducted a retrospective analysis of 13 984 electrical brain stimulations in 220 patients with pharmaco-resistant epilepsy who underwent stereo-electroencephalography for presurgical evaluation between 2011 and 2020. **Results:** Twenty-nine patients reported a bodily self disturbance during electrical brain stimulation. Electrical brain stimulation mainly disturbed the body image, but also self-location and agency. Changes in the body self were mostly evoked by stimulation of the cingulate cortex, inferior parietal lobule and insula. **Discussion:** The neural bases of the bodily self, as revealed by electrical brain stimulation, are localised in parietal, insular and cingulate regions known to integrate sensory afferents. These regions differ from the cortices involved in reflexive and cognitive levels related to self-representations.

THE N6-METHYLADENOSINE RNA METHYLATION MACHINERY, A POTENTIAL THERAPEUTIC TARGET FOR TEMPORAL LOBE EPILEPSY

POSTER SESSION 04 - SECTION: EPILEPSY AND EPILEPTOGENESIS

Justine Mathoux[1,2], David Henshall[1,2], Gary Brennan[1,3]
[1]Royal College of Surgeon in Ireland, Futureneuro Sfi Research Centre For Chronic And Rare Neurological Diseases, Dublin, Ireland, [2]Royal College of Surgeon in Ireland, Physiology, Dublin, Ireland, [3]University College Dublin, School Of Biomolecular And Biomedical Science. Conway Institute, Dublin, Ireland

Temporal Lobe epilepsy is the most severe form of epilepsy in adults. Around 30% of patients are refractory to treatment, hence the need to improve treatments. Epileptogenesis is the period following a brain injury during which the brain becomes epileptic through several molecular and cellular changes potentially driven by gene expression. N6-methyladenosine (m^6A) RNA methylation is the most abundant RNA modification which can drastically alter translational efficiency and mRNA stability. The modification is catalyzed by m^6A writers including METTL3, reversed by m^6A erasers (FTO and ALKBH5) and recognized by m^6A readers like YTHDF2. m^6A is involved in important neurological processes and appears dysregulated in many pathologies like Alzheimer's disease. However, its contribution during epileptogenesis and epilepsy is unknown. Using the intra-amygdala Kainic acid mouse model of epilepsy, we investigate if m^6A methylation processes are disturbed during epileptogenesis and in epilepsy. We assess variation in m^6A machinery protein and RNA levels in hippocampal extracts by western blot and qPCR and then, profile m^6A across the transcriptome using m^6A MeRIP-sequencing. Our data indicates an increase of METTL3 protein levels and m^6A methylation during epileptogenesis. MeRIP-seq revealed extensive differential methylation across the entire transcriptome and an increase of m^6A levels during epileptogenesis. Our results suggest that the m^6A methylation processes are perturbed during epileptogenesis and may contribute to the pathogenic gene dysregulation observed in epilepsy. Further investigation is needed to understand the influence of m^6A modification during epileptogenesis and to assess its inhibition as a new treatment strategy for epilepsy.

BRAF HYPERACTIVATING MUTATION IN FOREBRAIN GABAERGIC INTERNEURONS INCREASES ANXIETY AND IMPAIRS WORKING MEMORY IN MICE

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Jeimmy Cerón[1], Oliver Stork[1,2]
[1]Otto-von-Guericke-University Magdeburg, Institute Of Biology, Magdeburg, Germany, [2]Otto-von-Guericke Universität, Center For Behavioral Brain Sciences, Magdeburg, Germany

Congenital changes leading to aberrant up-regulation of the Ras-mitogen activated protein kinase (Ras/MAPK) signaling cascade can cause a family of developmental disorders collectively called RASopathies. These conditions affect approximately 1 in 1000 individuals and share an overlapping pattern of physical abnormalities (e.g. craniofacial dysmorphology, cardiac malformations) and a variable degree of cognitive impairment. The identification of specific treatments for the RASopathy-associated neurocognitive deficits is still hampered by the lack of understanding of the underlying neuronal mechanisms. Aiming to increase our comprehension of the specific contributions of individual cell types to the neurocognitive alterations found in RASopathies, a conditional mutant mouse was generated with a selected knock-in hyperactivating mutation of the BRAF gene (a central component of the Ras/MAPK pathway) exclusively in forebrain GABAergic interneurons ($BRAF^{Q241R floxed/wt}$-$DLX5/6^{Cre/+}$or DBRAF mice) and its effects on cognitive and emotional behavior were characterized. We observed that DBRAF mice exhibit a strong anxiety phenotype in both the elevated plus maze and the open field tasks, as well as a pronounced deficit in working memory, indicated by reduced spontaneous alternation in the Y-maze task. Additionally, preliminary results suggest that DBRAF mice exhibit a hypoactivation of cells in the granular layer of the dentate gyrus in both dorsal and ventral hippocampus (measured through a cFos immunostaining) 1.5 hours after being tested in the elevated plus maze. These results reveal a potential role of the Ras/MAPK signaling in GABAergic interneurons in the emergence of anxiety and cognitive dysregulations and might contribute to the identification of new potential therapeutic intervention sites. Human endogenous retroviruses (HERVs) are elements derived from exogenous retroviral infections throughout the evolution of the genome. Evidence implicates elevated expression of HERV type W envelope (ENV) in psychotic disorders, including schizophrenia and bipolar disorder. To gain insights, we generated and characterized a novel mouse model mimicking transgenic expression of this retroviral element in mice. We generated transgenic mice expressing HERV-W ENV under the CAG promoter. Adult transgenic (TG) mice and wild-type (WT) littermates were subjected to behavioral and cognitive tetsung to asses basal locomotor activity, innate anxiety-like behavior, social approach behavior and social recognition memory, sensorimotor gating, and novel object recognition. RNA sequencing of hippocampus was used to identify transcriptional changes in TG mice relative to WT. Through ingenuity pathway analysis (IPA) signaling pathways affected by HERV-W ENV was explored. TG mice displayed behavioral and cognitive anomalies compared to Wt mice; increased locomotor activity in novel environments, impairments in social recognition memory and novel object recognition, and deficits in prepulse inhibition of the acoustic startle reflex. We found 199 genes to be deregulated in the hippocampus of TG mice relative to WT; several genes previously identified as genetic risk variants for schizophrenia and other psychotic disorders. IPA demonstrated that those genes annotated with the functional nodes “neurodevelopmental disorders”, “schizophrenia”, “quantity of dendritic spines” and “synapse formation”. Our data provides causal evidence for HERV-W ENV expression in disrupting behavioral and cognitive functions implicated in schizophrenia. Moreover, we demonstrate that expression of HERV-W ENV has the capacity to change the brain transcriptome and deregulate genes associated with schizophrenia and other psychiatric disorders.

In Fetal Alcohol Spectrum Disorders (FASD), patients with Fetal Alcohol Syndrome (FAS) or without specific diagnostic features (non-syndromic, NS-FASD) show global brain growth insufficiency. However, some regions were proposed to be more severely reduced, especially the cerebellum. Considering changes in proportions with size (allometric scaling), we sought to specify the cerebellar and intracerebellar damage in paediatric FASD. We applied an original pipeline of cerebellar segmentation (*CERES* combined with *SUIT* to add the vermis) on 3DT1 brain MRI of 52 FAS, 37 NS-FASD and 126 controls (6-20y/o), providing 8 sub-volumes. After covariate (age, sex, site) correction, the scaling relationship ($V_i=bV_t^a$) between these sub-volumes (V_i) and the total brain or cerebellum volume (V_t) enabled us to compared FAS to controls (α=0.05). The cerebellum volume presented negative allometric scaling (a=0.38<<1) in controls, but proportional one (a=0.91»1) in FAS. Five sub-volumes (anterior and posterior hemispheres, whole, anterior, and inferior vermis) showed different intra-cerebellum scaling in FAS than controls. The mean difference between observed sub-volumes in FAS and expected ones according to the scaling law fitted in controls, revealed an anterior-inferior-posterior gradient of severity of volume reduction for the hemispheres (positive-null-negative respectively) and for the vermis (decreasingly negative). For the same five sub-volumes, there were a significant excess of patients with too-small values (<2.5percentile of the scaling distribution of controls) in FAS, but also in NS-FASD. Our study described whole-cerebellum anterior-inferior-posterior gradients of volume reduction in FAS. Furthermore, the recurrent abnormalities identified in FAS were also found in NS-FASD, suggesting a FASD neuroanatomical signature.

EFFECTS OF NEONATAL HYPOXIA ON THE DEVELOPMENT OF SEROTONERGIC INNERVATION AND COGNITIVE FUNCTIONS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Karen Lee[1,2], Bidisha Chattopadhyaya[1,2], Antônia Fernandes Do Nascimento[2], Bénédicte Amilhon[1,2], Graziella Di Cristo[1,2]
[1]Université de Montréal, Neuroscience, Montréal, Canada, [2]CHU Sainte-Justine Research Center, Neuroscience, Montréal, Canada

Recent studies suggest that children who experienced mild perinatal hypoxia(MPH), prolonged oxygen deprivation at birth, show long lasting subtle cognitive and behavioral deficits, increasing the risk of learning disabilities, emotional problems or ASD, which becomes more apparent as the child develops. However, not only are the mechanisms underlying MPH not well understood, whether serotonin(5-HT) dysregulations contribute to MPH-induced cognitive problems is also unclear.
We have recently established a MPH mouse model, showing long-term deficits in cognitive flexibility, social interaction, and memory. To investigate whether MPH affects 5-HT system development, we characterized 5-HT expression levels and innervation in the auditory and prefrontal cortex of female and male MPH mice. Immunohistochemistry data suggest 5-HT expression is reduced in adult MPH mice especially in the prefrontal cortex. In addition, HPLC-based quantification revealed altered levels of HIAA or 5-HT in the hippocampus of MPH mice. Assessment of body temperature regulation following pharmacological 5-HT modulation by 5-HT1A receptor agonist also demonstrates deficits in 5-HT auto-receptor function on raphe neurons in MPH mice. Adult MPH mice of both sexes display recognition and spatial memory impairments, social deficits, and dysfunctional cognitive flexibility, but normal anxiety-related behaviour. Chronic treatment with SSRI or 5-HT1A receptor agonist rescues cognitive flexibility and memory impairments observed in MPH mice.
Identifying MPH effects on serotonergic system development will lead to a better understanding of how social, attention, cognitive flexibility and memory dysfunctions associated with MPH occur and may pave a path towards the development of pharmacological strategies for treating children exposed to MPH.

Gating of long-term potentiation (LTP) in the thalamocortical auditory system of rats by serotonergic (5-HT) receptors.
The neuromodulator serotonin (5-hydroxytryptamine, 5-HT) plays an important role in controlling the induction threshold and maintenance of long-term potentiation (LTP) in the visual cortex and hippocampus of rodents. Serotonergic fibers also innervate the rodent primary auditory cortex (A1), but the regulation of A1 plasticity by 5-HT receptors (5-HTRs) is largely uncharted. Thus, we examined the role of several, predominant 5-HT receptor classes (5-HTRs, 5-HTRs, and 5-HTRs) in gating in vivo LTP induction at A1 synapses of adult, urethane-anesthetized rats. Theta-burst stimulation (TBS) applied to the medial geniculate nucleus resulted in successful LTP induction of field postsynaptic potentials (fPSPs) generated by excitation of thalamocortical and intracortical A1 synapses. Local application (by reverse microdialysis in A1) of the broad-acting 5-HTR antagonist methiothepin suppressed LTP at both thalamocortical and intracortical synapses. In fact, rather than LTP, TBS elicited long-term depression during methiothepin application, an effect that was mimicked by the selective 5-HTR antagonist ketanserin, but not the 5-HTR blocker WAY 100635. Interestingly, antagonism of 5-HTRs by granisetron selectively blocked LTP at thalamocortical, but not intracortical A1 synapses. Further, in the absence of TBS, granisetron application resulted in a pronounced increase in fPSP amplitude, suggesting that 5-HTRs play an important role in regulating baseline (non-potentiated) transmission at A1 synapses. Together, these results indicate that activation of 5-HTRs and 5-HTRs, but not 5-HTRs, exerts a clear, facilitating effect on LTP induction at A1 synapses, allowing 5-HT to act as a powerful regulator of long-term plasticity induction in the fully matured A1 of mammalian species.

UNRAVELLING THE ENDOPHENOTYPIC CHARACTERISTICS OF GENERATED GRIN-RELATED DISORDERS ZEBRAFISH MODELS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Sílvia Locubiche Serra[1,2], Mireia Olivella[3], Flavia De Santis[1], Xavier Altafaj[2], Davide Rubbini[1], Javier Terriente[1]
[1]ZeClinics, Institut De Recerca Germans Trias I Pujol (igtp), Badalona, Spain, [2]Universitat de Barcelona, Medical School, August Pi I Sunyer Biomedical Research Institute (idibaps), Barcelona, Spain, [3]Universitat de Vic - Universitat Central de Catalunya, Bioinformatics And Medical Statistics Group, Biosciences Department, Vic, Spain

NMDA-type ionotropic glutamate receptors play pivotal roles in synaptic development, plasticity, neural survival, and cognition. Recent advances on Next-Generation Sequencing revealed the association of *de novo* mutations affecting *GRIN* genes (encoding GluN subunits of the NMDAR) with neurodevelopmental disorders, so-called GRIN-related disorders (GRD). GRD is a rare condition with a clinical spectrum dictated by both the affected *GRIN* gene and the functional outcomes of the mutated residue/s, primarily affecting glutamatergic neurotransmission and causing synaptopathies. Accordingly, generation of an *in vivo* library is required to delineate the neurological alterations and ultimately to identify personalized therapeutic approaches for GRDs. In the context of GRD, zebrafish appear as an optimal animal model, since it provides several advantages from biomedical and industrial points of view.
To address this objective, CRISPR-Cas9-based genome editing technology has been applied for the obtention of knockout models of Zebrafish paralogous *GRIN1*, *GRIN2A* and *GRIN2B* genes. Single mutant larvae showed no effect on survival rate, and allowed to define the spatio-temporal expression pattern of *grin* genes in larval stages. Phenotypic assessments have been performed in pharmacological acute GRD models, revealing the presence of both behavioral and motor phenotypes, allowing the optimization of the behavioral paradigms of interest. Currently, the proposed procedure is being used to evaluate the generated GRD models. In the short term, the comprehensive phenotyping of Zebra-GRIN models will allow to define GRD-like alterations and, importantly, to evaluate the therapeutic efficacy of repurposed and EMA-approved putative NMDAR allosteric modulators, to ultimately allow personalized therapies for GRD patients.

L-Serine dietary supplementation is associated with clinical improvement of loss-of-function -related pediatric encephalopathy.
Autosomal dominant mutations in are associated with severe encephalopathy, but little is known about the pathophysiological outcomes and any potential therapeutic interventions. Genetic studies have described the association between de novo mutations of genes encoding the subunits of the -methyl-d-aspartate receptor (NMDAR) and severe neurological conditions. Here, we evaluated a missense mutation in , causing a proline-to-threonine switch (P553T) in the GluN2B subunit of NMDAR, which was found in a 5-year-old patient with Rett-like syndrome with severe encephalopathy. Structural molecular modeling predicted a reduced pore size of the mutant GluN2B-containing NMDARs. Electrophysiological recordings in a HEK-293T cell line expressing the mutated subunit confirmed this prediction and showed an associated reduced glutamate affinity. Moreover, GluN2B(P553T)-expressing primary murine hippocampal neurons showed decreased spine density, concomitant with reduced NMDA-evoked currents and impaired NMDAR-dependent insertion of the AMPA receptor subunit GluA1 at stimulated synapses. Furthermore, the naturally occurring coagonist d-serine restored function to GluN2B(P553T)-containing NMDARs. l-Serine dietary supplementation of the patient was hence initiated, resulting in the increased abundance of d-serine in the plasma and brain. The patient has shown notable improvements in motor and cognitive performance and communication after 11 and 17 months of l-serine dietary supplementation. Our data suggest that l-serine supplementation might ameliorate -related severe encephalopathy and other neurological conditions caused by glutamatergic signaling deficiency.

Disease-associated GRIN protein truncating variants trigger NMDA receptor loss-of-function.

De novo GRIN variants, encoding for the ionotropic glutamate NMDA receptor subunits, have been recently associated with GRIN-related disorders, a group of rare paediatric encephalopathies. Current investigational and clinical efforts are focused to functionally stratify GRIN variants, towards precision therapies of this primary disturbance of glutamatergic transmission that affects neuronal function and brain. In the present study, we aimed to comprehensively delineate the functional outcomes and clinical phenotypes of GRIN protein truncating variants (PTVs)-accounting for ~20% of disease-associated GRIN variants-hypothetically provoking NMDAR hypofunctionality. To tackle this question, we created a comprehensive GRIN PTVs variants database compiling a cohort of nine individuals harbouring GRIN PTVs, together with previously identified variants, to build-up an extensive GRIN PTVs repertoire composed of 293 unique variants. Genotype-phenotype correlation studies were conducted, followed by cell-based assays of selected paradigmatic GRIN PTVs and their functional annotation. Genetic and clinical phenotypes meta-analysis revealed that heterozygous GRIN1, GRIN2C, GRIN2D, GRIN3A and GRIN3B PTVs are non-pathogenic. In contrast, heterozygous GRIN2A and GRIN2B PTVs are associated with specific neurological clinical phenotypes in a subunit- and domain-dependent manner. Mechanistically, cell-based assays showed that paradigmatic pathogenic GRIN2A and GRIN2B PTVs result on a decrease of NMDAR surface expression and NMDAR-mediated currents, ultimately leading to NMDAR functional haploinsufficiency. Overall, these findings contribute to delineate GRIN PTVs genotype-phenotype association and GRIN variants stratification. Functional studies showed that GRIN2A and GRIN2B pathogenic PTVs trigger NMDAR hypofunctionality, and thus accelerate therapeutic decisions for this neurodevelopmental condition.

Absence of the astrocyte-specific membrane protein MLC1 is responsible for megalencephalic leukoencephalopathy with subcortical cysts (MLC), a rare and orphan type of leukodystrophy characterized by early-onset macrocephaly and progressive white matter vacuolation that lead to ataxia, spasticity, and cognitive decline. During postnatal development (from P5 to P15 in the mouse), MLC1 forms a membrane complex with GlialCAM (another astrocytic transmembrane protein) at the junctions between perivascular astrocytic processes. Perivascular astrocytic processes along with blood vessels form the gliovascular unit, where astrocytes participate to several brain vascular functions, including the integrity of the blood-brain barrier, the homeostasis between the brain and the immune system, the transfer of metabolites, and the regulation of cerebral blood flow. Those functions are relying on a specific molecular repertoire that is enriched in perivascular astrocytic processes. Despite MLC1 enrichment in this interface, its role in the physiology and development of the gliovascular unit was not previously known. Using the *Mlc1* knock-out mouse model of MLC, we demonstrated that MLC1 controls the postnatal development and organization of perivascular astrocytic processes, vascular smooth muscle cell contractility, neurovascular coupling, and intraparenchymal interstitial fluid clearance. Our data suggest that MLC is a developmental disorder of the gliovascular unit, and perivascular astrocytic processes and vascular smooth muscle cell maturation defects are primary events in the pathogenesis of MLC and therapeutic targets for this disease.

UNUSUAL DOUBLE MUTATION IN MECP2 AND CDKL5 GENES IN RETT-LIKE SYNDROME : EFFECT ON GENES EXPRESSION AND GENOTYPE PHENOTYPE CORRELATION

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Faiza Fakhfakh[1], Marwa Benjdila[1], Fatma Kamoun[2], Chahnez Triki[2]
[1]faculty of science university of sfax, Molecular And Functional Genetics Laboratory, Sfax, Tunisia, [2]CHU hedi chaker Sfax, Child Neurology Department, Sfax, Tunisia

Rett syndrome (RTT) is a neuro-developmental disorder affecting almost exclusively females and itdivided into classical and atypical forms of the disease. RTT-like syndrome was also described and presents anoverlapping phenotype of RTT. RTT-like syndrome has been associated with several genes including MECP2 andCDKL5 having common biological pathways and regulatory interactions especially during neural maturation andsynaptogenesis. We report patient with Rett-like syndrome for whom clinical features and their progression guided toward the screening of two candidate genes MECP2 and CDKL5 by sequencing. Severity score was evaluated by“Rett Assessment Rating Scale” (R.A.R.S.). Predictions of pahogenicity and functional effects used several bioinformatic tools and qRT-PCR was conducted to evaluate gene expression. Mutational screening revealed two mutations c.1065 C > A (p.S355R) in MECP2 gene and c.616G > A (p.D206N) mutation in CDKL5 gene in the patient with a high R.A.R.S. Bioinformatic investigations predicted a moderate effect of p.S355R in MECP2 gene but a more pathogenic one of p.D206N mutation inCDKL5. Effect of c.616 G > A mutation on structure and stability of CDKL5 mRNA was confirmed by qRT-PCR. Additionally, analysis of gene expression revealed a drastic effect of CDKL5 mutant on its MeCP2 and Dnmt1 substrates and also on its MYCN regulator. In conclusion, the co-existence of the two mutations in CDKL5 and MECP2 genes could explain the severe phenotype in our patient with RTT-Like and is consistent with the data related to the interactions of CDKL5 with MeCP2 and Dnmt1 proteins.

PHENOTYPE CHARACTERIZATION OF A ZEBRAFISH MODEL FOR THE STUDY OF KCNB1 IN DEVELOPMENTAL AND EPILEPTIC ENCEPHALOPATHIES

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Lauralee Robichon, Claire Bar, Lisa Lehmann, Solène Renault, Sorana Ciura, Edor Kabashi, Rima Nabbout
Institut Imagine, Translational Research For Neurological Disorders Laboratory, Paris, France

Developmental and epileptic encephalopathies (DEE) refer to a heterogeneous group of devastating neurodevelopmental and epileptic disorders diagnosed during early childhood. *De novo* variants in *KCNB1,* encoding a voltage-dependent potassium channel, have been reported in DEE patients by displaying loss of function properties. Therefore, we need to better comprehend pathophysiological cascades involving *KCNB1* in DEE pathogenesis. We functionally characterized a transgenic deletion mutant transgenic line targeting and inactivating the zebrafish orthologue of KCNB1 (*kcnb1* gene) to explore neuronal dysregulations in this model. Phenotypic, morphological analyses and electrophysiological recordings were performed during the early stages of development. In parallel, larvae were exposed to the proconvulsant pentylenetetrazol (PTZ) in order to evaluate the epileptogenic threshold of fish. The *kcnb1* knockout model does not reveal any morphological alterations in major organs compared to *kcnb1*+/- and wild-type larvae. However, uncontrolled swimming behavior was recorded at various stages of development (coiling, evoked and spontaneous swimming). PTZ treatment induced an increased and maintained swimming distance in both *kcnb1*+/- and *kcnb1*-/- larvae indicating a greater seizure-susceptibility. These data are in correlation with an increase of c-Fos positive neurons and by greater changes in electrophysiological recordings into the optic tectum of transgenic lines. The *kcnb1* knock-out zebrafish model presents a physiological and behavioral phenotype similar to previous genetic models of epilepsy. Therefore, this novel model will be a useful tool to decipher pathological mechanisms due to *kcnb1* mutations and can pave the way of new therapeutic development for this genetic cause of rare epilepsies and related DEE disorders.

Neurons and circuits maintain a constant excitation/inhibition (E/I) balance in response to fluctuations of input activity. $GABA_B$ receptors (GBRs) contribute to the control of the E/I balance by providing prolonged pre- and postsynaptic inhibition in response to ambient and synaptically released GABA. GBRs are obligatory heterodimers composed of GB1 and GB2 subunits. GB2 variants were identified in Rett syndrome ($GB2^{RTT}$/A567T) and epileptic encephalopathy ($GB2^{EE1}$/S695I, $GB2^{EE2}$/I705N) patients (Vuillaume et al., *Ann Neurol, 83*(2), 2018; Yoo et al., *Ann Neurol, 823*(3), 2017). Several GB1 variants (GB1/E368D, GB1/A397V, GB1/A535T and GB1/G673D) were recently identified in patients presenting mild to severe neurodevelopmental delay, epilepsy, intellectual disability, and psychiatric conditions (unpublished). We have functionally analyzed GB1 and GB2 variants in heterologous cells. Consistent with earlier data, we found that $GB2^{RTT}$/A567T and $GB2^{EE2}$/I705N reduce the efficacy of GABA, while $GB2^{EE1}$/S695I is unresponsive to GABA. All GB2 variants exhibit elevated constitutive activity and are partially blocked by the GBR inverse agonist CGP54626. The newly identified GB1/E368D reduces potency and efficacy of GABA, while GB1/E397V and GB1/A535T selectively reduce efficacy of GABA. GB1/G673D receptors are inactive, consistent with a lack of receptor expression at the cell surface. Epileptic seizures in several patients carrying GBR variants suggests that impaired receptor responses to GABA result in an E/I imbalance. Positive allosteric modulators (PAMs) of GBRs could potentially be used to increase potency and efficacy of GABA at the variant receptors. We therefore present a characterization of the activity of the PAM ADX71441 at receptor variants.

Aims: Understanding the shared genetic aetiology of psychiatric and medical comorbidity in neurodevelopmental disorders (NDDs) could improve patient diagnosis, stratification and treatment options. Rare TANC2 (Tetratricopeptide Repeat, Ankyrin Repeat and Coiled-Coil Containing 2) disrupting variants were pathogenic in NDD patients. This post-synaptic scaffold protein, essential for dendrite formation in synaptic plasticity, plays an unclarified but critical role in development and multi-organ expression suggests pleiotropic functions outside the brain. With focus on *Tanc2*, we aimed to illustrate the potential utility of the International Mouse Phenotyping Consortium (IMPC) preclinical database to identify medical comorbidity risk in NDDs due to pleiotropic gene function. **Methods:** We performed a comprehensive multi-systemic phenotyping analysis of a *Tanc2*$^{-em1/CRISPR/Cas}$ homozygous null mutant mouse model generated for the IMPC using CRISPR/Cas mutagenesis. **Results:** Mutant mice were hyperactive and had impaired sensorimotor gating consistent with NDD patient psychiatric endophenotypes. Yet, a multi-systemic analysis revealed growth failure, hepatocellular damage and aberrant liver function including altered hepatocellular metabolism. Integrative analysis indicates that these disrupted *Tanc2* systemic effects relate to interaction with Hippo developmental signalling pathway proteins and will increase the risk for comorbid somatic disease. **Conclusion:** This highlights how NDD gene pleiotropy can augment medical comorbidity susceptibility underscoring the benefit of holistic NDD patient diagnosis and treatment for which large-scale preclinical functional genomics in the IMPC can provide complementary pleiotropic gene function information.

Congenital hydrocephalus is a common heritable anomaly. Multiple PDZ domains (*Mpdz/Mupp1*) gene in implicated in some severe forms of the congenital hydrocephalus in human, associated with a differential diagnosis of hearing loss, often resulting in severe psychiatric, neurological and mental complications. However, the precise role of MPDZ in social-psychological disorders are unknown. Here, we have created two mice line with an absence of the MPDZ/MUPP1 protein only in the forebrain and / or auditory system without hydrocephalus phenotype. We subjected our mice models to a series of behavioural tests in relation to neurodevelopmental disorders such as intellectual disability, autism spectrum disorder as well as in relation to emotional and disruptive Disorders. We also analysed them during development in tasks requiring motor coordination, balance and motor skills. Our data identified the exact nature of emotional, cognitive and social behavioural disorders associated with hearing and vestibular dysfunction specifically linked to the MPDZ gene.

Pontocerebellar hypoplasia type 2 A (PCH2A) is a rare, severe neurodevelopmental disorder that is usually diagnosed shortly after birth. Symptoms include developmental delay, seizures, and deficits in motor control. Anatomically, PCH2A has as hallmarks a cerebellum and pons of reduced size, as well as a progressive small size of the cerebrum. PCH2A is characterized by a single point mutation in TSEN54, which encodes a protein required for tRNA splicing. Despite its unique genetic cause and stereotypical clinical manifestation, the pathological mechanism at the cellular and molecular level is currently unknown and treatment options are limited and symptomatic. We aim to address this gap in knowledge by investigating PCH2A pathology using human brain organoids of patient-derived induced pluripotent stem cells. We characterize the cellular developmental trajectories in cerebellar organoids, since it is the main brain region where hypoplasia is observed. Subsequently, we aim to determine cell type-specific molecular changes in PCH2A through single-cell RNA-sequencing of organoids. We expect that our study will elucidate key disease mechanisms of PCH2A and have implications for other disorders induced by defects in tRNA splicing. Importantly, we will determine at which time point during cerebellar development differences between PCH2A and control organoids emerge. Hence, we will answer the question if PCH2A pathology emerges through the degeneration of existing structures, or whether the formation of the cerebellum is already altered. We will thus reveal a possible interplay between disrupted neurodevelopment and neurodegeneration. Our long-term goal is to define a therapeutic approach for PCH2A.

Cell-Type-Specific High Throughput Toxicity Testing in Human Midbrain Organoids.
Toxicity testing is a crucial step in the development and approval of chemical compounds for human contact and consumption. However, existing model systems often fall short in their prediction of human toxicity because they may not sufficiently recapitulate human physiology. The complexity of three-dimensional (3D) human organ-like cell culture systems ("organoids") can generate potentially more relevant models of human physiology and disease, including toxicity predictions. However, so far, the inherent biological heterogeneity and cumbersome generation and analysis of organoids has rendered efficient, unbiased, high throughput evaluation of toxic effects in these systems challenging. Recent advances in both standardization and quantitative fluorescent imaging enabled us to dissect the toxicities of compound exposure to separate cellular subpopulations within human organoids at the single-cell level in a framework that is compatible with high throughput approaches. Screening a library of 84 compounds in standardized human automated midbrain organoids (AMOs) generated from two independent cell lines correctly recognized known nigrostriatal toxicants. This approach further identified the flame retardant 3,3',5,5'-tetrabromobisphenol A (TBBPA) as a selective toxicant for dopaminergic neurons in the context of human midbrain-like tissues for the first time. Results were verified with high reproducibility in more detailed dose-response experiments. Further, we demonstrate higher sensitivity in 3D AMOs than in 2D cultures to the known neurotoxic effects of the pesticide lindane. Overall, the automated nature of our workflow is freely scalable and demonstrates the feasibility of quantitatively assessing cell-type-specific toxicity in human organoids .

A fully automated high-throughput workflow for 3D-based chemical screening in human midbrain organoids.
Three-dimensional (3D) culture systems have fueled hopes to bring about the next generation of more physiologically relevant high-throughput screens (HTS). However, current protocols yield either complex but highly heterogeneous aggregates ('organoids') or 3D structures with less physiological relevance ('spheroids'). Here, we present a scalable, HTS-compatible workflow for the automated generation, maintenance, and optical analysis of human midbrain organoids in standard 96-well-plates. The resulting organoids possess a highly homogeneous morphology, size, global gene expression, cellular composition, and structure. They present significant features of the human midbrain and display spontaneous aggregate-wide synchronized neural activity. By automating the entire workflow from generation to analysis, we enhance the intra- and inter-batch reproducibility as demonstrated via RNA sequencing and quantitative whole mount high-content imaging. This allows assessing drug effects at the single-cell level within a complex 3D cell environment in a fully automated HTS workflow.

SIMULTANEOUS PRENATAL ALCOHOL AND CANNABINOID EXPOSURE DURING THE SECOND TRIMESTER AUGMENTS REDUCTIONS IN FETAL CEREBRAL BLOOD FLOW FROM ALCOHOL EXPOSURE ALONE.

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Siara Rouzer, Rajesh Miranda
Texas A&M College of Medicine, Neuroscience & Experimental Therapeutics, Bryan, United States of America

Aims: Investigations of simultaneous prenatal alcohol and cannabinoid (SAC) exposure are currently minimal, although prenatal exposure to either substance can lead to fetal growth deficits. During the second trimester, brain vasculature emerges to support fetal growth and neural development. We therefore investigated whether second-trimester prenatal drug exposure would alter fetal-directed blood flow. **Methods**: We performed high-resolution *in vivo* ultrasound imaging in C57Bl/6J pregnant mice assigned to one of four exposure groups: drug-free control, alcohol or cannabinoid only, or SAC. Drug exposure occurred daily between Gestational Days (G)12-15, via i.p injections of cannabinoid agonist CP-55940 (750µg/kg), while ethanol (95%) was inhaled within vapor chambers for 30min. All dams were imaged on three days of pregnancy: G11 (pre-exposure), G13.5 (peri-exposure) and G16 (post-exposure). **Results:** Compared to controls, both PAE and SAC dams experienced a dip in gestational weight gain while undergoing drug exposure. Furthermore, SAC dams demonstrated higher (+42mg/dL) blood ethanol concentrations than PAE dams. Preliminary ultrasound data suggest that both alcohol and cannabinoid exposures alone produce delayed reductions in fetal blood flow on G16 in the middle cerebral and internal carotid arteries. Notably, SAC fetuses exhibit an augmented reduction in blood supply through the middle cerebral artery (-62%) compared to PAE offspring (-40%). Interestingly, alcohol and cannabinoid exposures lead to acute reductions in umbilical blood flow that recover by G16. **Conclusions**: Our results indicate that prenatal drug exposure may lead to both acute and delayed reductions in fetal-directed blood flow, and SAC may augment deficits specifically in cerebral arterial blood flow.

CEREBELLAR MALFORMATIONS IN MOUSE MODEL OF WILLIAMS-BEUREN SYNDROME

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Manuele Novello[1], Laurens Bosman[1], Lieke Kros[1], Hamid El Azzouzi[2], Jeroen Essers[3], Chris De Zeeuw[1]
[1]Erasmus MC, Department Of Neuroscience, Rotterdam, Netherlands, [2]Erasmus MC, Molecular Genetics, Rotterdam, Netherlands, [3]Erasmus MC, In Vivo Molecular Imaging Of Cancer And Cardiovascular Disease, Rotterdam, Netherlands

Williams-Beuren syndrome (WBS) is a neurodevelopmental disorder characterized by cardiovascular deficits, hypersociability, and cerebellar ataxia. In order to better understand the cerebellar involvement in causing the neurological symptoms of WBS, we generated a novel mouse model replicating the clinical features of WBS patients. Quantification of the lobulation of the cerebellum, demonstrated that WBS mice showed an enlargement of lobule IV/V in the cerebellar vermis, and by deformation at the onset of the copula pyramidis in the cerebellar hemispheres. In particular in lobule IV/V, we noted a significant decrease of linear density of Purkinje cells. These alterations were specific for the cerebellum, as none of the other relevant brain areas showed significant deformations in WBS mice.
Since the involvement of lobule IV/V in forelimbs movement and in affective states, and copula pyramidis in hindlimb movements, anatomical alterations of these structures in mice may explain social and motor dysregulations seen in humans, suggesting, ulteriorly, how the cerebellum is implicated in motor and non-motor functions and might be involved in WBS behavior.

PREDICTION OF CHILDREN PSYCHOPHYSIOLOGICAL AGE USING PATTERNS OF AUDITORY EVENT-RELATED POTENTIALS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Ilya Mikheev[1], Olga Martynova[2], Felix Zakirov[3]
[1]Higher School of Economics, Department Of Psychology, Moscow, Russian Federation, [2]Higher School of Economics, Centre For Cognition & Decision Making, Moscow, Russian Federation, [3]Sechenov University, Faculty Of Medicine, Moscow, Russian Federation

Although there are various psychological scales for determining whether a child's age corresponds to the population norm, patterns of brain bioelectrical activity could also reflect child development and serve as valuable markers of psychophysiological age. This study aimed to determine the psychophysiological age of children using components of auditory event-related potentials (ERPs). The novelty of the study approach is that age was predicted at an individual level by regression models of machine learning. ERPs were recorded in response to auditory tones presented with different loudness in three groups of children (N=7, age range 4.14-6.42; N=16, 7.08-11.98; N=9, 12.04-17.98). Averaged amplitudes and latencies of ERPs were compared by Kruskal-Wallis Test and served as classification features for Catboost machine learning algorithm. The most informative features are determined by the numbers of times the feature is used in a model. We observed significant group differences in amplitudes of P1, P2, N2 latencies of P1 and P2 components of ERPs ($p<.05$). The classification accuracy between the three age groups was .85, ROC/AUC - .88. The most informative features for correct age recognition were latency of P1 and amplitude of N2. The study findings confirm that auditory ERPs reflect brain developmental changes. The application of the machine learning approach for the classification of ERP data allowed us to determine the psychophysiological age range at the individual level.

22q11 deletion syndrome (DS) is a syndrome characterized by structural abnormalities in dendrites maturation, spines formation and by behavioral and cognitive deficits (Karayiorgou et al., 2010). Among the genes deleted in the 22q11, six encode for mitochondrial proteins. Here, we examined mitochondrial genes expression in neuronal and astrocyte cell cultures derived from a mouse model of 22q11DS (Meechan et al., 2009) and found that, among other mitochondrial-related genes, *Bcl-Xl*was specifically downregulated in astrocytes but not in neuronal cells. Similar analysis performed in brain tissues of LgDel mice confirmed that *Bcl-Xl* was significantly downregulated in the prefrontal cortex. We thus checked whether the decreased levels of *Bcl-Xl* could have a role in the neuroanatomical abnormalities associated to 22q11DS. At first, we analysed the mitochondrial distribution and the morphology of astrocytes and neurons *in vivo* by labelling single cells with a plasmid expressing a cytoplasmic fluorescent protein (mTAGBFP2) and a mitochondrial matrix-targeted fluorescent protein (mt-YFP) with IUE. Morphometric analysis of these parameters revealed remarkable differences between the LgDel and control mice. Then, we chronically treated LgDel mice with a biologically active peptide consisting of a domain of BCL-XL fused to the protein transduction domain of the HIV-TAT protein and found a significant rescue of mitochondrial phenotypes and a consistent improvement of astrocytes morphogenesis and of the dendritic and spine abnormalities. Finally, the beneficial effect of TAT peptide was confirmed on cognitive deficits of LgDel mice. *Support: SNFS NCCR "Synapsy" (51NF40-158776) and Swiss National Science Foundation SNSF (310030_185363) and Telethon Italy (GGP20037) (to P.B.)*

The mechanisms controlling the post-natal maturation of astrocytes play a crucial role in ensuring correct synaptogenesis. We show that mitochondrial biogenesis in developing astrocytes is necessary for coordinating post-natal astrocyte maturation and synaptogenesis. The astrocytic mitochondrial biogenesis depends on the transient upregulation of metabolic regulator peroxisome proliferator-activated receptor gamma (PPARγ) co-activator 1α (PGC-1α), which is controlled by metabotropic glutamate receptor 5 (mGluR5). At tissue level, the loss or downregulation of astrocytic PGC-1α sustains astrocyte proliferation, dampens astrocyte morphogenesis, and impairs the formation and function of neighboring synapses, whereas its genetic re-expression is sufficient to restore the mitochondria compartment and correct astroglial and synaptic defects. Our findings show that the developmental enhancement of mitochondrial biogenesis in astrocytes is a critical mechanism controlling astrocyte maturation and supporting synaptogenesis, thus suggesting that astrocytic mitochondria may be a therapeutic target in the case of neurodevelopmental and psychiatric disorders characterized by impaired synaptogenesis. BEHAVIORAL ANALYSES OF BRAIN-SPECIFIC SNORD116 AND SNORD115 GENES.

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Julie Riviere[1], Virginie Marty[2], Jérôme Cavaillé[2], Laure Verret[3]
[1]Centre de Biologie intégrative, Centre De Recherches Sur La Cognition Animale, TOULOUSE, France, [2]Unité de biologie Moléculaire, cellulaire et du développement, Centre De Biologie Intégrative, Toulouse, France, [3]Centre de Biologie Intégrative, Centre De Recherches Sur La Cognition Animale, TOULOUSE, France

Box C/D small nucleolar RNAs (SNORD) are part of ribonucleoprotein complexes which function mostly in guiding **sequence-specific 2'-O-ribose methylation** of ribosomal RNAs, spliceosomal U6 snRNAs or transfer RNAs. By fine-tuning pre-mRNA splicing and translation, they are now considered as key players in **gene expression regulation**. Intriguingly, some placental mammal-specific SNORD genes are embedded within large imprinted chromosomal domains and show predominant **neuronal expression**. Among these epigenetically-regulated SNORD genes, **SNORD116** and **SNORD115** genes at human Chr15.q11q13 (mouse chr7C) are of particular interest since recent clinical studies suggest that their loss-of-function may contribute to the pathophysiology of the **Prader-Willi syndrome (PWS)**. PWS is a rare human disorder associated with a complex set of metabolic, hormonal and behavioural abnormalities, notably a true obsession with food (hyperphagia) which, in the absence of strict dietary restrictions, leads to morbid obesity. Despite recent undeniable progress, the mode of action of SNORD116 and SNORD115 remain highly elusive. We therefore still need to clarify their biological relevance *in vivo*, not only to unveil novel, unsuspected SNORD-mediated neuronal functions but also to improve our knowledge on the aetiology of PWS. Through the use of novel SNORD-deficient mouse models, we are now probing the involvement of SNORD116 and SNORD115 genes in higher brain functions, with particular attention to **hippocampal and non-hippocampal memories, cognitive flexibility** and **sleep architecture**.

NEUROINFLAMMATORY MECHANISMS OF PAIN HYPERSENSITIZATION IN A MOUSE MODEL OF ATTENTION DEFICIT/HYPERACTIVITY DISORDER (ADHD).

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Sarah Bou Sader Nehme[1], Sandra Sánchez-Sarasúa[1], Louison Brochoire[1], Marie Tuifua[1], Otmane Bouchatta[2], Eric Boué-Grabot[1], Saadia Ba M'Hamed[3], Mohamed Bennis[3], Walid Hleihel[4], Marc Landry[1]

Clinical evidence suggest that pain hypersensitivity develops in subjects with attention deficit hyperactivity disorder (ADHD). However, the mechanisms and neural circuits involved in these interactions remain unknown because of the paucity of studies in animal models. We previously validated a mouse model of ADHD obtained by neonatal 6-Hydroxydopamine (6-OHDA) injection. Here, we demonstrated that 6-OHDA mice exhibited a marked sensitization to thermal and mechanical stimuli, suggesting that ADHD conditions increase nociception. In addition, sensitization to pathological inflammatory pain is amplified in 6-OHDA mice as compared to shams. ADHD-related hyperactivity and anxiety, but not inattention and impulsivity, are worsened in persistent inflammatory pain. These results indicate a potential implication of neuroinflammation in the etiology of ADHD. By combining in vivo electrophysiology, optogenetics and behavioral analyses, we demonstrated that the anterior cingulate cortex (ACC) hyperactivity alters the 'ACC – posterior insula' circuit, and triggers changes in spinal networks that underlie pain sensitization. Altogether, our results point to unprecedented mechanisms underlying the comorbidity between ADHD and pain sensitization. They indicate that ADHD and pain sensitization are mutually worsening comorbid disorders. We make the hypothesis that neuroinflammation is a major factor triggering ACC hyperactivity and the associated pain. To test this hypothesis, we aim at identifying potential markers of inflammation and oxidative stress in the ACC, and to study astrocytes and microglia activation. The identification of shared mechanisms, engaging overlapping neuronal circuits and inflammation, and underlying both disorders, is key to better treatments.

INVESTIGATION OF KCNQ1 FUNCTION IN HUMAN NEURONS WITH A SPECIFIC FOCUS ON INSULIN SIGNALLING

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Dorothea Schall[1], Claudio Acuna[2], Gudrun Rappold[1], Simone Berkel[1]
[1]Heidelberg University Hospital, Institute Of Human Genetics, Heidelberg, Germany, [2]Heidelberg University, Institute Of Anatomy And Cell Biology, Heidelberg, Germany

KCNQ1 is the pore-forming alpha subunit of a voltage-dependent potassium channel complex. Four KCNQ1 monomers, together with a member of the KCNE family, form the functional potassium channel. The *KCNQ1* gene has been linked to disorders with impaired insulin signalling (so-called insulinopathies) including type 2 diabetes, obsessive compulsive disorder, and Alzheimer's disease. Interestingly, KCNQ1 is known to inhibit insulin secretion in the pancreas, however, its function in the human brain is unknown.
In this project we aim to elucidate the function of KCNQ1 in human neurons with a specific focus on insulin signalling. As a model we use human induced pluripotent stem cells (hiPSCs) which will be differentiated into neuronal stem cells (NSCs) and cortical neurons.
First, we established a neuronal differentiation protocol and analyzed KCNQ1 expression in hiPSCs, NSCs and neurons. All analyzed cell types show KCNQ1 expression. To elucidate KCNQ1 function, we generated KCNQ1 knockout hiPSC lines using CRISPR/Cas9 genome editing. In the next step these hiPSCs will be differentiated into NSCs and further into cortical neurons. The KCNQ1 knockout cells will be compared to isogenic control cells by analyzing different cell properties (e.g. neurite outgrowth, cell type composition, number of synapses), the transcriptome, protein expression and phosphorylation of members of the insulin signalling pathway, and the neuronal function.

Reelin (RELN) is a secreted glycoprotein critical for multiple steps of cerebral cortex development in mice. In human *RELN* recessive mutations leading to null alleles were associated with cortical malformations, but were not functionally characterized. Here we identified novel missense *RELN* mutations in both compound and *de novo* heterozygous patients exhibiting an array of neuronal migration disorders (NMDs) as diverse as pachygyria, polymicrogyria and heterotopia. We assessed how different mutations affected RELN function using a set of assays in culture and in the developing cerebral cortex, with the latter being based on the capacity of ectopic expression of RELN *in utero* to drive the formation of caudally positioned neuronal aggregates. Mutations associated with polymicrogyria behave as gain-of-function by forming neuronal aggregates in extracaudal positions, while those with pachygyria behave as loss-of-function by causing defective RELN secretion, neuronal aggregation and migration *in vitro* and *in vivo*. In particular, *de novo* heterozygous RELN mutations act as dominant negative preventing WT RELN secretion, thereby causing dominant NMDs. This work shows that the behavior of the mutant proteins *in vitro* and *in vivo* predicts the severity of cortical malformations, providing valuable insight into the pathogenesis of the associated disorders.

Schizophrenia is a devastating mental disorder of neurodevelopmental origin which affects ~1% of the population worldwide. It is characterized by a broad pattern of cognitive symptoms, including for example decreased attention, impaired memory and alterations in social cognition. These symptoms are the earlier observed and are predictive of the risk of transition to schizophrenia. They are poorly controlled by currently available antipsychotics which mainly reduce positive symptoms and, to a lesser extent, negative symptoms. Although improving symptomatic treatments remains an important goal, progress in disease management will likely require shift to novel modes of intervention initiated at an early stage of the disease in high-risk patients. The serotonin 5-HT6 receptor holds special promise, highest receptor densities are found in brain regions involved in mnemonic functions and we previously demonstrated that a sustained non-physiological activation of mechanistic Target Of Rapamycin (mTOR) elicited by 5-HT6 receptors specifically in the prefrontal cortex mediates deficits in social cognition and episodic memory in two developmental models of schizophrenia. We propose a novel disease modifier strategy to prevent emergence of cognitive deficits at the adult stage, in the Disc1-L100P genetic model of schizophrenia. This strategy is based on early blockade of 5-HT6 receptor-operated mTOR signaling during adolescence, a critical phase of prefrontal cortex maturation. Here, we show that early administration of 5-HT6 receptor antagonist or rapamycin prevents the behavioral deficits observed at the adult stage in this model.

Meyer Children's Hospital, Department Of Neuroscience, Pharmacology And Child Health, Florence, Italy, [3]San Raffaele Scientific Institute, Division Of Neuroscience, Milano, Italy

Aims: Periventricular Nodular Heterotopia (PNH), the most common type of malformations of cortical development, is characterized by the presence of ectopic neuronal nodules lining the lateral ventricles. Mutations in *Filamin A* (*FLNA*) are the main cause of PNH, which combines epilepsy, intellectual disability, and autistic features. Underlying molecular mechanisms responsible for epileptogenesis remain largely obscure. It has been hypothesized that dysfunctional cortical circuitry, rather than ectopic neurons, may explain the occurrence of seizures. However, the intrinsic role of FLNA in neural circuit formation and function remains poorly understood. Methods: To address this issue, we depleted FLNA from layer II/III pyramidal neurons of mice harboring a Flna conditional allele (*Flna*$^{fl/fl}$) by timed *in utero* electroporation of Cre-recombinase. Results: We found that neuronal-specific loss of *Flna* markedly increase dendritic arborisation by preventing Rac1 activation through its interaction with the Rho-GTPase Activating Protein 24 (Arhgap24). Indeed, we show that *in vivo*, overexpression of Arhgap24 or the dominant-negative form of Rac1 rescue the dendritic overgrowth induced by depletion of Flna. These defects are associated with changes in spine morphology and distribution. Conclusions: These findings suggest that FLNA is crucial for the morpho-functional maturation of L2/3 pyramidal neurons in a cell-autonomous manner and provide strong support for neural circuit dysfunction being a pathological consequence of FLNA mutations.

TARGETING NEUROINFLAMMATION AS A POTENTIAL THERAPEUTIC INTERVENTION FOR ALTERED PAIN SENSITIVITY IN ATTENTION-DEFICIT HYPERACTIVITY DISORDER MOUSE MODEL

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Maria Meseguer-Beltrán[1], Sandra Sánchez-Sarasúa[2], Ana María Sánchez-Pérez[1], Marc Landry[3], Nóra Kerekes[4]
[1]University Jaume I, Predepartmental Medicine Unit, Castellón de la Plana, Spain, [2]University of Bordeaux, Institut Des Maladies Neurodégénératives - Cnrs Umr 5293, Bordeaux, France, [3]University of Bordeaux, Imn Cnrs Umr 5293, Bordeaux, France, [4]University West, Health Sciences/inst For Hälsovetenskap, Trollhättan, Sweden

Attention deficit hyperactivity disorder (ADHD) is a common neurodevelopmental disorder in children and adolescents worldwide. It often coexists with anxiety and aspects of the autism spectrum disorder, among others. Additionally, the prevalence of ADHD symptoms increases dramatically in children with chronic pain. Recent research suggests that increased inflammation during neurodevelopment can trigger ADHD symptoms and disturbances in pain transmission. Our hypothesis is that there are neuroinflammation in specific brain areas could underlie both processes and that targeting inflammation will reduce symptoms and comorbid pain sensitivity. To test the hypothesis, we aim to establish a mice model of ADHD through neonatal lesion with 6-OHDA, which is neurotoxic to dopaminergic neurons. The mice will be treated with Abscisic Acid (ABA) a phytohormone with anti-inflammatory properties as a therapeutic intervention, for a month. The dopamine injury model and ABA effect will be evaluated in various behavioural paradigms (memory, sociability, anxiety) as well as pain (thermal and mechanical sensitivity). In the post-mortem analysis we will analyse the morphology of reactive microglia as an inflammatory biomarker in specific areas involved in the DA projections from the ventral tegmental area and the substantia nigra. Preliminary results indicate that the lesion increases sensitivity thermal stimulation in females and that treatment with ABA counteracts this effect. In addition, there are sex-dependent differences in response to lesion and ABA treatment, which opens interesting perspectives regarding the implication of estrogens in this neurodevelopmental syndrome.

IRS1 expression in hippocampus is age-dependent and is required for mature spine maintenance and neuritogenesis.
Insulin and insulin-like growth factor type I (IGF-1) play prominent roles in brain activity throughout the lifespan. Insulin/IGF1 signaling starts with the activation of the intracellular insulin receptor substrates (IRS). In this work, we performed a comparative study of IRS1 and IRS2, together with the IGF1 (IGF1R) and insulin (IR) receptor expression in the hippocampus and prefrontal cortex during development. We found that IRS1 and IRS2 expression is prominent during development and declines in the aged hippocampus, contrary to IR, which increases in adulthood and aging. In contrast, IGF1R expression is unaffected by age. Expression patterns are similar in the prefrontal cortex. Neurite development occurs postnatally in the rodent hippocampus and cortex, and it declines in the mature and aged brain and is influenced by trophic factors. In our previous work, we demonstrated that knockdown of IRS1 by shRNA impairs learning and reduces synaptic plasticity in a rat model, as measured by synaptophysin puncta in axons. In this study, we report that shIRS1 alters spine maturation in adult hilar hippocampal neurons. Lastly, to understand the role of IRS1 in neuronal neurite tree, we transfect shIRS1 into primary neuronal cultures and observed that shIRS1 reduced neurite branching and neurite length. Our results demonstrate that IRS1/2 and insulin/IGF1 receptors display different age-dependent expression profiles and that IRS1 is required for spine maturation, demonstrating a novel role for IRS1 in synaptic plasticity.

DIFFERENTIAL PROGENITOR RESPONSES TO MATERNAL INFLAMMATION IN THE DEVELOPING NEOCORTEX

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Laura Wolbeck, Navneet Vasistha, Konstantin Khodosevich
University of Copenhagen, Biotech Research And Innovation Center, Copenhagen, Denmark

Infections during pregnancy are associated with an increased risk for disorders such as autism and schizophrenia. Virus infections induce maternal immune system activation (MIA) and the release of several cytokines that cross the placental barrier and severely impact the development of the cerebral cortex. We have previously shown that MIA has a non-uniform impact on cell types in the developing mouse brain. Specifically, MIA displays a developmental time and germinal niche dependent impairment on progenitors that give rise to inhibitory neurons. Progenitor proliferation in the medial (MGE) and caudal ganglionic eminence (CGE) is affected during early- and mid-neurogenesis stages respectively. Furthermore, despite the acute nature of MIA, the impact on neuronal lineages is enduring and continues even after birth leading to physiological dysfunction. Finally, using high-throughput single-nuclei RNA sequencing technology on embryonic tissue, we observed a differential impact on the transcriptome of neuronal cells and their progenitors. We could trace some of the effects of MIA to the expression of cytokine receptors as well as important developmental signaling pathways. Our study hence emphasizes the fundamental differences between neural progenitor cells and how this shapes the development of the neocortex. Understanding the mechanistic basis behind such differential vulnerability is also crucial to resolve the pathogenesis of neurodevelopmental disorders.

Institut du Cerveau - Paris Brain Institute - ICM, Sorbonne Université, Inserm, Cnrs, Hôpital De La Pitié Salpêtrière, Paris, France

Mutations of the mTOR pathway genes leading to mTORC1 hyperactivity are one of the major causes of genetic focal epilepsies with or without focal cortical dysplasia type II (FCD), a malformation of cortical development. The occurrence of brain-specific somatic mutations leading to mosaic mTORC1 hyperactivity has been reported in a number of FCD II cases. Here we ask whether variable proportions of mutated cells reflect the phenotypic spectrum between patients.
To assess the effect of mTORC1 hyperactivity on human neurodevelopment, we generated mosaic cortical spheroids (CSs) from patient-derived hiPSCs in different proportions to model small FCD or larger FCD such as hemimegalencephaly. First, we demonstrated mTORC1 hyperactivity by assessing the levels of phosphorylated ribosomal protein S6, one of the main downstream mTORC1 targets. Moreover, we found a defect in the formation of neuroectodermal rosettes in high mosaic rate CSs. Strikingly, single-cell transcriptomic profiling and immunohistological assays of these CSs showed a cell fate shift. Lastly, we observed increased neuronal activity in mutated organoids compared to controls using MEA recordings. These findings validate our model as an FCD and an epilepsy model.

Neurological symptoms can inform on degree of neurodevelopmental load and may be useful for early detection of psychosis. Aim: to develop tablet-based tasks to provide behavioral markers for detection of first-episode psychosis (FEP). Marker specificity was assessed against groups of: healthy controls, persons with autism spectrum disorder (ASD), and stabilized patients with schizophrenia (SCZ). Tablet markers were compared to scores of conventional neurological soft signs (NSS) and to neurophysiological measures.
Method : 20 persons with FEP, 20 with SCZ, 20 with ASD, and 20 healthy controls were included. Five tablet-tasks assessed different motor and cognitive functions: Finger Recognition (FR) for mental rotation, Rhythm Tapping (RhT) for temporal judgement, Sequence Tapping (ST) for procedural memory, Multi Finger Tapping (MFT) for motor inhibition, and Line Tracking (LT) for visuomotor precision and attentional modulation. NSS and medication data were also collected. Transcranial magnetic stimulation was used to measure resting motor thresholds and short latency intracortical inhibition (SICI).
Results : Compared to controls, FEP patients showed slower reaction times and higher errors in FR, and more variability in rhythmic finger tapping (RhT). ROC curves showed 90% sensitivity and 75% specificity for detection of FEP vs. controls. RhT performance allowed for discrimination between FEP and ASD/SCZ patients. FEP had similar motor threshold but reduced SICI compared to controls and other groups. Some tablet-based measures correlated with NSS in each patient group. In FEP, total NSS correlated with LT duration.
Conclusion : Manual task performance on easy-to-use tablet applications provides promising markers for detection of FEP.

COGNITIVE IMPAIRMENT IN MICE WITH A GAIN-OF-FUNCTION MUTATION IN RETINOIC ACID RECEPTOR BETA (RARB)

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Devanshi Shah[1,2], Eve Racette[1,2], Marc Danik[1], Nicolas Lemmetti[1,2], Jacques Michaud[1,2]
[1]CHU Ste-Justine, Research Center, Montreal, Canada, [2]Université de Montreal, Department Of Neuroscience, Montreal, Canada

Retinoic acid (RA) signaling regulates brain development and function. In target cells, RA transduces its signal by binding to heterodimers formed by retinoic acid receptor (RAR) and retinoic X receptor (RXR), which function as transcription factors by binding to RA response elements. Our group has shown that dominant variants in *RARB* cause a disorder characterized by motor and cognitive impairment. We found that these mutations increase the RA-induced transcriptional activity of RARB *in vitro*, suggesting a gain-of-function (GOF) mechanism. We hypothesized that these GOF mutations impair cognition by affecting the development and/or function of the striatum, where RARB is primarily expressed. To investigate this hypothesis, mice carrying the variant p.Arg394Cys homologous to the variant p.Arg387Cys found in 40% of affected individuals were generated. *Rarb*$^{R394C/R394C}$ mice die perinatally whereas *Rarb*$^{R394C/+}$ mice survive and show a motor behavior that is reminiscent of that of the patients. Behavioral assessment of *Rarb*$^{R394C/+}$ mice at P60-65 showed impaired behavior in the contextual fear conditioning paradigm as well as deficits in exploration time and discrimination index between the novel and familiar object in the novel object recognition paradigm. Interestingly, transcriptomic studies of the neonatal and adult Rarb$^{R394C/+}$ striatum showed that downregulated, but not upregulated genes, are significantly enriched for direct targets of RARB, including components of the dopamine signaling pathway. Altogether, these results suggest that p.R394C affects cognition not by acting as a GOF but rather as a Loss-of-function (LOF) allele *in vivo.*

Spatiotemporal analysis of soluble aggregates and autophagy markers in the R6/2 mouse model.
Maintenance of cellular proteostasis is vital for post-mitotic cells like neurons to sustain normal physiological function and homeostasis, defects in which are established hallmarks of several age-related conditions like AD, PD, HD, and ALS. The Spatio-temporal accumulation of aggregated proteins in the form of inclusion bodies/plaques is one of the major characteristics of many neurodegenerative diseases, including Huntington's disease (HD). Toxic accumulation of HUNTINGTIN (HTT) aggregates in neurons bring about the aberrant phenotypes of HD, including severe motor dysfunction, dementia, and cognitive impairment at the organismal level, in an age-dependent manner. In several cellular and animal models, aggrephagy induction has been shown to clear aggregate-prone proteins like HTT and ameliorate disease pathology by conferring neuroprotection. In this study, we used the mouse model of HD, R6/2, to understand the pathogenicity of mHTT aggregates, primarily focusing on autophagy dysfunction. We report that basal autophagy is not altered in R6/2 mice, whilst being functional at a steady-state level in neurons. Moreover, we tested the efficacy of a known autophagy modulator, Nilotinib (Tasigna™), presently in clinical trials for PD, and HD, in curbing mHTT aggregate growth and their potential clearance, which was ineffective in both inducing autophagy and rescuing the pathological phenotypes in R6/2 mice.

Differential Regulation of Translation by FMRP Modulates eEF2 Mediated Response on NMDAR Activity.
SYNGAP1, a Synaptic Ras-GTPase activating protein, regulates synapse maturation during a critical developmental window. Heterozygous mutation in ( ) has been shown to cause Intellectual Disability (ID) in children. Recent studies have provided evidence for altered neuronal protein synthesis in a mouse model of . However, the molecular mechanism behind the same is unclear. Here, we report the reduced expression of a known translation regulator, FMRP, during a specific developmental period in mice. Our results demonstrate that FMRP interacts with and regulates the translation of mRNA. We further show reduced translation leads to decreased FMRP level during development in which results in an increase in translation. These developmental changes are reflected in the altered response of eEF2 phosphorylation downstream of NMDA Receptor (NMDAR)-mediated signaling. In this study, we propose a cross-talk between FMRP and SYNGAP1 mediated signaling

which can also explain the compensatory effect of impaired signaling observed in mice.

In the past few decades, the increasing interest of the scientific community in understanding the interaction between gut microbiota and the brain has brought to novel and important insights into the role of intestinal bacteria in modulating host neural function and development. The involvement of the gut microbiota has been also recently demonstrated for a variety of neuropsychiatric and neurodevelopmental disorders, whose aetiology remains mostly unknown. Cyclin-Dependent Kinase-Like 5 (CDKL5) deficiency disorder (CDD) is a rare X-linked developmental encephalopathy caused by pathogenic variants of the CDKL5 gene. It can manifest in a broad range of clinical symptoms including gastrointestinal dysfunction, a condition that may be related to alterations in the intestinal microbiota composition. Here, we explored whether probiotic supplementation (via Vivomixx®) is able to improve behavioral and neuronal deficits in a CDD murine model. Our results demonstrate a significant amelioration in the nesting performance of Vivomixx-treated knock-out (KO) mice compared to the respective untreated KO, and the same trend was also observed in the Y-maze task. Likewise, the intrinsic optical imaging analysis revealed an amelioration in the visual cortical response of the treated KO mice. The overall picture emerging from this preliminary study indicates an improvement of behavioral and visual deficits in probiotic-treated mice, supporting a potential clinical role for probiotic intervention as a non-invasive way to ameliorate symptoms in CDD patients.

AUDIOGENIC SEIZURES IN MICE: AN ENTRY POINT TO CENTRAL NERVOUS SYSTEM DISORDERS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Olivier Postal[1,2,3], Alexa Buck[1,2], Typhaine Dupont[1,2], Carolina De Campos Pina[1,2], Nicolas Michalski*[2,4], Boris Gourévitch[1,2]
[1]Institut Pasteur, Institute De L'audition, Paris, France, [2]INSERM, Ua06, Paris, France, [3]Sorbonne Universités, Complexité De Vivants, Paris, France, [4]Institut Pasteur, Institut De L'audition, Paris, France

Audiogenic seizures, reflex seizures induced by loud sounds, are a common feature of many mouse models for central nervous system disorders such as autism and epilepsy. However, the mechanisms underlying these seizures are still poorly understood. They are thought to reflect an imbalance between neuronal excitation and inhibition in the central auditory pathways. Interestingly both peripheral and central hearing impairments, either acquired or congenital, increase the susceptibility to these seizures. In addition, several areas of the auditory pathway (cochlea, brainstem, inferior colliculus, auditory cortex) are involved in the initiation and propagation of these seizures, but the precise role of each of them remains unclear. Here, we have used a genetic mouse model of deafness highly susceptible to these audiogenic seizures, in order to decipher the mechanisms underlying the generation and propagation of the neuronal hyperactivity characterizing the audiogenic seizures. To do so, we developed a method to record surface activity in several regions simultaneously in awake head-fixed mice before, during and after the seizures. This methodology provides an opportunity to identify the features and origin of audiogenic seizures in several mouse models in order to ascertain and better characterise the neuronal deficits in mouse models of central nervous system disorders.

DUAL ROLE OF P2X7 RECEPTOR DURING PHYSIOLOGICAL AND PATHOLOGICAL BRAIN DEVELOPMENT AND DENDRITOGENESIS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Paula Mut-Arbona, Lumei Huang, Maria Baranyi, Pál Tod, Andras Iring, Beata Sperlagh
Institute of Experimental Medicine, Laboratory Of Molecular Pharmacology, Budapest, Hungary

Aim. Increased concentration of extracellular ATP under pathological conditions activates P2X7 receptor (P2X7R) while its role during early embryonic stages remains unclear, where ATP influences cellular differentiation, proliferation and apoptosis. Our objective is to determine the role of the receptor on the regulation of neuronal outgrowth from primary murine hippocampal neurons. Dendritic branching is studied as a marker for correct brain development and the correlation of abnormal dendritogenesis and human pathologies may offer some understanding of the cognitive deficits related to neurodevelopmental diseases. Methods. Morphological analyses were performed with Sholl analysis from primary hippocampal neurons from P2X7R wild-type (WT) and knockdown mice (KO) obtained from E17.5–E18.5 embryos. To understand the role of P2X7R also in pathogenic conditions, we extended our investigations to primary hippocampal neurons from a maternal immune activation (MIA) model for schizophrenia. A series of tests were performed to study schizophrenia-like behaviours in the young adult offspring. Results. Deficits in dendritic outgrowth were detected in both P2X7R-deficient primary neurons and derived from control embryos exposed to MIA but not KO exposed to MIA. Schizophrenia-like behaviours (deficits in spontaneous alternation in T maze and novel object recognition, PPI) correlated with these changes. Conclusion. P2X7R seems to have different functions regarding the time point in the individual (developmental stages or young adulthood) and being a key element during a pathological inflammatory event (e.g., when it is activated in an immune activation model like MIA during pregnancy, driving schizophrenia-like behaviours)

Microglia and the Purinergic Signaling System.
Microglia are the main resident immune-competent cell type of the central nervous system (CNS); these cells are highly sensitive to subtle changes in the chemical environment of the brain. Microglia are activated during diverse conditions, such as apoptosis, trauma, inflammation, and infection. The specific activities of microglia result from the confluence of environmental stimuli and the cellular state. It is likely that several signaling systems with different biological functions operate in competition and/or synergy, thus regulating similar microglial behaviors. The purinergic system is one of the fundamental signaling systems that establish microglial behavior in a wide spectrum of conditions. Adenosine tri-phosphate (ATP) belongs to the purinergic signaling system, which includes P2X, P2Y, and P1 receptors, as well as other proteins participating in ATP secretion and extracellular ATP degradation, and molecules that recognize purines as a ligand. In this review, we focus on the latest pre-clinical and basic purinergic system and microglial research, with particular attention to data collected in vivo and ex vivo. This chapter is divided into sections related to microglial ATP release, ATP degradation, and ATP-related actions mediated by P2X and P2Y receptor activation.

Adhesive ligand binding to integrin alpha IIb beta 3 stimulates tyrosine phosphorylation of novel protein substrates before phosphorylation of pp125FAK.
Tyrosine phosphorylation of multiple platelet proteins is stimulated by thrombin and other agonists that cause platelet aggregation and secretion. The phosphorylation of a subset of these proteins, including a protein tyrosine kinase, pp125FAK, is dependent on the platelet aggregation that follows fibrinogen binding to integrin alpha IIb beta 3. In this report, we examined whether fibrinogen binding, per se, triggers a process of tyrosine phosphorylation in the absence of exogenous agonists. Binding of soluble fibrinogen was induced with Fab fragments of an anti-beta 3 antibody (anti-LIBS6) that directly exposes the fibrinogen binding site in alpha IIb beta3. Proteins of 50-68 KD and 140 kD became phosphorylated on tyrosine residues in a fibrinogen-dependent manner. This response did not require prostaglandin synthesis, an increase in cytosolic free calcium, platelet aggregation or granule secretion, nor was it associated with tyrosine phosphorylation of pp125FAK.

Tyrosine phosphorylation of the 50-68-kD and 140-kD proteins was also observed when (a) fibrinogen binding was stimulated by agonists such as epinephrine, ADP, or thrombin instead of by anti-LIBS6; (b) fragment X, a dimeric plasmin-derived fragment of fibrinogen was used instead of fibrinogen; or (c) alpha IIb beta 3 complexes were cross-linked by antibodies, even in the absence of fibrinogen. In contrast, no tyrosine phosphorylation was observed when the ligand consisted of monomeric cell recognition peptides derived from fibrinogen (RGDS or gamma 400-411). Fibrinogen-dependent tyrosine phosphorylation was inhibited by cytochalasin D. These studies demonstrate that fibrinogen binding to alpha IIb beta 3 initiates a process of tyrosine phosphorylation that precedes platelet aggregation and the phosphorylation of pp125FAK. This reaction may depend on the oligomerization of integrin receptors and on the state of actin polymerization, organizational processes that may juxtapose tyrosine kinases with their substrates.

UNCOVERING NEUROBIOLOGICAL PATHWAYS INVOLVED IN SETBP1 HAPLOINSUFFICIENCY DISORDER DURING EARLY DEVELOPMENT USING HUMAN BRAIN ORGANOIDS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Maggie Mei-Ki Wong[1], Joery Den Hoed[1], Lukas Lütje[1], Willemijn Claassen[1], Bregje Van Bon[2], Simon Fisher[1,3]

Aims: *SETBP1* haploinsufficiency causes a heterogeneous neurodevelopmental syndrome with a broad range of clinical features including varying intellectual functioning and speech/language impairments. The precise functions of *SETBP1*, encoding the SET-binding protein 1, are yet to be discovered. Therefore, the molecular mechanisms or neuronal pathways by which reduced SETBP1 dosage affects neurodevelopment remain largely unknown. In this study, we aim to dissect these by employing induced pluripotent stem cell (iPSC)-derived brain organoids and transcriptomic approaches. **Methods:** We generated iPSC lines carrying *SETBP1* mutations using CRISPR/Cas9 gene-editing, as well as from *SETBP1* haploinsufficiency patients and their sex-matched parents. We differentiated heterozygous and homozygous knockout iPSCs into brain organoids, analysing their morphology and expression of key marker genes and proteins. Transcriptomic profiles are being investigated via RNA-sequencing at both whole organoid and single-cell levels to identify differences in cell type and lineage. **Results:** *SETBP1* homozygous knockout organoids showed disorganised morphology, with fewer and more elongated ventricles. We detected reduced expression of progenitor markers (*SOX2, PAX6* and *NESTIN),* neuronal marker *TBR1,* and forebrain marker *FOXG1*. Moreover, these *SETBP1*-/- organoids contained significantly fewer neural progenitors and neurons as shown by immunocytochemistry. **Conclusions:** Abnormally low SETBP1 dosage during early organoid development results in fewer neural progenitors and neurons. In the long-term, cell-culture models may provide a platform for testing drug panels with the potential to rescue the aberrant molecular/cellular phenotypes that we observe. Together, this work promises to offer insights into fundamental neuronal mechanisms that go awry in *SETBP1* haploinsufficiency disorder.

Clinical delineation of SETBP1 haploinsufficiency disorder.
SETBP1 haploinsufficiency disorder (MIM#616078) is caused by haploinsufficiency of SETBP1 on chromosome 18q12.3, but there has not yet been any systematic evaluation of the major features of this monogenic syndrome, assessing penetrance and expressivity. We describe the first comprehensive study to delineate the associated clinical phenotype, with findings from 34 individuals, including 24 novel cases, all of whom have a SETBP1 loss-of-function variant or single (coding) gene deletion, confirmed by molecular diagnostics. The most commonly reported clinical features included mild motor developmental delay, speech impairment, intellectual disability, hypotonia, vision impairment, attention/concentration deficits, and hyperactivity. Although there is a mild overlap in certain facial features, the disorder does not lead to a distinctive recognizable facial gestalt. As well as providing insight into the clinical spectrum of SETBP1 haploinsufficiency disorder, this reports puts forward care recommendations for patient management.

Speech and language deficits are central to SETBP1 haploinsufficiency disorder.
Expressive communication impairment is associated with haploinsufficiency of SETBP1, as reported in small case series. Heterozygous pathogenic loss-of-function (LoF) variants in SETBP1 have also been identified in independent cohorts ascertained for childhood apraxia of speech (CAS), warranting further investigation of the roles of this gene in speech development. Thirty-one participants (12 males, aged 0; 8-23; 2 years, 28 with pathogenic SETBP1 LoF variants, 3 with 18q12.3 deletions) were assessed for speech, language and literacy abilities. Broader development was examined with

standardised motor, social and daily life skills assessments. Gross and fine motor deficits (94%) and intellectual impairments (68%) were common. Protracted and aberrant speech development was consistently seen, regardless of motor or intellectual ability. We expand the linguistic phenotype associated with SETBP1 LoF syndrome (SETBP1 haploinsufficiency disorder), revealing a striking speech presentation that implicates both motor (CAS, dysarthria) and language (phonological errors) systems, with CAS (80%) being the most common diagnosis. In contrast to past reports, the understanding of language was rarely better preserved than language expression (29%). Language was typically low, to moderately impaired, with commensurate expression and comprehension ability. Children were sociable with a strong desire to communicate. Minimally verbal children (32%) augmented speech with sign language, gestures or digital devices. Overall, relative to general development, spoken language and literacy were poorer than social, daily living, motor and adaptive behaviour skills. Our findings show that poor communication is a central feature of SETBP1 haploinsufficiency disorder, confirming this gene as a strong candidate for speech and language disorders.

A Simplified Method for Generating Purkinje Cells from Human-Induced Pluripotent Stem Cells.
The establishment of a reliable model for the study of Purkinje cells in vitro is of particular importance, given their central role in cerebellar function and pathology. Recent advances in induced pluripotent stem cell (iPSC) technology offer the opportunity to generate multiple neuronal subtypes for study in vitro. However, to date, only a handful of studies have generated Purkinje cells from human pluripotent stem cells, with most of these protocols proving challenging to reproduce. Here, we describe a simplified method for the reproducible generation of Purkinje cells from human iPSCs. After 21 days of treatment with factors selected to mimic the self-inductive properties of the isthmic organiser-insulin, fibroblast growth factor 2 (FGF2), and the transforming growth factor β (TGFβ)-receptor blocker SB431542-hiPSCs could be induced to form En1-positive cerebellar progenitors at efficiencies of up to 90%. By day 35 of differentiation, subpopulations of cells representative of the two cerebellar germinal zones, the rhombic lip (Atoh1-positive) and ventricular zone (Ptf1a-positive), could be identified, with the latter giving rise to cells positive for Purkinje cell progenitor-specific markers, including Lhx5, Kirrel2, Olig2 and Skor2. Further maturation was observed following dissociation and co-culture of these cerebellar progenitors with mouse cerebellar cells, with 10% of human cells staining positive for the Purkinje cell marker calbindin by day 70 of differentiation. This protocol, which incorporates modifications designed to enhance cell survival and maturation and improve the ease of handling, should serve to make existing models more accessible, in order to enable future advances in the field.

Neurodegeneration in SCA14 is associated with increased PKCγ kinase activity, mislocalization and aggregation.
Spinocerebellar ataxia type 14 (SCA14) is a subtype of the autosomal dominant cerebellar ataxias that is characterized by slowly progressive cerebellar dysfunction and neurodegeneration. SCA14 is caused by mutations in the PRKCG gene, encoding protein kinase C gamma (PKCγ). Despite the identification of 40 distinct disease-causing mutations in PRKCG, the pathological mechanisms underlying SCA14 remain poorly understood. Here we report the molecular neuropathology of SCA14 in post-mortem cerebellum and in human patient-derived induced pluripotent stem cells (iPSCs) carrying two distinct SCA14 mutations in the C1 domain of PKCγ, H36R and H101Q. We show that endogenous expression of these mutations results in the cytoplasmic mislocalization and aggregation of PKCγ in both patient iPSCs and cerebellum. PKCγ aggregates were not efficiently targeted for degradation. Moreover, mutant PKCγ was found to be hyper-activated, resulting in increased substrate phosphorylation. Together, our findings demonstrate that a combination of both, loss-of-function and gain-of-function mechanisms are likely to underlie the pathogenesis of SCA14, caused by mutations in the C1 domain of PKCγ. Importantly, SCA14 patient iPSCs were found to accurately recapitulate pathological features observed in post-mortem SCA14 cerebellum, underscoring their potential as relevant disease models and their promise as future drug discovery tools.

Recent advances in modelling of cerebellar ataxia using induced pluripotent stem cells.
The cerebellar ataxias are a group of incurable brain disorders that are caused primarily by the progressive dysfunction and degeneration of cerebellar Purkinje cells. The lack of reliable disease models for the heterogeneous ataxias has hindered the understanding of the underlying pathogenic mechanisms as well as the development of effective therapies for these devastating diseases. Recent advances in the field of induced pluripotent stem cell (iPSC) technology offer new possibilities to better understand and potentially reverse disease pathology. Given the neurodevelopmental phenotypes observed in several types of ataxias, iPSC-based models have the potential to provide significant insights into disease progression, as well as opportunities for the development of early intervention therapies. To date, however, very few studies have successfully used iPSC-derived cells to model cerebellar ataxias. In this review, we focus on recent breakthroughs in

generating human iPSC-derived Purkinje cells. We also highlight the future challenges that will need to be addressed in order to fully exploit these models for the modelling of the molecular mechanisms underlying cerebellar ataxias and the development of effective therapeutics.

Induced pluripotent stem cell technology for modelling and therapy of cerebellar ataxia.
Induced pluripotent stem cell (iPSC) technology has emerged as an important tool in understanding, and potentially reversing, disease pathology. This is particularly true in the case of neurodegenerative diseases, in which the affected cell types are not readily accessible for study. Since the first descriptions of iPSC-based disease modelling, considerable advances have been made in understanding the aetiology and progression of a diverse array of neurodegenerative conditions, including Parkinson's disease and Alzheimer's disease. To date, however, relatively few studies have succeeded in using iPSCs to model the neurodegeneration observed in cerebellar ataxia. Given the distinct neurodevelopmental phenotypes associated with certain types of ataxia, iPSC-based models are likely to provide significant insights, not only into disease progression, but also to the development of early-intervention therapies. In this review, we describe the existing iPSC-based disease models of this heterogeneous group of conditions and explore the challenges associated with generating cerebellar neurons from iPSCs, which have thus far hindered the expansion of this research.

IDENTIFYING THERAPEUTICS TO TREAT RESPIRATORY DEFICITS ASSOCIATED WITH THE CONGENITAL CENTRAL HYPOVENTILATION SYNDROME (CCHS)

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Gabriel Pitollat[1], Laura Cardoit[2], Muriel Thoby-Brisson[3]
[1]University of Bordeaux, Incia - Cnrs Umr5287, Bordeaux, France, [2]University of Bordeaux, Incia Cnrs Umr 5287, Bordeaux, France, [3]Institut de Neurosciences Cognitives et Intégratives d'Aquitaine, CNRS, Université De Bordeaux, Bordeaux, France

Congenital central hypoventilation syndrome (CCHS) is a rare genetic life-threatening disorder characterized by hypoventilation and lack of central chemosensitivity. CCHS is caused by the mutation of *PHOX2B*, a gene encoding a transcription factor required for the proper development of the autonomic system that includes brainstem circuits controlling breathing. Breathing relies on the preBötzinger complex (preBötC) controlling respiratory rhythmogenesis and the retrotrapezoïd/parafacial respiratory group involved in central chemoception. Mouse models of CCHS harboring the most frequent human *PHOX2B* mutation (+7 alanine; Phox2b$^{27Ala/+}$) recapitulate CCHS breathing anomalies and die at birth from respiratory failures. Using Phox2b$^{27Ala/+}$ embryos we aimed to identify a molecule capable of restoring normal breathing and to decipher the underlying mechanisms. Drug screening suggested that AT

BOARD NUMBER: S002, a derivative of the antibiotic geldanamycin with anti-neuroinflammatory effects, might be a good candidate. To test this we performed electrophysiological recordings of respiratory-related activities on *in vitro* preparations obtained from Phox2b$^{27Ala/+}$ embryos before and after AT

BOARD NUMBER: S002 treatment. We observed that AT

BOARD NUMBER: S002 exposure 1) restored a respiratory frequency comparable to that of wild-type embryos and 2) significantly improved response to acidification (mimicking hypercapnia). These effects resulted from an action on the preBötC network and a modification of the activation state of brainstem microglia, resident macrophages of the nervous system known to play important roles in circuits wiring. Mechanisms involved in chemoception rehabilitation remain to be further investigated. Overall, our work started to establish AT

BOARD NUMBER: S002 as a potential cure against CCHS-associated respiratory deficits. Deciphering its mechanisms of action will help further identifying other candidate molecules.

CEREBRAL BLOOD FLOW ALTERATIONS IN VERY PRETERM-BORN ADULTS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Aurore Menegaux[1], Maria Mora Alvarez[1], Ronja Berg[1], Claus Zimmer[1], Christine Preibisch[1], Esther Rieger-Fackeldey[2], Peter Bartmann[3], Christian Sorg[1]

Aim: Preterm birth (i.e., birth before 37 weeks of gestation) is associated with long term alterations in brain structure and function. However, although altered brain perfusion in preterm infants or in animal models of prematurity has previously been reported, it is still unknown whether perfusion changes are still present in preterm born adults. We aimed at investigating this question in a pilot study of 10 very preterm-born adults (born before 32 weeks of gestation) and 12 term-born controls aged 22 to 45 years. **Methods:** Using pseudo-continuous arterial spin labeling MRI with a post-label delay of 1800 ms, and T1-weighted MRI, cerebral blood flow (CBF) maps were derived using the BASIL toolbox from the FMRIB Software Library. Group differences in CBF, controlling for age and gender, were investigated via ANCOVA using the SPSS statistical package. **Results:** We found significantly lower global grey matter CBF in very preterm compared to term-born adults ([F(3,22) = 4.134, p=0.022]). In order to investigate more specifically the location of changes, we used the Harvard oxford atlas to perform a region of interest approach. Significantly lower CBF in widespread cortical regions such as temporal pole ([F(3,22) = 6.333, p=0.007]) and subcortical regions such as the thalamus was observed ([F(3,22) = 7.034, p=0.003]). **Conclusion:** These preliminary results suggest long-lasting reductions in brain perfusion after very preterm birth. Follow up studies with more participants are necessary to confirm this finding and to investigate the impact of neonatal complications such as intraventricular hemorrhage on these CBF differences.

Aberrant cortico-thalamic structural connectivity in premature-born adults.
Premature birth is associated with alterations in brain structure, particularly in white matter. Among white matter, alterations in cortico-thalamic connections are present in premature-born infants, and they have been suggested both to last until adulthood and to contribute to impaired cognitive functions. To test these hypotheses, 70 very premature-born adults and 67 full-term controls underwent cognitive testing and diffusion-weighted imaging. Each cortical hemisphere was parcellated into six lobes, from which probabilistic tractography was performed to the thalamus. Connection probability was chosen as metric of structural connectivity. We found increased cortico-thalamic connection probability between left prefrontal cortices and left medio-dorsal thalamus and reduced connection probability between bilateral temporal cortices and bilateral anterior thalami in very premature-born adults. Aberrant prefronto- and temporo-thalamic connection probabilities were correlated with birth weight and days on ventilation, respectively, supporting the suggestion that these connectivity changes relate with the degree of prematurity. Moreover, an increase in left prefronto-thalamic connection probability also correlated with lower verbal comprehension index indicating its relevance for verbal cognition. Together, our results demonstrate that cortico-thalamic structural connectivity is aberrant in premature-born adults, with these changes being linked with impairments in verbal cognitive abilities. Due to corresponding findings in infants, data suggest aberrant development of cortico-thalamic connectivity after premature birth with lasting effects into adulthood.

Linking the impact of aging on visual short-term memory capacity with changes in the structural connectivity of posterior thalamus to occipital cortices.
Aging impacts both visual short-term memory (vSTM) capacity and thalamo-cortical connectivity. According to the Neural Theory of Visual Attention, vSTM depends on the structural connectivity between posterior thalamus and visual occipital cortices (PT-OC). We tested whether aging modifies the association between vSTM capacity and PT-OC structural

connectivity. To do so, 66 individuals aged 20-77 years were assessed by diffusion-weighted imaging used for probabilistic tractography and performed a psychophysical whole-report task of briefly presented letter arrays, from which vSTM capacity estimates were derived. We found reduced vSTM capacity, and aberrant PT-OC connection probability in aging. Critically, age modified the relationship between vSTM capacity and PT-OC connection probability: in younger adults, vSTM capacity was negatively correlated with PT-OC connection probability while in older adults, this association was positive. Furthermore, age modified the microstructure of PT-OC tracts suggesting that the inversion of the association between PT-OC connection probability and vSTM capacity with aging might reflect age-related changes in white-matter properties. Accordingly, our results demonstrate that age-related differences in vSTM capacity links with the microstructure and connectivity of PT-OC tracts.

Reduced apparent fiber density in the white matter of premature-born adults.
Premature-born adults exhibit lasting white matter alterations as demonstrated by widespread reduction in fractional anisotropy (FA) based on diffusion-weighted imaging (DWI). FA reduction, however, is non-specific for microscopic underpinnings such as aberrant myelination or fiber density (FD). Using recent advances in DWI, we tested the hypothesis of reduced FD in premature-born adults and investigated its link with the degree of prematurity and cognition. 73 premature- and 89 mature-born adults aged 25-27 years underwent single-shell DWI, from which a FD measure was derived using convex optimization modeling for microstructure informed tractography (COMMIT). Premature-born adults exhibited lower FD in numerous tracts including the corpus callosum and corona radiata compared to mature-born adults. These FD alterations were associated with both the degree of prematurity, as assessed via gestational age and birth weight, as well as with reduced cognition as measured by full-scale IQ. Finally, lower FD overlapped with lower FA, suggesting lower FD underlie unspecific FA reductions. Results provide evidence that premature birth leads to lower FD in adulthood which links with lower full-scale IQ. Data suggest that lower FD partly underpins FA reductions of premature birth but that other processes such as hypomyelination might also take place.

Theory of visual attention thalamic model for visual short-term memory capacity and top-down control: Evidence from a thalamo-cortical structural connectivity analysis.
In the theory of visual attention (TVA), it is suggested that objects in a visual scene compete for representation in a visual short-term memory (vSTM) store. The race towards the store is assumed to be biased by top-down controlled weighting of the objects according to their task relevance. Only objects that reach the store before its capacity limitation is reached are represented consciously in a given instant. TVA-based computational modeling of participants' performance in whole- and partial-report tasks permits independent parameters of individual efficiency of top-down control α and vSTM storage capacity K to be extracted. The neural interpretation of the TVA proposes recurrent loops between the posterior thalamus and posterior visual cortices to be relevant for generating attentional weights for competing objects and for maintaining selected objects in vSTM. Accordingly, we tested whether structural connectivity between posterior thalamus and occipital cortices (PT-OC) is associated with estimates of top-down control and vSTM capacity. We applied whole- and partial-report tasks and probabilistic tractography in a sample of 37 healthy adults. We found vSTM capacity K to be associated with left PT-OC structural connectivity and a trend-wise relation between top-down control α and right PT-OC structural connectivity. These findings support the assumption of the relevance of thalamic structures and their connections to visual cortex for top-down control and vSTM capacity.

Impaired visual short-term memory capacity is distinctively associated with structural connectivity of the posterior thalamic radiation and the splenium of the corpus callosum in preterm-born adults.
Preterm birth is associated with an increased risk for lasting changes in both the cortico-thalamic system and attention; however, the link between cortico-thalamic and attention changes is as yet little understood. In preterm newborns, cortico-cortical and cortico-thalamic structural connectivity are distinctively altered, with increased local clustering for cortico-cortical and decreased integrity for cortico-thalamic connectivity. In preterm-born adults, among the various attention functions, visual short-term memory (vSTM) capacity is selectively impaired. We hypothesized distinct associations between vSTM capacity and the structural integrity of cortico-thalamic and cortico-cortical connections, respectively, in preterm-born adults. A whole-report paradigm of briefly presented letter arrays based on the computationally formalized Theory of Visual Attention (TVA) was used to quantify parameter vSTM capacity in 26 preterm- and 21 full-term-born adults. Fractional anisotropy (FA) of posterior thalamic radiations and the splenium of the corpus callosum obtained by diffusion tensor imaging were analyzed by

tract-based spatial statistics and used as proxies for cortico-thalamic and cortico-cortical structural connectivity. The relationship between vSTM capacity and cortico-thalamic and cortico-cortical connectivity, respectively, was significantly modified by prematurity. In full-term-born adults, the higher FA in the right posterior thalamic radiation the higher vSTM capacity; in preterm-born adults this FA-vSTM-relationship was inversed. In the splenium, higher FA was correlated with higher vSTM capacity in preterm-born adults, whereas no significant relationship was evident in full-term-born adults. These results indicate distinct associations between cortico-thalamic and cortico-cortical integrity and vSTM capacity in preterm-and full-term-born adults. Data suggest compensatory cortico-cortical fiber re-organization for attention deficits after preterm delivery.

Aberrant Claustrum Microstructure in Humans after Premature Birth.
Several observations suggest an impact of prematurity on the claustrum. First, the claustrum's development appears to depend on transient subplate neurons of intra-uterine brain development, which are affected by prematurity. Second, the claustrum is the most densely connected region of the mammalian forebrain relative to its volume; due to its effect on pre-oligodendrocytes, prematurity impacts white matter connections and thereby the development of sources and targets of such connections, potentially including the claustrum. Third, due to its high connection degree, the claustrum contributes to general cognitive functioning (e.g., selective attention and task switching/maintaining); general cognitive functioning, however, is at risk in prematurity. Thus, we hypothesized altered claustrum structure after premature birth, with these alterations being associated with impaired general cognitive performance in premature born persons. Using T1-weighted and diffusion-weighted magnetic resonance imaging in 70 very preterm/very low-birth-weight (VP/VLBW) born adults and 87 term-born adults, we found specifically increased mean diffusivity in the claustrum of VP/VLBW adults, associated both with low birth weight and at-trend with reduced IQ. This result demonstrates altered claustrum microstructure after premature birth. Data suggest aberrant claustrum development, which is potentially related with aberrant subplate neuron and forebrain connection development of prematurity.

Automated claustrum segmentation in human brain MRI using deep learning.
In the last two decades, neuroscience has produced intriguing evidence for a central role of the claustrum in mammalian forebrain structure and function. However, relatively few in vivo studies of the claustrum exist in humans. A reason for this may be the delicate and sheet-like structure of the claustrum lying between the insular cortex and the putamen, which makes it not amenable to conventional segmentation methods. Recently, Deep Learning (DL) based approaches have been successfully introduced for automated segmentation of complex, subcortical brain structures. In the following, we present a multi-view DL-based approach to segment the claustrum in T1-weighted MRI scans. We trained and evaluated the proposed method in 181 individuals, using bilateral manual claustrum annotations by an expert neuroradiologist as reference standard. Cross-validation experiments yielded median volumetric similarity, robust Hausdorff distance, and Dice score of 93.3%, 1.41 mm, and 71.8%, respectively, representing equal or superior segmentation performance compared to human intra-rater reliability. The leave-one-scanner-out evaluation showed good transferability of the algorithm to images from unseen scanners at slightly inferior performance. Furthermore, we found that DL-based claustrum segmentation benefits from multi-view information and requires a sample size of around 75 MRI scans in the training set. We conclude that the developed algorithm allows for robust automated claustrum segmentation and thus yields considerable potential for facilitating MRI-based research of the human claustrum. The software and models of our method are made publicly available.

Aberrant gyrification contributes to the link between gestational age and adult IQ after premature birth.
Gyrification is a hallmark of human brain development, starting in the second half of gestation in primary cortices, followed by unimodal and then transmodal associative cortices. Alterations in gyrification have been noted in premature-born newborns and children, suggesting abnormal cortical folding to be a permanent feature of prematurity. Furthermore, both gyrification and prematurity are tightly linked with cognitive performance, indicating a link between prematurity, gyrification, and cognitive performance. To investigate this triangular relation, we tested the following two hypotheses: (i) gyrification is aberrant in premature-born adults; and (ii) aberrant gyrification contributes to the impact of prematurity on adult cognitive performance. One hundred and one very premature-born adults (i.e. adults born before 32 weeks of gestation, and/or with birth weight <1500 g) and 111 mature-born adults were assessed by structural MRI and cognitive testing at 27 years of age. Gyrification was measured by local cortical absolute mean curvature (AMC), evaluated through structural MRI. Cognitive performance

was assessed by the Wechsler Adult Intelligence Scale, full-scale IQ test. Two-sample t-tests, regression and mediation analyses were used to assess AMC group differences and the relation between AMC, birth-related variables, and full-scale IQ. Three key findings were identified. First, local AMC was widely increased in fronto-temporo-parietal primary and associative cortices of very premature-born adults. Increase of AMC was inversely associated with gestational age and birth weight and positively associated with medical complications at birth, respectively. Second, increased AMC of temporal associative cortices specifically contributed to the association between prematurity and reduced adult IQ (two-path mediation), indicating that aberrant gyrification of temporal associative cortices is critical for impaired cognitive performance after premature birth. Finally, further investigation of the relationship of gyrification between the early folding postcentral cortices and associative temporal cortices, folding later during neurodevelopment, revealed that the effect of gyrification abnormalities in associative temporal cortices on adult IQ is influenced itself by gyrification abnormalities occurring in the early folding postcentral cortices (three-path mediation). These results indicate that gyrification development across cortical areas in the brain conveys prematurity effects on adult IQ. Overall, these results provide evidence that premature birth leads to permanently aberrant gyrification patterns suggesting an altered neurodevelopmental trajectory. Statistical mediation modelling suggests that both aberrant gyrification itself as well as its propagation across the cortex express aspects of impaired neurodevelopment after premature birth and lead to reduced cognitive performance in adulthood. Thus, markers of gyrification appear as potential candidates for prognosis and treatment of prematurity effects.

29712788: Vosberg DE, Zhang Y, Menegaux A, Chalupa A, Manitt C, Zehntner S, Eng C, DeDuck K, Allard D, Durand F, Dagher A, Benkelfat C, Srour M, Joober R, Lepore F, Rouleau G, Théoret H, Bedell BJ, Flores C, Leyton M
Mesocorticolimbic Connectivity and Volumetric Alterations in Mutation Carriers.
The axon guidance cue receptor DCC (deleted in colorectal cancer) plays a critical role in the organization of mesocorticolimbic pathways in rodents. To investigate whether this occurs in humans, we measured (1) anatomical connectivity between the substantia nigra/ventral tegmental area (SN/VTA) and forebrain targets, (2) striatal and cortical volumes, and (3) putatively associated traits and behaviors. To assess translatability, morphometric data were also collected in -haploinsufficient mice. The human volunteers were 20 mutation carriers, 16 relatives, and 20 unrelated healthy volunteers (UHVs; 28 females). The mice were 11 and 16 wild-type C57BL/6J animals assessed during adolescence and adulthood. Compared with both control groups, the human carriers exhibited the following: (1) reduced anatomical connectivity from the SN/VTA to the ventral striatum [: = 0.0005, () = 0.60; UHV: = 0.0029, = 0.48] and ventral medial prefrontal cortex (: = 0.0031, = 0.53; UHV: = 0.034, = 0.35); (2) lower novelty-seeking scores (: = 0.034, = 0.82; UHV: = 0.019, = 0.84); and (3) reduced striatal volume (: = 0.0009, = 1.37; UHV: = 0.0054, = 0.93). Striatal volumetric reductions were also present in mice, and these were seen during adolescence (= 0.0058, = 1.09) and adulthood (= 0.003, = 1.26). Together these findings provide the first evidence in humans that an axon guidance gene is involved in the formation of mesocorticolimbic circuitry and related behavioral traits, providing mechanisms through which mutations might affect susceptibility to diverse neuropsychiatric disorders. Opportunities to study the effects of axon guidance molecules on human brain development have been rare. Here, the identification of a large four-generational family that carries a mutation to the axon guidance molecule receptor gene, , enabled us to demonstrate effects on mesocorticolimbic anatomical connectivity, striatal volumes, and personality traits. Reductions in striatal volumes were replicated in -haploinsufficient mice. Together, these processes might influence mesocorticolimbic function and susceptibility to diverse neuropsychiatric disorders.

Presynaptic D2 dopamine receptors control long-term depression expression and memory processes in the temporal hippocampus.
Dysfunctional mesocorticolimbic dopamine signaling has been linked to alterations in motor and reward-based functions associated with psychiatric disorders. Converging evidence from patients with psychiatric disorders and use of antipsychotics suggests that imbalance of dopamine signaling deeply alters hippocampal functions. However, given the lack of full characterization of a functional mesohippocampal pathway, the precise role of dopamine transmission in memory deficits associated with these disorders and their dedicated therapies is unknown. In particular, the positive outcome of antipsychotic treatments, commonly antagonizing D2 dopamine receptors (D2Rs), on cognitive deficits and memory impairments remains questionable.

EARLY AXON GUIDANCE AND SYNAPSE MATURATION DEFECTS IN A ZEBRAFISH MODEL OF MUCOPOLYSACCHARIDOSIS TYPE II

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Rosa Manzoli[1], Lorenzo Badenetti[2], Rosella Tomanin[2], Enrico Moro[3]
[1]Università degli Studi di Padova, Department Of Biology/ Department Of Molecular Medicine, Padova, Italy, [2]Università degli Studi di Padova, Women's And Children's Health, Padova, Italy, [3]Università degli Studi di Padova, Molecular Medicine, Padova, Italy

Mucopolysaccharidosis type II (MPS II) is a rare X-linked lysosomal storage disorder caused by a deficit of the lysosomal enzyme iduronate-2-sulfatase (IDS), a hydrolase involved in the degradation of dermatan and heparan sulfate (HS) glycosaminoglycans. Disease manifestations include progressively severe central nervous system defects resulting in epilepsy, hyperactivity, loss of attention and aggressive behaviors. It is well known that HS plays a critical role in neurodevelopment by shaping the neural extracellular matrix and modulating neuroligand-receptor interactions. The goal of our investigation is to deeply characterize the mechanistic basis of MPS II-related brain defects using an established zebrafish Ids knock out (KO) model. Towards this aim, we preliminarily performed a complementary approach (based on Western Blot, immunofluorescence and other techniques) to investigate axon guidance and synapse maturation defects in KO and age-matched control larvae at early developmental stages. In the former case, we found in KO fish a consistent dysregulation of Netrin1 and Deleted in colorectal cancer (DCC), two well-known molecules involved in axonal chemoattraction. Concerning the synaptic maturation, we detected an overactivation of the canonical Wnt pathway and increased expression of the postsynaptic density protein 95 (PSD-95) in Ids loss of function fish. All abnormalities have been documented before any overt HS accumulation, suggesting that a hierarchy of multiple aberrant cellular and signaling cascades, rather than the simple lysosomal engorgement, underlies the altered MPS II neurophysiology.

Children born prematurely are at higher risk to develop brain lesions especially perinatal white matter injury (PWMI). Shreds of evidence in humans and rodents demonstrate that systemic inflammation induces glial reactivity, which is relevant in PWMI physiopathology. A new challenge in perinatal brain injuries is to develop new neuroprotective strategies targeting neuroinflammation to prevent PWMI. Serotonin (5-HT) and its receptors, including HTR7/5-HT7 receptor, might regulate brain inflammation by modulation of glial reactivity. In a perinatal inflammation mouse model of PWMI induced by IL-1β injections, some key lesions can be summarized as (i) systemic inflammation (ii) pro-inflammatory glial reactivity, and (iii) inhibition of oligodendrocyte maturation, leading to PWMI. In this model, *Htr7* mRNA was significantly overexpressed in the anterior cortex, suggesting its key function in PWMI etiology. LP-211, a specific HTR7 agonist with a high affinity that crosses the blood-brain barrier (BBB), was used to modulated HTR7 activity in our model. LP-211 prevented the glial reactivity and the downregulation of myelin basic protein (MBP, a key protein in the myelination process) induced by IL-1β injections. To confirm that the neuroprotective effect of HTR7 activation occurred in the brain and not in the periphery, we compared LP-211 and AS-19 (another HTR7 agonist that does not pass BBB) effects both on systemic inflammation and MBP expression. Both LP-211 and AS-19 did not reduce peripheric inflammation. LP-211, unlike AS-19, was able to rescue MBP optimal expression. Therefore, HTR7 could represent an innovative therapeutic target to protect the developing brain from preterm brain injuries.

IS THE ADHD BRAIN A SLEEPY BRAIN? ELECTROENCEPHALOGRAPHIC MARKERS OF SLEEP INTRUSIONS IN AWAKE, BEHAVING ADHD ADULTS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Alessia Ruyant Belabbas[1,2], Redmond O'Connell[3], Mark Bellgrove[4], Thomas Andrillon[1]
[1]Sorbonne Université, Inserm-CNRS, Paris Brain Institute, Paris, France, [2]École Normale Supérieure, Département D'Études Cognitives, Paris, France, [3]Trinity College Dublin, Trinity College Institute Of Neuroscience & School Of Psychology, Dublin, Ireland, [4]Monash University, School Of Psychological Sciences, Turner Institute For Brain And Mental Health, Melbourne, Australia

Background: Attention-Deficit/Hyperactivity Disorder (ADHD) is a neurodevelopmental condition characterized by above-normal levels of inattentive, hyperactive and/or impulsive behaviors, which seriously challenges everyday-life activities and even reduce the life expectancy of the 5% of individuals affected by this disorder worldwide. However, despite the frequency of this trouble, little is known about its etiology. The frequent observation of sleep disturbances in the ADHD population suggests that attentional disorders may stem from a dysregulation of arousal, depicting the ADHD brain as hypo-vigilant. **Aim:** Test whether ADHD symptoms are at least partially linked to a phenomenon of 'local sleep'. **Methods:** We studied a group of controls and individuals with ADHD performing the CTET attentional task. We recorded their EEG, extracted markers of hypo-vigilance such as theta power and sleep-like slow waves. **Results:** The increase of both theta power and slow waves' amplitude in the ADHD population compared to controls describes sleepier ADHD brains. Moreover, the amplitude of slow waves observed during the task negatively correlated with behavioral performance. **Conclusions:** Consequently, attentional disturbances in ADHD individuals could be partly explained by vigilance troubles. In particular, local sleep intrusions during wakefulness, detected through the presence of sleep-like slow waves, could provide a novel framework to explain attentional lapses, in both the general and ADHD populations, as well as the impulsive manifestations of ADHD. Therefore, these high-amplitude slow waves could be used as a new biomarker, facilitating the diagnosis of ADHD and offering new therapeutic leads. *Keywords : ADHD, hypo-vigilance, local sleep, attentional lapses, impulsivity, electroencephalography*

HEPARANASE INHIBITION TO PREVENT DEGRADATION OF HEPARAN SULFATE AND ACCUMULATION OF INTERMEDIATE HS DEGRADATION PRODUCTS IN SANFILIPPO SYNDROME

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Laura Modernell[1], Eduardo Sanches[2], Yohan Van De Looij[3], Analina Da Silva[3], Stéphane Sizonenko[2], Noemi Veraldi[2]
[1]School of Medicine, University, Division Of Child Development And Growth, Department Of Gynecology, Geneva, Switzerland, [2]School of Medicine, University, Division Of Child Development And Growth, Department Of Gynecology , Obstetrics And Pediatrics, Geneva, Switzerland, [3]Ecole polytechnique de Lausanne, Centre D'imagerie Biomédicale, Lausanne, Switzerland

Mucopolysaccharidosis IIIA (Sanfilippo syndrome) is a hereditary disease caused by mutations in the enzymes responsible for the catabolism of heparan sulfates (HS), leading to lysosomal HS fragments accumulation, multisystemic disease and premature death. Currently, there is no cure and available therapies are scarce. Here, we tested the effects of ip injection of the marine sulphated carbohydrate A5_3 (20µg/g in 40µl 3x/week for 8 weeks) in a mouse model of MPSIIIA from 4 to 12 weeks of age. Both male and female mice were used in this study and were divided into 4 groups (n=14; WT, MPSIIIA, MPSIIIA+A5_3; MPSIIIA+Saline). High field 9.4T ^{1}H-MRSpectroscopy revealed increased levels of glutamate, glutamine, GSH and NAA at 4 weeks in MPSIIIA animals. These alterations indicate dysfunction in the coupling neurons-astrocytes leading to glutamatergic excitotoxicity. Moreover, phosphocreatine and creatine levels were reduced, indicating energetic metabolism failure in the cortex. Treatment with A5_3 partially reversed the alterations in the cortex and hippocampus observed by MRS at 12 weeks. Also, decreased transcription levels of the glutamate transporter Slc1a together with increased IL-1α and TLR4 were observed in MPSIIIA and reversed by treatment. Increased protein expression of LAMP1, GFAP and pro-caspase3 was observed in MPSIIA mice, with no major effects of treatment. Finally, behavioural analysis at 11 weeks revealed decreased exploratory activity and anxiety in MPSIIIA mice, while no difference was observed upon treatment. Despite no evidence of functional protection, A5_3 caused preservation in the cortical metabolism and partial anti-inflammatory effects in MPSIIIA mice.

Dose-Dependent Neuroprotective Effects of Bovine Lactoferrin Following Neonatal Hypoxia-Ischemia in the Immature Rat Brain.
Injuries to the developing brain due to hypoxia-ischemia (HI) are common causes of neurological disabilities in preterm babies. HI, with oxygen deprivation to the brain or reduced cerebral blood perfusion due to birth asphyxia, often leads to severe brain damage and sequelae. Injury mechanisms include glutamate excitotoxicity, oxidative stress, blood-brain barrier dysfunction, and exacerbated inflammation. Nutritional intervention is emerging as a therapeutic alternative to prevent and rescue brain from HI injury. Lactoferrin (Lf) is an iron-binding protein present in saliva, tears, and breast milk, which has been shown to have antioxidant, anti-inflammatory and anti-apoptotic properties when administered to mothers as a dietary supplement during pregnancy and/or lactation in preclinical studies of developmental brain injuries. However, despite Lf's promising neuroprotective effects, there is no established dose. Here, we tested three different doses of dietary maternal Lf supplementation using the postnatal day 3 HI model and evaluated the acute neurochemical damage profile using H Magnetic Resonance Spectroscopy (MRS) and long-term microstructure alterations using advanced diffusion imaging (DTI/NODDI) allied to protein expression and histological analysis. Pregnant Wistar rats were fed either control diet or bovine Lf supplemented chow at 0.1, 1, or 10 g/kg/body weight concentration from the last day of pregnancy (embryonic day 21-E21) to weaning. At postnatal day 3 (P3), pups from both sexes had their right common carotid artery permanently occluded and were exposed to 6% oxygen for 30 min. Sham rats had the incision but neither surgery nor hypoxia episode. At P4, MRS was performed on a 9.4 T scanner to obtain the neurochemical profile in the cortex. At P4 and P25, histological analysis and protein expression were assessed in the cortex and hippocampus. Brain volumes and ex vivo microstructural analysis using DTI/NODDI parameters were performed at P25. Acute metabolic disturbance induced in cortical tissue by HIP3 was reversed with all three doses of Lf. However, data obtained from MRS show that Lf neuroprotective effects were modulated by the dose. Through western blotting analysis, we observed that HI pups supplemented with Lf at 0.1 and 1 g/kg were able to

counteract glutamatergic excitotoxicity and prevent metabolic failure. When 10 g/kg was administered, we observed reduced brain volumes, increased astrogliosis, and hypomyelination, pointing to detrimental effects of high Lf dose. In conclusion, Lf supplementation attenuates, in a dose-dependent manner, the acute and long-term cerebral injury caused by HI. Lf reached its optimal effects at a dose of 1 g/kg, which pinpoints the need to better understand effects of Lf, the pathways involved and possible harmful effects. These new data reinforce our knowledge regarding neuroprotection in developmental brain injury using Lf through lactation and provide new insights into lactoferrin's neuroprotection capacities and limitation for immature brains.

Aims: Cytomegalovirus (CMV) is a member of the *Herpesviridae* family. Congenital CMV infections represent one leading cause of human neurodevelopmental disorders. Despite their high prevalence (0.7 to 1% of all live births) and possible severity, the pathophysiology remains elusive and no satisfactory prevention or therapy is available. Besides neural-based mechanisms, the possible involvement of immune responses in CMV-related neuropathogenesis has been increasingly questioned. Insights into the early immune events following CMV infection of the developing brain are particularly needed. Methods: We have created a novel model of CMV infection of the rat developing brain by *in utero* injection at E15 of a recombinant rat CMV allowing for GFP expression in the infected cells. Current investigations at various levels non-exhaustively include postnatal phenotyping of rat pups, electrophysiological recordings, microglia- and chemokine-targeting rescue assays, immunophenotyping of brain leukocytes, RNA sequencing of flow-sorted microglia. Results: Rat pups recapitulated several characteristics of the human disease, including altered sensorimotor development and epileptic seizures. Brain immune alterations were detected at the cellular and molecular levels. Our data indicate that fetal microglia on the one hand, and a chemokine encoded by the viral genome on the other hand, might both play pivotal roles in CMV-related neuropathogenesis. Conclusions: Our findings provide novel insights into the pathophysiological mechanisms possibly involved in neuropathogenesis of congenital CMV, and would contribute as proof-of-principle to the future design of innovative therapeutic options.

Rett syndrome (RTT) is a neurodevelopmental disorder caused by mutations in the transcriptional modulator gene *MECP2*, and patients display global dysregulation of the neuronal transcriptome. However, despite MECP2 being a highly abundant protein, the changes in mRNA levels are surprisingly small in RTT models suggesting that mRNA stability mechanisms significantly shape the mRNA levels in RTT. To uncover the dynamics between transcription and mRNA levels in RTT models, we directly measured transcription rate and mRNA half-life changes in iPSC-derived RTT patient neurons using RATE-seq and RNA-seq from nuclear and whole-cell fractions of RTT mice models. Expectedly, we found thousands of genes with dysregulated transcription rates in both RTT models. Surprisingly, we found that combined frequencies of three dinucleotides were better predictors of transcriptional dysregulation than CA/CG, described DNA-binding sites of MECP2. Moreover, we found a similarly widespread alteration in mRNA stabilities leading to the buffering of transcriptional dysregulation of most genes. Using an unbiased computational approach, we found microRNA and RNA-Binding Protein (RBP) sequence elements enriched in 3'UTRs of buffered genes. We also found a significant number of mRNAs exclusively dysregulated at the stability levels in both RTT models. Our findings identify post-transcriptional mechanisms in humans and mice RTT models that alter mRNA half-life to buffer transcription rate changes uncovering new actionable mechanisms to be explored in translational approaches.

The use of induced pluripotent stem cells (iPSC) as models of development and disease has brought insights into the heterogeneity of cell lineages during early neurodevelopment. This is of relevance to the study of neurodevelopmental disorders (NDD) as their underlying mechanisms remain largely unknown. NDDs are frequently caused by loss-of-function mutations in chromatin-modifying enzymes. **Aim** To understand how these mutations affect neurodevelopmental processes, we studied Kabuki Syndrome (KS), a representative NDD mainly caused by haploinsufficiency of *KMT2D* and *KDM6A*, enzymes involved in histone methylation. **Methods** We created a KS cortical model and differentiated wildtype and KS-patient-derived iPSC lines into neural precursors cells. We profiled the cells using immunocytochemistry, bulk and single-cell transcriptomics, as well as single-cell ATAC and multi-omic sequencing to capture chromatin accessibility and gene expression from the same cells. **Results & Conclusions** Our model highlights an asynchronous delayed differentiation into the cortico-neural lineage. The RNA-seq analysis revealed significant events of differential splicing in *DNMT3*, a DNA methyltransferase and a known NDD gene. Leveraging the chromatin accessibility profile, we identified an enrichment of specific TF binding motifs in KS cells compared to controls. We observed large inter-patient variability, which suggests that different molecular pathways might contribute to the condition. Currently, to control for genetic background effects, we are using CRISPR-Cas9 to create isogenic control iPSC lines and wildtype lines carrying engineered KS disease mutations. We aim to better understand the molecular pathways and developmental stages underlying KS and optimise our model to extend the study to other NDDs.

A CLOSER LOOK AT CUX1 HETEROZYGOSIS IN THE NEOCORTEX, WHEN ONE COPY IS NOT ENOUGH

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Elia Marcos-Grañeda, Linnea Weiss, Marta Nieto
Spanish National Centre for Biotechnology (CNB-CSIC), Molecular And Cellular Biology, Madrid, Spain

Neurodevelopmental disorders can emerge due to abnormal neuronal function and/or connectivity. Cortical wiring requires a variety of neuronal subtypes whose identity is defined by specific transcription factors (TF). Some of them are dosage-dependent, meaning that a single functional copy of the gene cannot maintain the wild-type phenotype. In the neocortex, upper layer neurons, which participate in the most complex and evolved circuits, are defined by the expression of Cux1 TF. This gene is involved in their dendritogenesis, synaptogenesis and the establishment of interhemispheric projections as shown by knock-down experiments. Moreover, heterozygous patients carrying a mutant Cux1 allele have neurological diseases such as epilepsy, intellectual disability, and autism spectrum disorder. However, the overall cortical development and brain structures seem normal in heterozygous condition. Thus, a deeper characterization of the heterozygous scenario is needed. For this purpose, we characterized the Cux1 heterozygous mouse; studied Cux1 expression in different functional areas of the cortex during development; and analysed their susceptibility to kainate-induced seizures. Our results show a significant reduction in Cux1 expression in the neocortex at postnatal day (P) 10, specially in the barrel field of the somatosensory area. These differences are attenuated in adulthood (P30), suggesting a possible rescue mechanism that leads to a catch-up phenotype. We also demonstrate that Cux1 heterozygosis increases predisposition to develop seizures in mice. Taken together, our findings highlight the relevance of Cux1 levels of expression during cortical development and point to the necessity of investigating the consequences of Cux1 haploinsufficiency at a molecular level.

PHF2 histone demethylase prevents DNA damage and genome instability by controlling cell cycle progression of neural progenitors.
Histone H3 lysine 9 methylation (H3K9me) is essential for cellular homeostasis; however, its contribution to development is not well established. Here, we demonstrate that the H3K9me2 demethylase PHF2 is essential for neural progenitor proliferation in vitro and for early neurogenesis in the chicken spinal cord. Using genome-wide analyses and biochemical assays we show that PHF2 controls the expression of critical cell cycle progression genes, particularly those related to DNA replication, by keeping low levels of H3K9me3 at promoters. Accordingly, PHF2 depletion induces R-loop accumulation that leads to extensive DNA damage and cell cycle arrest. These data reveal a role of PHF2 as a guarantor of genome stability that allows proper expansion of neural progenitors during development.

CHARACTERIZATION OF LONG-RANGE MONOAMINERGIC NEUROMODULATORY PROJECTIONS IN FOCAL CORTICAL DYSPLASIA

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Norisa Meli[1,2], Sandra Blaess[1], Albert Becker[2]

Focal Cortical Dysplasia (FCD) represents a large variety of cortical malformations associated with abnormal cortical layering and/or appearance of dysmorphic neuronal elements, often occurring in the frontal cortex. FCD is a common cause of pharmaco-resistant epilepsies and altered local neuronal activity has been reported in human FCD tissue samples. Local cortical microcircuits are extensively modulated by monoaminergic axonal projections arising from the brain stem. Previous analysis of monoaminergic modulatory inputs in human FCD biopsies suggested altered density and distribution of these monoaminergic axons. However, a systematic investigation is still pending. Here we perform a comprehensive analysis of monoaminergic axonal projections, with a focus on dopaminergic (DA) innervation, in human FCD biopsies and in the medial prefrontal cortex (mPFC) of FCD mouse models (mTOR hyperactivation model). Moreover, we analyse the expression of dopamine receptors *Drd1* and *Drd2* via multiplex fluorescent RNA in situ in human specimen and the mPFC of this mouse model. Our preliminary results suggest that the overall DA innervation density is not altered in adult human FCD samples compared to the control area. However, the DA innervation distribution displays a variable lamination pattern between FCD and the control area. In the mTOR hyperactivation mouse model, we observe a transient increase in DA axonal innervation in the deep layers of mPFC during adolescence. *Drd1* and *Drd2* receptors seem differentially expressed in the mTOR-mutated cells compared to normally-developed neurons. Overall, our results suggest alterations in dopaminergic neurotransmission in FCD that may be important for understanding disease mechanisms in FCD.

The Development of the Mesoprefrontal Dopaminergic System in Health and Disease.
Midbrain dopaminergic neurons located in the substantia nigra and the ventral tegmental area are the main source of dopamine in the brain. They send out projections to a variety of forebrain structures, including dorsal striatum, nucleus accumbens, and prefrontal cortex (PFC), establishing the nigrostriatal, mesolimbic, and mesoprefrontal pathways, respectively. The dopaminergic input to the PFC is essential for the performance of higher cognitive functions such as working memory, attention, planning, and decision making. The gradual maturation of these cognitive skills during postnatal development correlates with the maturation of PFC local circuits, which undergo a lengthy functional remodeling process during the neonatal and adolescence stage. During this period, the mesoprefrontal dopaminergic innervation also matures: the fibers are rather sparse at prenatal stages and slowly increase in density during postnatal development to finally reach a stable pattern in early adulthood. Despite the prominent role of dopamine in the regulation of PFC function, relatively little is known about how the dopaminergic innervation is established in the PFC, whether and how it influences the maturation of local circuits and how exactly it facilitates cognitive functions in the PFC. In this review, we provide an overview of the development of the mesoprefrontal dopaminergic system in rodents and primates and discuss the role of altered dopaminergic signaling in neuropsychiatric and neurodevelopmental disorders.

STRUCTURAL PLASTICITY IN THE MONKEY ENTORHINAL AND PERIRHINAL CORTICES FOLLOWING SELECTIVE HIPPOCAMPAL LESION

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Justine Villard[1], Loïc Chareyron[1], Olivia Piguet[1], Pauline Lambercy[1], Gianni Lonchampt[1], Pamela Banta Lavenex[2], David Amaral[3,4], Pierre Lavenex[1]
[1]University of Lausanne, Laboratory Of Brain And Cognitive Development, Institute Of Psychology, Lausanne, Switzerland, [2]Unidistance Suisse, Faculty Of Psychology, Brig, Switzerland, [3]UC Davis, Mind Institute And Department Of Psychiatry And Behavioral Sciences, Sacramento, United States of America, [4]UC Davis, California Primate Research Center, Sacramento, United States of America

Populations of Bcl2-positive immature neurons are present in several regions of the adult mammalian brain, including the amygdala, and the entorhinal and perirhinal cortices. We have previously shown that neonatal and adult hippocampal lesions increase the differentiation of immature neurons in the monkey amygdala. Here, we determined whether similar changes occur in the entorhinal and perirhinal cortices in the same animals. We performed design-based stereological analyses of Nissl-stained and Bcl2-stained sections to estimate the number and soma size of immature and mature neurons in different subdivisions of the entorhinal and perirhinal cortices. We found different lesioned-induced structural changes in the entorhinal and perirhinal cortices following hippocampal lesion. Following neonatal hippocampal lesion, the number of immature neurons was generally higher in the entorhinal and perirhinal cortices, as compared to control and adult-lesioned monkeys. The number of mature neurons was higher in layer III of area Er of the entorhinal cortex, but it did not differ from controls in layer II of area 36 of the perirhinal cortex. Following adult hippocampal lesion, the number of immature neurons was lower in the entorhinal cortex but it did not differ from controls in the perirhinal cortex. The number of small mature neurons was lower in layer II of area 36, but it did not differ from controls in layer III of Er. Consistent with prior findings in the amygdala, hippocampal damage may have influenced neuroblast migration and the differentiation of immature neurons in a subdivision-specific manner in the entorhinal and perirhinal cortices.

The prefrontal cortex (PFC) plays a key role in high-level cognitive processes and emotional behaviors. The maturation of PFC circuits is characterized by critical developmental time windows, which shape functional connectivity among neurons. Early life insults can alter PFC function, increasing the risk for brain disorders. Perinatal exposure to fluoxetine (FLX), a selective serotonin reuptake inhibitor (SSRI), affects PFC development and yield significant depressive- and anxiety-like phenotypes in the adult. We found that early postnatal FLX-treatment results in strong hypoactivity and reduced firing rate of putative pyramidal neurons (PNs) of adult mice. *Ex-vivo*, patch-clamp recordings indicate that early-life FLX treatment affects the firing dynamics of a specific subpopulation of PNs, which transiently expresses the serotonin transporter SERT during the PFC critical period (SERT-positivePN). Conversely the excitability of SERT-negative PNs, and parvalbumin-positive interneurons was unaffected by early FLX treatment. Genetic and pharmacological experiments indicate that hypoexcitability of PFC PNs mainly depended on 5HT-7 receptor. Surprisingly, spontaneous glutamatergic and GABAergic neurotransmission onto PFC PNs was unaltered in mice that underwent perinatal FLX treatment. We are currently investigating potential anatomical differences that that could be induced by the early-life insult caused by FLX treatment. Our results suggest potential novel neurobiological mechanisms, underlying detrimental neurodevelopmental consequences of early-life environmental insult.

Affecting around 10% of world population, chronic pain and its related psychiatric comorbidities (depression and anxiety) are major health issues. Pathways and modulation of pain are well documented in the spinal cord, but the implication of neuropeptides in this modulation remains poorly described in the brain. Relaxin-3 neuropeptide displays antidepressant and anxiolytic effects, and our preliminary results indicate an analgesic role in rats and mice. Relaxin-3 is expressed by nucleus incertus neurons that project to different cortical (e.g. anterior cingulate cortex (ACC)) and subcortical (e.g. amygdala) areas of the pain matrix. Because of the prominent expression of the relaxin-3 G protein-coupled receptor (RXFP3) in those areas, we aim at studying the pain modulatory effects of relaxin-3 by using pharmacological, behavioral, and anatomical approaches in a mouse model of persistent inflammatory pain obtained by the injection of Complete Freud's Adjuvant in the hind paw. Intra-amygdalar injection of RXFP3 agonists (A2 or A5) alleviates both mechanical and thermal pain, while intra-ACC injection has an effect only on mechanical sensitization. AAV-mediated chronic release of another RXFP3 agonist (I5/R3) in the ACC prevents mechanical but not thermal sensitization. Multiplex fluorescent in-situ hybridization (RNAscope) shows RXFP3 mRNA expression in somatostatin interneurons both in the ACC and amygdala. We develop quantitative 3D immunolabelling to determine the organisation of relaxin-3/RXFP3 microcircuits. Our data highlight a novel role for this peptide family and suggest their therapeutic potential in persistent pain conditions.

POSTNATAL IL-4 ADMINISTRATION INDUCES LONG-TERM DYSFUNCTION IN CEREBELLAR-VTA CONNECTIVITY

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Pedro Ferreira[1,2], Joana Guedes[1,3], Tiago Reis[1], Jéssica Costa[1], Ana Luísa Cardoso[1,3], João Peça[1,2]

Interleukin-4 (IL-4) is a Th2 cytokine that is central to the regulation of allergic inflammation and a critical regulator of microglia. We have recently discovered that postnatal increases in IL-4 induce deficits in cerebellar development, leading to an increase in Purkinje cell excitatory inputs. Moreover, IL-4-treated mice present hyperactivity and increased stereotypies reminiscent of ADHD-like behaviors. Recently, direct projections from the cerebellum to the VTA have been described to modulate activity in this region. Since dopaminergic signaling is highly implicated in the pathophysiology of ADHD, we now aim to probe our animal model for dysfunction in this circuit. To this end, we delivered a viral construct (AAV-ChR2-GFP) to the deep cerebellar nuclei (DCN), allowing us to specifically stimulate DCN-VTA inputs using acute brain slices for whole-cell electrophysiology recordings. Through this, we could corroborate the existence of the recently described DCN-VTA projections, and we also observed that postnatal IL-4 administration was sufficient to induce deficits in short-term plasticity in VTA neurons innerved by DCN afferents. Whole-cell patch clamp was also used to assess whether the presynaptic alterations seen in the previous experiment would alter the number of synapses formed in VTA dopaminergic neurons. These data indicate that IL-4 injected animals present a dysfunctional connection between the cerebellum and the VTA, possibly underlying the hyperactive and impulsive behavioral phenotype previously observed in these mice through a deregulation of the dopaminergic system.

Abnormal mGluR-mediated synaptic plasticity and autism-like behaviours in Gprasp2 mutant mice.
Autism spectrum disorder (ASD) is characterized by dysfunction in social interactions, stereotypical behaviours and high co-morbidity with intellectual disability. A variety of syndromic and non-syndromic neurodevelopmental disorders have been connected to alterations in metabotropic glutamate receptor (mGluR) signalling. These receptors contribute to synaptic plasticity, spine maturation and circuit development. Here, we investigate the physiological role of Gprasp2, a gene linked to neurodevelopmental disabilities and involved in the postendocytic sorting of G-protein-coupled receptors. We show that Gprasp2 deletion leads to ASD-like behaviour in mice and alterations in synaptic communication. Manipulating the levels of Gprasp2 bidirectionally modulates the surface availability of mGluR and produces alterations in dendritic complexity, spine density and synaptic maturation. Loss of Gprasp2 leads to enhanced hippocampal long-term depression, consistent with facilitated mGluR-dependent activation. These findings demonstrate a role for Gprasp2 in glutamatergic synapses and suggest a possible mechanism by which this gene is linked to neurodevelopmental diseases.

Social subordination induced by early life adversity rewires inhibitory control of the prefrontal cortex via enhanced Npy1r signaling.
Social hierarchies are present in most mammalian species. In nature, hierarchies offer a tradeoff between reduction of in-group fighting between males, at the expense of an asymmetric sharing of resources. Early life experiences and stress are known to influence the rank an individual attains in adulthood, but the associated cellular and synaptic alterations are poorly understood. Using a maternal separation protocol, we show that care-deprived mice display a long-lasting submissive phenotype, increased social recognition, and enhanced explorative behavior. These alterations are consistent with an adaptation that favors exploration rather than confrontation within a group setting. At the neuronal level, these animals display dendritic atrophy and enhanced inhibitory synaptic inputs in medial prefrontal cortex (mPFC) neurons. To determine what could underlie this synaptic modification, we first assessed global gene expression changes via RNAseq, and next focused

on a smaller subset of putatively altered synaptic receptors that could explain the changes in synaptic inhibition. Using different cohorts of maternally deprived mice, we validated a significant increase in the expression of Npy1r, a receptor known to play a role in maternal care, anxiety, foraging, and regulation of group behavior. Using electrophysiological recordings in adult mice while blocking NPY1R signaling, we determined that this receptor plays a key role in enhancing GABAergic currents in mice that experience maternal deprivation. Taken together, our work highlights the potential of regulating NPY1R in social anxiety disorders and the alterations induced in brain circuitry as a consequence of early life stress and adversity.

The old guard: Age-related changes in microglia and their consequences.
Among all major organs, the brain is one of the most susceptible to the inexorable effects of aging. Throughout the last decades, several studies in human cohorts and animal models have revealed a plethora of age-related changes in the brain, including reduced neurogenesis, oxidative damage, mitochondrial dysfunction and cell senescence. As the main immune effectors and first responders of the nervous tissue, microglia are at the center of these events. These cells experience irrevocable changes as a result from cumulative exposure to environmental triggers, such as stress, infection and metabolic dysregulation. The age-related immunosenescent phenotype acquired by microglia is characterized by profound modifications in their transcriptomic profile, secretome, morphology and phagocytic activity, which compromise both their housekeeping and defensive functions. As a result, aged microglia are no longer capable of establishing effective immune responses and sustaining normal synaptic activity, directly contributing to age-associated cognitive decline and neurodegeneration. This review discusses how lifestyle and environmental factors drive microglia dysfunction at the molecular and functional level, also highlighting possible interventions to reverse aging-associated damage to the nervous and immune systems.

Interleukin-4 (IL-4) is a classical Th2 cytokine with pleiotropic functions in allergies, microglia activation and cognitive processes. Epidemiologically, severe allergies such as atopy, asthma and dermatitis share high comorbidity with Attention-Deficit/Hyperactivity Disorder (ADHD). However, the mechanistic link between these conditions is unknown. Here, we find that early postnatal allergies (asthma mouse model of house dust mites) increase the levels of IL-4 in the cerebellum, a brain region that is undergoing profound remodeling during this period. This immune challenge leads to decreased engulfment of granule cells by microglia, deficits in Purkinje cell connectivity and overall hyperactivity in juvenile mice. Interestingly, these dysfunctions are reproduced by peripherally injecting IL-4 alone during this critical period of cerebellar development. We also find that the levels of this cytokine are tightly regulated to allow the physiological phagocytic activity of microglia to prune cerebellar granule cells. We propose that a pathological increase in IL-4 is sufficient to mediate neuronal survival, promote an excessive number of parallel fibers and induce hyperkinetic and impulsive-like behaviors reminiscent of ADHD. Our data provides the first mechanistic link between allergies and hyperactivity, and reinforces the hypothesis that environment-dependent alterations in immune mediators during the postnatal period may impair the maturation of brain regions with protracted development.

miR-155 modulates microglia-mediated immune response by down-regulating SOCS-1 and promoting cytokine and nitric oxide production.
Innate immunity constitutes the first line of defence against both external and endogenous threats in the brain, and microglia cells are considered key mediators of this process. Recent studies have shown that microRNAs (miRNAs) may play a determinant role in the regulation of gene expression during innate immune responses. The major goal of this work was to investigate the contribution of a specific miRNA - miR-155 - to the modulation of the microglia-mediated immune response. For this purpose, in vitro studies were performed in N9 microglia cells to evaluate changes in the levels of this miRNA following microglia activation. A strong up-regulation of miR-155 expression was observed following microglia exposure to lipopolysaccharide, which was consistent with a decrease in the levels of the suppressor of cytokine signalling 1 (SOCS-1) protein, a key inhibitor of the inflammatory process and a predicted target of miR-155. The miR-155 knockdown by anti-miRNA oligonucleotides up-regulated SOCS-1 mRNA and protein levels and significantly decreased the production of nitric oxide and the expression of inflammatory cytokines and inducible nitric oxide synthase. Finally, treatment of neuronal primary cultures with conditioned medium obtained from microglia cells, in which miR-155 was inhibited before cell activation, decreased inflammatory-mediated neuronal cell death. Overall, our results show that miR-155 has a pro-inflammatory role in microglia and is necessary for the progression of the immune response through the modulation of SOCS-1, suggesting that, in a chronic inflammatory context, miR-155 inhibition can have a neuroprotective effect.

Early miR-155 upregulation contributes to neuroinflammation in Alzheimer's disease triple transgenic mouse model.
MicroRNAs (miRNAs) have emerged as a class of small, endogenous, regulatory RNAs that exhibit the ability to epigenetically modulate the translation of mRNAs into proteins. This feature enables them to control cell phenotypes and,

consequently, modify cell function in a disease context. The role of inflammatory miRNAs in Alzheimer's disease (AD) and their ability to modulate glia responses are now beginning to be explored. In this study, we propose to disclose the functional role of miR-155, one of the most well studied immune-related miRNAs in AD-associated neuroinflammatory events, employing the 3xTg AD animal model. A strong upregulation of miR-155 levels was observed in the brain of 12-month-old 3xTg AD animals. This event occurred simultaneously with an increase of microglia and astrocyte activation, and before the appearance of extracellular Aβ aggregates, suggesting that less complex Aβ species, such as Aβ oligomers may contribute to early neuroinflammation. In addition, we investigated the contribution of miR-155 and the c-Jun transcription factor to the molecular mechanisms that underlie Aβ-mediated activation of glial cells. Our results suggest early miR-155 and c-Jun upregulation in the 3xTg AD mice, as well as in Aβ-activated microglia and astrocytes, thus contributing to the production of inflammatory mediators such as IL-6 and IFN-β. This effect is associated with a miR-155-dependent decrease of suppressor of cytokine signaling 1. Furthermore, since c-Jun silencing decreases the levels of miR-155 in Aβ-activated microglia and astrocytes, we propose that miR-155 targeting can constitute an interesting and promising approach to control neuroinflammation in AD.

Roles of Microglial and Monocyte Chemokines and Their Receptors in Regulating Alzheimer's Disease-Associated Amyloid-β and Tau Pathologies.
Chemokines and their receptors have been shown to affect amyloid-β (Aβ) and tau pathologies in mouse models of Alzheimer's disease (AD) by regulating microglia and monocyte-associated neuroinflammation, microglial movement and monocyte recruitment into the brain. These cells in turn can promote and mediate Aβ phagocytosis and degradation and tau phosphorylation. In this review we discuss published work in this field in mouse models of AD and review what is known about the contributions of microglial and monocyte chemokines and their receptors to amyloid and tau pathologies. We focus on the roles of the chemokine/chemokine receptor pairs CCL2/CCR2, CX3CL1/CX3CR1, CCL5/CCR5, CXCL10/CXCR3 and CXCL1/CXCR2, highlighting important knowledge gaps in this field. A full understanding of the functions of chemokines and their receptors in AD may guide the development of novel immunotherapies for this devastating disease.

22q11 DS is caused by a microdeletion of 30-50 genes of chromosome 22. Consistent early perinatal clinical manifestation is dysphagia whose origins remain poorly understood. We have shown that the LgDel mouse mimics the human phenotypic spectrum of 22q11.2 DS, including dysphagia, and alterations of the neuronal excitability in the hypoglossal nucleus (nXII) motor neurons, which control the tongue movement during suckling and swallowing. Here we analyzed whether alteration in neuronal excitability is induced by changes in neurotransmitters content in the nXII. Confocal 3D reconstructions of motor neurons demonstrated dendritic and axonal abnormalities, including degenerating dendrites. Backscatter scanning electron microscopy enabled large-scale analysis of neuronal ultrastructural characteristics in motoneurons affected by the genetic lesion. nXII motoneurons of one-week old LgDel showed dilated mitochondrial cristae, paler mitochondrial matrix, and swollen Golgi and endoplasmic reticulum. At later ages, we found that LgDel nXII motor neurons and interneurons displayed sparse organelles, paler cytoplasm, reduced synaptic frequency and occasional neurodegeneration. We found hypertrophy of perineuronal, perivascular, and perisynaptic astrocytic processes, indicating glial response. To explore alterations in the inhibitory/excitatory afferents, we quantified the number of presynaptic terminals contacting the nXII motor neurons at P7 using SEM. Using postembedding immunogold or confocal imaging, we found a significant decrease in the GABA presynaptic content in nXII of LgDel synapses, supporting the notion of imbalanced neurotransmission levels that could directly affect the functionality of nXII and more generally the feeding and swallowing effector channels. **Support: NICHD: P01HD083157 and P50HD105328.**

Aims: Fetal alcohol spectrum disorder is characterized by physical and behavioral disabilities induced by prenatal and lactation alcohol exposure (PLAE). Since the expanded endocannabinoid system (ECS) is altered by alcohol, we aimed to investigate the role of N-acylethanolamines (NAEs) – peroxisome proliferator activated receptor-gamma (PPARg) axis in PLAE-induced memory deficits. **Methods:** We used pregnant C57BL/6 female mice with time-limited access to either water or a 20% v/v alcohol solution as a model of alcohol binge drinking. First, we analyzed molecules of the expanded ECS in hippocampus and prefrontal cortex at post-partum day (PD) 25 and 70. To investigate the role of NAEs-PPARg axis in the PLAE-induced memory deficits, we performed two pharmacological approaches from PD25 to PD35: i) URB597 (FAAH inhibitor to increase NAE levels) co-administration with GW9662 (PPARg antagonist to block its activation); ii) pioglitatzone administration (PPARg agonist) to explore whether a direct PPARg activation is sufficient. After this, a battery of memory tests was performed at PD60. **Results:** We showed that PLAE induces general reduction of NAEs and PPARg in the hippocampus at PD25. Moreover, URB597 treatment restores memory deficits induced by PLAE through a PPARg-dependent mechanism, as shown when co-administered with GW9662. Finally, PPARg agonist is sufficient to improve the PLAE-induced memory impairments. **Conclusions:** Our findings suggest that either endogenous (by NAEs) or exogenous PPARg activation rescues memory deficits in PLAE mice. Therefore, NAEs-PPARg pathway is involved in said impairments, which indicates this system might be a potential target to counteract cognitive symptoms of PLAE mice.

CDKL5 SCULPTS FUNCTIONAL CALLOSAL CONNECTIVITY TO PROMOTE COGNITIVE FLEXIBILITY

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Patricia Awad[1], Valerio Zerbi[2], Erin Johnson-Venkatesh[1], Francesca Damiani[1], Marco Pagani[3], Marija Markicevic[2], Sarah Nickles[1], Alessandro Gozzi[3], Hisashi Umemori[1], Michela Fagiolini[1]

Functional connectivity deficits in short and long-range projections have been observed in numerous models of neurodevelopmental disorders. Interhemispheric callosal projection neurons (CPN) represent one of the major long-range projections in the brain and mediate higher-order cognitive function and flexibility. However, little is known about the contribution of CPN in neural network miswiring and behavioral deficits in neurodevelopmental disorders, like the rare CDKL5 Deficiency Disorder (CDD). CDD is caused by de novo mutations in the X-linked gene *CDKL5* and is characterized by early-onset seizures, developmental delays, and cognitive impairment. We explored here whether long-range connectivity of CPN is altered and whether it underlies cognitive deficits in CDD. We found an increase in the number of callosal synaptic inputs but decreased local synaptic connectivity in the cingulate cortex of juvenile CDKL5 KO mice. These deficits were associated with functional hyperconnectivity across higher cognitive areas and homotopic interhemispheric connections, and accompanied by cognitive impairments in adult KO mice. Likewise, selective deletion of CDKL5 in CPNs resulted in increased callosal connectivity, without significantly altering intracortical cingulate network. Notably, these callosal-specific changes were sufficient to recapitulate the cognitive defects observed in CDKL5 KO. Finally, when CDKL5 was selectively expressed only in CPNs, it was sufficient to prevent the cognitive impairments of CDKL5 mutants. Together, these results reveal a novel role of *CDKL5* by demonstrating that it is both necessary and sufficient for proper CPN connectivity and cognitive flexibility and highlights a causal relationship between CPN dysfunction and cognitive impairment in a model of neurodevelopmental disorder.

SPEECH SIGNAL ANALYSIS TO CLASSIFY BIPOLAR DISORDER SYMPTOMS IN ADHD PATIENTS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Ester Bruno[1,2], Emilie Martz[3,4], Luisa Weiner[3,4], Alberto Greco[1,2], Nicola Vanello[1,2]
[1]University of Pisa, Centro Di Ricerca “e. Piaggio”, Pisa, Italy, [2]University of Pisa, Dipartimento Di Ingegneria Dell' Informazione, Pisa, Italy, [3]University of Strasbourg, Laboratoire De Psychologie Des Cognitions, Strasbourg, France, [4]University Hospital of Strasbourg, Department Of Psychiatry, Strasbourg, France

Aim Clinical diagnosis in psychiatric is primarily based on behavioral symptoms. A major research issue lies in the identification of biomarkers that could support clinicians' diagnosis. Speech signal processing has been found to be relevant when investigating mood disorders. In this study, we extract speech features from different Verbal Fluency Tests (VFT) conditions to classify comorbid Bipolar Disorder (BD) in adults suffering from Attention Deficit Hyperactivity Disorder (ADHD). **Methods** 57 adults with ADHD and 29 adults with ADHD+BD comorbidity were recruited. Subjects filled out several questionnaires on clinical symptoms before completing five conditions of the VFT. For each condition, speech features were extracted from audio recordings and investigated. Then, a Support Vector Machine – Recursive Features Elimination (SVM-RFE) was performed using a model trained on clinical labels and speech features. The final classification was obtained by combining the marginal classification outcomes from the different conditions using majority voting. Performance scores as accuracy and F1 score were estimated. **Results** Accuracy ranged from 0.72 to 0.89 across the five verbal fluency conditions. After applying the majority voting procedure, accuracy and F1 score increased to 0.94 and 0.95, respectively. Among the ADHD subjects, a correct classification was achieved in 52 out of 57 patients and the 29 subjects with ADHD+BD were correctly classified. The misclassification rates were correlated to the tendency to oscillate from anxiety to depression. **Conclusions** Results highlight that significant information is carried by speech features which could be a promising support for the clinical diagnosis of the ADHD+BD comorbidity.

THE LATENCY OF AUDITORY EVENT RELATED POTENTIAL P300 PROLONGED IN UNILATERAL HEARING LOSS SCHOOL AGE PUPILS IN MANDARIN LEARNING ENVIRONMENT

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Hiu Che Foo[1], Chenwei Tang[2], Yuting Kao[1], Hsingmei Wu[3], Chelun Chang[4], Meiyao Wu[5], Yuchun Lo[6], Shih-Ming Weng[1]
[1]National Taipei University Of Nursing And Health Sciences, Department Of Speech Language Pathology And Audiology, Taipei, Taiwan, [2]Shin Kong Wu-Ho-Su Memorial Hospital, Department Of Ophthalmology, Taipei, Taiwan, [3]Shin Kong Wu-Ho-Su Memorial Hospital, Department Of Otolaryngology, Taipei, Taiwan, [4]Artise Biomedical Co., Ltd, Artise Biomedical Co., Ltd, Hsinchu, Taiwan, [5]Donghu Elementary School, Donghu Elementary School, Taipei, Taiwan, [6]Taipei Medical University, The Ph.d. Program For Neural Regenerative Medicine, College Of Medical Science And Technology, Taipei, Taiwan

Our study investigated the differences in speech performance and neurophysiological response in groups of school-aged children with unilateral hearing loss (UHL) or typically developed (TD) characteristics. Total 16 primary school-aged children were recruited in our study (UHL=9/TD=7,diagnosed in Shin Kong Wu-Ho-Su Memorial Hospital). Word comprehension is tested by the Peabody Picture Vocabulary Test-Revised (PPVT-R), and the PPVT-R PR value is proportional to the auditory memory score (by The Children's Oral Comprehension Test) in both groups. Later we assessed the latency and amplitude of auditory ERP P300 and found that the latency of auditory ERP P300 in UHL group is prolonged compared with which in TD group. Although UHL pupils have one-side normal hearing, based on our results, long-term one-side hearing deprivation might be the origin of aberrant reorganization of brain areas for auditory or even visual perceptions attributed to speech delay and learning difficulties.
Key words: learning difficulties, unilateral hearing loss, ERP/P300

TRANSIENT DEVELOPMENTAL INCREASE IN CORTICAL PROJECTIONS TO AMYGDALA GABAERGIC NEURONS CONTRIBUTE TO CIRCUIT DYSFUNCTION FOLLOWING EARLY LIFE STRESS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Sari Lauri[1], Joni Haikonen[1], Jonas Englund[2], Shyrley Paola Amarilla[3], Zoia Kharybina[4], Alexandra Shintyapina[1], Kristel Kegler[4], Marta Saez Garcia[1], Tsvetomira Atanasova[4], Tomi Taira[4], Henrike Hartung[1]

Early life stress (ELS) results in enduring dysfunction of the cortico-limbic circuitry, underlying emotional and social behavior. However, the neurobiological mechanisms by which ELS affects development of the circuitry remain elusive. Here, we have combined viral tracing and electrophysiological techniques to study the effects of maternal separation (MS) on fronto-limbic connectivity and function in young (P14-21) rats. We report that aberrant prefrontal (mPFC) inputs to basolateral amygdala (BLA) GABAergic interneurons transiently increase the strength of feedforward inhibition in the BLA, which raises LTP induction threshold in MS treated male rats. The enhanced GABAergic activity after MS exposure associates with lower functional synchronization within prefrontal-amygdala networks *in vivo*. Intriguingly, no differences in these parameters were detected in females, which were also resistant to MS dependent changes in anxiety-like behaviors. Impaired plasticity and synchronization during the sensitive period of circuit refinement may contribute to long-lasting functional changes in the prefrontal-amygdaloid circuitry that predispose to neuropsychiatric conditions later on in life.

INVESTIGATION OF THE MECHANISMS FOR NOVEL SHQ1 VARIANTS IN THE PATHOGENESIS OF BRAIN DEVELOPMENTAL DISORDER

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Chien-Hui Chang[1], Chia-Wei Huang[1], Wang-Tso Lee[2], Jin-Wu Tsai[1]
[1]Institute of Brain Science, School Of Medicine, National Yang-ming Chiao-tung University, Taipei City, Taiwan, [2]Divison of Pediatric Neurology, Department Of Pediatrics, National Taiwan University Hospital, Taipei City, Taiwan

Aims: SHQ1 is an assembly factor of H/ACA ribonucleoproteins (H/ACA RNPs) which are involved in many critical biological pathways, including ribosome biogenesis, mRNA splicing and telomere maintenance. Mutations found in H/ACA RNPs components have been reported to cause dyskeratosis congenita (DKC), a genetic disorder characterized by bone marrow failure and poor telomere maintenance. Here, we identified novel SHQ1 compound heterozygous mutations from a patient with multiple neurological disorders, including developmental delay, movement disorders, epilepsy, and microcephaly. In this study, we aim to investigate the potential role of SHQ1 in brain development. **Methods:** To modulate Shq1 expression in developing brains, we introduced short-hairpin RNA (shRNA) into neural progenitors in the embryonic mouse cortex by utilizing *in utero* electroporation. The distributions and identities of electroporated cells were examined by immunostaining. To elucidate the pathogenic mechanism of SHQ1 mutations, we then performed co-immunoprecipitation to investigate the interaction between SHQ1 and DKC1 which is a core protein of H/ACA RNPs. **Results:** We found that decreased SHQ1 impaired neuronal migration but not neural differentiation during brain development. In addition, we found that most of SHQ1 variants attenuated their binding ability toward DKC1. These results implied SHQ1 mutations may influence brain development through disrupting the assembly and biogenesis of H/ACA RNPs. **Conclusions:** SHQ1 plays an essential role in brain development through regulating the behaviors of neural progenitors and their neuronal progeny. Our study gave a glimpse of the functions of SHQ1 in brain and provided a possible pathogenic mechanism for H/ACA RNPs-related disorders.

MOLECULAR MECHANISM OF NOVEL FOXG1 VARIANTS IN CAUSING CORTICAL MALFORMATIONS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Tsai-Yu Lin[1], Wang-Tso Lee[2], Pei-Shan Hou[3], Jin-Wu Tsai[1]
[1]Institute of Brain Science, School Of Medicine, National Yang Ming Chiao Tung University (nycu), Taipei City, Taiwan, [2]National Taiwan University Hospital, Department Of Pediatrics, Taipei City, Taiwan, [3]Institute of Anatomy and Cell Biology, School Of Medicine, National Yang Ming Chiao Tung University (nycu), Taipei City, Taiwan

FOXG1 is an important transcriptional repressor which binds to transcription factors, such as COUP-TF1, to regulate neuronal migration and cell fate during cortical development. Recently, we found four novel FOXG1 variants in patients with FOXG1 syndrome, which has been reported to cause microcephaly and epilepsy. However, the relationship between FOXG1 variants and clinical symptoms remains unclear. In this study, we aimed to elucidate how FOXG1 variants affect transcriptional regulation and lead to cortical malformation. To examine protein expression level of FOXG1 variants, we used western blotting to identify the changes of expression level. Luciferase assay was used to test transcriptional regulatory function of FOXG1 variants, we found that FOXG1 variants fail to repress COUP-TF1 expression through transcriptional abnormality. By using *in utero* electroporation (IUE), we delivered mutant FOXG1 to embryonic cortices to verify the FOXG1 dysfunction effects. We found some FOXG1 loss-of-function variants cause neuronal migration delay 3 days after IUE. In postnatal day 7, cells stayed in layer 4 instead of layer 2/3 and showed spiny stellate neuron morphology. FOXG1 variants also affected the connectivity of callosal projection in corpus callosum. These results were highly correlated with clinical symptoms of FOXG1 syndrome. Our study suggests that disease causing FOXG1 variants not only affect transcriptional regulation but also cause neuronal migration defects and cell fate change during corticogenesis. The correlation between *in vitro* and *in vivo* phenotypes and clinical symptoms may provide a reference for FOXG1 variants in genetic diagnosis.

A SYSTEMATIC REVIEW ON THE ASSOCIATION OF BIRTH INTERVALS AND RISK OF AUTISM SPECTRUM AND ATTENTION DEFICIT HYPERACTIVITY DISORDERS

POSTER SESSION 04 - SECTION: NEURODEVELOPMENTAL DISORDERS

Parnian Poursafa, Maryam Bemanalizadeh, Roya Kelishadi
Research Institute for Primordial Prevention of Non-Communicable Disease, Isfahan University of Medical Sciences, Child Growth And Development Research Center, Isfahan, Iran

Background This systematic review aimed to assess the relationship of short and long inter-pregnancy intervals (IPIs) with the risk of autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD). **Methods** We performed a systematic search on electronic databases including Pubmed, Web of Science, Scopus, and Embase. We included observational studies that evaluated the association between IPIs and the risk of ASD and ADHD. Two reviewers independently screened and then extracted data on study characteristics, IPIs/ birth intervals, and outcome measures. The methodological quality of the included studies was evaluated following the Joanna Briggs Institute (JBI) critical appraisal checklist. **Results** At the final step, 19 out of 161 studies were included in our systematic review. Among them, 16 and 5 studies assessed the association between IPI and the risk of ASD and ADHD, respectively. In 9 studies, findings supported the association between short intervals and an increased risk of ASD. In addition, 7 studies reported significant association between both short and long intervals and an increased risk of ASD. Moreover, 3 studies demonstrated an association between short intervals and ADHD risk, while long birth interval was merely assessed in 2 studies with conflicting results. **Conclusion** This systematic review strongly confirmed the association of short and long birth intervals with ASD and ADHD. Future studies should investigate the mechanisms underlying these associations and the possible modifiers to decrease the risk of such disorders.

Aims: Neurodevelopmental disorders (NDD) such as attention deficit hyperactivity (ADHD), or social communication disorders, are commonly studied in childhood, that have complex clinical phenotypes. Strong overlaps across NDD phenotypes make both group and distinction of each disorder difficult. Recently, digital phenotyping is a new approach aimed at measuring human behavior. Despite promising, this method has been mostly for NDD assessment at lab scale. Digit-tracking, among digital phenotyping, gives a quantitative and qualitative measure of longitudinal and time-dependent behaviour, allowing to gather metrics for curve-matching, acceleration, and continuous dynamic time wrapping (DTW). However, this method has never been applied for NDD classification. In this paper, we explore the feasibility of an ecological processing of digit-tracking data to further give insight into the NDD stratification. Methods: We investigate how digit-tracking combined with clinical phenotypes constitutes a new method for NDD profiling in children aged 7 to 12 years. A total of 50 children performed a task on a touch-screen device. We extracted specific features related to the digit-tracking data and are investigating predicting variables to improve classification of NDD. Results: Our preliminary results strongly suggest that the defined metrics are relevant predictive variables to improve NDD clustering. Conclusions: Digit-tracking is an ecological measure, easily available for digital screening of NDD in large paediatric population. Combined with clinical data, this approach may enhance the capability and sensitivity in early identification and diagnosis of NDD in real-life practice.

CDKL5 deficiency disorder (CDD) is a rare X-linked neurodevelopmental disease, characterized by drug-resistant epilepsy, autistic-like traits, sensorimotor and visual abnormalities. Currently, very little is known on the neurobiological alterations underlying the disease in humans thus hampering the identification of mechanisms potentially relevant for therapiesCDKL5 is highly expressed in forebrain glutamatergic neurons and can shuttle between the nucleus and the cytoplasm. Data obtained from CDD mouse models revealed that CDKL5 loss primarily leads to morphofunctional synaptic defects. Whether synaptic and/or gene expression impairments are present in CDD patient's brain cells is still unknown. In this study by employing a multidisciplinary approach on post-mortem BA17 cortical samples, we investigated the molecular organization of excitatory synapses in human brains carrying CDKL5 mutations and their role in the regulation of both epigenetic and transcriptional processes. First, we found by using immunofluorescence and western blotting that excitatory postsynaptic compartments in humans share defects with CDKL5 KO mice. By RRBS techniques, we found that CDD brains displayed altered DNA methylation. Intriguingly, RNA-seq analysis revealed that epigenetic alterations were paralleled with changes in genes involved in the formation and/or maintenance of myelin. Finally, we validated by immunohistochemistry the presence of defects in the myeloarchitecture in CDD patients. Our study discloses that both synaptic defects and abnormal myeloarchitecture are a key endophenotype of human CDD.

ACTIVITY DYNAMICS OF HIPPOCAMPAL CA1 PYRAMIDAL NEURONS DURING VIRTUAL NAVIGATION IN MICE

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Kata Szamosfalvi[1], Snezana Raus Balind[1], Rita Nyilas[1], Balázs Lükő[1], Balázs Ujfalussy[2], Judit Makara[1]

The hippocampus plays a critical role in spatial and episodic memory by creating and storing unique representations of visited environments as activity matrices of principal neurons tuned to specific locations. However, the generation, consolidation and use of hippocampal spatial representations during learning and navigating in environments under variable cognitive demands is incompletely understood. To examine the development and flexible reorganization of place coding activity by hippocampal CA1 pyramidal cells (CA1PCs), we implemented a virtual spatial navigation paradigm for head-fixed mice allowing two-photon imaging of Ca2+ activity in CA1PCs. Transgenic Thy1-GCaMP6s mice were implanted with a hippocampal imaging cannula and a metal head plate for head fixation. Water-restricted mice were trained to collect water rewards at specific locations in two visually different virtual environments. We recorded behavioral parameters (speed, licks) and imaged GCaMP6s-mediated Ca2+ signals in hundreds of CA1PCs over consecutive days, including during 1) initial learning, 2) switches between randomly varied or continuous blocks of presented environments, and 3) exposure to a novel environment. Mice were able to efficiently differentiate between the two distinct virtual corridors and learn the location of the reward zone in both, whereas the behavior pattern was disrupted in a novel environment. We observed reliable place cell activity, gradually developing selective representations of familiar environments, global remapping in the new environment, and flexible reward-associated enrichment depending on cognitive demand. Our results indicate refinement of CA1 coding dynamics during learning and in response to subtle and robust changes in the environment and task structure.

ENTORHINAL GRID-LIKE CODES AND TIME-LOCKED NETWORK DYNAMICS TRACK OTHERS NAVIGATING THROUGH SPACE

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Isabella Wagner[1], Luise Graichen[1], Boryana Todorova[1], Andre Lüttig[1], David Omer[2], Matthias Stangl[3], Claus Lamm[1]
[1]University of Vienna, Faculty Of Psychology, Vienna, Austria, [2]Hebrew University of Jerusalem, The Edmond And Lily Safra Center For Brain Sciences, Jerusalem, Israel, [3]University of California Los Angeles, Ucla Semel Institute, Los Angeles, United States of America

Navigating through crowded, dynamically changing social environments requires the ability to keep track of other individuals. Grid cells in the entorhinal cortex are a central component of self-related navigation but whether they also track others' movement is unclear. Here, we propose that entorhinal grid-like codes make an essential contribution to socio-spatial navigation. Sixty human participants underwent functional magnetic resonance imaging (fMRI) while observing and re-tracing different paths of a demonstrator that navigated a virtual reality environment. Results revealed that grid-like codes in the entorhinal cortex tracked the other individual navigating through space. Further, the activity of grid-like codes was time-locked to increases in co-activation and entorhinal-cortical connectivity that included the striatum, the hippocampus, parahippocampal and right posterior parietal cortices, altogether modulated by accuracy when subsequently re-tracing the paths. This suggests that network dynamics time-locked to entorhinal grid-cell-related activity might serve to distribute information about the 'socio-spatial map' throughout the brain.

ANIMAL-TO-ANIMAL VARIABILITY IN PARTIAL HIPPOCAMPAL REMAPPING

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Parsa Nilchian, Matthew Wilson, Honi Sanders
Massachusetts Institute of Technology, Department Of Brain And Cognitive Sciences, Cambridge, United States of America

Hippocampal place cells form a map of an animal's environment. The hippocampal map changes in response to changes in the environment, a phenomenon known as remapping. Different animals can have different remapping responses to the same environments. This variability across animals in remapping behavior is not well understood. In this work, we analyzed electrophysiological recordings from the CA3 region of the hippocampus performed by Alme et al. (2014), in which five male rats were exposed to 11 different environments, including a variety of repetitions of those environments. To compare the hippocampal maps between two experiences, we computed average rate map correlation coefficients. We found changes in the hippocampal maps between different sessions in the same environment. These changes consisted of partial remapping: a form of remapping in which some place cells maintain their place fields while other place cells remap their place fields. Each animal exhibited partial remapping differently. We discovered that the heterogeneity in animals' hippocampal representational changes is structured: individual animals had consistently different levels of partial remapping across a range of independent comparisons. Our findings highlight that partial hippocampal remapping between repeated environments depends on animal-specific factors.

EPH-EPHRIN SIGNALING-DEPENDENT ANATOMICAL AND FUNCTIONAL MODULES IN LAYER II OF MEDIAL ENTORHINAL CORTEX

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Naoki Yamamoto[1], Hisayuki Osanai[1], William Marks[1], Mark Henkemeyer[2], Takashi Kitamura[1,2]
[1]University of Texas Southwestern Medical Center, Psychiatry, Dallas, United States of America, [2]University of Texas Southwestern Medical Center, Neuroscience, Dallas, United States of America

The layer II of medial entorhinal cortex (MECII) has hexagonally arranged cell clusters of Wolfram syndrome1 (Wfs1)+ pyramidal cells surrounded by Reelin+ stellate cells. Accumulating evidence suggests that cells coding similar spatial information tend to be clustered in MECII, implicating that the Wfs1+ cell clusters may generate the functional modules which contributed to the processing of spatial information. However, it remains unknown the molecular basis for the formation of anatomical cell clusters and whether the anatomical modules affect functional modules. Here, we hypothesized that the cell clusters may be generated by cell-cell-mediated interaction/repulsion. We first comprehensively examined expression patterns of EphBs/ephrin-Bs genes, which are well known as initiators of cell-contact-mediated repulsion signals by fluorescent in situ hybridization. We found that EphB1 was expressed in Reelin+ cells, while ephrin-B2 was expressed in Wfs1+ cells. Loss-of-function studies using knockout (KO) animals revealed that the cell clusters were scattering in the ephrin-B2 hetero knockout (EB2) mice. These results suggest that the EphB1/ephrin-B2 signaling are critical for formation of cell clusters in the MECII. Next, to examine whether anatomical arrangement of cells coding similar spatial information in MECII was impaired in the EB2 mutant, we conducted *in vivo* Ca2+ imaging of MECII in free-moving mouse. The hexagonally arranged periodic firing fields of grid cells was impaired in EB2 mutant, and the grid phase cluster was significantly obscured. These results supported the hypothesis that the anatomical structure in MECII may provide geometrical platform for regulation of grid activities.

Single-stranded noncoding RNAs mediate local epigenetic alterations at gene promoters in rat cell lines.
A growing number of noncoding RNAs (ncRNAs) are thought to be involved in sequence-specific alterations of epigenetic processes, mostly causing gene repression. In this study, promoter-associated ncRNAs (pancRNAs >200 nucleotides in size) that were endogenously generated from the sense strand at Map2b, antisense strand at Nefl, and both strands at Vim were investigated regarding their epigenetic potential as positive or negative regulators in rat pheochromocytoma (PC12) and fibroblast (normal rat kidney) cell lines. The respective antisense pancRNAs were associated with several active chromatin marks at the Nefl and Vim promoters. Forced expression of fragments expressing the antisense pancRNAs caused sequence-specific DNA demethylation, whereas a decrease of expression induced methylation of the same sequences. In contrast, perturbing the expression of the two sense pancRNAs did not change the DNA methylation status. These results suggest that a fraction of naturally occurring ncRNAs acts in cis as a single-stranded form and that the transcriptional orientation of pancRNA is important for the establishment of sequence-specific epigenetic modifications consistent with open chromatin structure.
J Biol Chem, 2011; 286

Bidirectional promoters link cAMP signaling with irreversible differentiation through promoter-associated non-coding RNA (pancRNA) expression in PC12 cells.
Bidirectional promoters are the major source of gene activation-associated noncoding RNA (ncRNA). PC12 cells offer an interesting model for understanding the mechanism underlying bidirectional promoter-mediated cell cycle control. Nerve growth factor (NGF)-stimulated PC12 cells elongate neurites, and are in a reversible cell-cycle-arrested state. In contrast, these cells irreversibly differentiate and cannot re-enter the normal cell cycle after NGF plus cAMP treatment. In this study, using directional RNA-seq, we found that bidirectional promoters for protein-coding genes with promoter-associated ncRNA (pancRNA) were enriched for cAMP response element consensus sequences, and were preferred targets for transcriptional regulation by the transcription factors in the cAMP-dependent pathway. A spindle-formation-associated gene, Nusap1 and

pancNusap1 were among the most strictly co-transcribed pancRNA-mRNA pairs. This pancRNA-mRNA pair was specifically repressed in irreversibly differentiated PC12 cells. Knockdown (KD) and overexpression experiments showed that pancNusap1 positively regulated the Nusap1 expression in a sequence-specific manner, which was accompanied by histone acetylation at the Nusap1 promoter. Furthermore, pancNusap1 KD recapitulated the effects of cAMP on cell cycle arrest. Thus, we conclude that pancRNA-mediated histone acetylation contributes to the establishment of the cAMP-induced transcription state of the Nusap1 locus and contributes to the irreversible cell cycle exit for terminal differentiation of PC12 cells.

Complementary roles of differential medial entorhinal cortex inputs to the hippocampus for the formation and integration of temporal and contextual memory (Systems Neuroscience).
In humans and rodents, the entorhinal cortical (EC)-hippocampal (HPC) circuit is crucial for the formation and recall of memory, preserving both spatial information and temporal information about the occurrence of past events. Both modeling and experimental studies have revealed circuits within this network that play crucial roles in encoding space and context. However, our understanding about the time-related aspects of memory is just beginning to be understood. In this review, we first describe updates regarding recent anatomical discoveries for the EC-HPC network, as several important neural circuits critical for memory formation have been discovered by newly developed neural tracing technologies. Second, we examine the complementary roles of multiple medial entorhinal cortical inputs, including newly discovered circuits, into the hippocampus for the temporal and spatial aspects of memory. Finally, we will discuss how temporal and contextual memory information is integrated in HPC cornu ammonis 1 cells. We provide new insights into the neural circuit mechanisms for anatomical and functional segregation and integration of the temporal and spatial aspects of memory encoding in the EC-HPC networks.

Cell-Type-Specific Optogenetic Techniques Reveal Neural Circuits Crucial for Episodic Memories.
The formation and maintenance of episodic memories are important for our daily life. Accumulating evidence from extensive studies with pharmacological, electrophysiological, and molecular biological approaches has shown that both entorhinal cortex (EC) and hippocampus (HPC) are crucial for the formation and recall of episodic memory. However, to further understand the neural mechanisms of episodic memory processes in the EC-HPC network, cell-type-specific manipulation of neural activity with high temporal resolution during memory process has become necessary. Recently, the technological innovation of optogenetics combined with pharmacological, molecular biological, and electrophysiological approaches has significantly advanced our understanding of the circuit mechanisms for learning and memory. Optogenetic techniques with transgenic mice and/or viral vectors enable us to manipulate the neural activity of specific cell populations as well as specific neural projections with millisecond-scale temporal control during animal behavior. Integrating optogenetics with drug-regulatable activity-dependent gene expression systems has identified memory engram cells, which are a subpopulation of cells that encode a specific episode. Finally, millisecond pulse stimulation of neural activity by optogenetics has further achieved (a) identification of synaptic connectivity between targeted pairs of neural populations, (b) cell-type-specific single-unit electrophysiological recordings, and (c) artificial induction and modification of synaptic plasticity in targeted synapses. In this chapter, we summarize technological and conceptual advancements in the field of neurobiology of learning and memory as revealed by optogenetic approaches in the rodent EC-HPC network for episodic memories.

Entorhinal cortical Island cells regulate temporal association learning with long trace period.
Temporal association learning (TAL) allows for the linkage of distinct, nonsynchronous events across a period of time. This function is driven by neural interactions in the entorhinal cortical-hippocampal network, especially the neural input from the pyramidal cells in layer III of medial entorhinal cortex (MECIII) to hippocampal CA1 is crucial for TAL. Successful TAL depends on the strength of event stimuli and the duration of the temporal gap between events. Whereas it has been demonstrated that the neural input from pyramidal cells in layer II of MEC, referred to as Island cells, to inhibitory neurons in dorsal hippocampal CA1 controls TAL when the strength of event stimuli is weak, it remains unknown whether Island cells regulate TAL with long trace periods as well. To understand the role of Island cells in regulating the duration of the learnable trace period in TAL, we used Pavlovian trace fear conditioning (TFC) with a 60-sec long trace period (long trace fear conditioning [L-TFC]) coupled with optogenetic and chemogenetic neural activity manipulations as well as cell type-specific neural ablation. We found that ablation of Island cells in MECII partially increases L-TFC performance. Chemogenetic manipulation of Island cells causes differential effectiveness in Island cell activity and leads to a circuit imbalance that disrupts L-TFC. However, optogenetic terminal inhibition of Island cell input to dorsal hippocampal CA1 during the temporal association period allows for long trace intervals to be learned in TFC. These results demonstrate that Island cells have a

critical role in regulating the duration of time bridgeable between associated events in TAL.

Development of a new in vitro assay system for evaluating the effects of chemicals on DNA methylation.
Epigenetic toxicity, a phenomenon in which chemicals exert epigenetic effects and produce toxicity, has been attracting attention in recent years due to advances in toxicology accompanying the development of life sciences. However, it has been difficult to identify epigenetic toxicants due to the lack of a simple experimental system to evaluate epigenetic toxicity. In this study, we developed a prototype of an in vitro reporter assay system for assessing the effects of chemicals on DNA methylation using two promoters showing different degrees of DNA methylation, Agouti IAP and Daz1 promoters, and a luciferase reporter. The system successfully detected DNA demethylating activity using 5-azacytidine, a chemical having DNA demethylation activity, as a positive control chemical, and demethylation of cytosine of CpG in the promoter was confirmed by pyrosequencing analysis. Next, in order to improve the detection sensitivity of the DNA demethylating activity of this system, we tried to increase the basal level of methylation of the Daz1 promoter by pre-methylase treatment of the reporter vectors. As a result, the detection sensitivity of the system was successfully improved in cells where the basal level of methylation was indeed increased by methylase treatment. Thus, the developed assay system here is effective for the simple evaluation of chemicals that affect DNA methylation.

A PLACE WITH A VIEW: PARIETAL AND HIPPOCAMPAL NEURONAL ACTIVITIES DURING VIRTUAL NAVIGATION IN THE MACAQUE

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Marie Vericel[1], Pierre Baraduc[2], Jean-René Duhamel[3], Sylvia Wirth[3]
[1]Institut des Sciences Cognitives, Cnrs Umr-5229/université Claude Bernard Lyon 1, Bron, France, [2]Gipsa-Lab, UMR-5216, Speech And Cognition, Saint-Martin-d'Héres, France, [3]Institut des Sciences Cognitives, Cnrs Umr-5229, Bron, France

Knowing where one is and how to reach a new goal from there requires complex computational processes, which are not yet fully understood. To examine the role of the ventral and lateral intraparietal areas in spatial navigation, we recorded neuronal activity in rhesus monkeys performing an orientation task based on salient visual cues, in a virtual environment. We hypothesize that parietal cortex should play a role, along with the hippocampus, in the processing of the visual cues of the environment to support self-position. Using unsupervised clustering analysis, we showed that position-related activity grouped parietal neurons into clusters representing specific maze locations more strongly than hippocampal neurons. Next, we showed that saccade-related parietal activity was modulated by the maze segment in which these saccades were made more strongly than in the hippocampus. This suggests that task-relevant variables influence the amplitude of saccade-related responses, consistent with a link between oculomotor control and the salience of visual cues. Finally, we showed that parietal cells divided into cells that respond strongly to direct fixation of landmarks, or when landmarks are at the periphery of the visual field. Those two populations displayed different temporal dynamics, taking part respectively in the acquisition of stimuli, and in their anticipation. Overall, the results underline a strong recruitment of parietal cortex during active navigation, upstream the hippocampus, which allows tracking of the animal's position into his environment through a task-based processing of the visual cues, hence shedding light on the neural processes linking place and view.

AN OPEN-SOURCE DEVICE FOR OPEN- AND CLOSED-LOOP VESTIBULAR STIMULATION IN HEAD-FIXED MICE

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Alexandra Tran Van Minh[1], Xavier Cano-Ferrer[2], Ede Rancz[1,3]
[1]The Francis Crick Institute, Cortical Circuits Laboratory, London, United Kingdom, [2]The Francis Crick Institute, Making Science And Technology Platform, London, United Kingdom, [3]Institut de Neurobiologie de la Méditerranée, Cortical Circuits Team, Marseille, France

Visual virtual reality (VR) is widely used to study cortical processing in awake, behaving mice. It allows for tight control of animal-driven visual stimuli and provides the ability to change the coupling between behaviour and visual stimulus. However, most visual VR approaches render animals motionless in space (i.e., head-fixed), resulting in the vestibular system being taken out of play. Consequently, the head-direction (HD) system, which is primarily driven by vestibular input and plays a pivotal role in navigation, is severely compromised. Here we present a novel experimental apparatus to overcome this limitation. Using an open-source approach, we have built a modular and affordable device allowing the rotation of head-fixed, behaving mice. It can be used in open-loop mode to study vestibular sensory representation and processing. In closed-loop mode, the apparatus allows animals to navigate in rotational space and self-generate vestibular input, providing a better substrate for 2D navigation in virtual environments. We show that our approach is compatible with the electrical recording of brain activity at the cellular level and results in the robust recruitment of HD cells. We further demonstrate its utility by combining the recording of vestibular and visual evoked eye-movements with optogenetic interference of specific neuronal populations.

NOVEL VIRTUAL REALITY-ENABLED PATH INTEGRATION TASK FOR FREELY MOVING RATS.

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Fabian Stocek
GSN - Ludwig-Maximilians-Universität München, Biology Ii -, Planegg-Martinsried, Germany

Spatial navigation of rodents is supported by a flexible combination of multisensory-based allothetic representation of space and self-referenced path integration. How the two navigational strategies relate to neural representation of space remains poorly understood, in part due to a difficulty in dissociating which strategy is used by the freely-moving behaving animal. In this study we designed a path integration task that relies on a 3D virtual reality beacon to mark an arbitrary homing location in the arena. Rearing behavior serves as a readout of both initiation of outbound foraging and path integration-dependent completion of the inbound trajectory in the darkness. Randomized computer-controlled variation over blocks of trials of the homing location makes the task majorly reliant on path integration. We combine the task with perturbation of the idiothetic sensory inputs via vestibular and optic flow manipulations to understand their respective roles in path integration. We quantify animal performance on the task and effect of perturbation with measures characterizing their trajectories and rearing patterns. In order to understand how spatial representation is related to behavioral strategy of navigation we use wireless silicon probe recordings in the rats performing the task and numerous controls. We quantify the effect of the task and perturbations on spatial coding of the populations of hippocampal place cells.

Complementary Control over Habits and Behavioral Vigor by Phasic Activity in the Dorsolateral Striatum.
Despite clear evidence linking the basal ganglia to the control of outcome insensitivity (i.e., habit) and behavioral vigor (i.e., its behavioral speed/fluidity), it remains unclear whether or how these functions relate to one another. Here, using male Long-Evans rats in response-based and cue-based maze-running tasks, we demonstrate that phasic dorsolateral striatum (DLS) activity occurring at the onset of a learned behavior regulates how vigorous and habitual it is. In a response-based task, brief optogenetic excitation at the onset of runs decreased run duration and the occurrence of deliberative behaviors, whereas midrun stimulation carried little effect. Outcome devaluation showed these runs to be habitual. DLS inhibition at run start did not produce robust effects on behavior until after outcome devaluation. At that time, when the DLS was plausibly most critically required for performance (i.e., habitual), inhibition reduced performance vigor measures and caused a dramatic loss of habitual responding (i.e., animals quit the task). In a second cue-based "beacon" task requiring behavior initiation at the start of the run and again in the middle of the run, DLS excitation at both time points could improve the vigor of runs. Postdevaluation testing showed behavior on the beacon task to be habitual as well. This pattern of results suggests that one role for phasic DLS activity at behavior initiation is to promote the execution of the behavior in a vigorous and habitual fashion by a diverse set of measures. Our research expands the literature twofold. First, we find that features of a habitual behavior that are typically studied separately (i.e., maze response performance, deliberation movements, running vigor, and outcome insensitivity) are quite closely linked together. Second, efforts have been made to understand "what" the dorsolateral striatum (DLS) does for habitual behavior, and our research provides a key set of results showing "when" it is important (i.e., at behavior initiation). By showing such dramatic control over habits by DLS activity in a phasic time window, plausible real-world applications could involve more informed DLS perturbations to curb intractably problematic habits.

LONG-TERM STABLE SPATIAL REPRESENTATION IN DENTATE GRANULE CELLS

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Antje Kilias, Marlene Bartos
University of Freiburg, Medical Faculty, Institute Of Physiology I, Freiburg, Germany

After long periods, we remain able to recall personal experiences and places associated with long-term memories but the identity of long-term storage sites is controversially discussed. Despite the currently prevailing theory that episodic memories are reallocated to cortical areas after an initial encoding phase within the hippocampus, lesion studies suggest that memories might be partially retained within the hippocampus. Recordings of hippocampal activity, however, ruled out stable long-term storage of spatial information in CA1-3. We therefore tested the hypothesis that sparsely active and spatially tuned DG granule cells (GCs) efficiently store and retrieve episodic memories over extended live spans. We employed two-photon *in vivo* calcium imaging of GCs in mice navigating through virtual environments to investigate the formation, discrimination and recall of spatial memories. We show that formation and stabilization of spatial maps representing novel environments emerge in the DG over the course of 4-5 subsequent days. After map formation, representations remain remarkably stable, with individual GCs even maintaining their place field characteristics for up to 90 days. In marked contrast, CA1 place maps emerge on the first day of exposure but map stability rapidly declines over days. Moreover, artificial increase in GCs excitability using depolarizing DREADDs created novel place cells but their reactivation on subsequent days did not result in the stabilization of their place fields or enlargement of map representations. Thus, GC place cells form long-lasting, highly stable and context-specific ensembles. We propose that this ability is an important requirement for long-term storage of spatial and contextual memories.

INHIBITORY TUNING IN THE CORTICAL HEAD-DIRECTION SYSTEM REFLECTS THE FOURIER COMPONENTS OF LOCALLY ENCODED FEATURES

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

The activity of cortical neurons in sensory and spatial systems results from balanced excitation and inhibition. While excitatory neurons are often fine-tuned to the encoded features, the tuning of inhibitory neurons is not well characterized. We thus aimed to elucidate the principles of cortical inhibitory tuning using a simple neural system encoding a 1-dimensional variable - the head-direction (HD) system. To this end, we recorded neurons in the postsubiculum (PoSub), the primary cortical hub of the HD system. In contrast to canonical, excitatory HD cells, HD tuning curves of fast-spiking interneurons (PoSub-FS cells) were not confined to discrete HD values. However, they were stable across time and were anchored to distal landmarks. Furthermore, we show that when HD tuning curves are decomposed in Fourier space, the average Fourier spectrum of PoSub-FS cell tuning matches that of local PoSub-HD cells. Additionally, while individual HD cells are, by definition, fine-tuned in the HD feature space and thus homogenous in their Fourier spectra, FS cells are narrowly-tuned in Fourier space, resulting in their HD tuning often showing 1-, 2- and even 3-fold radial symmetries. Finally, to determine the origin of PoSub-FS tuning, we optogenetically modulated the gain of the thalamic input to PoSub. This modulation had an exclusively additive effect on PoSub-FS cell tuning, indicating its independence from the thalamic input. These findings suggest that collectively the tuning of PoSub-FS cells is a Fourier transformation of the signal encoded by local excitatory cells. They thus provide new constraints on biologically plausible computational models involving inhibition.

Internal representations of self-location in an environment are constantly refined by sensory information. The goal of this study is to dissect the neuronal pathways for updating spatial maps based on visual and tactile cues. We focus on the retrosplenial cortex (RSC), a structure reciprocally connected to both sensory and mnemonic areas throughout the brain. We hypothesize that the RSC-mediated circuits might play different roles in sensory-guided navigation and related learning process. In this study, mice were head-restrained and ran on a linear treadmill with tactile cues. Each recording session consists of three environmental conditions (light, open-loop visual stimulation and darkness, respectively). By combining 2-photon cellular imaging and genetic circuit mapping, we characterized the multimodal representations of RSC neurons and their role in learning. Our results demonstrated that different functional representations of RSC neurons are topographically distributed along the rostral-caudal axis. Cells in the anterior RSC predominantly encoded spatial information, whereas the posterior RSC showed a larger fraction of visually-responsive neurons. Notably, RSC-place cells maintained their firing fields in darkness and were modulated by somatosensory inputs. RSC place cells were initially strongly driven by tactile cues, but became less cue-driven with experiences. Finally, we probed the activity of neurons in teh RSC that project to dorsal subiculum (dS), suggesting that dS receives a mixture of spatial and visual inputs from the RSC. Together, these findings provide insights into diverse representations of RSC, that might serve an integrative role in learning and memory formation.

Morpho-physiological properties and connectivity of vasoactive intestinal polypeptide-expressing interneurons in the mouse hippocampal dentate gyrus.
The hippocampus is a key brain structure for cognitive and emotional functions. Among the hippocampal subregions, the dentate gyrus (DG) is the first station that receives multimodal sensory information from the cortex. Local-circuit inhibitory GABAergic interneurons (INs) regulate the excitation-inhibition balance in the DG principal neurons (PNs) and therefore are critical for information processing. Similar to PNs, GABAergic INs also receive distinct inhibitory inputs. Among various classes of INs, vasoactive intestinal polypeptide-expressing (VIP) INs preferentially target other INs in several brain regions and thereby directly modulate the GABAergic system. However, the morpho-physiological characteristics and postsynaptic targets of VIP INs in the DG are poorly understood. Here, we report that VIP INs in the mouse DG are highly heterogeneous based on their morpho-physiological characteristics. In approximately two-thirds of morphologically reconstructed cells, their axons ramify in the hilus. The remaining cells project their axons exclusively to the molecular layer (15%), to both the molecular layer and hilus (10%), or throughout the entire DG layers (8%). Generally, VIP INs display variable intrinsic properties and discharge patterns without clear correlation with their morphologies. Finally, VIP INs are recruited with a long latency in response to theta-band cortical inputs and preferentially innervate GABAergic INs over glutamatergic PNs. In summary, VIP INs in the DG are composed of highly diverse subpopulations and control the DG output via disinhibition.

Generation of Functional Dopaminergic Neurons from Reprogramming Fibroblasts by Nonviral-based Mesoporous Silica Nanoparticles.
Direct-lineage conversion of the somatic cell by reprogramming, in which mature cells were fully converted into a variety of other cell types bypassing an intermediate pluripotent state, is a promising regenerative medicine approach. Due to the risk of tumorigenesis by viral methods, a non-viral carrier for the delivery of reprogramming factors is very desirable. This study utilized the mesoporous silica nanoparticles (MSNs) as a non-viral delivery system for transduction of the three key factors to

achieve conversion of mouse fibroblasts (MFs) into functional dopaminergic neuron-like cells (denoted as fDA-neurons). At the same time, a neurogenesis inducer, ISX-9, was co-delivered with the MSNs to promote the direct conversion of neuron-like cells. Good transfection efficiency of plasmid@MSN allowed repeated dosing to maintain high exogenous gene expression analyzed by qPCR and the changes in neural function markers were monitored. To further validate the dopaminergic function and the electrophysiological properties of fDA-neurons, the results of ELISA assay showed the high levels of secreted-dopamine in the conditional medium and rich Na/K-channels were observed in the fDA-neurons on Day 22. The results demonstrated that MSN nanocarrier is effective in delivering the reprogramming factors for the conversion of functional dopaminergic neurons from adult somatic cells.

Causal Evidence for the Role of Specific GABAergic Interneuron Types in Entorhinal Recruitment of Dentate Granule Cells. The dentate gyrus (DG) is the primary gate of the hippocampus and controls information flow from the cortex to the hippocampus proper. To maintain normal function, granule cells (GCs), the principal neurons in the DG, receive fine-tuned inhibition from local-circuit GABAergic inhibitory interneurons (INs). Abnormalities of GABAergic circuits in the DG are associated with several brain disorders, including epilepsy, autism, schizophrenia, and Alzheimer disease. Therefore, understanding the network mechanisms of inhibitory control of GCs is of functional and pathophysiological importance. GABAergic inhibitory INs are heterogeneous, but it is unclear how individual subtypes contribute to GC activity. Using cell-type-specific optogenetic perturbation, we investigated whether and how two major IN populations defined by parvalbumin (PV) and somatostatin (SST) expression, regulate GC input transformations. We showed that PV-expressing (PV+) INs, and not SST-expressing (SST+) INs, primarily suppress GC responses to single cortical stimulation. In addition, these two IN classes differentially regulate GC responses to θ and γ frequency inputs from the cortex. Notably, PV+ INs specifically control the onset of the spike series, whereas SST+ INs preferentially regulate the later spikes in the series. Together, PV+ and SST+ GABAergic INs engage differentially in GC input-output transformations in response to various activity patterns.

EVOLUTION OF HIPPOCAMPAL PLACE CELL REPRESENTATIONS IN SLOWLY MORPHING ENVIRONMENTS

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Susan Leemburg, Stepan Kapl, Patricia Karkusova, Michael Mares, František Zitrický, Karel Jezek
Charles University, Medical Faculty In Pilsen, Plzen, Czech Republic

The hippocampus forms spatially modulated cell activity patterns that are considered physiological substrates of spatial memories. Like memories, these behave in an attractor-like manner and are reactivated instantaneously in response to corresponding sensory cues. Here, we studied the dynamics of hippocampal network state reactivation during real-time morphing between familiar environments. Rats implanted with tetrodes in CA3 were trained to maintain separate representations for two different light-cue conditions in a square arena. After baseline recording with stable cues, lights for one condition were slowly faded out, while those for the other were faded in over 2 minutes. Data was binned according to local theta and population vectors and specificity indices were calculated based on templates for each stable session. All animals were capable of map switching in an instant teleportation paradigm and showed clear remapping between stable conditions. Morphing between conditions surprisingly resulted in global switching of hippocampal representations only in some rats, but not others. Non-switchers showed predominant activation of the representation matching cue-conditions at the start of morphing and maintained this throughout. A slight increase in cycles showing high correlation with both templates occurred, unrelated to the degree of cue-mixing. Switchers, by contrast, showed a proportional increase resp. decrease in cue-consistent cycles during morphing, resulting in a period with many of repetitive transitions between representations starting at 30-60% of the morphing duration. Our results indicate that CA3 can sustain active spatial representations that contradict environmental cues for a prolonged time, as long as these cues are introduced very slowly.

NEURONAL REPLAY SEQUENCES IN THE HIPPOCAMPUS OF BATS IN A VERY LARGE ENVIRONMENT (200 METERS)

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Tamir Eliav, Shir Maimon, Liora Las, Nachum Ulanovsky
Weizmann Institute of Science, Brain Sciences, Rehovot, Israel

In sleeping or immobile rodents, ensembles of hippocampal place-cells exhibit sequential reactivations of previously-experienced trajectories (termed replay). Such neuronal sequences are thought to be important for memory consolidation. Recently, we found a multifield musltiscale representation in the hippocampus of bats flying in a 200-meter long tunnel, whereby individual place-cells exhibited multiple place-fields with very different sizes (Eliav et al., Science 2021). This surprising finding opened intriguing questions regarding replay in very-large naturalistic environments: Are there ultra-long sequences in bats? Do individual replay-sequences cover the entire environment, or just small parts of it during each sequence? Are the sequences being time-compressed, as in rodents? How is the multifield-multiscale representation manifested in such replay-sequences? To investigate this, we applied a clusterless state-space model to decode sequential reactivations when bats were stationary: during rest-times between flight epochs in the 200-meter long tunnel, and during subsequent sleep. Preliminary analysis revealed time-compressed replay sequences. Surprisingly, these sequences depicted trajectories covering relatively small pieces of the environment (between a few meters and several dozen meters), unlike sequences in rodents in small setups which typically cover the entire environment. These sequences expressed similar time-compression to rodents. These findings provide the first demonstration of hippocampal replay in a non-rodent species. Our findings may have important implications for understanding hippocampal replay in mammals: The piecewise replay of information in this large environment might be akin to using small information-packets for transmitting large messages in artificial communication systems – but here seen for the first time in the biological brain.

Multiscale representation of very large environments in the hippocampus of flying bats.
Hippocampal place cells encode the animal's location. Place cells were traditionally studied in small environments, and nothing is known about large ethologically relevant spatial scales. We wirelessly recorded from hippocampal dorsal CA1 neurons of wild-born bats flying in a long tunnel (200 meters). The size of place fields ranged from 0.6 to 32 meters. Individual place cells exhibited multiple fields and a multiscale representation: Place fields of the same neuron differed up to 20-fold in size. This multiscale coding was observed from the first day of exposure to the environment, and also in laboratory-born bats that never experienced large environments. Theoretical decoding analysis showed that the multiscale code allows representation of very large environments with much higher precision than that of other codes. Together, by increasing the spatial scale, we discovered a neural code that is radically different from classical place codes.

Nonoscillatory Phase Coding and Synchronization in the Bat Hippocampal Formation.
Hippocampal theta oscillations were proposed to be important for multiple functions, including memory and temporal coding of position. However, previous findings from bats have questioned these proposals by reporting absence of theta rhythmicity in bat hippocampal formation. Does this mean that temporal coding is unique to rodent hippocampus and does not generalize to other species? Here, we report that, surprisingly, bat hippocampal neurons do exhibit temporal coding similar to rodents, albeit without any continuous oscillations at the 1-20 Hz range. Bat neurons exhibited very strong locking to the non-rhythmic fluctuations of the field potential, such that neurons were synchronized together despite the absence of oscillations. Further, some neurons exhibited "phase precession" and phase coding of the bat's position-with spike phases shifting earlier as the animal moved through the place field. This demonstrates an unexpected type of neural coding in the mammalian brain-nonoscillatory phase coding-and highlights the importance of synchrony and temporal coding for hippocampal function across species.

A DISTRIBUTED POPULATION CODE FOR OBJECT REPRESENTATION IN CA1 OF THE HIPPOCAMPUS

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Sebastian Andersson, Anne Nagelhus, Soledad Gonzalo Cogno, Edvard Moser, May-Britt Moser
NTNU, Kavli Institute For Systems Neuroscience And Centre For Neural Computation, Trondheim, Norway

The hippocampus may, through its place cells that fire in specific locations, construct a cognitive map of the animal's environment. While discrete objects are fundamental parts of the environment, how objects are incorporated into the cognitive map remains incompletely understood. So far, researchers have tried to solve the problem by asking how single cells encode object features and locations. In contrast to the single-cell level of description, we wondered if additional encoding of object features takes place at the neural population level. Using Neuropixels 2.0, we simultaneously record hundreds of cells in CA1 of the hippocampus and, to understand the high-dimensional data, use a combination of decoding algorithms and information theory. We find that population activity reorganises systematically as a function of the animal's distance from the object. Close to the object, the reorganisation of hippocampal activity is large; further away, the reorganisation is small. The reorganisation is distributed across all CA1 cells and does not depend on single-cell properties. The more cells we record, the stronger evidence we find for the reorganisation and its distance-dependence. Our results are suggestive of a novel type of remapping at the population level where objects induce large-scale changes in population activity patterns that are (1) location-dependent; (2) object-relative and (3) elusive at the single-cell level. The computational goal for such a distributed neural code must now be investigated, and our findings underscore the importance of discrete objects for cognitive maps in the hippocampus.

The hippocampal CA1 region is crucial for contextual memory formation by generating abstract relational maps by pyramidal cells (PCs) selectively tuned to locations or events. While the hippocampal map is thought to support behavioral adaptation, the organization and refinement of representations during this process is poorly understood. Here we aimed to elucidate the dynamic changes in tuning of CA1PCs during the evolution of task-relevant behavioral responses. We trained water-restricted, head-fixed Thy1-GCaMP6s mice to run on a cue-less treadmill in virtual reality environments, and distinguish two visually distinct corridors by selectively licking in a hidden reward zone (RZ) in one of them. We monitored CA1PC activity by two-photon Ca2+ imaging during improvement of task performance, as assessed by measuring running speed and lick rate. We observed enrichment of spatially tuned CA1PC activity at task-relevant locations of the virtual corridors, i.e. at the start and near the RZ. In low performance sessions, tuned cells showed relatively similar activity patterns in rewarded and unrewarded corridors. However, in expert animals, the number of tuned CA1PCs increased selectively in the rewarded corridor and decorrelated representations of the two corridors emerged. Accordingly, the number of corridor-selective CA1PCs increased with learning, especially in the rewarded corridor and predominantly at the RZ. These changes in single neuron tuning during experience were also reflected by an increased difference in the position decoding accuracy between the corridors. Our results suggest that hippocampal CA1PCs may initially generalize between environments but dynamically reorganize their activity according to behavioral relevance of corridor identity.

Brainstem nucleus incertus controls contextual memory formation.
Hippocampal pyramidal cells encode memory engrams, which guide adaptive behavior. Selection of engram-forming cells is regulated by somatostatin-positive dendrite-targeting interneurons, which inhibit pyramidal cells that are not required for memory formation. Here, we found that γ-aminobutyric acid (GABA)-releasing neurons of the mouse nucleus incertus (NI) selectively inhibit somatostatin-positive interneurons in the hippocampus, both monosynaptically and indirectly through the inhibition of their subcortical excitatory inputs. We demonstrated that NI GABAergic neurons receive monosynaptic inputs from brain areas processing important environmental information, and their hippocampal projections are strongly activated by salient environmental inputs in vivo. Optogenetic manipulations of NI GABAergic neurons can shift hippocampal network state and bidirectionally modify the strength of contextual fear memory formation. Our results indicate that brainstem NI GABAergic cells are essential for controlling contextual memories.

Acetaminophen Relieves Inflammatory Pain through CB Cannabinoid Receptors in the Rostral Ventromedial Medulla.
Acetaminophen (paracetamol) is a widely used analgesic and antipyretic drug with only incompletely understood mechanisms of action. Previous work, using models of acute nociceptive pain, indicated that analgesia by acetaminophen involves an indirect activation of CB receptors by the acetaminophen metabolite and endocannabinoid reuptake inhibitor AM 404. However, the contribution of the cannabinoid system to antihyperalgesia against inflammatory pain, the main indication of acetaminophen, and the precise site of the relevant CB receptors have remained elusive. Here, we analyzed acetaminophen analgesia in mice of either sex with inflammatory pain and found that acetaminophen exerted a dose-dependent antihyperalgesic action, which was mimicked by intrathecally injected AM 404. Both compounds lost their antihyperalgesic activity in mice, confirming the involvement of the cannabinoid system. Consistent with a mechanism downstream of proinflammatory prostaglandin formation, acetaminophen also reversed hyperalgesia induced by intrathecal prostaglandin E

To distinguish between a peripheral/spinal and a supraspinal action, we administered acetaminophen and AM 404 to mice, which lack CB receptors from the peripheral nervous system and the spinal cord. These mice exhibited unchanged antihyperalgesia indicating a supraspinal site of action. Accordingly, local injection of the CB receptor antagonist rimonabant into the rostral ventromedial medulla blocked acetaminophen-induced antihyperalgesia, while local rostral ventromedial medulla injection of AM 404 reduced hyperalgesia in wild-type mice but not in mice. Our results indicate that the cannabinoid system contributes not only to acetaminophen analgesia against acute pain but also against inflammatory pain, and suggest that the relevant CB receptors reside in the rostral ventromedial medulla. Acetaminophen is a widely used analgesic drug with multiple but only incompletely understood mechanisms of action, including a facilitation of endogenous cannabinoid signaling via one of its metabolites. Our present data indicate that enhanced cannabinoid signaling is also responsible for the analgesic effects of acetaminophen against inflammatory pain. Local injections of the acetaminophen metabolite AM 404 and of cannabinoid receptor antagonists as well as data from tissue-specific CB receptor-deficient mice suggest the rostral ventromedial medulla as an important site of the cannabinoid-mediated analgesia by acetaminophen.

Cell-specific STORM super-resolution imaging reveals nanoscale organization of cannabinoid signaling.
A major challenge in neuroscience is to determine the nanoscale position and quantity of signaling molecules in a cell type- and subcellular compartment-specific manner. We developed a new approach to this problem by combining cell-specific physiological and anatomical characterization with super-resolution imaging and studied the molecular and structural parameters shaping the physiological properties of synaptic endocannabinoid signaling in the mouse hippocampus. We found that axon terminals of perisomatically projecting GABAergic interneurons possessed increased CB1 receptor number, active-zone complexity and receptor/effector ratio compared with dendritically projecting interneurons, consistent with higher efficiency of cannabinoid signaling at somatic versus dendritic synapses. Furthermore, chronic Δ(9)-tetrahydrocannabinol administration, which reduces cannabinoid efficacy on GABA release, evoked marked CB1 downregulation in a dose-dependent manner. Full receptor recovery required several weeks after the cessation of Δ(9)-tetrahydrocannabinol treatment. These findings indicate that cell type-specific nanoscale analysis of endogenous protein distribution is possible in brain circuits and identify previously unknown molecular properties controlling endocannabinoid signaling and cannabis-induced cognitive dysfunction.

Multiple mechanistically distinct modes of endocannabinoid mobilization at central amygdala glutamatergic synapses.
The central amygdala (CeA) is a key structure at the limbic-motor interface regulating stress responses and emotional learning. Endocannabinoid (eCB) signaling is heavily implicated in the regulation of stress-response physiology and emotional learning processes; however, the role of eCBs in the modulation of synaptic efficacy in the CeA is not well understood. Here we describe the subcellular localization of CB1 cannabinoid receptors and eCB synthetic machinery at glutamatergic synapses in the CeA and find that CeA neurons exhibit multiple mechanistically and temporally distinct modes of postsynaptic eCB mobilization. These data identify a prominent role for eCBs in the modulation of excitatory drive to CeA neurons and provide insight into the mechanisms by which eCB signaling and exogenous cannabinoids could regulate stress responses and emotional learning.

Endocannabinoid-dependent plasticity at spinal nociceptor synapses.
Neuroplastic changes at the spinal synapses between primary nociceptors and second order dorsal horn neurons play key roles in pain and analgesia. NMDA receptor-dependent forms of long-term plasticity have been studied extensively at these synapses, but little is known about possible contributions of the endocannabinoid system. Here, we addressed the role of cannabinoid (CB)1 receptors in activity-dependent plasticity at these synapses. We report that conditional low-frequency stimulation of high-threshold primary sensory nerve fibres paired with depolarisation of the postsynaptic neuron evoked robust long-term depression (LTD)of excitatory synaptic transmission by about 40% in the vast majority (90%) of recordings made in wild-type mice. When recordings were made from global or nociceptor-specific CB(1) receptor-deficient mice (CB(1)(−/−) mice and sns-CB(1)(−/−) mice), the portion of neurons exhibiting LTD was strongly reduced to about 25%. Accordingly, LTD was prevented to a similar extent by the CB1 receptor antagonist AM251 and mimicked by pharmacological activation of CB1 receptors. In a subset of neurons with EPSCs of particularly high stimulation thresholds, we furthermore found that the absence of CB(1) receptors in CB(1)(−/−) and sns-CB(1)(−/−) mice converted the response to the paired conditioning stimulation protocol from LTD to long-term potentiation (LTP). Our results identify CB1 receptor-dependent LTD as a form of synaptic plasticity previously unknown in spinal nociceptors. They furthermore suggest that prevention of LTP may be a

second hither to unknown function of CB1 receptors in primary nociceptors. Both findings may have important implications for our understanding of endogenous pain control mechanisms and of analgesia evoked by cannabinoid receptor agonists.

Activation of type 5 metabotropic glutamate receptors and diacylglycerol lipase-α initiates 2-arachidonoylglycerol formation and endocannabinoid-mediated analgesia.
Acute stress reduces pain sensitivity by engaging an endocannabinoid signaling circuit in the midbrain. The neural mechanisms governing this process and molecular identity of the endocannabinoid substance(s) involved are unknown. We combined behavior, pharmacology, immunohistochemistry, RNA interference, quantitative RT-PCR, enzyme assays, and lipidomic analyses of endocannabinoid content to uncover the role of the endocannabinoid 2-arachidonoyl-sn-glycerol (2-AG) in controlling pain sensitivity in vivo. Here, we show that footshock stress produces antinociception in rats by activating type 5 metabotropic glutamate receptors (mGlu(5)) in the dorsolateral periaqueductal gray (dlPAG) and mobilizing 2-AG. Stimulation of mGlu(5) in the dlPAG with DHPG [(S)-3,5-dihydroxyphenylglycine] triggered 2-AG formation and enhanced stress-dependent antinociception through a mechanism dependent upon both postsynaptic diacylglycerol lipase (DGL) activity, which releases 2-AG, and presynaptic CB(1) cannabinoid receptors. Pharmacological blockade of DGL activity in the dlPAG with RHC80267 [1,6-bis(cyclohexyloximinocarbonylamino)hexane] and (-)-tetrahydrolipstatin (THL), which inhibit activity of DGL-α and DGL-β isoforms, suppressed stress-induced antinociception. Inhibition of DGL activity in the dlPAG with THL selectively decreased accumulation of 2-AG without altering levels of anandamide. The putative 2-AG-synthesizing enzyme DGL-α colocalized with mGlu(5) at postsynaptic sites of the dlPAG, whereas CB(1) was confined to presynaptic terminals, consistent with a role for 2-AG as a retrograde signaling messenger. Finally, virally mediated silencing of DGL-α, but not DGL-β, transcription in the dlPAG mimicked effects of DGL inhibition in suppressing both endocannabinoid-mediated stress antinociception and 2-AG formation. The results indicate that activation of the postsynaptic mGlu(5)-DGL-α cascade triggers retrograde 2-AG signaling in vivo. This pathway is required for endocannabinoid-mediated stress-induced analgesia.

Spinal endocannabinoids and CB1 receptors mediate C-fiber-induced heterosynaptic pain sensitization.
Diminished synaptic inhibition in the spinal dorsal horn is a major contributor to chronic pain. Pathways that reduce synaptic inhibition in inflammatory and neuropathic pain states have been identified, but central hyperalgesia and diminished dorsal horn synaptic inhibition also occur in the absence of inflammation or neuropathy, solely triggered by intense nociceptive (C-fiber) input to the spinal dorsal horn. We found that endocannabinoids, produced upon strong nociceptive stimulation, activated type 1 cannabinoid (CB1) receptors on inhibitory dorsal horn neurons to reduce the synaptic release of gamma-aminobutyric acid and glycine and thus rendered nociceptive neurons excitable by nonpainful stimuli. Our results suggest that spinal endocannabinoids and CB1 receptors on inhibitory dorsal horn interneurons act as mediators of heterosynaptic pain sensitization and play an unexpected role in dorsal horn pain-controlling circuits.

Molecular architecture of endocannabinoid signaling at nociceptive synapses mediating analgesia.
Cannabinoid administration suppresses pain by acting at spinal, supraspinal and peripheral levels. Intrinsic analgesic pathways also exploit endocannabinoids; however, the underlying neurobiological substrates of endocannabinoid-mediated analgesia have remained largely unknown. Compelling evidence shows that, upon exposure to a painful environmental stressor, an endocannabinoid molecule called 2-arachidonoylglycerol (2-AG) is mobilized in the lumbar spinal cord in temporal correlation with stress-induced antinociception. We therefore characterized the precise molecular architecture of 2-AG signaling and its involvement in nociception in the rodent spinal cord. Nonradioactive in situ hybridization revealed that dorsal horn neurons widely expressed the mRNA of diacylglycerol lipase-alpha (DGL-alpha), the synthesizing enzyme of 2-AG. Peroxidase-based immunocytochemistry demonstrated high levels of DGL-alpha protein and CB(1) cannabinoid receptor, a receptor for 2-AG, in the superficial dorsal horn, at the first site of modulation of the ascending pain pathway. High-resolution electron microscopy uncovered postsynaptic localization of DGL-alpha at nociceptive synapses formed by primary afferents, and revealed presynaptic positioning of CB(1) on excitatory axon terminals. Furthermore, DGL-alpha in postsynaptic elements receiving nociceptive input was colocalized with metabotropic glutamate receptor 5 (mGluR(5)), whose activation induces 2-AG biosynthesis. Finally, intrathecal activation of mGluR(5) at the lumbar level evoked endocannabinoid-mediated stress-induced analgesia through the DGL-2-AG-CB(1) pathway. Taken together, these findings suggest a key role for 2-AG-mediated retrograde suppression of nociceptive transmission at the spinal level. The striking positioning of the molecular players of 2-AG synthesis and action at nociceptive excitatory synapses suggests that pharmacological

manipulation of spinal 2-AG levels may be an efficacious way to regulate pain sensation.

Enzymatic machinery for endocannabinoid biosynthesis associated with calcium stores in glutamatergic axon terminals.
Endocannabinoids are regarded as retrograde signaling molecules at various types of synapses throughout the CNS. The lipid derivatives anandamide and 2-arachidonoylglycerol (2-AG) are generally thought to be the key molecular players in this process. Previous anatomical and electrophysiological studies provided compelling evidence that the biosynthetic enzyme of 2-AG is indeed localized in the postsynaptic plasma membrane, whereas its target, the CB1 cannabinoid receptor, and the enzyme responsible for its inactivation are both found presynaptically. This molecular architecture of 2-AG signaling is a conserved feature of most synapses and supports the retrograde signaling role of 2-AG. Conversely, the molecular and neuroanatomical organization of synaptic anandamide signaling remains largely unknown. In contrast to its predicted role in retrograde signaling, here we show that N-acylphosphatidylethanolamine-hydrolyzing phospholipase D (NAPE-PLD), a biosynthetic enzyme of anandamide and its related bioactive congeners, the N-acylethanolamines (NAEs), is concentrated presynaptically in several types of hippocampal excitatory axon terminals. Furthermore, high-resolution quantitative immunogold labeling demonstrates that this calcium-sensitive enzyme is localized predominantly on the intracellular membrane cisternae of axonal calcium stores. Finally, the highest density of NAPE-PLD is found in mossy terminals of granule cells, which do not express CB1 receptors. Together, these findings suggest that anandamide and related NAEs are also present at glutamatergic synapses, but the sites of their synthesis and action are remarkably different from 2-AG, indicating distinct physiological roles for given endocannabinoids in the regulation of synaptic neurotransmission and plasticity.

Grid cells and place cells are key building blocks of the hippocampal formation's cognitive map. The firing patterns of these cells are usually viewed as encoding an animal's current location; however, previous studies have shown that they can also encode location in the recent past and near future. The relationship between these cells' spatiotemporal coding patterns is unclear. To address this, we analysed the firing patterns of co-recorded medial entorhinal grid cells and CA1 place cells in freely foraging rats. Both cell types mainly encode space prospectively, firing ~150ms before the rat entered a cell's preferred location. Grid cells' time shifts are proportional to their scale; similarly, CA1 place cells' time shifts increase with firing field size. In place cells, firing at different phases of the theta cycle was associated with different time shift lengths. This supports previous hypotheses that the cycle may be used to organise the encoding and retrieval of memories. We speculate that communication between CA1 and mEC may be involved in anticipating future trajectories, while CA1-CA3 communication may be used to compare past and present locations.

The current knowledge of spatial maps and spatial coordinate systems in the brain is based to a large extent on neural recordings from animals that move freely in simple open arenas (open fields). In recordings from the hippocampus, neurons have both been shown to represent pure allocentric space (place cells), and to have additional firing rate modulation to angular variables (e.g., place cells with head direction or egocentric bearing modulation). Here, in agreement with previous work, we find indications for modulation of place cell activity by angular variables using previously defined methods for detection in real data from open field environments. However, our findings also raise the possibility that activity in hippocampal neurons can be falsely attributed to angular variables as a result of collinearity and inconsistencies in the analytical methods. By developing a simulation framework composed of functional cell types with various types of spatial tuning and by applying classical statistical approaches, we find higher than expected false positive rates for cells with conjunctive angular or egocentric tuning. False positive rates vary across cell types, behavioral sessions, noise levels, and firing field sizes, pointing to factors that might potentially account for misattribution to angular or egocentric tuning in experimental studies. We propose here that with simple improvements in experimental design and analysis, such issues can be mediated. Further, we suggest that such studies with potentially confounding factors should be investigated routinely and prior to data collection if possible.

A metabolic function of the hippocampal sharp wave-ripple.
The hippocampus has previously been implicated in both cognitive and endocrine functions. We simultaneously measured electrophysiological activity from the hippocampus and interstitial glucose concentrations in the body of freely behaving rats to identify an activity pattern that may link these disparate functions of the hippocampus. Here we report that clusters of sharp wave-ripples recorded from the hippocampus reliably predicted a decrease in peripheral glucose concentrations within about 10 min. This correlation was not dependent on circadian, ultradian or meal-triggered fluctuations, could be mimicked with optogenetically induced ripples in the hippocampus (but not in the parietal cortex) and was attenuated to chance levels by pharmacogenetically suppressing activity of the lateral septum, which is the major conduit between the hippocampus and the hypothalamus. Our findings demonstrate that a function of the sharp wave-ripple is to modulate peripheral glucose homeostasis, and offer a mechanism for the link between sleep disruption and blood glucose dysregulation in type 2 diabetes.

ERROR CORRECTION IN THE HIPPOCAMPAL-MEDIAL-ENTORHINAL COGNITIVE MAP.

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Tereza Vargova[1], Pauline Kerekes[1], Marius Bauza[2], Julija Krupic[1]
[1]University of Cambridge, Physiology, Development And Neuroscience, Cambridge, United Kingdom, [2]University College London, Sainsbury Wellcome Centre, Cambridge, United Kingdom

Hippocampal place cells and medial entorhinal grid cells, border cells and head direction cells are thought to support cognitive map-based navigation. However, they are also known to accumulate error and recent studies have shown that environmental cues have a complex influence on their firing patterns. We investigated the effect of environmental landmarks on error correction in spatially modulated cells during one dimensional navigation in a virtual reality environment, using in vivo chronic multi-tetrode recordings from mouse hippocampus and medial entorhinal cortex. Increasing the number of available visual cues resulted in an increase in the number of firing fields, decrease in the field size and variability, and increase in peak firing rate. A cell-type specific preference for field position relative to cue location was observed. Average drift in field position decreased significantly with increasing number of cues, while precision with which cells corrected their drift significantly increased. This effect was stronger in fields located closer to the visual cues. The presence of a non-visually cued fixed reward location decreased drift, suggesting that error in spatial cell firing can also be modulated by non-visual cues. Increasing the spatial information content of the presented visual cues further increased these stabilizing effects. The above changes resulted in the animal's increased precision in anticipating the reward location. These results suggest that increasing the number and information content of cues in the environment helps correct error in the firing of spatial cells by stabilizing their firing fields and increasing their spatial resolution.

Bilateral Discrimination of Tactile Patterns without Whisking in Freely Running Rats.
A majority of whisker discrimination tasks in rodents are performed on head-fixed animals to facilitate tracking or control of the sensory inputs. However, head fixation critically restrains the behavior and thus the incoming stimuli compared with those occurring in natural conditions. In this study, we investigated whether freely behaving rats can discriminate fine tactile patterns while running, in particular when stimuli are presented simultaneously on both sides of the snout. We developed a two-alternative forced-choice task in an automated modified T-maze. Stimuli were either a surface with no bars (smooth) or with vertical bars spaced irregularly or regularly. While running at full speed, rats encountered simultaneously the two discriminanda placed on the two sides of the central aisle. Rats learned to recognize regular bars versus a smooth surface in 8 weeks. They solved the task while running at an average speed of 1 m/s, so that the contact with the stimulus lasted <1 typical whisking cycle, precluding the use of active whisking. Whisker-tracking analysis revealed an asymmetry in the position of the whiskers: they oriented toward the rewarded stimulus during successful trials as early as 60 ms after the first possible contact. We showed that the whiskers and activity in the primary somatosensory cortex are involved during the discrimination process. Finally, we identified irregular patterns of bars that the rats can discriminate from the regular one. This novel task shows that freely moving rodents can make simultaneous bilateral tactile discrimination without whisking. The whisker system of rodents is a widely used model to study tactile processing. Rats show remarkable abilities in discriminating surfaces by actively moving their whiskers (whisking) against stimuli, typically sampling them several times. This motor strategy affects considerably the way that tactile information is acquired and thus the way that neuronal networks process the information. However, when rats run at high speed, they protract their whiskers in front of the snout without large movements. Here, we investigated whether rats are able to discriminate regular and irregular patterns of vertical bars while running without whisking. We found that the animals can perform a bilateral simultaneous discrimination without whisking and that this involves both whiskers and barrel cortex activity.

THE RATE OF PLACE CELL REMAPPING DEPENDS ON ACCUMULATED EXPERIENCE WITHIN CONTEXT AND NOT ON PASSAGE OF TIME

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Dorgham Khatib[1], Aviv Ratzon[1], Mariell Sellevoll[1], Omri Barak[1], Genela Morris[1,2], Dori Derdikman[1]
[1]Technion, Rappaport Faculty Of Medicine, Haifa, Israel, [2]Tel-Aviv Sourasky Medical Center, Division Of Neurosurgery, Tel-Aviv, Israel

Place cells can represent different spaces and contexts in a process known as *remapping.* Several studies have shown that although place cells are stable throughout a single exposure, they undergo remapping with repeated exposures to the same environment. Why do place cells remap even without any change to the context, and what could modulate this change? To answer this, we recorded place cells in freely moving mice traversing two similar and familiar linear tracks. The mice spent minutes in track A vs. hours in track B in each recording session. We asked whether the accumulated experience in a track (the amount of time spent in it), is the driving force behind the change in representation. We found that the correlations between the spatial representations five hours apart were lower in track B than in track A, in which they spent less time. Our result suggests that spatial representation is a dynamic process that is related to the ongoing experiences within the specific context, such that the more time is spent within the context, the more it is changed. This implies that the remapping of place cells is related to the accumulation of new memories and not to passive forgetting.

RETROSPLENIAL CORTEX REPRESENTS BOTH LOCAL AND GLOBAL SPACE

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Célia Laurent[1], Pierre-Yves Jacob[2], Francesca Sargolini[1]
[1]Laboratoire de Neurosciences Cognitives, Neural Basis Of Spatial Cognition, Marseille, France, [2]Aix-Marseille uUniversity, Centre National De Le Recherche Scientifique (cnrs), Marseille, France

Every day, we navigate between connected rooms to reach goals. This requires a mental map of the environment based on two reference frames: one for each room (local reference frame) and one including all connected rooms (global reference frame). Recent studies in rodents suggest that the retrosplenial cortex (RSC) may simultaneously code for both reference frames. Indeed, single unit recording in rats exploring two symmetrical connected rooms show that RSC contains two distinct functional cell populations: head direction cells (HDC) firing when the animal faces a particular direction thus providing a global directional signal; and bi-directional cells (BDC) displaying distinct directions each specific for one room, suggesting that their activity is anchored to a local space. Here we tested whether these two populations of cells still provide global and local directional signals in environments with two or four visually different connected rooms. We found that HDC firing direction is maintained regardless of the number of rooms. Furthermore, BDC fire in two directions when rodents navigate between two different connected rooms and tend to fire in four directions in four connected rooms. We also observed that non-directional RSC cells show spatial firing patterns that either repeat between rooms (local coding) or remain constant in all rooms (global coding). This indicates that coding of local and global spaces is not limited to HDC and BDC. Altogether, these results confirm that RSC may form global and local reference frames necessary for the construction of a cognitive map which allows navigation in complex environments.

PERSISTENT HOMOLOGY OF THE UMAP COMPLEX REVEALS TORI IN THE ENTORHINAL CORTEX OF HEAD-FIXED MICE

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Erik Hermansen, David Klindt, Benjamin Dunn
NTNU, Department Of Mathematical Sciences, Trondheim, Norway

In this work, we uncovered toroidal structure in population activity of medial entorhinal recordings of head-fixed mice using the manifold learning technique, UMAPH. Each neuron had a single receptive field on the hexagonal torus, with the toroidal representation stable across conditions; baseline, dark and gain manipulation (for which the relation between the movement of the running wheel and the linear VR-track was varied). This is consistent with the grid cell tori recently discovered in rats. Furthermore, we decoded the internal dynamics and observed smooth trajectories on the neural manifold. The trajectories evolved in line with the mouse's progression along the VR-track and seemingly made turns which accommodated the continual repetition of the track. Moreover, the gain could be predicted by estimating the length of the internal trajectories. We also observed that even in baseline trials the mapping from the toroidal state space to external space occasionally shifted its representation or drifted over trials. In mice where several MEC subpopulations were recorded, this occurred simultaneously, suggesting a coordinated mapping across toroidal modules at different spatial scales. UMAPH builds on the two most used methods in topological data analysis, UMAP and persistent homology, and we show that the method performs well with synthetic data sets and is able to decode the expected head direction representation of the anterodorsal thalamic nucleus during wake, REM and SWS sleep. We find the UMAPH approach promising, in particular in opening the door to more detailed analysis of grid cell networks in head-fixed animals.

Toroidal topology of population activity in grid cells.
The medial entorhinal cortex is part of a neural system for mapping the position of an individual within a physical environment. Grid cells, a key component of this system, fire in a characteristic hexagonal pattern of locations, and are organized in modules that collectively form a population code for the animal's allocentric position. The invariance of the correlation structure of this population code across environments and behavioural states, independent of specific sensory inputs, has pointed to intrinsic, recurrently connected continuous attractor networks (CANs) as a possible substrate of the grid pattern. However, whether grid cell networks show continuous attractor dynamics, and how they interface with inputs from the environment, has remained unclear owing to the small samples of cells obtained so far. Here, using simultaneous recordings from many hundreds of grid cells and subsequent topological data analysis, we show that the joint activity of grid cells from an individual module resides on a toroidal manifold, as expected in a two-dimensional CAN. Positions on the torus correspond to positions of the moving animal in the environment. Individual cells are preferentially active at singular positions on the torus. Their positions are maintained between environments and from wakefulness to sleep, as predicted by CAN models for grid cells but not by alternative feedforward models. This demonstration of network dynamics on a toroidal manifold provides a population-level visualization of CAN dynamics in grid cells.

RAPID WITHIN-SESSION DYNAMICS OF CA1 PLACE CODES IN MICE EXPLORING A NOVEL ENVIRONMENT

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Vladimir Sotskov[1], Viktor Plusnin[2], Nikita Pospelov[1], Konstantin Anokhin[1,3]
[1]Lomonosov Moscow State University, Institute For Advanced Brain Studies, Moscow, Russian Federation, [2]National Research Center "Kurchatov Institute", Neuroscience Department, Moscow, Russian Federation, [3]P.K. Anokhin Institute of Normal Physiology RAS, Laboratoty Of Neurobiology Of Memory, Moscow, Russian Federation

The ability of hippocampal CA1 cells to form and maintain stable spatial codes of an environment across days is well described. Much less is known about the short-term properties of such codes at the first episodes of exploratory behavior in a novel environment. We have imaged CA1 place cells with head-mounted Nvista miniscopes in mice exploring a novel environment in three consequent 15-minute sessions 24h apart. To estimate the within-session stability of place fields, we used a selectivity score calculated for each attendance of a field as a rate of place-specific calcium events. We observed that a significant (25%) part of place fields became stable at the first attendance, while the average latency of place field stabilization equaled 247s at the first session. This latency decreased in the next session in the same environment, however, the average selectivity score demonstrated no cumulation between sessions, starting with similar levels at each session. Importantly, these results were shown non-depending on the retention of place codes on the second session. To verify these results we performed population analysis which revealed latent variables corresponding to trajectories of mice, allowing us to decode the position of animals. Moreover, within-session dynamics of the precision of such decoding was found consistent with the average place field selectivity score dynamics in these animals. Our data thus reveal the fast emergence of place codes in a novel environment and may serve as a basis for further studies. **This study was supported by Russian Ministry of Science and Higher Education Project №075-15-2020-801 and by Russian Science Foundation Project №20-15-00283.**

DYNAMICS OF DENTATE GYRUS GRANULE CELL ACTIVITY DURING COMBINATORIAL MODIFICATION OF SPACE.

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Qi Li, Hung-Ling Chen, Claudio Elgueta, Marlene Bartos
Albert-Ludwigs-University Freiburg, Medical Faculty, Institute Of Physiology I, Freiburg im Breisgau, Germany

Theoretical and experimental data support the hypothesis that the Dentate Gyrus (DG) is important for context discrimination. The small number and low activity of granule cells (GCs) engaged in a spatial representation contribute to the sparsification of the rich multimodal input arriving from the entorhinal cortex and the orthogonalization of overlapping information. The DG can efficiently distinguish different spatial contexts, either by the activity of different GCs or by changes in their firing properties. But it is currently unclear which features of a spatial experience induce GC remapping, how newly-formed representations change over time and how they might relate to past experience.
To investigate this, we recorded Ca^{2+} signals from mature GCs in freely moving Thy1-GCaMP mice using head-mounted miniscope during the presentation of three different contextual conditions. First, animals explored two very different novel environments during eight consecutive days. In these conditions, GC activity was sparse and showed high spatial selectivity from the first day of recording. Afterwards, the two contexts were merged into a larger arena by removing a separating wall. Interestingly, this generated an abrupt and progressive increase in the number of recruited GCs during eight consecutive recording days, and an increase in the mean network activity. Intriguingly, the representation of the combined environment included both, GCs that were previously active in one of the separated arenas, and a high number of cells selective for the merged arena. Therefore, a combined environment is represented in the DG as more than the sum of its individual components.

BEHAVIOUR OF MEDIAL ENTORHINAL CORTEX CELLS DURING A RADIAL EIGHT ARM MAZE TASK

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Yosman Bapatdhar, Jozsef Csicsvari
Institute of Science and Technology (IST) Austria, Neuroscience, Klosterneuburg, Austria

How non-grid spatial cells in the medial entorhinal cortex (mEC) behave during navigation is not understood. Also, the role of hippocampus independent replay in the mEC is unknown.The mEC has a myriad of very interesting cells that exhibit spatial properties but are not grid cells per say. The role of these non-grid spatial cells during navigation is still not well understood. The aim of the project is to elucidate the role of this replay and to understand how different cell types in the mEC behave during a spatial task. We performed multichannel, extracellular electrophysiology on rats while they performed a radial eight arm maze task. Rats were implanted with microdrives targeting the dorsal CA1 and layers II/III of mEC while performing an eight arm maze task where they were expected to learn which 3 arms were rewarded. re rewarded. Each trial started with a delay of 1min. Animals performed 30 trials per day.
We establish how the different kinds of spatial cells in mEC behave during this task. We show how grid and non-grid spatial cells behave differently at different phases during the task. We show how at key moments of immobility the trajectory replayed by mEC cells isn't always the same as that replayed by CA1 cells.These results are a demonstration of the influence of non-geometric factors on the activity of the mEC space coding cells. They also demonstrate how independent replay in the mEC could be part of a parallel memory circuit in the brain.

COORDINATED DYNAMICS OF DIRECTION AND POSITION REPRESENTATIONS IN MEDIAL ENTORHINAL CIRCUITS

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Richard Gardner, Abraham Vollan, Torgeir Waaga, May-Britt Moser, Edvard Moser
Kavli Institute for Systems Neuroscience, Faculty Of Medicine And Health Sciences, Trondheim, Norway

Grid cells are believed to provide a universal coordinate system for mapping an animal's ongoing experience. Stereotyped predictive "sweep" trajectories are putatively generated within grid-cell networks, and may serve a specific spatial metric function. To investigate this possibility, we used Neuropixels probes to record from many hundreds of cells in medial entorhinal cortex in rats while they explored 2-D and 1-D environments. First, we identified a novel latent population code, the "internal direction" (ID), which correlated with the animal's head direction but displayed independent theta-paced dynamics, tending to alternately represent directions to the left and right side of the animal's head direction. Surprisingly, when we decoded sweep trajectories from grid cells (or all position-modulated cells), the trajectories aligned to ID much more reliably than to the animal's head direction. Sweeps decoded independently from different grid-cell modules were co-aligned to ID, but with different lengths which were proportional to the module grid spacing. Notably, sweeps never exceeded half the grid spacing – thus, the represented locations were constrained within a local grid "tile". The partially discrepant module sweep trajectories suggest that modules may function as semi-independent, locally predictive maps. Consistent with this idea, module activity levels showed independent behavioural-timescale fluctuations. Finally, we found that decoded sweep trajectories extrapolated the cognitive map into unexplored regions of space: grid-cell maps extended through opaque walls and beyond the edges of elevated running tracks. This supports the notion of sweeps as an automatic and fundamental process underlying the measurement of space, irrespective of its content.

SPATIAL PERIODIC FIRING IN THE SUBICULUM OF MICE

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Jorge Brotons Mas[1,2]
[1]Universidad Cardenal Herrera, Medicine Department, Alicante, Spain, [2]Instituto de Neurociencias UMH-CSIC, Neurosciences, San Juan de Alicante, Spain

Spatial cognition relies on a complex circuitry in which the hippocampal formation seems to be crucial. The subiculum is a region located at the core of this circuit, it receives inputs from grid cells located in the medial entorhinal cortex (MEC) and place cells from the CA1 area of the hippocampus. It integrates input from these two relevant spatial information sources and mediates the output from the hippocampus to cortical and sub-cortical areas also involved in spatial coding. Despite the potential relevance of the subiculum, its role in memory and spatial coding is still poorly understood. Previous work described a very heterogeneous population of spatial neurons in the subiculum, with evidence of its role in coding the geometry of the environment and in spatial navigation in darkness. However, its role in spatial coding remains to be unveiled. With the aim of understanding further the properties of spatial coding in the subiculum, we implanted mice with microdrives mounting tetrodes and multisite electrodes aiming at the CA1 and subicular area, and recorded neuronal activity across different behavioral paradigms. Our results indicate that place cells in CA1 present higher spatial resolution and sharper firing fields than those of subicular neurons. Also, place cells in the CA1 area seem to be differentially modulated by the local field potential. Interestingly, we found pyramidal neurons in the subiculum with periodic firing, the first evidence of this type of regular firing in subicular pyramidal neurons.

UNIFORMITY OF GRID PHASES IN LARGE ENVIRONMENTS

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Valentin Normand[1], Torgeir Waaga[1], Erik Hermansen[2], Richard Gardner[1], Yasser Roudi[1], Benjamin Dunn[2], Edvard Moser[1], May-Britt Moser[1]
[1]NTNU, Kavli Institute For Systems Neuroscience And Centre For Neural Computation, Trondheim, Norway, [2]NTNU, Department Of Mathematical Sciences, Trondheim, Norway

Grid cells in the medial entorhinal cortex (MEC) show place-modulated activity at specific regions of an environment, generating a symmetrical, hexagonal lattice. The properties of the grid, such as spacing and orientation, vary along the dorso-ventral (D-V) axis of the MEC. Functional clusters of grid cells, called grid modules, share common properties. Within those clusters, each individual cell has a phase, referring to the relative position of their map in the environment. Two different models have been put forward to interpolate the generation of the grid cell network; continuous attractor models (CAN) and feed-forward learning models. One condition for CAN is the random distribution of the grid phases, implying a uniform coverage of space by the grid maps. In opposition, feedforward models can imply a clustered phase distribution. Using neuropixels recordings of rats foraging in an environment of 4x4 meters, we create ideal conditions to study the grid phases of hundreds of neurons. These experiments allow simultaneous recording of multiple D-V levels, providing the unprecedented opportunity to study very large modules. At the same time, small spacing grids show a high number of fields in this megaspace, which allows investigation of the stability of the phase pattern through this large environment. In agreement with the CAN models, our data demonstrate a random, non organised, distribution of phases for most of the grid modules in the MEC.

HEMISPHERE-SPECIFIC SPATIAL REPRESENTATION BY HIPPOCAMPAL GRANULE CELLS

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Thibault Cholvin, Marlene Bartos
University of Freiburg, Institute For Physiology, Dept. I, Freiburg, Germany

The dentate gyrus (DG) plays a key role in the emergence of spatial and contextual map representation within the hippocampus during learning. Differences in neuronal activity have been observed across the left and right CA1-3 areas, implying functional lateralization in spatial coding. Whether bilateral differences of DG granule cell (GC) assemblies encoding spatial information exist remains largely unexplored. Here, we employed two-photon calcium imaging in the left or right hemisphere to record the activity of GC populations over five consecutive days in head-fixed mice navigating through familiar and novel virtual environments. Imaging revealed similar mean activity of GCs between both sides. However, spatial tuning, context-selectivity and run-to-run place field reliability was markedly higher for GC place cells in the left than the right hemisphere. Moreover, the proportion of GCs reconfiguring their place fields between contexts was greater in the left DG. Thus, our data suggest that contextual information in GCs is differentially processed between hemispheres, with a high spatial discrimination between environments in the left DG but a bias towards generalization in the right DG. These data provide a potential explanation to recent divergent results about the degree of neuronal discrimination between environments observed in the DG.

IMPACT OF VISUAL THALAMUS LESION ONTO HIPPOCAMPAL PLACE CELL ACTIVITY.

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Jean-Yves Montenay[1], Julien Poitreau[2], Etienne Save[3], Vincent Hok[3]
[1]Laboratoire de Neurosciences Cognitives UMR 7291, Aix-Marseille université, Neural Basis Of Spatial Cognition, Marseille, France, [2]Laboratoire de Neurosciences Cognitives UMR 7291, Bases Neurales De La Navigation Spatiale, Marseille, France, [3]Laboratory of Cognitive Neuroscience, UMR 7291, Aix Marseille University, Cnrs, Marseille, Cedex, France

Hippocampal place cells are spatially tuned neurons in mammalian brain which are thought to reflect the memory trace of the spatial position of the animal in its environment. Their discovery led to the hypothesis that they are the neural substrate of a ‘cognitive map’ and play a major role in the mapping of the environment. Recently, a very similar spatial activity has been discovered in the dorsal lateral geniculate nucleus (dLGN), a thalamic structure widely known to be involved in early visual information processing. The existence of such activity suggests that a spatial map is formed one synapse after the retina. The aim of this study is to examine the impact of dLGN lesions onto hippocampal function. We performed bilateral excitotoxic lesions (NMDA) in the dLGN and recorded the spatial activity of CA1 hippocampal place cells in freely-moving rats while they explore either a familiar or novel asymmetric environments in total darkness. This allowed us to quantify place cell activity in the absence of visual inputs investigating therefore a putative non-visual role of dLGN in space processing. In both lesioned and SHAM rats, hippocampal place fields appeared to be more linked to specific parts of the environment suggesting a control by the geometric shape of the environment. In addition, hippocampal place fields in lesioned rats were more numerous, larger but less stable than in Sham rats. Overall, the dLGN functionally interacts with hippocampal place cells and may contribute to stabilize and increase the spatial selectivity of hippocampal place cells.

EFFECTS OF UNILATERAL VESTIBULAR LOSS ON HEAD-DIRECTION CELL ACTIVITY

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Nada El Mahmoudi[1], David Péricat[2], Brahim Tighilet[1], Pierre-Yves Jacob[3], Francesca Sargolini[1]
[1]Aix Marseille University, Laboratoire De Neurosciences Cognitives, MARSEILLE, France, [2]Université Paul - Sabatier, Ipbs, Toulouse, France, [3]Aix-Marseille uUniversity, Centre National De Le Recherche Scientifique (cnrs), Marseille, France

Vestibular information processing is essential in various brain' functions including navigation and spatial memory. Unilateral vestibular loss (UVL) induces long-term deficits in various domains of spatial memory associated with altered hippocampal plasticity. The origin of the deficits could be diverse as several pathways relaying vestibular information to the hippocampus have been described, including the head-direction pathway. As head direction cells (HDC) encode specific position of the head in a given environment, they strongly rely on vestibular information which make them a potential target for explaining spatial memory deficits induced by UVL. Particularly, the anterior nucleus (AN) of the thalamus, a key structure for memory and navigation, is known to receive vestibular information and to be the first structure generating proper HDC activity. Here we recorded neuronal activity in the ipsilesional AN before and after UVL in the adult rat. Surprisingly, we observed that HDC activity is still present in the ipsilesional AN after UVL. While other analyses must be conducted to better understand UVL impact on AN's activity, these results suggest that an alteration of the ipsilesional HDC pathway is not a convincing explanation for spatial memory deficits following UVL.

Breaking a dogma: acute anti-inflammatory treatment alters both post-lesional functional recovery and endogenous adaptive plasticity mechanisms in a rodent model of acute peripheral vestibulopathy.
Due to their anti-inflammatory action, corticosteroids are the reference treatment for brain injuries and many inflammatory diseases. However, the benefits of acute corticotherapy are now being questioned, particularly in the case of acute peripheral vestibulopathies (APV), characterized by a vestibular syndrome composed of sustained spinning vertigo, spontaneous ocular nystagmus and oscillopsia, perceptual-cognitive, posturo-locomotor, and vegetative disorders. We assessed the effectiveness of acute corticotherapy, and the functional role of acute inflammation observed after sudden unilateral vestibular loss.

Adult and endemic neurogenesis in the vestibular nuclei after unilateral vestibular neurectomy.
We previously revealed adult reactive neurogenesis in deafferented vestibular nuclei following unilateral vestibular neurectomy (UVN) in the feline model. We recently replicated the same surgery in a rodent model and aimed to elucidate the origin and fate of newly generated cells following UVN. We used specific markers of cell proliferation, glial reaction, and cell differentiation in the medial vestibular nucleus (MVN) of adult rats. UVN induced an intense cell proliferation and glial reaction with an increase of GFAP-Immunoreactive (Ir), IBA1-Ir and Olig2-Ir cells 3 days after the lesion in the deafferented MVN. Most of the newly generated cells survived after UVN and differentiated into oligodendrocytes, astrocytes, microglial cells and GABAergic neurons. Interestingly, UVN induced a significant increase in a population of cells colocalizing SOX2 and GFAP 3 days after lesion in the deafferented MVN indicating the probable presence of multipotent cells in the vestibular nuclei. The concomitant increase in BrdU- and SOX2-Ir cells with the presence of SOX2 and GFAP colocalization 3 days after UVN in the deafferented MVN may support local mitotic activity of endemic quiescent neural stem cells in the parenchyma of vestibular nuclei.

Sensorimotor Rehabilitation Promotes Vestibular Compensation in a Rodent Model of Acute Peripheral Vestibulopathy by Promoting Microgliogenesis in the Deafferented Vestibular Nuclei.

Acute peripheral vestibulopathy leads to a cascade of symptoms involving balance and gait disorders that are particularly disabling for vestibular patients. Vestibular rehabilitation protocols have proven to be effective in improving vestibular compensation in clinical practice. Yet, the underlying neurobiological correlates remain unknown. The aim of this study was to highlight the behavioural and cellular consequences of a vestibular rehabilitation protocol adapted to a rat model of unilateral vestibular neurectomy. We developed a progressive sensory-motor rehabilitation task, and the behavioural consequences were quantified using a weight-distribution device. This analysis method provides a precise and ecological analysis of posturolocomotor vestibular deficits. At the cellular level, we focused on the analysis of plasticity mechanisms expressed in the vestibular nuclei. The results obtained show that vestibular rehabilitation induces a faster recovery of posturolocomotor deficits during vestibular compensation associated with a decrease in neurogenesis and an increase in microgliogenesis in the deafferented medial vestibular nucleus. This study reveals for the first time a part of the underlying adaptative neuroplasticity mechanisms of vestibular rehabilitation. These original data incite further investigation of the impact of rehabilitation on animal models of vestibulopathy. This new line of research should improve the management of vestibular patients.

Identification of New Biomarkers of Posturo-Locomotor Instability in a Rodent Model of Vestibular Pathology.
The vestibular system plays a crucial role in maintaining postural balance. Unilateral vestibular lesions result in a typical syndrome characterized by postural imbalance, altered locomotor patterns and gaze stabilization, as well as cognitive and neurovegetative disorders. One of the main difficulties encountered in the development of new anti-vertigo drugs is the lack of sensitivity in the evaluation of this syndrome. Qualitative assessments of the vestibular syndrome have been developed, but methods of conducting quantitative evaluations are critically lacking. Recently, assessments with a dynamic weight-bearing device (DWB®, Bioseb) revealed postural alterations in rats subjected to unilateral vestibular neurectomy (UVN). Our team is evaluating a new version of this device capable of quantifying additional parameters of postural and locomotor equilibrium. The objective of this study was to use this device to assess these new posturo-locomotor parameters in a rat model of a vestibular pathology. The biomarkers measured by this device are as follows: the barycenter, the support surface and the weight distribution of the rats when they were moving or stationary. Before UVN, the rats showed a symmetric distribution of their weight along the lateral axis. In the acute phase after UVN on the left side, the rats distributed more weight on the right side than on the left side and then distributed more weight on the left side. These results corroborate those presented in our previous study. The support surface of the rats increased between 1 day and 30 days after UVN, and the barycenter distribution reflected the weight distribution. In addition, our results show smaller changes in the weight distributions when the animals are moving compared with when they are stationary in the acute phase after UVN. This study provides new information on the static and dynamic postural balance patterns observed after unilateral vestibular loss in rats. These data are relevant because they objectively quantify the posturo-locomotor component of vestibular syndrome as well as the compensatory strategies used after vestibular loss. These results may guide the development of rehabilitation protocols for vestibular patients and the validation of pharmacological compounds favoring the restoration of equilibrium.

Quantitative Evaluation of a New Posturo-Locomotor Phenotype in a Rodent Model of Acute Unilateral Vestibulopathy.
Vestibular pathologies are difficult to diagnose. Existing devices make it possible to quantify and follow the evolution of posturo-locomotor symptoms following vestibular loss in static conditions. However, today, there are no diagnostic tools allowing the quantitative and spontaneous analysis of these symptoms in dynamic situations. With this in mind, we used an open-field video tracking test aiming at identifying specific posturo-locomotor markers in a rodent model of vestibular pathology. Using Ethovision XT 14 software (Noldus), we identified and quantified several behavioral parameters typical of unilateral vestibular lesions in a rat model of vestibular pathology. The unilateral vestibular neurectomy (UVN) rat model reproduces the symptoms of acute unilateral peripheral vestibulopathy in humans. Our data show deficits in locomotion velocity, distance traveled and animal mobility in the first day after the injury. We also highlighted alterations in several parameters, such as head and body acceleration, locomotor pattern, and position of the body, as well as "circling" behavior after vestibular loss. Here, we provide an enriched posturo-locomotor phenotype specific to full and irreversible unilateral vestibular loss. This test helps to strengthen the quantitative evaluation of vestibular disorders in unilateral vestibular lesion rat model. It may also be useful for testing pharmacological compounds promoting the restoration of balance. Transfer of these novel evaluation parameters to human pathology may improve the diagnosis of acute unilateral vestibulopathies and could better follow the evolution of the symptoms upon pharmacological and physical rehabilitation.

EXPERIENCE DEPENDENT SPECIFICITY OF PLACE CELL DIRECTIONALITY IN ALZHEIMER'S RAT MODEL

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Athira Nataraj, Stephanie Pena, Annu Kala, Karel Jezek, Karel Blahna
Charles University, Faculty Of Medicine In Pilsen, Pilsen, Czech Republic

On linear track hippocampal place cells fire selectively at specific locations in a direction-dependent manner. Unidirectional cells express firing fields only in one direction while bidirectional cells fire on both. The directionality changes with experience and might be related to memory consolidation as it is higher in familiar environments compared to novel ones, however, its exact nature is not well understood. To understand the development of place cells directionality as possible indicator of memory consolidation in Alzheimer's disease, we compared transgenic 9-12 months old TgF344-AD animals carrying human genes for PS1 and APP with F344 controls. We examined the properties of CA1 place cell activity in familiar and novel linear track environments, namely their directionality and firing field size. Population analysis with respect to forward and reverse directions was also performed. To rule out the possibility of bidirectional cell effect occurred by chance, methods such as spatial selectivity and instantaneous speed were employed. In the familiar environment the measured parameters did not differ significantly between the groups. However, in the novel environment we observed significantly larger firing fields in TgF344-AD animals, as well as a higher proportion of bidirectional place cells compared to controls. The population vector analysis showed a higher similarity in TgF344-AD between neural codes for each direction in the novel environment. These results point towards an impairment in novel information encoding in the Alzheimer model and to its rather functional consolidation in the CA1 hippocampal network.

Early Spatial Memory Impairment in a Double Transgenic Model of Alzheimer's Disease TgF-344 AD.
Before the course of Alzheimer's disease fully manifests itself and largely impairs a patient's cognitive abilities, its progression has already lasted for a considerable time without being noticed. In this project, we mapped the development of spatial orientation impairment in an active place avoidance task-a highly sensitive test for mild hippocampal damage. We tested vision, anxiety and spatial orientation performance at four age levels of 4, 6, 9, and 12 months across male and female TgF-344 AD rats carrying human genes for presenilin-1 and amyloid precursor protein. We found a progressive deterioration of spatial navigation in transgenic animals, beginning already at the age of 4 months, that fully developed at 6 months of age across both male and female groups, compared to their age-matched controls. In addition, we described the gradual vision impairment that was accentuated in females at the age of 12 months. These results indicate a rather early onset of cognitive impairment in the TgF-344 AD Alzheimer's disease model, starting earlier than shown to date, and preceding the reported development of amyloid plaques.

TIME OR DISTANCE: PREDICTIVE CODING OF HIPPOCAMPAL CELLS

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Shai Abramson[1], Benjamin Kraus[2], John White[2], Michael Hasselmo[2], Genela Morris[3], Dori Derdikman[4]
[1]Rappaport Faculty of Medicine and Research Institute, Technion – Israel Institute of Technology, Neuroscience, Haifa, Israel, [2]Boston university, Center For Systems Neuroscience, Boston, United States of America, [3]Tel-Aviv Sourasky Medical Center, Neurosurgery Dept., Tel-Aviv, Israel, [4]Technion, Rappaport Faculty Of Medicine, Haifa, Israel

The discovery of place cells within the hippocampus has pointed to the importance of the hippocampus for navigation. The more recent discovery of hippocampal time cells has broadened the perspective of encoding in the hippocampus. One hypothesis is based on the notion that hippocampal cells deduce location by integrating travelled distance ("path integration"). Accordingly, time cells, which fire at particular times when animals are running on a treadmill without changing location, actually encode accumulated distance on the treadmill. To examine this hypothesis, Kraus et al. [1] performed treadmill experiments in which animals either ran for a fixed-time or a fixed-distance with varying velocities. Two distinct coding modes of hippocampal principal cells were found. Some cells encoded travelled distance and others elapsed time, thus refuting the notion that all hippocampal cells were performing path integration. Using the data from these experiments, we asked whether the two populations depended on the type of task the rats were engaged in. We performed an analysis based on the onset time of each run and defined metrics to evaluate whether the cell is better encoding time or distance. We show (figure 1) that indeed the type of experiment determined the cells' encoding and suggest possible mechanisms of predictive coding which may explain these results. [1] Kraus, B. LOCAL ACTIVATION GENERATES THETA PHASE PRECESSION IN CA1 PYRAMIDAL NEURONS

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Hadas Sloin, Amir Levi, Shirly Someck, Lidor Spivak, Roni Gattegno, Eran Stark
Tel Aviv University, Sagol School Of Neuroscience And Department Of Physiology And Pharmacology, Sackler Faculty Of Medicine, Tel Aviv, Israel

Multiple studies demonstrated the importance of theta phase precession as a spatial code and as a learning mechanism. However, the components contributing to precession and the locus of generation remain unclear. Here, we tested the hypothesis that a transient position-dependent rate increase of CA1 pyramidal neurons, combined with ongoing theta, suffices for generating precession. We implanted high-density silicon probes with miniature light sources in CA1 expressing ChR2 in pyramidal neurons (five mice). As the mice traversed a linear track, we used closed-loop illumination to generate place- and orientation-dependent spiking. Although illumination was indifferent to theta oscillations, 15% of the pyramidal cells exhibited induced spatial precession. Induced precession was especially prevalent among units with high firing rate gain during ripples, implying that precession is more readily generated in cells tuned to upstream information. During stimulation, rhythmically spiking pyramidal cells shifted to frequencies higher than theta oscillations, indicating induced temporal precession. To determine whether induced precession depends on hippocampal anatomy and inputs, we repeated experiments in parietal neocortex (three mice). Closed-loop illumination led to position-dependent firing of neocortical cells. However, although paced by volume-conducted hippocampal theta, neocortical cells did not exhibit induced precession. Thus, spatial and temporal precession can be generated locally in CA1, at odds with models of inheritance from CA3 or upstream regions. Instead, our results imply that precession is specifically produced by an intra-CA1 generator, which depends on local firing rate increase, theta oscillations, and upstream inputs. Response and sample bridging in a primate short-term memory task.
Freely-moving rodents can solve short-term memory (STM) tasks using "response bridging" strategies, relying on motor patterns instead of mnemonic functions. This limits the interpretational power of results yielded by some STM tasks in rodents. To determine whether head-fixed monkeys can employ parallel non-mnemonic strategies, we measured eye position and velocity of two head-fixed monkeys performing a delayed response reaching and grasping task. We found that eye position during the delay period was correlated with reach direction. Moreover, reach direction as well as grasp object could be predicted from eye kinematics during the delay. Both eye velocity and eye position contributed to the prediction of reach direction. These results show that motor signals carry sufficient information to allow monkeys to solve STM tasks without using any mnemonic functions. Thus, the potential of animals to solve STM tasks using motor patterns is more diverse than previously recognized.

Interactions between the circadian clock and TGF-β signaling pathway in zebrafish.
TGF-β signaling is a cellular pathway that functions in most cells and has been shown to play a role in multiple processes, such as the immune response, cell differentiation and proliferation. Recent evidence suggests a possible interaction between TGF-β signaling and the molecular circadian oscillator. The current study aims to characterize this interaction in the zebrafish at the molecular and behavioral levels, taking advantage of the early development of a functional circadian clock and the availability of light-entrainable clock-containing cell lines.

BioNSi: A Discrete Biological Network Simulator Tool.
Modeling and simulation of biological networks is an effective and widely used research methodology. The Biological Network Simulator (BioNSi) is a tool for modeling biological networks and simulating their discrete-time dynamics, implemented as a

Cytoscape App. BioNSi includes a visual representation of the network that enables researchers to construct, set the parameters, and observe network behavior under various conditions. To construct a network instance in BioNSi, only partial, qualitative biological data suffices. The tool is aimed for use by experimental biologists and requires no prior computational or mathematical expertise. BioNSi is freely available at http://bionsi.wix.com/bionsi , where a complete user guide and a step-by-step manual can also be found.

CEREBELLAR CONTROL OF A UNITARY SENSE OF DIRECTION

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Mehdi Fallahnezhad[1], Julia Le Méro[2], Xhensjana Zenelaj[2], Jean Vincent[2], Christelle Rochefort[2], Laure Rondi-Reig[2]
[1]Sorbonne Universite - CNRS - Inserm, Neurosciences Paris Seine, paris, France, [2]Sorbonne Universite - CNRS - Inserm, Neurosciences Paris Seine, Paris, France

The head-direction system, a key neural circuit in the animal's navigation system, consists of several anatomical structures with neurons that fire selectively to the animal's head direction. Population activity of these cells exhibits a ubiquitous temporal organization across different regions of the head-direction system, independent of the animal's behavioral state or sensory inputs, creating a single, stable, and persistent head-direction signal. However, the mechanistic processes behind this temporal organization are unknown. Since the cerebellum is involved in processing sensory signals, we examined how suppressing two forms of cerebellar plasticity in Purkinje cells (PKC-dependent synaptic depression and PP2B-dependent potentiation) affects the head-direction system. We first show that head-direction cell pairs from the anterodorsal thalamus and retrosplenial cortex exhibit a robust and stable neuronal coordination in the presence of an external landmark in both controls and cerebellar alteration conditions. However, when the external landmark cue was removed, neuronal coordination between the thalamus and retrosplenial cortex was abolished following the suppression of cerebellar PKC-dependent plasticity. In addition, we identify distinct roles for cerebellar PP2B- and PKC-dependent mechanisms in maintaining a stable thalamocortical head-direction signal during navigation by external landmark and self-motion inputs, respectively. These results identify new roles for the cerebellum in mediating a unitary and stable head-direction signal across the head-direction system.

THE INTERNAL DIRECTION SIGNAL IN MEDIAL ENTORHINAL CORTEX/PARASUBICULUM IS QUALITATIVELY DIFFERENT FROM THE HEAD DIRECTION SIGNAL IN UPSTREAM BRAIN REGIONS

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Abraham Vollan[1], Richard Gardner[2], Edvard Moser[2], May-Britt Moser[2]
[1]NTNU, Kavli Institute For Systems Neuroscience, Trondheim, Norway, [2]NTNU, Kavli Institute For Systems Neuroscience And Centre For Neural Computation, Trondheim, Norway

A large proportion of cells in the medial entorhinal cortex and parasubiculum (MEC/PaS) encode an internal direction (ID) signal that differs from head direction (HD) with theta-rhythmic, left-right-alternating dynamics (Gardner et al, same session). We were motivated to investigate where and how the ID signal is generated and asked if we could find features of ID in earlier stages of the classical HD circuit. To address this question, we recorded neural activity from hundreds of cells with Neuropixels probes in MEC/PaS and presubiculum (PrS) or anterodorsal thalamus (ADn) in rats during open field foraging, linear track running and sleep. We extracted the directional signals encoded by cells in each region by applying dimensionality reduction methods to population spike trains. The directional signals in ADn/PrS faithfully tracked HD, while the directional signal in MEC/PaS displayed left-right-alternating dynamics. During exploration and REM sleep, we observed occasional ‘decoupling events’ where the directional signals in ADn/PrS and MEC/PaS drifted independently. Except for during ‘decoupling events’, the ID signal in MEC/PaS was centred around the HD signal in ADn/PrS, and the anchoring between the two signals remained unchanged during sleep and after environmental manipulations. In summary, there is a functional split between the directional codes in ADn/PrS, which reliably track HD, and the ID signal in MEC/PaS. The two signals are correlated but differ on the theta-timescale and can transiently decouple. HD and ID are similarly anchored across brain states, suggesting that they might be different directional signals operating within the same cognitive map.

A FULLY AUTOMATED MAZE APPARATUS TO CHARACTERIZE SPATIAL STRATEGIES IN CLUTTERED ENVIRONMENTS

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Ju-Young Lee, Dahee Jung, Junho Sohn, Sebastien Royer
Korea Institute of Science and Technology, Brain Science Institute, Seoul, Korea, Republic of

Spatial navigation relies on diverse strategies and mechanisms that depend on the nature and familiarity of environments. For instance, animals preferentially use distal landmark/vector-relationship to goals in open environments while they might use the topology of local cues in obstacle-rich environments. How animal trajectories to goal locations develop over time in different environments still remain unclear. For this purpose, we developed a fully motorized maze apparatus, characterized by a central arena enclosure with multiple side doors, a tainted plexiglass cover, and two home boxes that move around the arena perimeter, alternatively serving as start and goal positions for the animal trajectories. We tested two distinct environments: an open arena, with two luminous objects on the periphery acting as orienting cues, and an arena enriched with scattered objects, constraining the animal paths but not the visibility of the two luminous objects on the periphery. On each trial, mice entered the arenas from a randomly chosen start position and had to navigate to the same goal position to receive water rewards. We monitored mouse trajectories across 15 days (10 trials per day). Exit mistake numbers, trajectory lengths and trajectory durations were reduced across days. All mice favored a strategy of circling in counter-clockwise direction in the open arena while they develop preferences for specific trajectory segments in the cluttered arena. These results demonstrate the effectiveness of the apparatus to investigate spatial learning and navigation strategies in cluttered environments.

Spatial navigation is crucial for animal survival. While previous work identified neuronal place cells in the hippocampus as key cellular correlates of spatial navigation, the involvement of glia in this process is less understood. Recent work demonstrates that intracellular calcium signals in astrocytes, a main type of glial cells, encode information about the animal's position and that information encoded into astrocytes is complementary to that encoded in the activity of nearby hippocampal neurons. Since variations in the intracellular concentration of calcium in astrocytes modulate the activity of surrounding synapses and neurons, we tested whether the perturbation of astrocytic calcium signalling in the hippocampus affects the neuronal representation of space. To this aim, we manipulated astrocytic calcium dynamics using pharmacogenetics, while simultaneously imaging pyramidal neurons in the CA1 hippocampal region of head-fixed mice running in a virtual corridor. We used viral injections to specifically express the Gq-coupled DREADD receptor in astrocytes and GCaMP6f in neurons and we performed two-photon functional imaging before and after DREADD activation with CNO. Preliminary results using information theory show that DREADD activation alters the information content of neuronal place cells. Further analyses of the features of neuronal place cells upon manipulation of astrocytic signalling are currently ongoing. These preliminary findings indicate that perturbation of astrocytic calcium dynamics influences the neuronal representation of space and suggest that the complementary place-dependence of the astrocytic calcium dynamics may facilitate the emergence of dynamic, context-dependent changes in population coding of CA1 neurons.

MAPPING SPACE WITH INTERNALLY GENERATED THETA SEQUENCES

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Eloy Parra-Barrero, Sen Cheng
Ruhr University Bochum, Institute For Neural Computation, Bochum, Germany

Flexible spatial navigation requires the representation of past, present and future locations. In mammals, this is thought to rely on hippocampal place cells. Within each cycle of the theta oscillation, place cells represent a temporally compressed trajectory starting behind the animal and reaching ahead. Assuming the animal ran at its typical running speed through each location, these theta trajectories would start at the position the animal had reached a fixed time interval into the past, and extend to the position the animal would reach a fixed time interval into the future (Parra-Barrero et al., 2021). These behavior-dependent theta sweeps result in longer theta trajectories where animals typically run faster, which is accompanied by bigger place fields with shallower phase precession in those areas. Here we propose a computational model for the neural mechanism underlying these effects. Spatial locations are mapped onto internally generated theta sequences that progress at a fixed pace in a neural space of simulated hippocampal cells by learning the associations between an array of sensory features and the hippocampal cells. As a result, locations mapped onto neighboring cells are further apart the faster the animal runs through an area. Hence, in areas of higher running speed, place fields are larger and less dense, and have shallower phase precession, which in turn leads to longer theta trajectories. Our results highlight the important role of intrinsic network structure and reveal how the hippocampal code can arise from the interplay between predefined internal dynamics, behavior and sensory input.

FUNCTIONAL INDEPENDENCE OF GRID CELL MODULES DURING HIPPOCAMPAL REMAPPING

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Christine Lykken, Anne Nagelhus, Benjamin Kanter, May-Britt Moser, Edvard Moser
NTNU, Kavli Institute For Systems Neuroscience And Centre For Neural Computation, Trondheim, Norway

Grid cells in the medial entorhinal cortex (MEC) create a universal metric of space that may be a basis for environment-specific maps and memories in the hippocampus. Grid cells are organized into discrete modules: All cells within a module operate coherently, but it is thought that different modules could, under some circumstances, operate independently of each other. This independence may underlie the generation of unique hippocampal maps for each environment. However, experimental evidence for discordant responses among grid modules is limited, and it has never been shown in conjunction with place cell remapping. To test whether grid modules realign independently during place cell remapping between distinct environments, we chronically implanted Neuropixels probes in MEC and hippocampus in rats to simultaneously record multiple grid modules and place cells. We found that place cells exhibited robust and stable remapping between rooms. There were only slight differences in rotation between grid modules, and this rotation was largely coherent with border and head direction cells. Despite this, each grid module shifted independently between rooms. The difference in the translation of grid modules was large: On average, we estimated that modules were separated by at least 20 cm. Realignment within each module was coherent, consistent with each module functioning as a continuous attractor network. Thus, these findings are the first experimental evidence demonstrating that functionally independent grid cell modules may underlie hippocampal remapping. We are currently investigating how grid modules (and other functional cell types) respond under conditions that elicit partial remapping in place cells.

GRID CELLS RESCALE TO MATCH GOAL DISTANCE DURING PATH-INTEGRATION

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Satoshi Kuroki, Sebastien Royer
Korea Institute of Science and Technology, Brain Science Institute, Seoul, Korea, Republic of

Spatial navigation rely on both landmarks and path integration information. While grid cells in the medial entorhinal cortex (MEC) display periodic firing fields that are believed to provide an intrinsic metric and to support path-integration, they are also controlled by landmarks as they typically encode stable locations of the environment. It is still unknown whether grid cells can compute reward distances and support goal-direct navigation in contexts that require the abstraction of environmental cues. To test this, we performed silicon probe recordings of MEC cells in mice that were running consecutively in an open field and on a cue-enriched treadmill belt. In the treadmill, the mice needed to use path integration to anticipate a water reward that was delivered after a fixed travel distance (shorter than the belt length). Grid cells identified in the open field showed periodic field activity in the treadmill belt. Interestingly, the spatial period of grid cells varied over time, often matching submultiples of the reward distance or of the belt length. Grid cell ensembles switched synchronously, in a coherent manner, between time windows where grid cell periodicities matched reward distance and time windows where they matched the belt length. During reward distance-matching time windows, the firing fields of grid cells were better aligned to reward locations and mouse anticipatory lickings were more accurate.
These results suggest that grid cells can flexibly rescale to match reward distance and support goal-directed navigation under path integration.

ASSESSING SPATIAL CODING IN LARGE SCALE ENVIRONMENTS USING VIRTUAL REALITY, ELECTROPHYSIOLOGICAL RECORDINGS AND DEEP LEARNING

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Alla Solod[1,2,3], Paul Uteza[1,2,3], Hervé Rouault[1,2,4], Jérôme Epsztein[1,3]
[1]Aix-Marseille University, Bouches-du-rhône, Marseille, France, [2]CENTURI, Bouches-du-rhône, Marseille, France, [3]Institut de Neurobiologie de la Méditerranée (Inmed), Inserm, Marseille, France, [4]Centre de Physique Théorique (CPT), Cnrs, Marseille, France

Animals can flexibly navigate their environment by following different paths toward goals. This ability is thought to rely on a cognitive map. Place cells in the hippocampus, a key brain structure for spatial navigation, are pyramidal neurons that fire action potentials whenever an animal is at a specific position within its environment (their place field). Place cell coding and navigation have been studied for decades in small (e.g. 1m in size) homogeneous environments. However, in the wild, animals including rodents can navigate several kilometers away to various food locations through an inhomogeneous landscape. During such large-scale navigation, different parts of the environment could be coded at different spatial resolutions through “nested hierarchies” of coarse and fine grain coding with large and small place fields observed for the same neurons (Eliav et al., 2021; Harland et al., 2021). However, it is unclear how place fields size and number are influenced by specific features of the environment. To address this question, we developed a behavioral task where mice navigate a 30 m long curved path in a 100 m^2 semi-realistic virtual environment with inhomogeneous distribution of visual cues and rewards. In addition, we measure pupil dilation and eye movements to control for visual attention. To better understand how visual information alone could influence the precision of self-location, we further trained an artificial neural network to self-locate using snapshots of the virtual environment. Using this framework, we will investigate the modulation of spatial coding resolution during large-scale navigation in inhomogeneous environments.

The Atlantic herring (*Clupea harengus*), an ecological and economical key species in the Northern Hemisphere, shows pronounced seasonal migratory behaviour from their feeding areas to overwintering grounds to their spawning areas. Goal oriented migration over distances of several hundred kilometres is a difficult task and requires the right cues for orientation and navigation. Fish can use a range of sensory cues for orientation and long-distance navigation, such as magnetic sensing or sun compass. So far, only non-migrating Atlantic herring larvae at the age of 14-28 days post hatching had been tested in different orientation experiments. Results of this study propose the potential use of a sun compass, but could not exclude the use of other orientational cues within the experiment. In our study we tested juveniles shortly before they start their migration in a controlled experiment focusing solely on the sun as a visual cue. The herring showed a significant orientation to the east-southeast (mean vector 108°) which corresponds to a natural migration route. For confirmation of a time-compensated sun compass, we clock-shifted a second experimental group 6 hours backwards. This group showed a significant group orientation towards north-northeast (mean vector 33°). After compensating for the sun azimuth shift during the day, we found no significant difference between the two datasets. For the first time we showed that juvenile Baltic herring use a time-compensated sun compass.

Selected Ionotropic Receptors and Voltage-Gated Ion Channels: More Functional Competence for Human Induced Pluripotent Stem Cell (iPSC)-Derived Nociceptors.
Preclinical research using different rodent model systems has largely contributed to the scientific progress in the pain field, however, it suffers from interspecies differences, limited access to human models, and ethical concerns. Human induced pluripotent stem cells (iPSCs) offer major advantages over animal models, i.e., they retain the genome of the donor (patient), and thus allow donor-specific and cell-type specific research. Consequently, human iPSC-derived nociceptors (iDNs) offer intriguingly new possibilities for patient-specific, animal-free research. In the present study, we characterized iDNs based on the expression of well described nociceptive markers and ion channels, and we conducted a side-by-side comparison of iDNs with mouse sensory neurons. Specifically, immunofluorescence (IF) analyses with selected markers including early somatosensory transcription factors (BRN3A/ISL1/RUNX1), the low-affinity nerve growth factor receptor (p75), hyperpolarization-activated cyclic nucleotide-gated channels (HCN), as well as high voltage-gated calcium channels (VGCC) of the Ca2 type, calcium permeable TRPV1 channels, and ionotropic GABA receptors, were used to address the characteristics of the iDN phenotype. We further combined IF analyses with microfluorimetric Ca measurements to address the functionality of these ion channels in iDNs. Thus, we provide a detailed morphological and functional characterization of iDNs, thereby, underpinning their enormous potential as an animal-free alternative for human specific research in the pain field for unveiling pathophysiological mechanisms and for unbiased, disease-specific personalized drug development.

Rho GTPases in the Physiology and Pathophysiology of Peripheral Sensory Neurons.
Numerous experimental studies demonstrate that the Ras homolog family of guanosine triphosphate hydrolases (Rho GTPases) Ras homolog family member A (RhoA), Ras-related C3 botulinum toxin substrate 1 (Rac1) and cell division cycle 42 (Cdc42) are important regulators in somatosensory neurons, where they elicit changes in the cellular cytoskeleton and are involved in diverse biological processes during development, differentiation, survival and regeneration. This review summarizes the status of research regarding the expression and the role of the Rho GTPases in peripheral sensory neurons and how these small proteins are involved in development and outgrowth of sensory neurons, as well as in neuronal regeneration after injury, inflammation and pain perception. In sensory neurons, Rho GTPases are activated by various extracellular signals through membrane receptors and elicit their action through a wide range of downstream effectors, such as Rho-associated protein kinase (ROCK), phosphoinositide 3-kinase (PI3K) or mixed-lineage kinase (MLK). While RhoA is implicated in the assembly of stress fibres and focal adhesions and inhibits neuronal outgrowth through growth cone collapse, Rac1 and Cdc42 promote neuronal development, differentiation and neuroregeneration. The functions of Rho GTPases are critically important in the peripheral somatosensory system; however, their signalling interconnections and partially antagonistic actions are not yet fully understood.

Paraoxonase-2 regulates coagulation activation through endothelial tissue factor.
Oxidative stress and inflammation of the vessel wall contribute to prothrombotic states. The antioxidative protein paraoxonase-2 (PON2) shows reduced expression in human atherosclerotic plaques and endothelial cells in particular. Supporting a direct role for PON2 in cardiovascular diseases, deficiency in mice promotes atherogenesis through incompletely understood mechanisms. Here, we show that deregulated redox regulation in deficiency causes vascular inflammation and abnormalities in blood coagulation. In unchallenged mice, we find increased oxidative stress and endothelial dysfunction. Bone marrow transplantation experiments and studies with endothelial cells provide evidence that increased inflammation, indicated by circulating interleukin-6 levels, originates from deficiency in the vasculature. Isolated endothelial cells from mice display increased tissue factor (TF) activity in vitro. Coagulation times were shortened and platelet procoagulant activity increased in mice relative to wild-type controls. Coagulation abnormalities of mice were normalized by anti-TF treatment, demonstrating directly that TF increases coagulation. PON2 reexpression in endothelial cells by conditional reversal of the knockout cassette, restoration in the vessel wall using bone marrow chimeras, or treatment with the antioxidant -acetylcysteine normalized the procoagulant state. These experiments delineate a PON2 redox-dependent mechanism that regulates endothelial cell TF activity and prevents systemic coagulation activation and inflammation.

On the Ultrastructure and Function of Rhogocytes from the Pond Snail Lymnaea stagnalis.
Rhogocytes, also termed "pore cells", occur as solitary or clustered cells in the connective tissue of gastropod molluscs. Rhogocytes possess an enveloping lamina of extracellular matrix and enigmatic extracellular lacunae bridged by cytoplasmic bars that form 20 nm diaphragmatic slits likely to act as a molecular sieve. Recent papers highlight the embryogenesis and ultrastructure of these cells, and their role in heavy metal detoxification. Rhogocytes are the site of hemocyanin or hemoglobin biosynthesis in gastropods. Based on electron microscopy, we recently proposed a possible pathway of hemoglobin exocytosis through the slit apparatus, and provided molecular evidence of a common phylogenetic origin of molluscan rhogocytes, insect nephrocytes and vertebrate podocytes. However, the previously proposed secretion mode of the respiratory proteins into the hemolymph is still rather hypothetical, and the possible role of rhogocytes in detoxification requires additional data. Although our previous study on rhogocytes of the red-blooded (hemoglobin-containing) freshwater snail Biomphalaria glabrata provided much new information, a disadvantage was that the hemoglobin molecules were not unequivocally defined in the electron microscope. This made it difficult to trace the exocytosis pathway of this protein. Therefore, we have now performed a similar study on the rhogocytes of the blue-blooded (hemocyanin-containing) freshwater snail Lymnaea stagnalis. The intracellular hemocyanin could be identified in the electron microscope, either as individual molecules or as pseudo-crystalline arrays. Based on 3D-electron microscopy, and supplemented by in situ hybridization, immunocytochemistry and stress response experiments, we provide here additional details on the structure and hemocyanin biosynthesis of rhogocytes, and on their response in animals under cadmium and starvation stress. Moreover, we present an advanced model on the release of synthesized hemocyanin molecules through the slit apparatus into the hemolymph, and the uptake of much smaller particles such as cadmium ions from the hemolymph through the slit apparatus into the cytoplasm.

GEOMETRY PRESERVED SCHEMA OF SPACE IN THE ORBITOFRONTAL CORTEX

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Raunak Basu, Hiroshi Ito
Max Planck Institute for Brain Research, Memory And Navigation Circuits, Frankfurt am Main, Germany

Planning efficient navigation strategies requires a geometry preserved internal map of the environment that enables estimating distances between two given locations. Previous research has identified place cells and grid cells in the hippocampus and the parahippocampal cortices that fire specifically when an animal visits a particular location(s), resulting in each location being encoded by different sets of neurons. However, it is unclear how such maps can estimate the distance between two locations that may be represented by entirely separate populations of neurons. Here we report a new kind of spatial map in the orbitofrontal cortex (OFC) that preserves the relative geometry between locations in space. In an environment with multiple equally spaced reward locations, OFC neural ensembles exhibit distinct and ordered firing patterns for each location. Further analysis revealed that the difference in the ensemble firing patterns representing two locations is proportional to the distance between the locations in physical space. Next, to test the generalizability of these maps, we trained animals in two geometrically distinct environments but with identically spaced reward locations. We observed that the OFC formed similar geometry preserved spatial maps of reward locations in both environments which could be further aligned using a linear transformation. Taken together, the OFC forms a geometrically preserved schema of locations that generalizes across environments, making it a potentially crucial brain region for navigational decisions.

The orbitofrontal cortex maps future navigational goals.
Accurate navigation to a desired goal requires consecutive estimates of spatial relationships between the current position and future destination throughout the journey. Although neurons in the hippocampal formation can represent the position of an animal as well as its nearby trajectories, their role in determining the destination of the animal has been questioned. It is, thus, unclear whether the brain can possess a precise estimate of target location during active environmental exploration. Here we describe neurons in the rat orbitofrontal cortex (OFC) that form spatial representations persistently pointing to the subsequent goal destination of an animal throughout navigation. This destination coding emerges before the onset of navigation, without direct sensory access to a distal goal, and even predicts the incorrect destination of an animal at the beginning of an error trial. Goal representations in the OFC are maintained by destination-specific neural ensemble dynamics, and their brief perturbation at the onset of a journey led to a navigational error. These findings suggest that the OFC is part of the internal goal map of the brain, enabling animals to navigate precisely to a chosen destination that is beyond the range of sensory perception.

Heterophilic Type II Cadherins Are Required for High-Magnitude Synaptic Potentiation in the Hippocampus.
Hippocampal CA3 neurons form synapses with CA1 neurons in two layers, stratum oriens (SO) and stratum radiatum (SR). Each layer develops unique synaptic properties but molecular mechanisms that mediate these differences are unknown. Here, we show that SO synapses normally have significantly more mushroom spines and higher-magnitude long-term potentiation (LTP) than SR synapses. Further, we discovered that these differences require the Type II classic cadherins, cadherins-6, -9, and -10. Though cadherins typically function via trans-cellular homophilic interactions, our results suggest presynaptic cadherin-9 binds postsynaptic cadherins-6 and -10 to regulate mushroom spine density and high-magnitude LTP in the SO layer. Loss of these cadherins has no effect on the lower-magnitude LTP typically observed in the SR layer, demonstrating that cadherins-6, -9, and -10 are gatekeepers for high-magnitude LTP. Thus, Type II cadherins may uniquely contribute to the specificity and strength of synaptic changes associated with learning and memory.

The intellectual disability gene Kirrel3 regulates target-specific mossy fiber synapse development in the hippocampus.
Synaptic target specificity, whereby neurons make distinct types of synapses with different target cells, is critical for brain function, yet the mechanisms driving it are poorly understood. In this study, we demonstrate Kirrel3 regulates target-specific synapse formation at hippocampal mossy fiber (MF) synapses, which connect dentate granule (DG) neurons to both CA3 and GABAergic neurons. Here, we show Kirrel3 is required for formation of MF filopodia; the structures that give rise to DG-GABA synapses and that regulate feed-forward inhibition of CA3 neurons. Consequently, loss of Kirrel3 robustly increases CA3 neuron activity in developing mice. Alterations in the Kirrel3 gene are repeatedly associated with intellectual disabilities, but the role of Kirrel3 at synapses remained largely unknown. Our findings demonstrate that subtle synaptic changes during development impact circuit function and provide the first insight toward understanding the cellular basis of Kirrel3-dependent neurodevelopmental disorders.
Elife, 2015; 4
25837840: Basu R, Taylor MR, Williams ME
The classic cadherins in synaptic specificity.
During brain development, billions of neurons organize into highly specific circuits. To form specific circuits, neurons must build the appropriate types of synapses with appropriate types of synaptic partners while avoiding incorrect partners in a dense cellular environment. Defining the cellular and molecular rules that govern specific circuit formation has significant scientific and clinical relevance because fine scale connectivity defects are thought to underlie many cognitive and psychiatric disorders. Organizing specific neural circuits is an enormously complicated developmental process that requires the concerted action of many molecules, neural activity, and temporal events. This review focuses on one class of molecules postulated to play an important role in target selection and specific synapse formation: the classic cadherins. Cadherins have a well-established role in epithelial cell adhesion, and although it has long been appreciated that most cadherins are expressed in the brain, their role in synaptic specificity is just beginning to be unraveled. Here, we review past and present studies implicating cadherins as active participants in the formation, function, and dysfunction of specific neural circuits and pose some of the major remaining questions.

ProSTRIP: A method to find similar structural repeats in three-dimensional protein structures.
The occurrence of similar structural repeats in a protein structure has evolved through gene duplication. These repeats act as a structural building block and form more than one compact structural and functional unit called a repeat domain. The protein families comprising similar structural repeats are mainly involved in protein-protein interactions as well as binding to other ligand molecules. The identification of internal sequence repeats in the primary structure is not sufficient for the analysis of structural repeats. Thus, a new method called ProSTRIP has been developed using dynamic programming to find the similar structural repeats in a three-dimensional protein structure. The detection of these repeats is made by calculating the protein backbone Calpha angles. An internet computing server is also created by implementing this method and enables graphical visualization of the results. It can be freely accessed at http://cluster.physics.iisc.ernet.in/prostrip/.

Entamoeba invadens: cloning and molecular characterization of chitinases.
Entamoeba histolytica, the causative agent of amebiasis infects through its cyst form and this transmission may be blocked using encystation specific protein as drug target. In this study, we have characterized the enzyme chitinase which express specifically during encystation. The reptilian parasite Entamoeba invadens, used as a model for encystation study contain three chitinases. We report the molecular cloning, over-expression and biochemical characterization of all three E. invadens chitinase. Cloned chitinases were over-expressed in bacterial system and purified by affinity chromatography. Their enzymatic profiles and substrate cleaving patterns were characterized. All of them showed binding affinity towards insoluble chitin though two of them lack the chitin binding domain. All the chitinases cleaved and released dimmers from the insoluble substrate and act as an exochitinase. Homology modeling was also done to understand the substrate binding and cleavage pattern.

SIGNATURES OF RAPID PLASTICITY IN HIPPOCAMPAL CA1 REPRESENTATIONS DURING NOVEL EXPERIENCES

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

James Priestley
Columbia University, Department Of Neuroscience, New York, United States of America

Neurons in the hippocampus exhibit striking selectivity for specific combinations of sensory features, forming representations which are thought to subserve episodic memory. Even during a completely novel experience, ensembles of hippocampal "place cells" are rapidly configured such that the population sparsely encodes visited locations, stabilizing within minutes of the first exposure to a new environment. What cellular mechanisms enable this fast encoding of experience? Here we leverage virtual reality and neural population recordings to dissect the effects of novelty and experience on the dynamics of place field formation. We show that the place fields of many CA1 neurons transiently shift locations and modulate the amplitude of their activity immediately after place field formation, rapid changes in tuning that are predicted by behavioral time scale synaptic plasticity. These correlates were particularly enriched during initial exploration of a novel context and decayed with experience. Our data suggest that novelty modulates the effective learning rate in CA1, favoring rapid mechanisms of field formation to encode new experience.

MULTIPLEXING OF SPATIAL AND TEMPORAL INFORMATION IN PREFRONTAL CORTEX DURING COMPLEX BEHAVIOR.

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Claudia Böhm, Albert Lee
HHMI Janelia Research Campus, Mcn, Ashburn - VA, United States of America

Prefrontal cortex has long been associated with higher order cognitive functions, such as working memory, decision making and rule and category encoding. Neural representations of task-relevant variables have been described in animals performing many behavioral tasks. Single neurons in prefrontal cortex are often selective for multiple variables (mixed selectivity). The principles of how neurons are endowed with functional selectivity are not well understood. We analyzed space and time encoding in rats performing a memory-guided navigation task with two behaviorally important spatial categories, starts and goals. In each trial the animal navigated from one of three start locations to one of three goal locations via one of multiple routes. Using chronically implanted Neuropixels probes, we found that all six locations as well as the category to which it belongs (goal or start) were encoded with high accuracy. While at either start or goal locations, time was encoded by cells' firing ramping down or, more rarely, up, instead of as a sequence of cells' firing. This time code was invariant to the location within a category, even though single neurons could be selective for both time and space. The encoding of spatial locations was roughly orthogonal to time encoding and largely stable over time. The overlap between the population of cells that encoded goal and start locations was higher than expected by chance, pointing towards a functional specialization of cells to encode specific variables relevant to performing behavioral tasks.

LONG-TERM DYNAMICS OF THE ENTORHINAL GRID CODE

POSTER SESSION 05 - SECTION: SPATIAL NAVIGATION AND MEMORY

Noa Sadeh, Meytar Zemer, Alon Rubin, Yaniv Ziv
Weizmann institute of science, Brain Sciences, Rehovot, Israel

The hippocampus and entorhinal cortex (mEC) form an “information loop”: Superficial layers of the mEC provide excitatory input to the hippocampus, and the deep layers of the mEC receive most of their input from the hippocampus. The mEC is crucial for the formation of spatial memory, and its inactivation impairs both recent and remote memory retrieval in navigation tasks- indicating a key role for the entorhinal in long term memory. Recent studies found that hippocampal place codes gradually change over days and weeks when the animal repeatedly visits a fixed familiar environment. However, the long-term dynamics of entorhinal spatial codes have remained unexplored. Here, we developed a novel imaging preparation that enables simultaneous imaging of hundreds of grid cells from up to four different modules within a single field of view in freely behaving mice. By tracking the same neurons over weeks, we longitudinally analyzed the long-term stability of grid cells, and compared it to that of hippocampal CA1 place cells. We found that entorhinal grid cells gradually changed their tuning over days, while maintaining activity rates. Conversely, hippocampal place cells displayed gradual changes in cell activity rates, but their spatial tuning remained relatively stable. Overall, we found a double dissociation between mEC and CA1 neurons with respect to properties of neural code stability, suggesting that different mechanisms may govern representational drift in these circuits. Moreover, our results suggest that stable tuning of entorhinal grid cells is not a prerequisite for stable tuning of hippocampal place cells.

Theta oscillations are one of the most extensively investigated rhythms of the brain, closely linked to locomotion, diverse types of learning and memory, and controlled by the medial septum circuitry. Previous studies (Whishaw et al, 1973; Bland et al, 2006) have reported that theta frequency predicts different heights in a jump avoidance test. The widely accepted view, in accordance to the “sensorimotor integration model”, is that theta frequency predicts the vigour of the subsequent movement. However, the jump avoidance tests involve a strong fear component, leading to an elusive conclusion whether theta activity predicts solely movement or codes also for the related fear response. To address this conundrum, we designed an experiment in which we performed 2 Photon imaging in combination with oscillations recordings and pharmacological medial septum inhibition, in mice running on a treadmill. To investigate the predictive coding of a motor- and fear- related stimuli, we first introduced a brake, and subsequently an air puff stimulus at two different locations. The analysis of oscillatory activity revealed that theta frequency was largely unaffected by the learned position of the brake, while a strong relationship between the increased frequency and the location of the air puff stimulus was observed. Calcium imaging data revealed that brake- and puff- related cells form largely non-overlapping populations. Finally, we discuss the effect of the medial septum inhibition on both types of coding. These results indicate that distinct hippocampal rhythms and circuits predict the valence of the subsequent locomotor activity rather than movement per se.

RELATIONSHIPS BETWEEN THE EFFICIENCY OF TEMPORAL INFORMATION PROCESSING ON MILLI- AND SUPRA-SECOND TIME DOMAINS

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Magdalena Stanczyk, Klaudia Krystecka, Aneta Szymaszek, Anna Bombinska, Elzbieta Szelag
Nencki Institute of Experimental Biology, Polish Academy of Sciences, Laboratory Of Neuropsychology, Warsaw, Poland

Temporal information processing (TIP) constitutes a neural underpinning of many cognitive functions. Although the previous studies indicated several temporal processing levels (or operational processing windows) in TIP, the between-levels relations remain unclear. This study is focussed on relationships between the efficiency on milli- and supra-second time levels and aimed at testing whether the better efficiency on milli-second level is accompanied by the better performance on supra-second one in young subjects. The participants were 118 healthy adults (M_{age} = 23). The measurement included two paradigms: (1) auditory temporal-order judgment task to assess subjects efficiency on millisecond domain, and (2) subjective accentuation task to evaluate their functioning on supra-second one. The former task was indexed by the temporal order threshold defined as the minimum gap between two successive sounds which is necessary to reproduce their order correctly which corresponded to the temporal resolution. During the latter task subjects were presented with various metronome beat frequencies and reported how many sounds they could unite into one perceptual unit indicating the extent of the temporal integration. The results revealed that subjects characterized by more efficient TIP on millisecond level could integrate beats in significantly longer units than those less efficient. Moreover, the former subjects in subjective accentuation relied more on a constant time rather than on the mental counting strategy. These findings provide the new insight into associations between TIP on milli- and supra-second time levels. Supported by National Science Centre, Poland, grant no. 2018/29/B/HS6/02038.

YOGA ALLEVIATES COGNITIVE IMPAIRMENT AND CARDIAC AUTONOMIC DYSFUNCTION IN BREAST CANCER PATIENTS RECEIVING CHEMOTHERAPY: A RANDOMIZED CONTROLLED STUDY.

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Inbaraj Ganagarajan[1], Sathyaprabha T N[1], Kaviraja Udupa[1], Raghavendra Rao M[2], Jamuna Rajeswaran[3], Amritanshu Ram[4], Krishna Nandakumar[4], Spoorthi M[4], Shekar Patil[5], Govind Babu[5]
[1]National Institute of Mental Health & Neurosciences, Neurophysiology, Bengaluru, India, [2]Central Council for Research in Yoga and Naturopathy, Director, Ccryn, New Delhi, India, [3]National Institute of Mental Health and Neurosciences, Clinical Psychology, Bengaluru, India, [4]HCG Comprehensive Cancer Care Hospital,, Department Of Yoga, Bengaluru, India, [5]HCG Cancer Hospital, Dept Of Medical Oncology, Bengaluru, India

Aim: Evidence suggests that chemotherapy treatment for breast cancer (BC) is associated with adverse effects such as cognitive impairment and cardiac autonomic dysfunction. This study aimed to determine the effect of the Integrated Yoga Therapy Program (IYTP) on cognition, cardiac autonomic function, and quality of life (QOL) in BC patients undergoing chemotherapy. **Methods:** Eighty-two BC patients were randomly assigned to: IYTP intervention (n = 43) or control group (n = 39). All patients underwent assessment at two-time points: baseline (before chemotherapy) and after six cycles of chemotherapy, for the following variables: a) Neuropsychological test battery: assessing various domains of cognition, include learning, memory, recall, focused attention, motor speed, planning and executive functioning; b) Heart rate variability; c) Montreal cognitive assessment scale and d) Perceived stress scale. **Results:** At baseline, both groups showed mild cognitive impairment with moderate stress and normal cardiac autonomic functioning. After six cycles of chemotherapy, the control group showed a significant decline in cognitive abilities in all domains with severe stress and reduced HRV, implying sympathovagal imbalance with sympathetic dominance. Whereas in the yoga group, after six cycles of chemotherapy, the cognitive abilities were preserved, with significant improvements in attention and planning. Furthermore, the yoga group has also shown increased HRV with modulation of cardiac autonomic function towards sympathovagal balance, proposing yoga to be an effective intervention for chemotherapy-induced adverse effects. **Conclusion:** The study suggests yoga as a potential adjuvant intervention for improving various domains of cognition, cardiac autonomic function and QOL in BC patients during chemotherapy.

Impact of Hatha Yoga on the Airway Resistances in Healthy Individuals and Allergic Rhinitis Patients.
There have been limited studies on Hatha yoga training as a complementary therapy to manage the symptoms of Allergic Rhinitis. The main Aim of the study was to check the impact of Hatha yogasanas on the Airway resistances in Healthy volunteers, a baseline data can be established and also to study the impact of Hatha yogasanas on the Airway resistances in Allergic Rhinitis patients in Bangalore, India. This is a prospective case series of 51 healthy volunteers (18 Males and 33 Females) Group 1 and 51 Allergic Rhinitis patients (18 Males and 33 Females) Group 2. The Objective analysis of the upper airway resistance was measured using a rhinomanometer and the lower airway resistance was measured using a spirometer. Then the subjects practiced specific Hatha yogasanas for three months. Then the airway resistance tests were again done at 3 months interval. The subjective analysis was done pre yoga and post yoga using the Short form-12 (SF-12) and Sino Nasal Outcome Test (SNOT) Questionnaires to assess the quality of life. The data was analyzed by doing a Paired (2-tailed) Test, using SPSS (Software Package for Social Sciences) version 16. Total Nasal Airway Resistance pre yoga and post yoga in 51 healthy volunteers had significantly reduced at 150 Pa and the Forced Vital Capacity(FVC) pre yoga and post yoga had significantly increased,Forced Expiratory volume (FEV1) & % Residual standard deviation (%RSD) had increased but not significant. The Physical component score (PCS) and Mental component score (MCS) of the SF-12 health survey questionnaire had significantly improved with and the SNOT questionnaire score had significantly reduced. The Total Nasal Airway Resistance in 51 Allergic Rhinitis had significantly reduced at 150 Pa and the FVC pre yoga and post yoga showed increase but change was not significant, FEV1 pre yoga and post yoga had significantly increased, %RSD pre yoga and post yoga had significantly increased. The PCS and MCS of the SF-12 health survey questionnaire had significantly increased and the SNOT questionnaire score had significantly decreased. The scientific documentation of the impact of Hatha Yoga on the

airway resistances can be an eye opener in the management of several other diseases of the airways.

HOUSEHOLD TOBACCO SMOKING STATUS AND THE TEMPERAMENT DIMENSION OF EFFORTFUL CONTROL AMONG U.S. YOUNG CHILDREN

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Ashley Merianos[1], Laura Nabors[1], Afolakemi Olaniyan[1], Matthew Smith[2], E. Mahabee-Gittens[3]
[1]University of Cincinnati, School Of Human Services, Cincinnati, United States of America, [2]Texas A&M University, Department Of Environmental And Occupational Health, College Station, United States of America, [3]Cincinnati Children's Hospital Medical Center, Division Of Emergency Medicine, Cincinnati, United States of America

Aims: The study objective was to assess the associations between household tobacco smoking status and the temperament dimension of effortful control among U.S. young children. **Methods:** We conducted a secondary analysis of 2019-2020 National Survey of Children's Health data including 11,100 children ages 3-5 years. Household tobacco smoking was defined as the child living with anyone who smoked cigarettes, cigars, or pipe tobacco. We assessed four ordinal response variables that measured effortful control, defined as the ability to manage attention and inhibit or activate behavior as needed, with 5-point scale responses ranging from always to never. Ordinal logistic regression models were built while adjusting for several covariates including child age, sex, race/ethnicity, health status, premature birth; parent education level; and family household structure and federal poverty level. **Results:** About 13% of children lived with a tobacco smoker. Children who lived with a smoker were at decreased odds to always keep working at something until they were finished (AOR=0.56, 95%CI=0.44-0.71) and able to sit still (AOR=0.56, 95%CI=0.44-0.71) compared to children who did not live with a smoker, after covariate adjustment. Children who lived with a smoker were at 1.59 increased odds (95%CI=1.24-2.04) to always be easily distracted than children who did not live with a smoker. No difference was found between household tobacco smoking status and following instructions to complete simple tasks. **Conclusions:** Household smoking is associated with lower effortful control among children ages 3-5 years, which is an important temperament dimension. Findings highlight the need to promote household tobacco cessation.

DISSOCIATION BETWEEN EXPLICIT AND IMPLICIT PRIORS IN HUMAN VISUAL PERCEPTION

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Caroline Bévalot, Florent Meyniel
INSERM - U992, Unicog, Gif-sur-Yvette, France

Perception must operate on noisy inputs that underdetermine sensory likelihood. To overcome this limitation and achieve high accuracy, perception relies on priors. Bayesian inference provides an optimal solution to combine likelihood and priors in perception. Many previous studies investigated the use of priors in normal and pathological perception, but with conflicting results. We propose that it is because priors were explicitly given to subjects or implicit (i.e. learned) in different studies. To test our hypothesis, we designed two experiments to characterize human computations underlying the perception of noisy images, with explicit and implicit priors. We compared choices of 217 subjects to an ideal Bayesian observer (and models capturing deviations from optimality) and quantified the weight of explicit and implicit priors in their inference. Subjects were less optimal when priors were explicit than implicit. In the explicit task, the weight of priors was more heterogeneous (and stronger on average) and the weight of likelihood weaker than in the implicit task. Across individuals, the likelihood weights were highly correlated between the two tasks whereas the prior weights were unrelated, marking a clear dissociation. This conclusion was true when using generative priors and priors adjusted to the subject's learning (using the best model out of 65 variants). Our results demonstrate that for the same visual stimuli, human perception makes a similar use of the likelihood but a different use of explicit and implicit priors. This distinction should be key to study the implementation of Bayesian inference and its alteration in diseases.

TEMPORAL LOOMING IMPROVES SYNCHRONISATION: ASYMMETRIES IN THE PREDICTION OF ACCELERATING SEQUENCES

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Keith Doelling[1], Sarmini Bavananthan[2], Luc Arnal[1]
[1]Institut Pasteur, Insitut De L'audition, Paris, France, [2]Université de Paris-Est Créteil, Biologie-santé, Créteil, France

Studies on temporal prediction in sequences often conflate predictability with periodicity. However, recent evidence suggests that the benefits for perception often found in prediction apply just as readily to predictable acceleration. While these sequences are equally predictable, their implications in an ecological setup can be vastly different. An accelerating pattern may suggest, for example, that a critical event is imminent and may therefore require faster reactions. As such, we hypothesized that there would likely be asymmetries in sensorimotor synchronization (SMS) to these sequences, despite their mathematical similarity to deceleration. We asked participants to tap along with accelerating, rhythmic and decelerating sequences, keeping the early portion of the sequence tightly controlled. Participants achieved synchrony more rapidly for the accelerating sequences compared to both rhythm and deceleration. Further, tap variance was significantly lower for acceleration and rhythm relative to deceleration, even when controlling for interval size. These results imply a surprising conclusion: synchronisation is more readily achieved for accelerating sequences relative even to rhythmic stimuli. Further, we manipulated the rules by which intervals changed (i.e., absolute vs proportional). Regardless of the true acceleration rule, participants inherently tapped at the interval predicted by a proportional model, suggesting limited flexibility in our accelerating predictions. The results bare clear links to findings in looming stimuli, whereby growing visual stimuli engender faster reaction times and higher arousal than shrinking. We suggest that models of prediction and SMS take these findings into account by developing dynamical models that account for these nonlinearities in human sequence prediction.

ACCURACY IN SELF-MONITORING OF TEMPORAL ERRORS IN HUMANS AND RODENTS.

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Sena Bilgin
Polish Academy of Sciences, Institute Of Psychology, Warsaw, Poland

Humans and rats have the ability to keep track of time with high precision and accuracy in a task where subjects have to press a lever for a certain amount of time to get a reward, suggesting the ability to monitor temporal errors. In a newly developed paradigm, rodents were able to report their temporal errors (Kononowicz, van Wassenhove, & Doyère, 2022). We adapted the procedure to human participants who were required to produce a target time interval and subsequently evaluate their error and compared two types of time production (duration of press vs time between two presses). During the training trials, participants were trained to associate a reward size, which was a function of error magnitude in their time production, with the location of one of two presented cards on the computer screen. The threshold for card/size assignment was set up such that it resulted in a 50% chance of receiving a reward after choosing the illuminated card. In test trials, the reward-card assignments remained, but both cards were illuminated and available for selection, thus, the amount of reward received was driven by the participants' choices. The results suggest that humans perform qualitatively similarly to rats. Participants showed high choice accuracy in test sessions demonstrating that they kept track of the values of the timing variables on which they based their decision. Here we will further focus on the quantitative comparison of human and rat performance in two data sets where both species produced a 2-sec duration.

VARIABILITY IN THE TIMING OF THE REPETITIVE MOVEMENTS IN PRESCHOOL CHILDREN

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Ivan Serbetar
FACULTY OF TEACHER EDUCATION, Dept Of Kinesiology, ZAGREB, Croatia

Aims The study aimed to examine the temporal accuracy and precision in repetitive movement task. Methods The subjects were 106 children aged 5 to 6 years. Subjects performed rhythmic tapping with index finger at a frequency of 2 Hz. In the first 20 seconds, the subjects followed the metronome tones (1000 Hz, 50 ms), then the tones ended and the subjects had to continue tapping at the predetermined rate for another 30 seconds. The target inter-response interval (IRI) was 450 ms. The dependent variables were mean IRI, mean SD, and mean absolute error (AE - difference from the target interval). Children completed 5 trials, and for each subject and each trial the mean of IRI, SD and AE were calculated. To check the effect of trials, repeated measures ANOVA was computed. Results IRI mean values for trials dropped from 349.78 to 334.81 ms, from the first to the last trial. Variability expressed in terms of SD was high - mean values ranged from 86.94 to 94.61 ms. Also, children substantially underestimated the target interval in all of the trials. AE ranged from -149.65 up to -161.59 ms from the first to the last trial, which equals 33% to 36% of the target interval. However, none of the three separate within-subjects ANOVAs confirmed the effect of trials on the mean IRI, mean SD and mean AE, respectively. Conclusion Enhanced variability reflects the developmental differences. Follow up study may benefit from partitioning of the variance on the "clock" and motor implementation variance.

ARE CHILDREN WITH "LIMITED PROSOCIAL EMOTIONS" EMOTIONALLY BLIND? EMOTIONAL PROCESSING AND FACIAL EMOTIONAL EXPRESSIONS IN RESPONSE TO THREE INTERVENTION PROGRAMS

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Chara Demetriou[1], Kostas Fanti[2]
[1]University of Cyprus, Department Of Psychology, Nicosia, Cyprus, [2]University of Cyprus, Psychology, Nicosia, Cyprus

The processing of emotions expressed by others have been supported as an important factor in children's moral and social development. Research indicated that the inability of individuals high on Callous-unemotional (CU) traits to recognize emotions might explain their reduced empathic reaction and increased antisocial behavior. This is study applies FaceReader methodology to assess the children's high on CU traits emotional processing and responding to different emotional contexts (i.e., happy, angry). By combining measures of facial emotional expression with socialization practices that enhance parental warmth and cognitive skills (i.e., identification of micro-expressions of different emotions) development, the current study aimed to assess the effectiveness of three different intervention programs in children's ability to respond adaptively. Specifically, we investigated the facial emotional expressions of children high on CU traits (n = 53), prior, immediately after and in a three-months period after the completion of the intervention. We identified an increase of sadness expression in response to distressing cues, and especially in expressions of fear, that can be attributed to an enhancement in children's ability to identify fear and share this emotional expression. The enhanced emotional engagement of children is also supported by an increase in anger and a decreased in surprised emotional expression. Expression of anger serves as an indication of the children response to provocation. Our findings draw research attention in the important influence of the family context and cognitive strategies employed in emotional processing in shaping the emotional functioning of children high on CU traits.

DOES HALLUCINATION PRONENESS ALTER SENSORY FEEDBACK IN EMOTIONAL SELF-VOICE PERCEPTION?

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Suvarnalata Xanthate Duggirala[1,2,3], Hanna Honcamp[3], Michael Schwartze[3], Therese Van Amelsvoort[4], Ana Pinheiro[1], David Linden[4,5], Sonja Kotz[5]
[1]University of Lisbon, Faculty Of Psychology, Lisbon, Portugal, [2]Maastricht University, School Of Mental Health And Neuroscience, Maastricht, Netherlands, [3]Maastricht University, Faculty Of Psychology And Neuroscience, Maastricht, Netherlands, [4]Maastricht University, Department Of Psychiatry And Neuropsychology, Maastricht, Netherlands, [5]Maastricht University, Department Of Neuropsychology And Psychopharmacology, Maastricht, Netherlands

Aims: Altered sensory feedback in self-generated speech may lead to auditory verbal hallucinations (AVH) in non-clinical and clinical voice hearers. Unlike non-clinical voice hearers, clinical voice hearers report hearing derogatory voices, accentuating their attentional bias towards negative emotions and salience (threat) misattribution. The current study altered the emotional quality and uncertainty in self-voice perception to elucidate how misattribution of self-generated speech results from neural changes in sensory feedback and/or attentional processes along the psychosis spectrum. **Methods:** Non-voice hearers, non-clinical and clinical voice hearers (age range of 16-40 years) participated in a standard button-press task, combined with EEG to elicit predictable (100% neutral and 100% angry self-voice) and unpredictable (60-40% neutral-angry, 50-50% neutral-angry and 40-60% neutral-angry self-voice) voices. Hallucination proneness (HP) is measured by the Launay Slade Hallucination Scale. Altered sensory feedback was expected to manifest in an event-related amplitude modulation of the N100 component. **Results:** Preliminary results of 15 participants show an N100 suppression effect in response to the fully predictable self-voice conditions, whereas unpredictable voices elicit a reduced N100 suppression effect. Furthermore, our results also show a trend towards an interaction between HP and self-voice quality. **Conclusions:** These findings suggest that sensory feedback processes are sensitive to the changes in the emotional quality of self-voice. Further, HP may alter self-voice processing as self-voice changes from neutral to emotional. These results constitute a critical advancement regarding the nature of AVH.

Interaction of emotion and cognitive control along the psychosis continuum: A critical review.
To better understand how emotion impacts cognitive control is important as both influence adaptive behavior in complex real-life situations. Performance changes in emotion and cognitive control as well as in their interaction are often described in psychotic patients as well as in non-clinical participants who experience psychosis-like symptoms. These changes are linked to low motivation and limited social interaction. However, it is unclear whether these changes are driven by emotion, cognitive control, or an interaction of both. This review provides an overview of neuroimaging evidence on the potential interaction of emotion and cognitive control along the psychosis continuum. The literature confirms that over-sensitivity towards negative and lowered sensitivity towards positive emotional stimuli in tasks exploring emotion-cognitive control interaction are associated with the severity of positive and negative symptoms in psychosis. Changes in the dynamic interplay between emotion and context-sensitive cognitive control, mediated by arousal, motivation, and reward processing may underlie poor interpersonal communication and real-life skills in psychosis. In addition, structural and functional changes in subcortical and cortical associative brain regions (e.g., thalamus, basal ganglia, and angular gyrus) may contribute to alterations in emotion and cognitive control interaction along the psychosis continuum. There is limited evidence on how antipsychotic medication and age at illness-onset affect this interaction.

Stimulus-dependent modulation of working memory for identity monitoring: A functional MRI study.
While the neural correlates of identity monitoring working memory (WM) have been well characterised in literature, the WM subsystems for different types of stimuli have not been established. The aim of our study was to examine the neural network subtending WM for identity monitoring of both verbal and visual stimuli. We used functional magnetic resonance imaging (fMRI) with words, objects, and faces as stimuli in an n-back WM task to delineate the similarities and differences in brain

activation during presentation of verbal and visual stimuli. The results revealed a predominantly left lateralized core fronto-parieto-cerebellar identity WM network comprising bilateral insula, left inferior frontal gyrus, inferior parietal gyrus, and cerebellum that is common to all stimuli. In addition, our results showed stimulus-specific recruitment of brain regions, with exclusive activations in left inferior frontal gyrus and inferior temporal gyrus for identity WM for verbal stimuli, and left middle occipital gyrus and cerebellum for identity WM for visual stimuli. The present study reveals the existence of a central identity WM network for both verbal and visual information, along with activation of distinct verbal and visual representational regions that are sensitive to respective stimuli.

UNPACKING RESTING STATE DYNAMICS IN HALLUCINATION-PRONE INDIVIDUALS USING A HIDDEN SEMI-MARKOV MODEL

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Hanna Honcamp[1], Suvarnalata Xanthate Duggirala[1], Aland Astudillo[2], Michael Schwartze[1], Wael El-Deredy[2], Therese Van Amelsvoort[3], David Linden[3], Sonja Kotz[1]
[1]Maastricht University, Faculty Of Psychology And Neuroscience, Maastricht, Netherlands, [2]Universidad de Valparaíso,, Center For Research And Development Of Health Engineering, Valparaiso, Chile, [3]Maastricht University Medical Center, Department Of Psychiatry And Neuropsychology, Maastricht, Netherlands

Aims: Hallucinatory experiences lie on a continuum ranging from healthy to pathological, which can be captured by hallucination proneness (HP). High HP is associated with an increased need for care and aberrant activity in functional networks at rest. However, the temporal dynamics of different networks and their contribution to HP are still elusive. We aim to bridge this gap by assessing changes in brain dynamics linked to HP using a Hidden Semi-Markov Model (HSMM) on resting state EEG (rsEEG) data. **Methods:** HSMM is a generative probabilistic modeling approach that characterizes hidden functional connectivity signatures on a sub-second timescale by allocating neural time-series data to a finite set of discrete hidden brain states. Ten minutes rsEEG data (5 min eyes-open, 5 min eyes-closed) were acquired in a sample of healthy participants varying in HP. The model was applied to cleaned and concatenated (multi-participant) alpha (8-12 Hz) amplitude envelopes. HP was assessed using the Launay-Slade Hallucination Scale. **Results:** Post-hoc statistics such as the state durations and between-state transition probabilities yield insights into the temporal dynamics of underlying functional networks. Preliminary results reveal that high HP relates to altered HSMM state durations. This suggests that the activation time of corresponding functional networks changed, which might indicate dysfunctional network engagement and stability. **Conclusion:** This study provides a new analytic take and perspective on HP in healthy participants. Accurate characterization of altered temporal dynamics linked to HP can inform about predictive disease markers and ultimately favors generating individual risk profiles, differential diagnosis, and targeted intervention.

THE ROLE OF VIRTUAL REALITY IN THE ASSESSMENT OF TIME PERCEPTION

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Greta Vianello[1], Michela Candini[2], Francesca Frassinetti[1,2]
[1]Clinical Scientific Institutes Maugeri IRCCS, Laboratory Of Neuropsychology, Mantua, Italy, [2]University of Bologna, Department Of Psychology, Bologna, Italy

Time perception seems to be selectively impaired in right brain damaged (RBD) patients, who underestimate time durations whereas no time deficit has been found following left brain damage (LBD). However, so far time perception has been investigated only using computerized paradigms. Virtual Reality (VR) has recently been used as an effective tool for the assessment and rehabilitation of cognitive deficits. Aim of the present study is to measure the impact of time deficits in everyday life by using VR and computerized tasks. A group of RBD and LBD patients, as well as age matched controls were recruited in the study. Participants were submitted to a time reproduction task using computerized and VR paradigms. In the computerized task, participants were required to reproduce the duration of a previously encoded stimulus. In the VR task, participants were submitted to virtual scenarios where they had to reproduce the duration of 16 actions immediately after having performed them. In the computerized task, RBD patients reproduced *longer* time intervals with respect to controls and LBD. In the VR task, the difference between reproduction and execution revealed that RBD patient were *as accurate as* controls and LBD in reproducing everyday actions. In line with the literature, our study shows the elective role of the right hemisphere in processing time. Moreover, results suggest that patients are more accurate in estimating the duration of a performed action rather than the duration of a visual stimulus, leading to a possible use of VR in the rehabilitation of time deficits.

INVESTIGATING BRAIN-COGNITION ASSOCIATIONS IN BIPOLAR DISORDER USING CANONICAL CORRELATION ANALYSIS

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Bethany Little[1], Peter Gallagher[1], David Counsins[1,2], Yujiang Wang[3]
[1]Newcastle University, Translational And Clinical Research Institute, Newcastle upon Tyne, United Kingdom, [2]Cumbria, Northumberland Tyne and Wear NHS Foundation Trust, Newcastle upon Tyne, United Kingdom, Academic Psychiatry, Newcastle upon Tyne, United Kingdom, [3]Newcastle University, Cnnp Lap, Interdisciplinary Computing And Complex Biosystems Group, School Of Computing, Newcastle upon Tyne, United Kingdom

Aims: Bipolar Disorder is associated with a range of neuropsychological impairments compared to healthy controls, even in euthymia. Studies have linked cognitive impairment to abnormal brain structure in patient groups, however most studies to date use univariate methods to test brain-cognition associations, which do not account for relationships between cognitive functions. Given that cognitive impairment in mood disorder groups may be hierarchical in nature, we used multivariate methods to investigate associations between neuropsychological performance and brain structure. Methods: N=56 euthymic patients with bipolar disorder and N=26 healthy controls underwent structural MRI scans and completed a neuropsychological test battery. Cognitive scores and cortical thickness for each brain region were standardised based on healthy control data, then Canonical Correlation Analysis was utilised to test associations between cognitive performance and cortical thickness patients and controls separately. Results: In the patient group, the first canonical correlation showed a linear correlation between the first canonical variate pair, with the first canonical variate being associated with cortical thickness in temporal pole, inferior temporal cortex and pericalcarine cortex regions in both hemispheres, as well as insula and frontal pole regions in the right hemisphere, and medial orbitofrontal and parahippocampal regions in the left hemisphere. Performance on tests measuring attention and processing speed were most strongly associated with the first canonical variate in patients. Conclusions: Impairments in attention and processing speed may be particularly associated with cortical abnormalities in patients with Bipolar Disorder.

TEMPORAL EXPECTATIONS FACILITATE BEHAVIOUR IN THE ABSENCE OF CONCOMITANT SPATIAL EXPECTATIONS AND IN DYNAMICALLY UNFOLDING ENVIRONMENTS

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Irene Echeverria-Altuna, Sage Boettcher, Anna Nobre
University of Oxford, Department Of Experimental Psychology, Oxford, United Kingdom

Attention can be proactively directed to locations in space, to object features and to points in time. In our environment, spatial, temporal and feature-based expectations interact to shape behaviour. Temporal expectations have been proposed to guide perception when accompanied by congruent spatial expectations. In two complementary studies, we set out to investigate whether cued temporal expectations can guide visual perception, even in the absence of spatial expectations, in a continuously changing environment. On each trial, participants (*online:* N = 49, *in-person*: N = 24) were presented with a stream of bilaterally appearing coloured circles, similar to a dual-stream rapid serial visual presentation task. Each stream was composed of three coloured targets and between 6 and 9 distractors. On each trial one of the targets always appeared at a fixed early time. One appeared at a fixed late time, and one could appear at any time. A coloured cue at the beginning of each trial indicated which of the three target circles was relevant. Specifically, participants were asked to respond to the side (left or right) in which the cued target appeared in any given trial. We found that participants were faster and more accurate in detecting targets that occurred at an expected time (early or late), compared to the randomly timed targets, even though participants had no information regarding the likely location of the target. From these results, we conclude that temporal expectations can improve behaviour in the absence of concomitant spatial expectations and in dynamically unfolding streams of stimuli.

Selective neuronal silencing using synthetic botulinum molecules alleviates chronic pain in mice.
Chronic pain is a widespread debilitating condition affecting millions of people worldwide. Although several pharmacological treatments for relieving chronic pain have been developed, they require frequent chronic administration and are often associated with severe adverse events, including overdose and addiction. Persistent increased sensitization of neuronal subpopulations of the peripheral and central nervous system has been recognized as a central mechanism mediating chronic pain, suggesting that inhibition of specific neuronal subpopulations might produce antinociceptive effects. We leveraged the neurotoxic properties of the botulinum toxin to specifically silence key pain-processing neurons in the spinal cords of mice. We show that a single intrathecal injection of botulinum toxin conjugates produced long-lasting pain relief in mouse models of inflammatory and neuropathic pain without toxic side effects. Our results suggest that this strategy might be a safe and effective approach for relieving chronic pain while avoiding the adverse events associated with repeated chronic drug administration.

IGNORING ASYNCHRONIES AND DELAYS IS NECESSARY FOR THE SENSE OF IMMERSION: EVIDENCE FROM RESULTS IN PATIENTS WITH SCHIZOPHRENIA

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Anne Giersch[1], Francois Foerster[1], Sébastien Weibel[1], Patrick Poncelet[1], André Dufour[2], Laurent Ott[3], Antonio Capobianco[4], Yvonne Delevoye-Turrell[3]
[1]INSERM U1114, Psychiatry Hospital Of Strasbourg, Strasbourg, France, [2]University of Strasbourg, Laboratory Of Cognitive And Adaptative Neuroscience, Strasbourg, France, [3]University of Lille, Laboratory Of Cognitive Science And Affective Science, Villeneuve d'Ascq, France, [4]University of Strasbourg, Engineering Science, Computer Science And Imaging Laboratory, Illkirch, France

The sensory consequences of our actions are predicted and adjusted in case of an error. Whether or not small delays in haptic feedback are taken into account depends on the task context. Healthy participants ignore small delays if mingled among large delays. Ignoring small delays may optimize our feeling of control and our sense of being immersed in the environment. Reversely, a deficit at filtering out small asynchronies may decrease the feeling of control. Recent results suggested a difficulty to ignore small asynchronies in patients with schizophrenia and we tested if this difficulty indeed leads to a drop of the feeling of control. 23 patients with schizophrenia, 18 patients with bipolar disorder, and 22 healthy participants performed a pointing task with a haptic device that provided haptic feedback without or with delays, which were processed consciously (65 ms) or unconsciously (15 ms). The trajectory of the hand was measured continuously, to track the deceleration in anticipation of the surface, and its modulation when sensory feedback was stable or unstable. Participants were asked to report their feeling of controlling the device. Following subliminally delayed haptic feedback, the feeling of control decreased, and deceleration durations were adapted, but only in patients with schizophrenia. These effects were correlated with psychotic symptoms. Overreactivity to subliminal delays was observed only when the distribution of delays was volatile. Ignoring small delays may participate to our adaptation and sense of immersion in an ever changing environment. In patients, not ignoring small delays may participate to psychotic symptoms.

THE SELF PROCESSES IN RUMINATION CONTEXT

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Risa Ratnasari
Taipei Medical University, Graduate Institute Mind, Brain And Consciousness, Wuxing, Taiwan

Abstract Flexibly switching between self-and non-self-related processes allows us to accommodate various external and internal demands. This flexibility, however, could be influenced by a particular condition, known as rumination. Rumination is defined as a condition when people continuously think about self-related thoughts. In pathological rumination conditions, people cannot flexibly switch their focus toward external stimuli, causing incoherent thoughts to the relevant condition. This study aims to investigate the relation of rumination and the switching process between self-related and non-self-related focus. We hypothesized that high rumination is associated with reduced flexibility in the self-related switching process. To examine this hypothesis, the rumination level was measured with the Ruminative response scale (RRS). A colour-switching task consisted of preference (self-related) and similarity (non-self-related) conditions that were adopted to examine flexibility. The result showed a unique pattern between rumination and cognitive flexibility with two different context tasks and potential further are suggested to improve the model of rumination measurement in cognitive approach. Keywords: rumination, task switching, self, cognitive flexibility, EEG

PREDICTION MISMATCH SIGNALLING IN ANTERIOR CINGULATE CORTEX DRIVES TASK-SWITCHING

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Nicholas Cole[1], Matthew Harvey[2], Dylan Myers-Joseph[2], Aditya Gilra[1], Adil Khan[2]
[1]King's College London, New Hunt's House, UL, United Kingdom, [2]King's College London, Centre For Developmental Neurobiology, UL, United Kingdom

Flexibly switching between tasks is a hallmark of cognitive behaviour. During task-switching, animals rapidly update their knowledge of current rules or contexts by constantly evaluating and detecting mismatches between predicted and observed outcomes of events. The anterior cingulate cortex (ACC) is implicated in task-switching, as well as in prediction mismatch signalling. However, the neural circuit mechanisms underlying task-switching are largely unknown. Here we trained mice to perform an attention-switching task in which they alternated between blocks of distinct task rules. Mice typically required a single experience of an expectation violation to accurately adapt their behaviour, differentially responding to the same stimulus under different rules. The behaviour was well-fit to a reinforcement learning (RL) model incorporating context-belief states, but not to a basic RL model. Chronic *in-vivo* two-photon calcium imaging during the task identified prediction-mismatch tuned cells in the ACC but not in V1. These cells maximally fired when a stimulus was expected but not received, and these responses were inhibited when the expected stimulus was received. Crucially, the magnitude of the mismatch responses in the ACC predicted successful behavioural transitions in the subsequent trial. Optogenetic inhibition of the anterior cingulate cortex during the period of mismatch signalling significantly impaired behavioural switching but had no effect once the mismatch signal had ceased. These results suggest an essential role for the ACC in driving rapid behavioural changes in response to changing context using prediction mismatch signals.

Multiplex imaging relates quantal glutamate release to presynaptic Ca homeostasis at multiple synapses in situ.
Information processing by brain circuits depends on Ca-dependent, stochastic release of the excitatory neurotransmitter glutamate. Whilst optical glutamate sensors have enabled detection of synaptic discharges, understanding presynaptic machinery requires simultaneous readout of glutamate release and nanomolar presynaptic Ca in situ. Here, we find that the fluorescence lifetime of the red-shifted Ca indicator Cal-590 is Ca-sensitive in the nanomolar range, and employ it in combination with green glutamate sensors to relate quantal neurotransmission to presynaptic Ca kinetics. Multiplexed imaging of individual and multiple synapses in identified axonal circuits reveals that glutamate release efficacy, but not its short-term plasticity, varies with time-dependent fluctuations in presynaptic resting Ca or spike-evoked Ca entry. Within individual presynaptic boutons, we find no nanoscopic co-localisation of evoked presynaptic Ca entry with the prevalent glutamate release site, suggesting loose coupling between the two. The approach enables a better understanding of release machinery at central synapses.

Serotonin 5-HT receptor boosts functional maturation of dendritic spines via RhoA-dependent control of F-actin.
Activity-dependent remodeling of excitatory connections underpins memory formation in the brain. Serotonin receptors are known to contribute to such remodeling, yet the underlying molecular machinery remains poorly understood. Here, we employ high-resolution time-lapse FRET imaging in neuroblastoma cells and neuronal dendrites to establish that activation of serotonin receptor 5-HT (5-HTR) rapidly triggers spatially-restricted RhoA activity and G13-mediated phosphorylation of cofilin, thus locally boosting the filamentous actin fraction. In neuroblastoma cells, this leads to cell rounding and neurite retraction. In hippocampal neurons in situ, 5-HTR-mediated RhoA activation triggers maturation of dendritic spines. This is paralleled by RhoA-dependent, transient alterations in cell excitability, as reflected by increased spontaneous synaptic activity, apparent shunting of evoked synaptic responses, and enhanced long-term potentiation of excitatory transmission. The 5-HTR/G13/RhoA signaling thus emerges as a previously unrecognized molecular pathway underpinning use-dependent

functional remodeling of excitatory synaptic connections.

EXPLORATORY ATTENTIONAL RESOURCE ALLOCATION IN A PROBABILISTIC FORAGING PARADIGM IN THE MONGOLIAN GERBIL

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Parthiban Saravanakumar[1], S Nowakowska[1], M Vollmer[1,2], Fw Ohl[1,3,4], Max Happel[1,4,5]

In our constantly changing world, it is necessary to continuously adapt choice options to current needs and if necessary to change our current behavioural strategy and explore the environment for the adaptive reallocation of resources. Eg. Imagine a Mongolian gerbil that forages a desert habitat for distributed food patches. When these patches become exhausted, the gerbil is in an exploitation/exploration dilemma: Should it exploit the current patch further or should it explore an alternative patch, suffering travel costs but enjoying potentially higher food density? The patch leaving decision needs to be made based on probabilistic information and in a potentially changing environment. Here, we present a new behavioural paradigm in the Mongolian gerbil based on a probabilistic foraging paradigm (adapted from Lottem et al., 2018, *Nat Comm*) wherein a random probability schedule, at a given food patch rewards decay exponentially per foraging attempt to zero. In contrast to a deterministic task, rule change cannot be inferred from a single reward omission but is based on accumulating gradual evidence. The stochastic nature of action-outcome associations inevitably leads animals to sample both sides, and hence, animals perform the task at hand without extensive pre-training sessions. Gerbils infer from the statistics of food delivery when to leave a 'depleted site' and explore another site despite the costs of travelling and uncertainty of future reward at another food source. Together, we present here a probabilistic foraging paradigm in the Mongolian gerbil as an ideal model system to investigate exploratory resource allocation.

MICE REGULATE THEIR ATTENTIONAL INTENSITY AND AROUSAL TO EXPLOIT INCREASES IN TASK UTILITY

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Jan Willem De Gee, Zakir Mridha, Marisa Hudson, Yanchen Shi, Hannah Ramsaywak, Spencer Smith, Nishad Karediya, Matthew Thompson, Kit Jaspe, Wenhao Zhang, Matthew Mcginley

Aims: Attention is limited in capacity and costly to utilize. Therefore, organisms are driven by ongoing behavioral incentives to choose *which* stimuli to attend to, and *how much* to attend to them. Global arousal is key to attention, but it is not clear if and how organisms self-regulate their arousal to match attentional intensity to its utility. **Methods:** Here, head-fixed mice licked for sugar-water reward upon detection of temporally unpredictable coherence in a sustained tone-cloud. We manipulated task utility by changing the reward size in blocks of trials, and recorded pupil size and walking speed. **Results:** We observed that detection performance was optimal during intermediate levels of arousal. After increases in task utility, mice stabilized pupil-linked arousal closer to this optimal (intermediate) level and became more sensitive decision-makers, resulting in a higher reward rate. Drift diffusion modeling indicated that evidence accumulation was more efficient and reliable. Periods of low task utility were associated with exploratory rather than resting behaviors. **Conclusions:** In sum, we find evidence for a tri-state model: rest / consolidation during low arousal, optimal task engagement during intermediate arousal, and task disengagement / exploration during high arousal. The self-regulation of arousal partly implements strategic adjustments of attentional intensity. In ongoing work, we are characterizing how reward prediction errors implemented by frontal-sensory interactions and neuromodulatory systems mediate adaptive shifts in attentional state.

Knowledge regarding the timing of events is critical for all mammals to produce efficient behavioral outcomes. Recent work examining the effect of expectancy based on the presentation of temporally predictable stimulus sequences has revealed that humans are able to extract regularities which in turn improve task performance (Ball et al., 2018). To determine if mice demonstrate a similar capacity, we established an equivalent behavioral paradigm. We trained mice on an audiovisual cue-target paradigm with fixed temporal delay between cue and target events. Mice were required to lick a reward spout at the time of the target event. We then randomly interleaved trials with either a short or long delay between the cue and target stimulus. Mice either encountered more short delay than long delay trials, or vice versa, leading to potential expectation of the temporal structure of target presentations. Our behavioral results indicate that mice can form expectations of the temporal structure of upcoming target events, which we can read-out as distinct patterns of behavior. Assessment of interindividual variability established differences in learning strategies based on the pattern of licking behavior, reaction times and task-related changes in pupil diameter. Ultimately, we aim to understand the underlying neural resources that allow us to continuously adapt to incoming sensory information. We will further investigate the functional activity during this learning paradigm in task-related brain regions.

INVESTIGATING THE IMPLICATION OF RAT DORSAL STRIATUM IN ACTION SELECTION USING A CONFLICT TASK

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Julien Poitreau[1], Pierre-Yves Jacob[2], Didier Loubet[1], Boris Burle[3], Francesca Sargolini[1]
[1]Laboratoire de Neurosciences Cognitives UMR 7291, Bases Neurales De La Navigation Spatiale, Marseille, France, [2]Aix-Marseille uUniversity, Centre National De Le Recherche Scientifique (cnrs), Marseille, France, [3]Centre National de le Recherche Scientifique (CNRS), Aix-Marseille University, Bouche-du-rhone, Marseille, France

Action control incurs both the selection of the appropriate response and the inhibition of irrelevant ones. In humans, this is often studied through “conflict tasks” like the Simon task in which stimuli have two dimensions: one, e.g. stimulus intensity, is task-relevant while the other, stimulus position, although task-irrelevant, automatically activates the spatially congruent response leading to interference when the stimulus is contralateral to the response. According to dual route architecture, stimulus intensity is processed in a controlled way, whereas stimulus position is processed automatically and activates the ipsilateral response which needs to be inhibited when stimulus and response side do not match. We developed a T-maze version of the Simon task adapted to rats to further investigate the neural substrates of the dual route architecture. We recorded single unit activity simultaneously from the dorsomedial and dorsolateral striatum, two structures that are generally involved in action-outcome associations or habitual responses, respectively. As in humans, incongruent trials (when the stimulus is contralateral to the required response) lead to longer reaction times and lower accuracy than congruent trials (when the stimulus is ipsilateral to the response). Ongoing analysis of the neural activity will possibly reveal a differential activation of the two striatal subregions. This work will bridge the gap between the studies of action control in rats and humans.

[1]Institut des Sciences Cognitives Marc Jeannord UMR5229, Centre National De La Recherche Scientifique, Bron, France, [2]Reference Center for Rare Diseases, Genopsy, Le Vinatier Hospital, Bron, France

Digit-tracking is a novel alternative to eye-tracking for the study of visual attention in human subjects. We presented Gaussian blurred stimuli mimicking the low spatial resolution of the peripheral retina on a touch-sensitive screen. Participants locally unblurred the image by sliding a finger over the display, thus providing a proxy for their eye movements and attention. Due to its simplicity and portability, this technique has a great potential in cognitive science, especially in animal studies. We trained non-human primates (NHPs) subjects to perform a free-viewing task in the laboratory or in their homecage and compared the results to eye-tracking and human digit-tracking results. Attention maps obtained from the two conditions were significantly correlated with eye-tracking and human attention maps. Moreover, we constructed a relevance map for each image by defining regions of interests and calculated the proportion of time spent in these regions. Relevance maps showed that NHPs, like humans, explored relevant features in the social scene like eyes and faces. We also collected eye-tracking and digit-tracking data simultaneously in several sessions and observed high synchrony between them. These results validated the effectiveness of the digit-tracking method in capturing reliable visual exploration behavior in NHPs.

DREADD-MEDIATED OXYTOCIN NEURONS ACTIVATION IN MACAQUE INCREASED ATTENTION TO EYE AND NOSE AREAS

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Antoine Ameloot, Inès Sebti, Yidong Yang, Eloïse Disarbois, Jean-René Duhamel
Centre National de la Recherche Scientifique, Institut Des Sciences Cognitives - Marc Jeannerod Umr5229, Bron, France

Oxytocin (OT), a neuropeptide mainly produced in the hypothalamus, has been shown to act as a key modulator of social behavior. However, in most human and non-human primates studies, the demonstration of OT effects relies on its external administration by inhalation. Due to the several limitations and pitfalls of OT inhalation, there is an urgent need for more precise tools that allow direct manipulation of oxytocin neurons activity. For that purpose, we induced the expression of an excitatory DREADD (hM3Dq) specifically in OT neurons of a long-tailed macaque. This chemogenetic tool, based on G protein-coupled receptors, have the ability to selectively and reversibly activate DREADD-expressing neurons after a single injection of its ligand. To evaluate the efficiency of the chemogenetic activation of OT neurons, we designed a free viewing task of neutral faces in unconstrained settings by taking advantage of the digit-tracking method. This method consists into presenting on a touch-sensitive display a blurred image simulating the low acuity of peripheral vision. The subject locally unblurred the image by sliding a finger over the display, thus providing a proxy for his eye movements and attention. We found that DREADD-mediated OT neurons activation strongly increased the time spent exploring the eye and nose areas. On the one hand, these results confirm the well-known OT attention enhancement to socially informative facial features. On the other hand, they provide behavioral evidence for the effectiveness of the DREADD-driven endogenous OT release, offering an exciting tool for a better understanding of OT functions in primates.

THE INFRA-SLOW BRAIN ACTIVITY AFFECTS BEHAVIOR IN CONDITIONS OF UNCERTAINTY

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Amaia De Diego Ajenjo[1], Jaspreet Kaur[1], Andreas Toft Sørensen[1], Rune Berg[1], Jesper Andreasen[2], Ulrik Gether[1], Mihai Moldovan[1,3], David Woldbye[1]
[1]University of Copenhagen, Neuroscience, Copenhagen, Denmark, [2]University of Copenhagen, Drug Design And Pharmacology, Copenhagen, Denmark, [3]Rigshospitalet, Clinical Neurophysiology, Copenhagen, Denmark

Objectives: The aim of this study was to investigate the relationship between infra-slow brain activity (ISA) and behaviour in rodents. We developed a method that can measure the strength of phase-amplitude coupling (PAC) between event-related neuronal activity and ISA during a task where mice trained to press a touchscreen during correct stimulus presentation (hits), followed by reward delivery. Specifically, we compared PAC changes in the medial prefrontal cortex (MPFC) during hits versus when touchscreen pressing occurred during distracter stimuli presentation (mistakes) at different levels of certainty. *Methods*: A Ca2+ indicator (GCaMP6f) was expressed in the MPFC of mice that learned the CPT task. Using *in vivo* confocal laser endomicroscopy we recorded, by flexible fiber-optics, neuronal activity synchronized with continuous performance test (CPT) events. The strength of PAC was quantified with Kullback-Leibler Modulation Index (KLMI). To induce uncertainty in behavioral responses, reward contingencies were modified by induction of acute anosmia and introduction of unrewarded hits. *Results:* We found ISA modulated event-related neuronal activity in the MPFC during the CPT. At baseline CPT task, for which mice were well trained, KLMI was higher at the time of mistakes than at the time of hits. Following an altered reward contingency, susceptibility to ISA modulation was larger at the time of hits. This complementarity could be modelled as a change in decisional certainty. *Conclusion:* We found that infra-slow brain activity acts as source of noise at the level of the medial prefrontal cortex, to an extent that can influence behaviour in conditions of uncertainty.

Neurotrophic Effects of Vascular Endothelial Growth Factor B and Novel Mimetic Peptides on Neurons from the Central Nervous System.
Vascular endothelial growth factor B (VEGFB) is a pleiotropic trophic factor, which in contrast to the closely related VEGFA is known to have a limited effect on angiogenesis. VEGFB improves survival in various tissues including the nervous system, where the effect was observed mainly for peripheral neurons. The neurotrophic effect of VEGFB on central nervous system neurons has been less investigated. Here we demonstrated that VEGFB promotes neurite outgrowth from primary cerebellar granule, hippocampal, and retinal neurons . VEGFB protected hippocampal and retinal neurons from both oxidative stress and glutamate-induced neuronal death. The VEGF receptor 1 (VEGFR1) is required for VEGFB-induced neurotrophic and neuroprotective effects. Using a structure-based approach, we designed short peptides, termed Vefin1-7, mimicking the binding interface of VEGFB to VEGFR1. Vefins were analyzed for their secondary structure and binding to VEGF receptors and compared with previously described peptides derived from VEGFA, another ligand of VEGFR1. We show that Vefins have neurotrophic and neuroprotective effects on primary hippocampal, cerebellar granule, and retinal neurons with potencies comparable to VEGFB. Similar to VEGFB, Vefins were not mitogenic for MCF-7 cancer cells. Furthermore, one of the peptides, Vefin7, even dose-dependently inhibited the proliferation of MCF-7 cells . Unraveling the neurotrophic and neuroprotective potentials of VEGFB, the only nonangiogenic factor of the VEGF family, is promising for the development of neuroprotective peptide-based therapies.

Differential effects of chemogenetic inhibition of dopamine and norepinephrine neurons in the mouse 5-choice serial reaction time task.
Attention-deficit/hyperactivity disorder (ADHD) is a psychiatric disorder characterized by inattention, aberrant impulsivity, and hyperactivity. Although the underlying pathophysiology of ADHD remains unclear, dopamine and norepinephrine signaling

originating from the ventral tegmental area (VTA) and locus coeruleus (LC) is thought to be critically involved. In this study, we employ Designer Receptor Exclusively Activated by Designer Drugs (DREADDs) together with the mouse 5-Choice Serial Reaction Time Task (5-CSRTT) to investigate the necessary roles of these catecholamines in ADHD-related behaviors, including attention, impulsivity, and motivation. By selective inhibition of tyrosine hydroxylase (TH)-positive VTA dopamine neurons expressing the Gi-coupled DREADD (hM4Di), we observed a marked impairment of effort-based motivation and subsequently speed and overall vigor of responding. At the highest clozapine N-oxide (CNO) dose tested (i.e. 2 mg/kg) to activate hM4Di, we detected a reduction in locomotor activity. DREADD-mediated inhibition of LC norepinephrine neurons reduced attentional performance in a variable stimulus duration test designed to increase task difficulty, specifically by increasing trials omissions, reducing mean score, and visual processing speed. These findings show that VTA dopamine and LC norepinephrine neurons differentially affect attention, impulsive and motivational control. In addition, this study highlights how molecular genetic probing of selective catecholamine circuits can provide valuable insights into the mechanisms underlying ADHD-relevant behaviors.

ASSESSING THE ROLE OF α7 NICOTINIC ACETYLCHOLINE RECEPTORS IN EXECUTIVE FUNCTION USING TOUCHSCREEN TECHNOLOGY IN RAT MODELS

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Gabriela Ferreira De Medeiros[1], Pegah Azizi[1], Francina Langa-Vives[2], Stéphanie Pons[1], Uwe Maskos[1], Morgane Besson[1]
[1]Institut Pasteur, Université de Paris, Cnrs Umr 3571, Integrative Neurobiology Of Cholinergic Systems, Paris, France, [2]Institut Pasteur, Université de Paris, Mouse Genetics Engineering Center Cigm, Paris, France

Dysfunctional α7 nicotinic acetylcholine receptors (α7*nAChRs) and their genetic regulation have been associated with several neuropsychiatric diseases including schizophrenia (SCZ) and Alzheimer's disease. Preclinical studies revealed that α7*nAChR ligands can improve executive function, commonly impaired across many neuropsychiatric disorders. Yet, a translational gap prevents these findings from resulting into clinically effective treatments. Our goal was to refine our understanding of the role of α7*nAChRs in executive function. We generated transgenic rats knockout for the α7 nicotinic subunit gene (α7KO) using the zinc finger nuclease technology. We submitted α7KO and their controls to two tests assessing executive function: the continuous performance task (CPT), a task of sustained attention which involves selection, vigilance and control; and the visual discrimination (VD) task, measuring associative learning and perceptive ability. These tasks were adapted from clinical research in a highly translational manner, thanks to the use of a touchscreen-based experimental setting. Strikingly, α7KO rats showed a response bias towards a global over-responding in the CPT, a strategy that was detrimental to task performance as reflected in a lower discrimination sensitivity - a deficit commonly reported in SCZ patients, and a higher persistence in error making. α7KO and control rats performed equally well and adopted identical strategies in the VD task. As in the CPT, α7KO rats also displayed a global over-responding to the screen in the VD task. Our results suggest that α7nAChRs are crucial to executive functioning for regulating behavioral inhibition, thereby facilitating the performance in tasks demanding high attentional load.

CEREBELLAR CONTRIBUTIONS TO INTERVAL TIMING

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Ellen Boven[1,2], Jasmine Pickford[1], Rui Costa[2], Nadia Cerminara[1], Richard Apps[1]
[1]University of Bristol, School Of Physiology, Pharmacology And Neuroscience, Bristol, United Kingdom, [2]University of Bristol, Department Of Computer Science, Bristol, United Kingdom

The ability to perceive time in the seconds-to-minute range, a mechanism known as interval timing, is important for adaptive behaviours such as foraging and decision-making. Neural substrates underlying interval timing include, amongst others, striatum and medial prefrontal cortex. By comparison, the cerebellum is mainly thought to be important in the control of movements with sub-second timing. However, given the well-established notion that the cerebellum is involved in the generation and updating of internal models through prediction error correction, we hypothesise that the cerebellum may also be involved in learning an internal model of supra-second stimulus time intervals to enable more accurate behaviour. We argue that, while other brain regions keep track of time once the association is acquired, the cerebellum plays a role in establishing temporal predictive associations earlier in learning. In order to test the predictive function of the cerebellum in the supra-second range, we trained rats to associate a sound duration with reward delivery. The effects of temporary chemogenetic inactivation of cerebellar output from the lateral nucleus were investigated at different stages during learning and performance on this task. Our study tests the prediction that cerebellar inactivation will slow learning of a novel stimulus time interval when compared to controls. Consistent with this proposal, preliminary analysis to date indicates that inactivation of cerebellar output does not affect interval timing behaviour after the association has been acquired. Further analysis and experiments to test the role of cerebellar output in learning temporal predictive associations at the supra-second timescale are ongoing.

THE ROLE OF BETA OSCILLATIONS IN MENTAL TIME TRAVEL

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Francesca Frassinetti[1], Mariano D'Angelo[2], Marinella Cappelletti[3]
[1]Maugeri, Istituti Clinici Scientifici Maugeri Irccs, Castel Goffredo (MN), Italy, [2]Karolinska Institutet, Department Of Neuroscience, Solna, Sweden, [3]Goldsmiths University, 4. department Of Psychology, London, United Kingdom

The brain is a time machine that tells time and mentally projects the self in the past and in the future. Short temporal intervals are encoded via cortical beta oscillations, whereas the ability to project the self in time, called Mental Time Travel (MTT), requires mental imagery associated with alpha oscillations. To clarify if MTT requires cortical oscillations involved in time processing, i.e., beta, rather than cortical oscillations involved in mental imagery, i.e., alpha, we combined a new task to assess MTT and brain stimulation, i.e., transcranial Alternating Current Stimulation (tACS). Thirty participants see faces of different ages presented one at a time with a phrase describing a life event, happening in middle age and perform a 2-alternative forced choice task: they indicate if it is likely or unlikely that the person has lived the life event 10 years ago (Past Condition) or will live the event in 10 years (Future condition). tACS is administered over the posterior parietal cortex, a key area for MTT and mental imagery. Results show that participants indicate a younger face as more likely to have lived an event 10 years ago during beta-tACS as compared to sham and alpha-tACS. For the future condition there were no significant differences during sham, alpha- and beta-tACS. These findings suggest that self-projection in the past, not in the future, relies on beta oscillations in posterior parietal regions and that beta oscillations are critical for processing also long duration in addition to their well-known role in supporting short durations.

DO YOU AUTOMATICALLY TRACK TIME?

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Yvan Nedelec, Virginie Van Wassenhove
Cognitive Neuroimaging Unit, INSERM, CEA, Cnrs, Université Paris-saclay, Neurospin Center, Gif/Yvette, France

Time perception can be assessed with behavior and electroencephalography (EEG). To demonstrate that the brain automatically detects changes in duration, EEG studies have used the Mismatch Negativity (MMN) paradigm in which infrequent duration changes (deviants) in a sequence of frequent durations (standards) elicit a negative wave (the MMN), whether participants paid attention or not to the sequence. However, two shortcomings in the literature were identified: whether the observed MMN results from a violation of the sequence temporal regularity or a change in duration, and whether the temporal scale of durations matter are unsettled questions. Consequently, we conducted an EEG study testing duration changes in rhythmic or non-rhythmic sequences and at two different temporal scales. The sequences consisted of empty intervals, delimited by auditory clicks, separated by fixed or variable (rhythmic or not, respectively) inter-stimulus intervals. Within each sequence, stimuli could be standard or deviant (+/- 30%) durations. We tested two temporal scales, a standard duration of 100 ms or 600 ms (below and above the temporal window of integration at 200 ms). We used control sequences where all durations were equally presented in a randomized order to properly compute differential waves. We hypothesized that because durations below 200 ms are building blocks of perception, they may elicit an MMN, whether embedded in a rhythmic sequence or not. On the contrary, durations above 200ms may elicit an MMN only in rhythmic sequences, as temporal regularities will facilitate the tracking of duration changes.

OBJETS, SHADOWS AND THE BRAIN

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Irini Giannopulu[1], Elahe Abdi[2], Tomoko Yonezawa[3]
[1]UNSW, Creative Robotics Lab, Sydney, France, [2]Monash University, Mechanical, Aerospace And Mechatronics Engineering, Melbourne, Australia, [3]Kansai University, Informatics, Osaka, Japan

Immersed in a virtual reality environment, 40 participants (20 female and 20 males) aged 25 years old in average were instructed to perceive and indicate the synchronicity or asynchronicity between a mobile object shadow with regard to a mobile object from the one side, and the synchronicity or asynchronicity between their own body shadow and position in space from the other. Their brain activity was recording using an EEG system and an fNIRS device. Bilateral beta (13.5-30 Hz) oscillations and OxyHb concentrations of frontal and parietal brain areas were analysed as they were considered predictors of perceptual and motor performance. According to the general hypothesis, beta oscillations and OxyHb concentrations associated with the perception of an object shadow would envision the neural activity of the body shadow. It was therefore expected that the fronto-patietal neural activations associated with perception of object shadow would anticipate the neural activations of body shadow. A series of Multiple Regression Analysis (MRA) revealed that body shadow specific modulations in the bilateral frontal areas reflect and infer object shadow relevant sensorimotor perception, and subsequent decision making in 3D virtual environments. The current data suggest the existence of a cortical network in which neural dynamics of object shadows would provide a mechanism for the formation of functional networks during internal re/activation of body relevant cortical representations, that is, a substitution of the physical body. They also suggest that prediction and anticipation along with inference and exploration might be general principles of cortical functioning in real and 3D virtual environments.

ARE PREDICTIVE PROCESSES ALTERED BY TMS OF THE CEREBELLUM?

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Ellen Joos[1], Camille Scherer[1], Romane Weill Rossi[2], Philippe Isope[3], Jack Foucher[4], Anne Giersch[1]
[1]INSERM, U1114, Strasbourg, France, [2]plateforme IRIS, Pôle Neuro-imagerie Humaine, Strasbourg, France, [3]CNRS, Institut Des Neurosciences Cellulaires Et Intégratives Upr 3212, Strasbourg, France, [4]INSERM, U666, Strasbourg, France

Improving the treatment of Schizophrenia is an important goal in psychiatry. Transcranial magnetic stimulation (TMS) of the Cerebellum was shown to improve symptoms in patients with Schizophrenia. Further, we know that the Cerebellum is related to time perception and prediction on the millisecond level. Interestingly, patients show deficits in time prediction, especially on the milliseconds level. Here, we investigate whether we can alter temporal predictive processes using TMS on Crus I/II (Cerebellum), which are involved in temporal processes. To establish this basic knowledge, we test only healthy controls. In a first MRI session, we obtain anatomical and functional data. Functional data is measured while presenting two different tasks: (1) The variable foreperiod paradigm in order to evoke the hazard function, i.e., the effect of temporal preparation on behavior; (2) A very recently discovered optical illusion, i.e., the collision task, which is interpreted to reflect millisecond predictions of movement and contrast. In the two following sessions, we present those two tasks before and after TMS interventions (treatment or SHAM). The functional MRI will reveal the possible involvement of Crus I/II and its related networks during the variable foreperiod paradigm and during the collision task. Further, we hypothesize that the effect of TMS of Crus I/II will (1) modify the hazard function and (2) alter the illusion perception rate. The study is on-going and I will present preliminary results. If our hypotheses were to be confirmed, we aim to test this approach in patients with Schizophrenia to possibly restore temporal processes.

THE FUNCTIONAL ROLE OF RESTING-STATE THETA-GAMMA COUPLING AND ITS RELEVANCE TO VISUAL SELECTIVE ATTENTION FOR PATIENTS WITH TIC DISORDER

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Ji Seon Ahn[1], Kyungun Jhung[2], Jooyoung Oh[3], Jaeseok Heo[1], Jae-Jin Kim[3], Jin Young Park[1]
[1]Yongin Severance Hospital, Yonsei University College Of Medicine, Dept. Of Psychiatry, Yongin, Korea, Republic of, [2]International St. Mary's Hospital, Catholic Kwandong University, Dept. Of Psychiatry, Incheon, Korea, Republic of, [3]Gangnam Severance Hospital, Yonsei University College of Medicine, Dept. Of Psychiatry, Seoul, Korea, Republic of

Tics are generated as repetitive movements, vocalization, and intrusive thoughts after aberrant sensory gating. Theta phase-gamma power coupling (TGC) has an important role in several different cognitive processes. Although spontaneous brain activity during the resting state is crucial for preparing for cognitive performance, the relationship between the functional role of resting-state TGC and cognitive function of patients with tic disorder (TD) remains unclear. Thirteen patients with TD and 13 healthy children participated in the experiment. Their resting-state TGC was measured while their eyes were closed. The relationship between this value and their clinical outcomes was determined. Resting-state TGC was significantly lower for patients with TD than for healthy children at the global level. While participants' eyes were closed, TGC during the resting state was significantly and negatively correlated with the attention quotient of omission errors according to a visual selective attention test. These findings support the view that TGC reflects information processing and signal interactions at global levels. Additionally, these findings suggest the low efficacy of the dysfunctional resting-state brain network of patients with TD, which is important for attentional processing of visual sensory information. Patients with TD may have difficulty gating irrelevant sensory information while their eyes are closed during the resting state.

DISTRACTORS WITH MORE TARGET FEATURES ATTRACT MORE ATTENTION REFLECTED BY N2PC: A CROSS-MODAL EEG STUDY

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Shao-Yang Tsai
Ludwig-Maximilian-Universität München, Department Psychologie, München, Germany

Task-irrelevant distractor often captures our attention, and avoiding distraction requires top-down attentional guidance. However, it remains controversial regarding the underlying neural mechanisms of how we handle attentional capture by distractors. Some argue that we proactively suppress task-irrelevant distractors in advance to avoid attentional capture (i.e., signal-suppression hypothesis). Some advocate attentional deployment to the distractor is reduced rather than suppressed (i.e., "no engagement" hypothesis). In contrast, others suggest irrelevant distractors still capture attention but disengaging from it is quicker (i.e., fast disengagement hypothesis). We conducted two cross-modal search tasks with EEG recording to distinguish the above accounts by observing key ERL components: N2pc, Pd, and CCN. To distinguish target- and distractor-related ERL components, we presented distractors 50 to 150 ms before the target. Specifically, the target had a specific visual shape and color, either located in the middle line or the lateral regions, and the salient distractors were varied within-dimension (the same as the target), across-dimension (different color/shape from the target), and across modalities (tactile vibrations). We observed the within-dimension distractor slowed down the reaction time most. The cross-dimension distractors induced minor interference. But the cross-modality distractor did not worsen performance. Distractors containing more target features attracted more attention and caused more attentional engagement reflected by N2pc. The following Pd represented disengagement from the distractor. The tactile distractor captured attention reflected by CCN, but it did not reduce the attentional deployment to the visual target. The current findings suggest the distractor with target-relevant features deteriorated performance because of top-down attentional engagement.

PSEUDONEGLECT AND HAND PREFERENCE OF SAIMIRI SCIUREUS IN BEHAVIOURAL TASKS

POSTER SESSION 05 - SECTION: TEMPORAL COGNITION, RHYTHMS & ATTENTION

Julie Royo[1,2], Thomas Orset[1,2], Pierre Pouget[1,2], Michel Thiebaut De Schotten[2,3]
[1]Institut du cerveau (ICM) - Paris Brain Institute, Inserm U 1127, Cnrs Umr 7225, Sorbonne Université - Movement Investigation And Therapeutics Team, Paris, France, [2]Sorbonne Universities, Brain Connectivity And Behaviour Laboratory, Paris, France, [3]CNRS, Institut Des Maladies Neurodégénératives-umr 5293-neurofunctional Imaging Group, Bordeaux, France

Converging anatomical, neurological and behavioural evidence demonstrate that manual preference is related to the lateralisation of visuospatial processing. Manual preference has been reported in many primates but remains debated in Saimiri sciureus. Pseudoneglect —an asymmetry in spatial exploration traditionally viewed as an effect of visuospatial brain lateralisation in humans— has never been studied in Saimiri sciureus. In two complementary behavioural tasks, the present study compared manual and visuospatial lateralisation in 15 female Saimiri sciureus. In the line task, ten grapes were aligned and centred in parallel to the animals' eyesight. In the puzzle task, grapes were hidden behind covers in a checkerboard fashion. We then recorded the hand used and the pseudoneglect — i.e. center of gravity of the exploration omissions — during both tasks. Half of the animals showed a strong left (3 animals) or right (4 animals) manual preference for the line task without significant effect in the group (Right vs Left : $p=0.97$). 14 animals showed a hand preference (Left 6 ; Right 8) for the puzzle task (Right vs Left : $p =0.25$). In addition, the difficulty of the task induced a stronger right laterality ($p<0.001$) than left laterality ($p<0.05$). The line task did not reveal any pseudoneglect effect ($p=0.47$) but 7 animals demonstrated an asymmetry in their spatial exploration of the puzzle task (group : $p=0.64$), albeit without any link to manual preference ($r=0.06$, $p=0.82$). These results indicate that Saimiri sciureus, like humans, show a manual preference related to task complexity but not associated with pseudoneglect.

THE HUMAN DORSAL PREFRONTAL SYSTEM REFLECTS THE SOURCE OF VALUE INFORMATION DURING RISKY DECISIONS

POSTER SESSION 05 - SECTION: DECISION-MAKING

Vasilisa Skvortsova[1,2,3], Fabien Cerrotti[2], Valentin Wyart[2], Stefano Palminteri[2]
[1]University College London, Max Planck Center For Computational Psychiatry And Ageing Research, London, United Kingdom, [2]Ecole Normale Superieure, Laboratoire De Neurosciences Cognitives Et Computationnelles, Inserm U960, Département D'etudes Cognitives, Paris, France, [3]Wellcome Centre for Human Neuroimaging, University College London, London, United Kingdom

When making a risky choice, a rational decision-maker integrates outcome magnitude and probability into an expected value (EV). These decision variables could come in two modalities: 1) presented in some descriptive form (e.g., pie-chart) or 2) inferred based on the previous experience. The first modality is mostly used in behavioral (neuro)economics while the latter is adopted in learning paradigms. Growing literature points towards an existence of experience-descriptive "gap". However, it remains unknown whether these two modalities rely on the same neural origins. We designed a two-armed restless bandit task with orthogonally manipulated modality (descriptive vs. experience-based) of magnitude and probability resulting in four decision contexts. While in the MRI-scanner, subjects (N=29) made consecutive choices between two colored shapes each associated with magnitude and probability which either had to be inferred based on the feedback or were displayed on the screen. Analysis of decision accuracy showed similar contributions of magnitude and probability regardless of their modality (p=0.77) with choices better explained by the model that integrated both modalities (Pexp= 0.99). At the neural level we found a dissociation between dorsal (dlPFC/dmPFC) and ventral (vmPFC) prefrontal networks. While the dorsal network differentiated between four decision contexts and showed context-dependent modulations of EV, EV correlates in the vmPFC were modality-nonspecific. Furthermore, the dorsal network showed earlier latency peaks for EV in the experiential relative to the descriptive context in line with the decision reaction times. Together, these results demonstrate a neural discrepancy between descriptive and experiential risky decision-making.

CONTEXT-DEPENDENCE AND ASYMMETRIC UPDATE IN RISKY DECISION-MAKING

POSTER SESSION 05 - SECTION: DECISION-MAKING

Ali Shiravand[1], Maëlle Gueguen[2], Sophie Bavard[3], Julien Bastin[4], Stefano Palminteri[1]
[1]École Normale Supérieure - PSL Research University, Département D'etudes Cognitives, Paris, France, [2]Rutgers University - New Brunswick, Department Of Psychiatry, Piscataway, NJ, United States of America, [3]University of Hamburg, Faculty Of Psychology And Human Movement Science, Hamburg, Germany, [4]Univ. Grenoble Alpes, Inserm, U1216, Grenoble Institut Neurosciences, Grenoble, France

Economic decisions are influenced by both outcome valence (i.e., whether an outcome entails gain or loss) and risk (the variance of outcomes). It has been shown in previous studies that people have different risk preferences when the prospects' information is described explicitly and when they are learning it by experience. However, the effect of valence on behavioral performance in an experienced-based learning task has been less investigated. To address this question, we used a novel instrumental learning task in 4 behavioral experiments designed to manipulate risk and valence independently while the difference of value between options was kept invariant. Each experiment consists of 2x2 design contexts; one dimension indicates whether the context's valence is loss or gain, and the other dimension is dedicated to whether the correct option is risky or safe. Consistent results in all experiments show a significant effect of prospect's riskiness in behavioral performance. Moreover, we found a significant effect of riskiness, valence and their interactions on subjects' reaction time. Finally, using model-fitting and reinforcement learning simulations, we indicated that a model with a learning rate asymmetry better accounts for behavioral data.

THE ROLE OF FEEDBACK IN DECISION MAKING UNDER RISK

POSTER SESSION 05 - SECTION: DECISION-MAKING

Antonios Nasioulas[1], Stefano Palminteri[2], Mael Lebreton[1]
[1]Paris School of Economics, Paris-jourdan Sciences Économiques, Paris, France, [2]École Normale Supérieure - PSL Research University, Département D'etudes Cognitives, Paris, France

Decision making under risk has been shown to differ depending on whether the outcome of the choice is revealed. We investigated how feedback affects decision making by comparing decisions from description only (outcome not disclosed) with decisions from description and experience (outcome disclosed). We ran a series of six factorial experiments (N=600) using the repeated binary choice task, contrasting a safe versus a risky lottery. We manipulated within-subjects the presence of feedback, which option has a higher expected value(EV), the probability, and the magnitude of the risky option. We also manipulated between-subjects the type of feedback (partial or complete), the presence of instructions at the beginning of each block on the availability of feedback, and whether the safe option was a sure-thing or a low variance lottery. We consistently found that feedback increases risky choice rate. Interestingly, this effect emerges immediately after the subjects realize they will receive feedback, suggesting it is induced by the mere anticipation of feedback, not by learning per se. Consistent with the increase in risky rate, descriptive modeling analysis using a Prospect Theory variant indicated decreased risk aversion and increased weighting for medium and large probabilities when feedback is provided. On the other hand, feedback seems to have no effect on EV-maximization. All in all, we found that feedback makes people more risk-seeking, but not necessarily more accurate (in terms of EV-maximization).

THE ROLE OF SIBLING AGGRESSION DURING CHILDHOOD IN DECISION-MAKING DURING ADULTHOOD

POSTER SESSION 05 - SECTION: DECISION-MAKING

Stacey Bedwell[1], Natalie Harrison[2], Matthew Brooks[3]
[1]King's College London, Ioppn, London, United Kingdom, [2]Bath Spa University, Psychology, Bath, United Kingdom, [3]Manchester Metropolitan University, Psychology, Manchester, United Kingdom

The role of sibling aggression during childhood in decision-making during adulthood Stacey A. Bedwell[1], Natalie Harrison[2] and Matthew Brooks[3] [1] Institute of Psychiatry, Psychology & Neuroscience, King's College London, London, UK [2] Department of Psychology, Bath Spa University, Bath, UK [3] Department of Psychology, Manchester Metropolitan University, Manchester, UK Sibling relationships during childhood are known to influence cognitive development, specifically in terms of executive functions associated with the prefrontal cortex. It is understood that the development of prefrontal networks can be influenced by experiences in developmental phases. However, it remains to be understood how experiences of sibling aggression contribute to the development of executive functions, specifically how decision-making is exhibited in adulthood. In the present two studies, we sought to uncover the relationship between experiences of childhood sibling aggression, decision-making style in adulthood and real-time risky decision-making. In study one, reports from 142 adults revealed that using sibling aggression to maintain dominance in childhood was linked to avoidant and spontaneous decision-making in adulthood. In study two, data collected from 75 adults revealed experiences of sibling aggression did not predict risky decision-making. These findings indicate that the types of decisions made may be influenced by childhood sibling aggression, but not the level of risk involved in decisions made.

CONTEXT INDUCED FALSE MEMORIES OF OUTCOME VALUES

POSTER SESSION 05 - SECTION: DECISION-MAKING

Magdalena Soukupova, Basile Garcia, Stefano Palminteri
École Normale Supérieure - PSL Research University, Département D'etudes Cognitives, Paris, France

Here we investigated whether context influences how values are learned and retrieved from memory. Our experiment consisted of a learning task followed by two post-learning memory tasks. These were an explicit valuation task, where participants had to recall the outcome of each symbol, and an implicit choice task, where they had to select the best symbol between a given pair. Crucially, we varied the learning architecture across experimental groups, i.e. which options were presented together during the learning phase. This allowed us to independently manipulate the global rank of an option (i.e. how good the option is compared to all other options in the task) and its local rank (i.e. how good the option is compared to its pairmate). Specifically, we ran three versions of the learning task: in the first two versions (V1&V2), options were presented in fixed pairs during the learning phase (stable local contexts), whereas in the last version (V3), options were presented in all possible combinations (no stable local context). While accuracy during the learning phase was similar across all versions, the learning architecture had a great impact on responses in the post-learning memory tasks. In V3, participants' responses reflected the global rank of the options (i.e. their *absolute* value), whereas in V1&V2, participants' responses reflected a mixture of the global and local ranks of the options (i.e. their *relative* value). We thus demonstrate that irrational preferences and value judgments systematically arise from learning architectures that favour contextual learning.

EVALUATION OF THE EFFECTIVENESS OF AN EXECUTIVE FUNCTION TRAINING PROGRAM COUPLED WITH TRANSCRANIAL STIMULATION IN BRAIN-INJURED PATIENTS: PRELIMINARY RESULTS OF A SINGLE CASE EXPERIMENTAL DESIGN

POSTER SESSION 05 - SECTION: DECISION-MAKING

Claire Lebely[1,2], Evelyne Lepron[3], Sebastien Scannella[4], Xavier De Boissezon[1,2]
[1]Hospitalier Universitaire de Toulouse CHU,, Department Of Rehabilitation And Physical Medicine,, TOULOUSE CEDEX, France, [2]UMR 1214-Inserm/UPS-ToNIC, Toulouse, Neuroimaging Center Hopital Purpan Université De Toulouse, TOULOUSE CEDEX, France, [3]ISAE SUPAERO, Universite Toulouse, TOULOUSE, France, [4]ISAE, Supaero, TOULOUSE, France

Cognitive remediations (CR) are designed to address the crucial need for symptom improvement in brain-damaged patients with deficit in executive functions. The aim of our study is to investigate the effectiveness of a CR in virtual reality (CoVirtua) coupled with transcranial stimulation (tRNS), in improving performance in ecological situations of patients with dysexecutive syndrome. Five patients were included in a multiple single case study (SCED) that included three phases (A1-B-A2) over 12 weeks. Phases A1 and A2 corresponded to occupational therapy and Phase B corresponded to the CR. The start of phase B was randomized. The intervention lasted four weeks and consisted of four Covirtua sessions per week coupled with a 20-min tRNS session. The effect of the intervention has been assessed by the Goal Attainment Scale (GAS) in the short and long terms. GAS results showed an effect of the intervention in the short term (A1 *vs*. B) and the long term (A1+B *vs.* A2) for 2 objectives for P01 ("Mailbox management" p= 0.01; "Concentration" p = 0.02) and for 1 objective for P03 ("Managing a shopping list" p=0.02). Regarding long-term effects, the intervention showed its effectiveness for 1 objective for P02 (“Following Household chores schedule” p=0.03); and for 2 objectives for P06 (“Following a recipe” p=0.005; “Managing groceries” p=0.02). These first results show of a positive effect of Covirtua coupled with tRNS on executive functioning in daily life, mainly in the long term. Other patients are currently being studied.

DECISION MAKING AND RISK-TAKING: THE ROLE OF COGNITIVE RESERVE

POSTER SESSION 05 - SECTION: DECISION-MAKING

Maura Crepaldi
Università degli Studi di Bergamo, Scienze Umane E Sociali, Bergamo, Italy

Decision-making (DM) competence and risk management are crucial for maintaining independence and autonomy, especially for older adults. The role that Cognitive Reserve (CR) plays in this process is poorly investigated. CR is a pivotal factor, both from a neural and cognitive-functional point of view, in coping with cognitive decline during the later stage of life. According to several authors, it involves efficient and flexible cognitive strategies learned throughout life. Moreover, divergent thinking (DT), was proved to be one of the predictors of CR. The present study aims to investigate the link between CR (assessed with the Cognitive Reserve Test, CoReT), DM styles (investigated with the General Decision Making Style, GDMS) and risk-taking in different domains (assessed with the Domain-Specific Risk-Taking, DOSPERT). Preliminary analyses of data collected in a sample of 32 healthy participants (60-81 years; age: mean= 65.8; SD=5.09; education: mean=14.3; SD=4.87; women F= 46.9%) show a correlation between CR, DM styles and risk-taking. In particular, functional DM styles seem to be related to CR and specifically to the components of DT. On the contrary, non-functional DM styles and risk-taking components are negatively correlated with the creative components of CR. The evidence of a relationship between DM, risk-taking and CR provides the conceptual basis for designing interventions to improve and increase the non-structural component of CR, increasing DT. Such interventions might consequently promote active ageing by supporting DM processes and therefore the efficient management of daily life activities.

BEHAVIOURAL AND NEURAL MECHANISMS OF COMMITMENT AND ABANDONMENT IN SEQUENTIAL GOAL PURSUIT

POSTER SESSION 05 - SECTION: DECISION-MAKING

Eleanor Holton[1], Jill O'Reilly[1], Nils Kolling[2]
[1]University of Oxford, Experimental Psychology, Oxford, United Kingdom, [2]University of Oxford, Department Of Psychiatry, Oxford, United Kingdom

Agents often need to pursue a goal for an extended period of time before any rewards are obtained. In dynamic environments, the relative value of the chosen goal compared to alternatives may change mid-pursuit, meaning agents must evaluate the optimal level of goal commitment. Being too committed to a poorly chosen goal could mean losing out on better options, while being too prone to abandonment risks the agent never completing any goals. We used a sequential goal pursuit task with fMRI to investigate how people move between states of goal selection and goal commitment, how they weigh up the different kinds of pressure to abandon a goal they are committed to (such as frustration with the current goal versus temptation from an alternative), and how this evaluation process varies with sunk costs. Participants' choices in the task were best explained by a sequence sampling model which sampled possible future trajectories of the different goal options. However, beyond capturing choices with this prospective model, participants consistently showed a bias to persevere with the current goal rather than switch to a better option, which worsened with the number of trials invested. The bias to persist was associated with reduced attention allocated to stimuli associated with non-selected goals during an independent spatial working memory task. It was also linked to a decreased representation of alternative goals in the dACC as people progressed through the current goal, suggesting goal commitment is manifested as progressive inhibition of alternative courses of action during goal pursuit.

SLEEP ONSET IS A CREATIVE SWEET SPOT

POSTER SESSION 05 - SECTION: DECISION-MAKING

Célia Lacaux[1], Thomas Andrillon[1], Isabelle Arnulf[1,2], Delphine Oudiette[1,2]
[1]Paris Brain Institute, Sorbonne Université, Paris, France, [2]AP-HP, Pitié-Salpêtrière Hospital, Sleep Disorder Unit, Paris, France

The ability to think creatively is paramount to facing new challenges, but how creativity arises remains mysterious. Here, we show that the brain activity common to the twilight zone between sleep and wakefulness (nonrapid eyemovement sleep stage 1 or N1) ignites creative sparks. Participants (N = 103) were exposed to mathematical problems without knowing that a hidden rule allowed solving them almost instantly. We found that spending at least 15 s in N1 during a resting period tripled the chance to discover the hidden rule (83% versus 30% when participants remained awake), and this effect vanished if subjects reached deeper sleep (N2). We substantiated these results using spectral analyses and discovered an optimal cocktail for creativity (above and beyond sleep stages), consisting of an intermediate level of alpha (a marker of the wake-to-sleep transition) and a low level of delta (which signs sleep depth). Our findings suggest that there is a creative sweet spot within the sleep-onset period, and hitting it requires individuals balancing falling asleep easily against falling asleep too deeply.

TWO-DIMENSIONAL ADAPTATION OF DECISION VARIABILITY TO REWARD VOLATILITY AND TRAIT COMPULSIVITY

POSTER SESSION 05 - SECTION: DECISION-MAKING

Jun Seok Lee
Ecole normale supérieure, Département D'études Cognitives, PARIS, France

The variability of reward-guided decisions arises from two distinct sources: imprecise reinforcement learning due to limited resources, and exploratory choices aimed at reducing uncertainty. But whether these two sources of decision variability adapt to specific forms of uncertainty remains unknown. Here we designed a two-armed bandit task in which we compared the effects of reward stochasticity and volatility on decision variability. Across three datasets (total N = 447 participants and 262,560 decisions), we show that humans decrease learning noise and make more ex- ploratory choices in response to volatile but not stochastic rewards. Through theoretical simulations, we demonstrate that these selective effects reflect cost-efficient adaptations to uncertainty. We further show that individual differences in trait compulsivity, measured using a validated transdiagnostic approach, account for variations in exploration but not learning precision. Together, these findings reveal a latent two-dimensional trade-off regulating decision variability under uncertainty.

LISTEN TO YOURSELF: AN FMRI STUDY OF MOTIVATIONAL INTERVIEWING EFFECTS ON DIETARY DECISION-MAKING IN HEALTHY PARTICIPANTS

POSTER SESSION 05 - SECTION: DECISION-MAKING

Belina Rodrigues, Martine Rampanana, Solène Frileux, Iraj Khalid, Liane Schmidt
Institute du Cerveau (ICM), UMR 7225, U1127, Institut National de la Santé et de la Recherche Médicale/Centre National de la Recherche Scientifique/Sorbonne Universités, Hôpital Pitié-Salpêtrière, Control - Interoception – Attention (cia), Paris, France

Motivational interviewing (MI) is an evidence-based communicational approach, which aims at resolving a person's ambivalence between changing (CT) and keeping (ST) unhealthy behaviour. However, its neurocognitive underpinnings are unknown. Here, we built on models of economic choices, which propose that decision-making involves a valuation phase during which features, such as for example the healthiness and tastiness of food, become integrated into stimulus value that drives choices. We aimed at testing how MI changes food valuation and food-valuation related brain responses during dietary decision making. Twenty-seven female participants (age=29 ± 2.01 SEM years, BMI = 23.4 ± 1.09 SEM kg/m^2) underwent an MI session from which 5 CT and 5 ST statements were extracted. One week later, during an fMRI session, participants listened to these statements before making a series of dietary choices. The results showed that participants based their food choices more on the healthiness and less on the tastiness of food after listening to CT. This interaction was independent of stimulus value assigned to food, which was similar for CT and ST. On the neural level the vmPFC and dlPFC correlated stronger to the healthiness of food when choices were made after listening to CT statements. The vmPFC correlated more to the tastiness of food when choices were made after listening to ST statements. These findings indicated that CT and ST differentially influenced how healthiness and tastiness features predicted food stimulus value, and how regions within the brain's valuation and cognitive self-regulation systems encoded these features during dietary decision-making.

PREDICTING A PLANNED EXECUTION OF AGGRESSIVE ACTION: A STUDY FOR PROACTIVE AGGRESSION IN A GREEK-CYPRIOT ADOLESCENT SAMPLE

POSTER SESSION 05 - SECTION: DECISION-MAKING

Georgia Frangou, Androulla Eleftheriou, Kostas Fanti
UNIVERSITY OF CYPRUS, Department Of Psychology, Aglantzia, Nicosia, Cyprus

Studies regarding narcissism and proactive aggression association have revealed contradicting results. This study aims to investigate whether narcissism, sensation seeking, popularity and media violence exposure predict the expression of a planned, controlled, and purposeful execution of an aggressive act with the aim of achieving a desired goal. The sample consists of 2306 Cypriot adolescents. Narcissism was evaluated with the Narcissistic Personality Inventory (Raskin & Hall, 1979) and Antisocial Process Screening Device-Youth Version (Frick and Hare 2001), proactive aggression with Proactive and Reactive Aggression Questionnaire (Raine et al. 2006), sensation seeking tendencies with Sensation Seeking Scale Form –V (Zuckerman, Eysenck, and Eysenck 1978), popularity with the Peer Pressure Questionnaire (Santor et al., 2000) and self-report for their grade as well as media exposure. A linear regression revealed that narcissism and sensation seeking in combination explain 48.2% of the variance in proactive aggression. When grade is factored in as well as a variable, only an additional 0.2% was explained. Narcissism explained 44% of the variance in proactive aggression, when popularity was factored in to the model 47.6% was explained. Finally, when media violence was added, the variance was explained by 53.7%. The data suggest that narcissism, popularity, and media violence significantly predict proactive aggression in this sample. Results can reveal a great pool of information regarding the type of appropriate interventions for adolescents with narcissistic traits. Hopefully, this study will explain the previous mixed results and also add to the importance of other co-occurring variables.

LIKING YOUR OWN IDEAS: COMPUTATIONALLY DECIPHERING THE ROLE OF PREFERENCES IN CREATIVITY

POSTER SESSION 05 - SECTION: DECISION-MAKING

Alizée Lopez-Persem, Sarah Moreno, Stella Guiet, Jules Brochard, Emmanuelle Volle
Institut du Cerveau, Frontlab, Paris, France

The cognitive and neural mechanisms of creativity are still poorly understood. Formally, creativity is defined as the ability to produce an object/idea that is both original and efficient. Then, creativity should involve an evaluative process of efficiency and originality, interacting with a generative process that generates candidate ideas. Through an original experimental design combining creativity and decision-making tasks, coupled with computational modeling, this study aims to investigate the evaluative component's specific role in creativity mechanisms. The central hypothesis is that valuation involves individual preferences that affect the exploration and/or selection process. Sixty-nine participants completed a free generation of associates task in which they had to provide creative associations in response to cue words. This task was followed by rating tasks in which they had to judge how much they liked their responses and how much associations were appropriate and original. We first found that participants were faster to provide responses they liked more. Then, using random walks applied to semantic networks, combined with decision functions, we found that preferences were more likely to drive the selection phase than the exploration phase of the creative idea generation. We compared the behavior predicted by the model to the behavior of a subgroup of participants excluded for the model development and found strikingly similar behavioral patterns. Finally, we found that preferences parameters and performance in the generation task correlated with creative abilities, measured via classical creativity tests. Altogether, our findings support a new framework for creativity by considering it as a reward-based behavior.

IMPACT OF DECISION AND ACTION OUTCOMES ON SUBSEQUENT DECISION AND ACTION BEHAVIORS

POSTER SESSION 05 - SECTION: DECISION-MAKING

Clara Saleri Lunazzi, Amélie Reynaud, David Thura
INSERM, Lyon Neuroscience Research Center - Impact Team - Inserm U1028, Bron, France

While traditionally considered as independent processes, recent studies suggest a close functional relationship between decisions and actions. For instance, humans can trade decision time for movement time to maximize their reward rate between blocks of trials. Besides, it is well established that choice outcomes largely impact subsequent decisions. But the impact of a choice on the next action has never been described, and whether and how a motor outcome influences the next decision is also unknown. We addressed these questions by analyzing trial-to-trial changes of choice and motor behaviors of human subjects instructed to perform successive perceptual decisions expressed with reaching movement whose duration was either bounded or unconstrained in separate tasks. Results indicate that after a bad decision, participants who were not constrained in their action decided more slowly and more accurately. Interestingly, they also shortened their subsequent movement duration by moving faster. Conversely, movement errors not only influenced the speed and the accuracy of the following movement, but those of the decision as well. If the movement had to be slowed down, the decision that precedes that movement was accelerated, and vice versa. These results indicate that decision and action do not only compensate each other over extended time scales, between blocks of trials, but also more locally, from one trial to another. The observed post-outcome adjustments also confirm that in a context allowing reward rate maximization, humans seek in each trial to optimize their global behavior instead of computing their decisions and actions independently of each other.

THE IMPASSABLE GAP BETWEEN EXPERIENTIAL AND SYMBOLIC VALUES

POSTER SESSION 05 - SECTION: DECISION-MAKING

Basile Garcia[1], Stefano Palminteri[2]
[1]Ecole Normale Supérieure, Département D'études Cognitives, Paris, France, [2]École Normale Supérieure - PSL Research University, Département D'etudes Cognitives, Paris, France

To choose between options of different natures, standard decision models presume that a single representational system ultimately indexes their subjective values on a common scale, regardless of how they are constructed. To challenge this assumption, we systematically investigated hybrid decisions between experiential options, whose value is built from past outcomes experience, and symbolic options which describe probabilistic outcomes. We show that participants' choices exhibited a pattern consistent with a systematic neglect of the experiential values. This normatively irrational decision strategy held after accounting for alternative explanations, and persisted when it bore an economic cost. Overall, our results demonstrate that experiential and symbolic values are not symmetrically considered in hybrid decisions, suggesting that they are not commensurable and recruit different representational systems which may be assigned different priority levels in the decision process. These findings challenge the dominant models commonly used in value-based decision-making research.

INCENTIVE MOTIVATION AFFECTS BELIEF AND CONFIDENCE DIFFERENTLY

POSTER SESSION 05 - SECTION: DECISION-MAKING

Nahuel Antonio Salem-Garcia[1,2], Sébastien Massoni[3], Mael Lebreton[1,2,4]
[1]University of Geneva, Basic Neuroscience, Geneva, Switzerland, [2]University of Geneva, Swiss Center For Affective Science, Faculty Of Psychology And Educational Sciences, Geneva, Switzerland, [3]University of Lorraine, Bureau For Economic Theory And Applications, Nancy, France, [4]Paris School of Economics, Paris-jourdan Sciences Économiques, Paris, France

Tracking uncertainty about the environment is crucial for adaptive behavior. However, humans often make errors when estimating probabilities about external states (belief) and their own actions (confidence), particularly being prone to numerous affective and motivational effects. Some theories of motivated cognition propose that a general *desirability bias* affects all probability judgements equally (overestimating the probability of states of the world associated with obtaining rewards or avoiding punishments). Here we challenge this view across multiple perceptual discrimination experiments (total N = 401), where we manipulated choice agency (whether participants were faced with free choices, imposed choices, observed choices, or their own choices from previous trials) and monetary incentives (magnitude and valence of potential outcomes for correct/incorrect choice), measuring their effects on probability judgements about choices being correct. We falsify a generalized desirability bias by demonstrating a) increased probability judgements with net rather than absolute incentive value, and b) higher effects of incentives on probability judgements about self-generated actions. These results show that probability judgements are affected by a *contextual valence effect* rather than a desirability bias, and that judgements about one's own behavior are differentially affected, being more sensitive to this effect.

USING CITIZEN SCIENCE TO STUDY NEUROCOGNITIVE MECHANISMS AND THEIR RELATION TO MENTAL HEALTH

POSTER SESSION 05 - SECTION: DECISION-MAKING

Nadescha Trudel, Vasilisa Skvortsova, Tobias Hauser
University College London, Max Planck Ucl Centre For Computational Psychiatry And Ageing Research, London, United Kingdom

Investigating inter-individual differences in cognitive mechanisms is often a challenging endeavor. In-person laboratory testing is slow and sample sizes are small, while online experiments using worker platforms are costly and likely to yield biased samples (e.g. professional participants, restricted age range). Both limitations can affect the generalisability and replicability of findings. Here, we present findings from an alternative approach. We developed a citizen science smartphone app, Brain Explorer (www.brainexplorer.net), that incorporated short versions of two tasks previously used in the laboratory to probe computational mechanisms underlying psychiatric traits such as impulsivity and compulsivity. The first “Treasure Hunt” (TH) game probed mechanisms underlying information search (Hauser et al., 2017) and the second game, “Milky Way” (MW) probed reinforcement learning in changing environments (Skvortsova et al., 2022). Users (N>2500) played both games and additionally answered self-reported surveys targeting compulsivity and impulsivity traits. Here, we investigate how such a citizen science approach affects the psychometric properties for these tasks, revealing moderate test-retest reliability and cross-task associations. Moreover, we show how associations with psychometric properties (here: impulsivity and compulsivity) hold across different task versions and recruitment pathways. Together these results support the usage of short gamified tasks to probe the computational mechanisms underlying psychiatric traits.

Causal manipulation of self-other mergence in the dorsomedial prefrontal cortex.
To navigate social environments, people must simultaneously hold representations about their own and others' abilities. During self-other mergence, people estimate others' abilities not only on the basis of the others' past performance, but the estimates are also influenced by their own performance. For example, if we perform well, we overestimate the abilities of those with whom we are co-operating and underestimate competitors. Self-other mergence is associated with specific activity patterns in the dorsomedial prefrontal cortex (dmPFC). Using a combination of non-invasive brain stimulation, functional magnetic resonance imaging, and computational modeling, we show that dmPFC neurostimulation silences these neural signatures of self-other mergence in relation to estimation of others' abilities. In consequence, self-other mergence behavior increases, and our assessments of our own performance are projected increasingly onto other people. This suggests an inherent tendency to form interdependent social representations and a causal role of the dmPFC in separating self and other representations.

Identification and disruption of a neural mechanism for accumulating prospective metacognitive information prior to decision-making.
More than one type of probability must be considered when making decisions. It is as necessary to know one's chance of performing choices correctly as it is to know the chances that desired outcomes will follow choices. We refer to these two choice contingencies as internal and external probability. Neural activity across many frontal and parietal areas reflected internal and external probabilities in a similar manner during decision-making. However, neural recording and manipulation approaches suggest that one area, the anterior lateral prefrontal cortex (alPFC), is highly specialized for making prospective, metacognitive judgments on the basis of internal probability; it is essential for knowing which decisions to tackle, given its assessment of how well they will be performed. Its activity predicted prospective metacognitive judgments, and individual variation in activity predicted individual variation in metacognitive judgments. Its disruption altered metacognitive judgments, leading participants to tackle perceptual decisions they were likely to fail.

Polarity of uncertainty representation during exploration and exploitation in ventromedial prefrontal cortex.
Environments furnish multiple information sources for making predictions about future events. Here we use behavioural modelling and functional magnetic resonance imaging to describe how humans select predictors that might be most relevant. First, during early encounters with potential predictors, participants' selections were explorative and directed towards subjectively uncertain predictors (positive uncertainty effect). This was particularly the case when many future opportunities remained to exploit knowledge gained. Then, preferences for accurate predictors increased over time, while uncertain predictors were avoided (negative uncertainty effect). The behavioural transition from positive to negative uncertainty-driven selections was accompanied by changes in the representations of belief uncertainty in ventromedial prefrontal cortex (vmPFC). The polarity of uncertainty representations (positive or negative encoding of uncertainty) changed between exploration and exploitation periods. Moreover, the two periods were separated by a third transitional period in which beliefs about predictors' accuracy predominated. The vmPFC signals a multiplicity of decision variables, the strength and polarity of which vary with behavioural context.

EXPLORING TOO MUCH? THE ROLE OF EXPLORATION IN IMPULSIVITY

POSTER SESSION 05 - SECTION: DECISION-MAKING

Magda Dubois, Tobias Hauser
University College London, Max Planck Ucl Centre For Computational Psychiatry And Ageing Research, London, United Kingdom

Deciding whether to forgo a good choice in favour of exploring a potentially more rewarding alternative is one of the most challenging arbitrations both in human reasoning and in artificial intelligence. Humans show substantial variability in their exploration, and theoretical but only limited empirical work has suggested that excessive exploration is a critical mechanism underlying the psychiatric dimension of impulsivity. We put these theories to test using a large online sample (N=580 healthy adults), dimensional analyses, and computational modelling in a pre-registered study. Capitalising on recent advances in disentangling distinct human exploration strategies, we demonstrate that impulsivity is associated with a specific form of exploration, value-free random exploration (correcting for multiple comparison using Bonferroni correction across 4 parameters x 3 factors, i.e. N=12; r(578)=0.257, p_uncorrected<.001, p_corrected<.001; accounting for age and IQ: r(573)=0.204, p_uncorrected<.001, p_corrected<.001), a computationally light exploration heuristic. Our results not only demonstrate this specific association with impulsivity, but also explore links between exploration and other psychiatric dimensions.

Pubmed:

33393461: Dubois M, Habicht J, Michely J, Moran R, Dolan RJ, Hauser TU
Human complex exploration strategies are enriched by noradrenaline-modulated heuristics.
An exploration-exploitation trade-off, the arbitration between sampling a lesser-known against a known rich option, is thought to be solved using computationally demanding exploration algorithms. Given known limitations in human cognitive resources, we hypothesised the presence of additional cheaper strategies. We examined for such heuristics in choice behaviour where we show this involves a value-free random exploration, that ignores all prior knowledge, and a novelty exploration that targets novel options alone. In a double-blind, placebo-controlled drug study, assessing contributions of dopamine (400 mg amisulpride) and noradrenaline (40 mg propranolol), we show that value-free random exploration is attenuated under the influence of propranolol, but not under amisulpride. Our findings demonstrate that humans deploy distinct computationally cheap exploration strategies and that value-free random exploration is under noradrenergic control.

Increased neural response to social rejection in major depression.
Being a part of community is critical for survival and individuals with major depressive disorder (MDD) have a greater sensitivity to interpersonal stress that makes them vulnerable to future episodes. Social rejection is a critical risk factor for depression and it is said to increase interpersonal stress and thereby impairing social functioning. It is therefore critical to understand the neural correlates of social rejection in MDD.

Annual Research Review: Developmental computational psychiatry.
Most psychiatric disorders emerge during childhood and adolescence. This is also a period that coincides with the brain undergoing substantial growth and reorganisation. However, it remains unclear how a heightened vulnerability to psychiatric disorder relates to this brain maturation. Here, we propose 'developmental computational psychiatry' as a framework for linking brain maturation to cognitive development. We argue that through modelling some of the brain's fundamental cognitive computations, and relating them to brain development, we can bridge the gap between brain and cognitive development. This in turn can lead to a richer understanding of the ontogeny of psychiatric disorders. We illustrate this perspective with examples from reinforcement learning and dopamine function. Specifically, we show how computational modelling deepens an understanding of how cognitive processes, such as reward learning, effort learning, and social learning might go awry in

psychiatric disorders. Finally, we sketch the promises and limitations of a developmental computational psychiatry.

TASTE MATTERS: HOW HUNGER RELEVANT FEATURES OF FOOD CONTRIBUTE TO EXPECTANCY-BASED PLACEBO EFFECTS ON HUNGER AND FOOD VALUATION ON THE NEURAL AND BEHAVIORAL LEVEL.

POSTER SESSION 05 - SECTION: DECISION-MAKING

Iraj Khalid[1], Belina Rodrigues[1], Hippolyte Dreyfus[1], Delphine Yeh[1], Solène Frileux[1], Karin Meissner[2], Philippe Fossati[1,3], Liane Schmidt[1]
[1]Institute du Cerveau (ICM), UMR 7225, U1127, Institut National de la Santé et de la Recherche Médicale/Centre National de la Recherche Scientifique/Sorbonne Universités, Hôpital Pitié-Salpêtrière, Control - Interoception – Attention (cia), Paris, France, [2]Institut für Medizinische Psychologie, Ludwig-Maximilians-Universität München, Placebo Research-meissner Lab, München, Germany, [3]Pitié-Salpêtrière Hospital, DMU Neuroscience, Sorbonne University, APHP, Department Of Psychiatry, Paris, France

Aims: This study tested whether cognitive regulation of contextual stimuli, which are relevant to the processing of interoceptive signals mediate expectancy-based placebo effects. **Methods:** The interoceptive outcome measure was hunger reported by 172 healthy female participants, who in the fasted and hungry state were administered a placebo suggested to either curb or enhance appetite. Participants then performed a dietary decision-making task in order to identify with computational modelling and functional magnetic resonance imaging underlying neurocomputational mechanisms of placebo effects on hunger. **Results:** The results replicated an expectancy-based placebo effect on hunger. The curbed-appetite group was less hungry than the enhanced-appetite group. Drift diffusion modelling of reaction times and food choices revealed that this placebo effect on hunger was driven by the enhanced-appetite group, who considered the tastiness of food more and more rapidly during evidence accumulation toward food wanting than the curbed-appetite group. FMRI in a subgroup of 57 participants revealed strong activations of the ventromedial prefrontal cortex, the dorsal anterior cingulate cortex, the precuneus and the posterior insula in response to food value during dietary decision-making. Importantly, these brain responses were stronger in the enhanced-appetite group than in the curbed-appetite group, and this contrast was modulated by how much the tastiness of food predicted food choices. **Conclusions:** These findings indicate that prognostic expectancies shaped the way interoceptive signals such as hunger were experienced through rapid attentional filtering of the tastiness of food, and the modulation of brain regions associated with valuation, attentional control, and secondary somatosensory processing.

DOES THE STRESS OF THREATENING SOCIAL EVALUATION INCREASE THE PREFERENCE FOR STATUS SIGNALS?

POSTER SESSION 05 - SECTION: DECISION-MAKING

Felix Jan Nitsch[1], Zsofia Margittai[2], Gideon Nave[3], David Dubois[1], Hilke Plassmann[1]
[1]INSEAD, Marketing Area, Fontainebleau, France, [2]Heinrich-Heine-University Düsseldorf, Comparative Psychology, Düsseldorf, Germany, [3]The Wharton School, University of Pennsylvania, Marketing, Philadelphia, United States of America

Previous theoretical and empirical consumer research suggests that social threats, which induce stress and insecurity, lead to increased consumption of status-signaling brands and products as a compensatory behavior. In our current project, we put this hypothesis to a rigorous and pre-registered empirical test, by submitting participant consumers to a social stress protocol, consisting of a mock interview and mental arithmetics in front of an evaluating panel, or a matched control condition. We characterise the response of our participants on a vector of psychological, biological and behavioural measures. Contrasting previous research, our results show that consumers experiencing social-evaluative threat did not show an increased preference for higher status brands, nor increased liking for products advertised with a status-positioning.

DECISION-MAKING IN DYNAMIC, CONTINUOUSLY EVOLVING ENVIRONMENTS: A NOVEL TASK DESIGN TO RELIABLY QUANTIFY THE FLEXIBILITY OF DECISION FORMATION AND ITS NEURAL SIGNATURES

POSTER SESSION 05 - SECTION: DECISION-MAKING

Lilian Weber[1], Maria Ruesseler[1], Layla Stahr[2], Luca Mezossy-Dona[1], Cameron Hassall[3], Tom Marshall[2], Jill O'Reilly[4], Laurence Hunt[3]
[1]University of Oxford, Psychiatry, Oxford, United Kingdom, [2]University of Oxford, Experimental Psychology, Oxford, United Kingdom, [3]University of Oxford, Department Of Psychiatry, Oxford, United Kingdom, [4]Oxford University, Dept Experimental Psychology, Oxford, United Kingdom

How do we choose the best course of action in a dynamic environment? How far back in time do we look for evidence to guide our current choice? To study the sub-components of decision-making, previous research has mostly employed trial-based choice paradigms, where participants choose between two options, the evidence for which remains fixed within (and often across) trials. However, in everyday life we do not make decisions in confined trials. Instead, we have to continuously accumulate information about decision options in the face of sensory noise and temporal uncertainty. Here, we present data from a novel continuous decision task designed to study decision-making in dynamic and temporally extended choice settings. In two EEG studies (N=28, N=23), participants had to continuously monitor a random dot motion display to detect transient changes in the dominant motion. We found that participants adapt the way they accumulate evidence for a decision to the dynamics of their environment: when signal changes were rare (stable environment), they integrated evidence over longer timescales compared to an environment with frequent changes (study 1). Similarly, when the noise in the evidence stream was higher, participants also adopted longer integration time windows as compared to low noise conditions (study 2). These behavioural differences were accompanied by changes in the neural response to changes in the evidence – an EEG signal which resembled the centro-parietal positivity known to track sensory evidence accumulation. Our findings demonstrate the flexibility of decision making in dynamic environments, and the advantages of continuous task designs.

CONTROLLABILITY REVEALS SPECIFIC SIGNATURES OF INFORMATION SEEKING DURING CHANGES OF MIND UNDER UNCERTAINTY

POSTER SESSION 05 - SECTION: DECISION-MAKING

Marion Rouault[1], Aurélien Weiss[2], Jun Seok Lee[2], Jan Drugowitsch[2], Valérian Chambon[2], Valentin Wyart[3]
[1]Ecole Normale Superieure of Paris, France, Department Of Cognitive Studies, Paris, France, [2]Ecole normale supérieure, Département D'études Cognitives, PARIS, France, [3]Ecole Normale Superieure, Laboratoire De Neurosciences Cognitives Et Computationnelles, Inserm U960, Département D'etudes Cognitives, Paris, France

Aims. In uncertain environments, seeking information about alternative choice options is essential for adaptive learning and decision-making. However, information seeking is usually confounded with changes-of-mind about the reliability of the preferred option. Here, we exploited the fact that information seeking requires control over which option to sample to isolate its behavioral and neurophysiological signatures. Methods. We employed an adaptive decision-making task that allows comparing the formation and revision of uncertain beliefs between controllable and uncontrollable conditions. We contrasted changes-of-mind occurring with and without control over information sampling. We tested four variants of this cognitive task for ensuring generalisability of our findings (N=84). Results. Behaviorally, we found that changes-of-mind required more evidence against current beliefs in controllable environments. These changes of mind were also associated with reduced confidence, but were nevertheless more likely to be confirmed on the next trial. Computational modelling explained these behavioural effects through more stable beliefs, rather than a reduced sensitivity to incoming evidence in controllable environments. Multimodal neurophysiological recordings showed that changes-of-mind occurring in controllable environments were preceded by a stronger involvement of a dorsal attentional network in magnetoencephalography, and followed by an increased pupil-linked arousal during decision evaluation. Conclusions. By bridging across historically distinct fields of decision research, these findings characterise specific signatures of human information seeking in controllable environments, and indicate that information seeking increases the saliency of evidence perceived as the direct consequence of one's own actions.

THE EFFECT OF HUNGER ON ATTENTION AND VALUATION IN PREFERENTIAL CHOICE

POSTER SESSION 05 - SECTION: DECISION-MAKING

Jennifer March
Universität Hamburg, Psychology, Hamburg, Germany

Hunger has been shown to affect food choices, such that hungrier participants prefer more hedonic food options. Eye-tracking and neuroimaging studies suggest that hunger induces an attentional bias towards hedonic food options and impairs cognitive control mechanisms as demonstrated by enhanced activation in the dorsolateral prefrontal cortex. Yet, the extent to which this attention-driven impairment applies to other forms of value-based decisions remains elusive. To fill this gap, we asked participants to make three different types of value-based choices (food choice, social preference, and delay discounting; within-subject design) in a hungry and a satiated state while their eye-movements were being recorded. We hypothesize that the effect of hunger on value-based choice is strongest for the food choice task, while we also predict substantial spill-over effects on social preference and delay discounting such that people make more self- and presence-oriented decisions when being hungry. In addition, we predict a modulating role of attention in all three choice tasks. More specifically, participants are expected to attend to hedonic food options as well as to self- and presence-oriented information earlier and longer which modulates the ultimate decision. Behavioral and computational modeling analyses will be conducted to investigate these hypotheses, including the implementation of a dynamic process model of decision making (i.e., a multi-alternative and time-dependent attentional drift diffusion model). We will present the results of our data, which will elucidate the effect of hunger on attentional dynamics and preference formation across various types of value-based decisions.

EFFICIENT COMPRESSION OF SENSORY INFORMATION DURING CATEGORICAL DECISIONS

POSTER SESSION 05 - SECTION: DECISION-MAKING

Julie Drevet[1], Qiao Zheng[2], Jan Drugowitsch[2], Valentin Wyart[1]
[1]Ecole Normale Superieure, Laboratoire De Neurosciences Cognitives Et Computationnelles, Inserm U960, Département D'etudes Cognitives, Paris, France, [2]Harvard Medical School, Department Of Neurobiology, Boston, United States of America

Perceptual decisions rely on a cognitive inference process that extracts the statistics of ambiguous sensory observations through imprecise computations. But theories diverge regarding whether this inference process integrates information in its native sensory space or in a compressed category space defined by current decision alternatives. Here we designed a visual categorization task in which we manipulated the ability of human observers to perform inference in sensory and category spaces. We found that human observers spontaneously integrate sensory information in category space by projecting it on the decision axis, upstream from inference. When observers are forced to integrate sensory information in its native space, they do so with lower precision and larger information loss. Magnetoencephalographic (MEG) brain activity showed compressed neural representations of stimulus and decision signals in conditions where observers perform inference in category space. Together, these findings indicate that humans mitigate the costs of imprecise inference by focusing limited resources on decision-relevant information.

COGNITIVE PROCESSES AND PERSONALITY TRAITS ASSOCIATED WITH PHENOTYPES OF SUSCEPTIBILITY TO (MIS)INFORMATION.

POSTER SESSION 05 - SECTION: DECISION-MAKING

Rafal Rygula[1], Karolina Noworyta[1], Michal Piksa[1], Jan Piasecki[2], Jonas Kunst[3], Aleksander Gundersen[3], Pawel Gwiazdzinski[2]
[1]Maj Institute of Pharmacology Polish Academy of Sciences, Department Of Pharmacology, Krakow, Poland, [2]Jagiellonian University Medical College, Faculty Of Health Sciences, Department Of Philosophy And Bioethics, Krakow, Poland, [3]University of Oslo, Department Of Psychology, Oslo, Norway

Misinformation poses a serious threat to modern societies. Thus, one of the biggest scientific challenges of this decade is to investigate the nature of cognitive mechanisms and personality traits that contribute to the assessment of news' veracity, failures in the discernment of their truthfulness, and the scale of behavioral engagement.
Our research aimed to establish cognitive mechanisms and psychological traits associated with various phenotypes of susceptibility to information.
For this, the participants completed online surveys that consisted of a new scale designed to classify people into one of four phenotypes of susceptibility to true and false information, advanced cognitive tests, and reliable psychological instruments.
The four identified phenotypes: doubters, knowers, duffers, and consumers, showed that believing in misinformation does not imply denying the truth. In contrast, the numerically largest phenotypes encompassed individuals who were either susceptible (consumers) or resistant (doubters), in terms of veracity judgment and behavioral engagement, to any news, regardless of its truthfulness. Significantly less numerous were the phenotypes characterized by excellent and poor discernment of the news' truthfulness (the knowers and the duffers, respectively). The phenotypes significantly differed in sensitivity to positive and negative feedback, cognitive judgment bias, extraversion, conscientiousness, agreeableness, emotional stability, grandiose narcissism, anxiety, and dispositional optimism.
Presented results reveal cognitive and psychological mechanisms underlying susceptibility to (mis)information.
The research leading to these results has received funding from the EEA Financial Mechanism 2014-2021. Project: 2019/35/J/HS6/03498.

DECISIONS ARE GUIDED BY LEARNING AND PERCEPTUAL BIASES IN A 2-ALTERNATIVE-FORCED-CHOICE TASK

POSTER SESSION 05 - SECTION: DECISION-MAKING

Elena Menichini[1], Liang Zhou[2], Victor Pedrosa[1], Peter Latham[2], Athena Akrami[1]
[1]University College London, Sainsbury Wellcome Centre, London, United Kingdom, [2]University College London, Gatsby Unit, London, United Kingdom

Traditionally, improved performance is a key hallmark of learning. However, even if the process of learning may eventually lead to near-perfect performance, the learning trajectory depends on many factors, such as trial order or how the task is represented. In addition, a myriad number of biases affect human and animal performance, for instance serial (Fritsche et al. 2017), choice (Busse et al. 2011, Abrahamyan et al. 2016) or sensory history biases (Akrami et al. 2018, Ashourian et al. 2011) in perceptual decision-making tasks. Here, we find that rats and humans show different learning patterns in a 2-alternative forced-choice (2AFC) task involving the categorization of auditory stimuli based on a perceptual boundary. We show that models based only on feedback-dependent learning, including those incorporating statistical decision confidence, are not sufficient to explain data about the effect of a previous stimulus on the current stimulus. Instead, we identify a stimulus-dependent repulsion effect that contributes to learning in this task. This repulsion effect, in tandem with a feedback-dependent component that may depend on confidence, can recreate patterns in the data with high fidelity. From there, we further isolate the stimulus-dependent component in a separate experiment that limits feedback to only a certain portion of trials and find that purely stimulus-dependent learning can account for the data. We conclude that both stimulus-dependent and feedback-dependent processes are necessary to explain patterns of learning.

COMPETING COGNITIVE PRESSURES ON HUMAN EXPLORATION IN THE ABSENCE OF TRADE-OFF WITH EXPLOITATION

POSTER SESSION 05 - SECTION: DECISION-MAKING

Clemence Almeras[1], Valérian Chambon[2], Valentin Wyart[1]
[1]Ecole normale supérieure, Département D'etudes Cognitives, Laboratoire De Neurosciences Cognitives Et Computationnelles, Inserm U960, Paris, France, [2]Ecole normale supérieure, Département D'etudes Cognitives, PARIS, France

Exploring novel environments through sequential sampling is essential for efficient decision-making under uncertainty. In the laboratory, human exploration has been studied in situations where exploration is traded against reward maximisation. By design, these 'explore-exploit' dilemmas confound the behavioural characteristics of exploration with those of the trade-off itself. Moreover, outside the laboratory, most choices do not yield immediate rewards. Aims: Here we wanted to document the novel patterns of human exploration arising when exploration is released from its trade-off with reward maximisation. Methods: We designed a novel sequential sampling task where exploration can be studied and compared in the presence and absence of a trade-off. Detailed model-based analyses of choice behaviour reveal specific patterns arising only in situations where information seeking is not weighed against reward seeking. Results: As expected, human choices are directed toward the most uncertain option available, but only after an initial sampling phase consisting of choice streaks from each novel option. These findings outline competing cognitive pressures on information seeking: the repeated sampling of the current option (for hypothesis testing), and the directed sampling of the most uncertain option available (for structure mapping). Interestingly, these two forms of information seeking are co-expressed in the same participants. Conclusions: This task overcomes the long-standing confound between the behavioural signatures of exploration and those of explore-exploit dilemmas. Second, our findings provide compelling insights into an undocumented competition between local and global forms of information seeking, that is only expressed when exploration is not traded-off against reward maximisation.

HISTORY-DEPENDENT PRIORS AS A MODEL FOR ANIMAL BEHAVIOUR IN WORKING MEMORY AND STIMULUS PREDICTION TASKS

POSTER SESSION 05 - SECTION: DECISION-MAKING

Victor Pedrosa[1], Athena Akrami[1], Yonatan Loewenstein[2]
[1]University College London, Sainsbury Wellcome Centre, London, United Kingdom, [2]The Hebrew University of Jerusalem, The Edmond And Lily Safra Center For Brain Sciences, Jerusalem, Israel

Animals integrate sensory evidence to make decisions. These decisions are by various types of history-dependent biases. Several models have been proposed to account for how humans use past experience to inform decision making. Most normative models assume that humans interpret new sensory evidence by integrating a noisy sensory stimulus with a time-invariant prior. However, subjects rarely have access to the entire sensory evidence at once. Here, we propose that subjects' priors evolve over time following exposure to new sensory evidence. Due to the continuous update of their priors, subjects use an estimated and imperfect prior to making decisions. By simulating a delayed comparison task, we show that our model can account for contraction bias and serial dependency. In addition, our model suggests that individuals can develop a positive feedback loop, due to sequential updates of their priors, and exhibit a form of perceptual confirmation bias. The intensity of this bias depends on internal, individual-dependent parameters and external sensory noise. We test the predictions from our model on human subjects performing a stimulus prediction task. In agreement with our predictions, we observe heterogeneity in participants' performance with some participants showing signatures of perceptual confirmation bias. The complex behaviour shown in this task could not be accounted for by any other model that integrates evidence over time whose prior remains unchanged over time. Instead, our model, based on continuous estimation of priors, provides a simple theoretical framework that accounts for human and animal behaviour in both working memory and stimulus prediction tasks.

Network-centered homeostasis through inhibition maintains hippocampal spatial map and cortical circuit function.
Despite ongoing experiential change, neural activity maintains remarkable stability. Although this is thought to be mediated by homeostatic plasticity, what aspect of neural activity is conserved and how the flexibility necessary for learning and memory is maintained is not fully understood. Experimental studies suggest that there exists network-centered, in addition to the well-studied neuron-centered, control. Here we computationally study such a potential mechanism: input-dependent inhibitory plasticity (IDIP). In a hippocampal model, we show that IDIP can explain the emergence of active and silent place cells as well as remapping following silencing of active place cells. Furthermore, we show that IDIP can also stabilize recurrent dynamics while preserving firing rate heterogeneity and stimulus representation, as well as persistent activity after memory encoding. Hence, the establishment of global network balance with IDIP has diverse functional implications and may be able to explain experimental phenomena across different brain areas.

The interplay between somatic and dendritic inhibition promotes the emergence and stabilization of place fields.
During the exploration of novel environments, place fields are rapidly formed in hippocampal CA1 neurons. Place cell firing rate increases in early stages of exploration of novel environments but returns to baseline levels in familiar environments. Although similar in amplitude and width, place fields in familiar environments are more stable than in novel environments. We propose a computational model of the hippocampal CA1 network, which describes the formation, dynamics and stabilization of place fields. We show that although somatic disinhibition is sufficient to form place fields, dendritic inhibition along with synaptic plasticity is necessary for place field stabilization. Our model suggests that place cell stability can be attributed to strong excitatory synaptic weights and strong dendritic inhibition. We show that the interplay between somatic and dendritic inhibition balances the increased excitatory weights, such that place cells return to their baseline firing rate after exploration. Our model suggests that different types of interneurons are essential to unravel the mechanisms underlying place field plasticity. Finally, we predict that artificially induced dendritic events can shift place fields even after place field stabilization.

Activity-Dependent Downscaling of Subthreshold Synaptic Inputs during Slow-Wave-Sleep-like Activity In Vivo.
Activity-dependent synaptic plasticity is critical for cortical circuit refinement. The synaptic homeostasis hypothesis suggests that synaptic connections are strengthened during wake and downscaled during sleep; however, it is not obvious how the same plasticity rules could explain both outcomes. Using whole-cell recordings and optogenetic stimulation of presynaptic input in urethane-anesthetized mice, which exhibit slow-wave-sleep (SWS)-like activity, we show that synaptic plasticity rules are gated by cortical dynamics in vivo. While Down states support conventional spike timing-dependent plasticity, Up states are biased toward depression such that presynaptic stimulation alone leads to synaptic depression, while connections contributing to postsynaptic spiking are protected against this synaptic weakening. We find that this novel activity-dependent and input-specific downscaling mechanism has two important computational advantages: (1) improved signal-to-noise ratio, and (2) preservation of previously stored information. Thus, these synaptic plasticity rules provide an attractive mechanism for SWS-related synaptic downscaling and circuit refinement.

Interneuron-specific plasticity at parvalbumin and somatostatin inhibitory synapses onto CA1 pyramidal neurons shapes hippocampal output.
The formation and maintenance of spatial representations within hippocampal cell assemblies is strongly dictated by patterns of inhibition from diverse interneuron populations. Although it is known that inhibitory synaptic strength is malleable, induction of long-term plasticity at distinct inhibitory synapses and its regulation of hippocampal network activity is not well understood. Here, we show that inhibitory synapses from parvalbumin and somatostatin expressing interneurons undergo long-term depression and potentiation respectively (PV-iLTD and SST-iLTP) during physiological activity patterns. Both forms of plasticity rely on T-type calcium channel activation to confer synapse specificity but otherwise employ distinct mechanisms. Since parvalbumin and somatostatin interneurons preferentially target perisomatic and distal dendritic regions respectively of CA1 pyramidal cells, PV-iLTD and SST-iLTP coordinate a reprioritisation of excitatory inputs from entorhinal cortex and CA3. Furthermore, circuit-level modelling reveals that PV-iLTD and SST-iLTP cooperate to stabilise place cells while facilitating representation of multiple unique environments within the hippocampal network.

The Role of Neuromodulators in Cortical Plasticity. A Computational Perspective.
Neuromodulators play a ubiquitous role across the brain in regulating plasticity. With recent advances in experimental techniques, it is possible to study the effects of diverse neuromodulatory states in specific brain regions. Neuromodulators are thought to impact plasticity predominantly through two mechanisms: the gating of plasticity and the upregulation of neuronal activity. However, the consequences of these mechanisms are poorly understood and there is a need for both experimental and theoretical exploration. Here we illustrate how neuromodulatory state affects cortical plasticity through these two mechanisms. First, we explore the ability of neuromodulators to gate plasticity by reshaping the learning window for spike-timing-dependent plasticity. Using a simple computational model, we implement four different learning rules and demonstrate their effects on receptive field plasticity. We then compare the neuromodulatory effects of upregulating learning rate versus the effects of upregulating neuronal activity. We find that these seemingly similar mechanisms do not yield the same outcome: upregulating neuronal activity can lead to either a broadening or a sharpening of receptive field tuning, whereas upregulating learning rate only intensifies the sharpening of receptive field tuning. This simple model demonstrates the need for further exploration of the rich landscape of neuromodulator-mediated plasticity. Future experiments, coupled with biologically detailed computational models, will elucidate the diversity of mechanisms by which neuromodulatory state regulates cortical plasticity.

PREFERENTIAL DECISIONS BY ASSOCIATION: THE INTERPLAY OF INTERNAL PREFERENCE ON HUMANS' EXTERNAL PERCEPTION

POSTER SESSION 05 - SECTION: DECISION-MAKING

Aysegul Ozkan, Jiaxiang Zhang
Cardiff University, Brain Research Imaging Centre, School Of Psychology, Cardiff, United Kingdom

Every day, everyone makes hundreds of decisions based on different types of information. In perceptual decisions, we aim to make a correct choice based on external information. In preference-based decisions, one's choices are dependent on their internal, subjective evaluations. Although these two types of decisions have been extensively investigated, less is known on direct comparisons between the two decision domains. The current study examined decision performance under the contexts of internal preference and external perception. To this end, sixty human participants performed an internet-based choice paradigm, using identical visual stimuli for both types of decisions. We parametrically morphed geometric shapes to vary between circle-like and diamond-like stimuli. Preference-based decisions, participants remembered mappings between different shapes and food items at different levels of subjective preference, and the participants were then required to decide whether a visual stimulus is associated with food items they prefer. Using the same set of visual stimuli, participants performed perceptual decisions in discriminating whether a given stimulus is more like a circle or a diamond. We showed that assigning internal preference values to geometric shapes led to a lower discriminating sensitivity than perceptual decisions, indexed by a decreased Weber ratio. There was no difference in participants' response bias between the two types of decisions. Preference decisions were associated with longer reaction time than perceptual decisions across stimulus levels. Our results suggested that a common computational process may underly preference-based and perceptual decisions and mapping internal preference onto external perceptual information results in additional noise in the decision-making process.

RODENTS MONITOR THEIR ERROR IN SELF-GENERATED DURATION ON A SINGLE TRIAL BASIS

POSTER SESSION 05 - SECTION: DECISION-MAKING

Tadeusz Kononowicz[1], Virginie Van Wassenhove[2], Valérie Doyère[3]
[1]Polish Academy of Sciences, Institute Of Psychology, Warszawa, Poland, [2]CEA NeuroSpin, Inserm Cognitive Neuroimaging Unit, Gif-sur-Yvette, France, [3]CNRS, Université Paris-Saclay, Institut Neuropsi, Saclay, France

When faced with a deadline, individuals' behavior suggests that they represent the mean and the uncertainty of an internal timer to make near-optimal time-dependent decisions. Whether this ability relies on simple trial-and-error adjustments, or whether it involves richer representations, is unknown. Richer representations enable a possibility of error monitoring, that is, the ability for an individual to assess its internal representation of the world and estimate discrepancy in the absence of external feedback. While rodents show timing behavior, whether they can represent and report temporal errors in their own produced duration on a single trial basis is unknown. We designed a novel paradigm requiring rats to produce a target time interval to receive a reward in a given location depending on the magnitude of their timing errors. During the test-trials, rats had to choose a port corresponding to the error magnitude of their just-produced duration to receive a reward. High choice accuracy demonstrates that rats kept track of the values of the timing variables on which they based their decision. Additionally, they kept a representation of the mapping between those timing values and the target value, as well as the history of the reinforcements. The results show for the first time that rats track their own timing errors, deepening our understanding of error monitoring abilities in rodents and the richness of their representation of elapsed time. This paradigm offers a new way to research the neural architecture underlying the ability of neural systems to monitor their own computations.

BAYESIAN ANALYSIS OF BEHAVIOURAL STRATEGIES AT TRIAL-RESOLUTION DURING TACTILE REVERSAL LEARNING

POSTER SESSION 05 - SECTION: DECISION-MAKING

Adam Chapman[1], Jasper Teutsch[1,2], Fritjof Helmchen[2], Mark Humphries[3], Silvia Maggi[3], Abhishek Banerjee[1,2]
[1]Newcastle University, Adaptive Decisions Lab, Biosciences Institute, Newcastle upon Tyne, United Kingdom, [2]University of Zurich, Brain Research Institute, Zurich, Switzerland, [3]University of Nottingham, School Of Psychology, Nottingham, United Kingdom

The ability to continuously discount evidence based on accumulated sensory and contextual information is an essential component of flexible behaviour. However, how animals modify their behavioural strategies to adapt to environmental changes remains understudied. To study the psychophysics of flexible behaviour, we implemented a Bayesian evidence accumulation model to track the probability of strategy implementation on a trial-by-trial basis. Mice were trained on a 'Go/No-go' tactile reversal learning task. We tested multiple choice-driven, cue-driven and history-dependent strategies, finding that naïve WT mice adopted a choice-driven approach during learning, followed by an increase in cue-driven strategies once expert. Following the reversal, naïve mice adopted choice-driven strategies in a greater proportion, with expert mice showing choice-driven and cue-driven strategies returning to pre-reversal adoption faster than during initial learning. Thus mice evolved their behavioural strategy both during and after learning, with task features guiding choice. Pharmacogenetic silencing of medial and lateral orbitofrontal cortex (mOFC and lOFC, respectively), areas contributing to feature-driven strategies, caused global increases in choice-driven strategy adoption. Silencing mOFC caused more exploratory strategies to emerge in response to reward omission, suggesting decreased bias towards the immediate reward. Lateral OFC silencing showed a sudden shift from purely choice-driven strategies while naive to purely cue-driven strategies at expert, implying a role of the lOFC in leveraging prior knowledge in response to novel stimuli. Our analysis sheds light on rule-based strategies underlying flexible behaviour and critical contributions of mOFC and lOFC in flexibly adapting behavioural strategy implementation through reward feedback and past experience.

IMPACT OF GAINING OR LOSING ON THE VIGOR OF ARM REACHING MOVEMENTS DURING DECISION-MAKING IN NON-HUMAN PRIMATES

POSTER SESSION 05 - SECTION: DECISION-MAKING

Milesa Simic, Hugues Orignac, Tho Haï Nguyen, Thomas Boraud, Marc Deffains
Université de Bordeaux, Imn, Umr Cnrs 5293, Bordeaux, France

In essence, decision-making is a higher-order brain function that consists in choosing between options. Basing decisions on expected value (defined as the product of the probability of reward associated to an option and the magnitude of that reward) maximizes future-discounted cumulative reward. Remarkably, people and animals have been shown to respond and move faster to outcomes they value more (i.e., with higher expected values). However, how movement vigor (i.e., latency and velocity of movement) is modulated when actions/choices aim at maximizing gains or minimizing losses is still unclear. To clarify this aspect, we trained two rhesus monkeys in a task where they had to choose by performing arm reaching movements between two lotteries that probabilistically predicted different quantities of gains or losses of the same reward. In doing so, we observed that animals chose the best option less frequently when lotteries involved potential losses rather than potential gains. Additionally, we found that latency (defined by reaction time) and velocity (defined by movement time) were longer when animals tried to minimize their losses rather than maximizing their gains. Finally, slower movements when lotteries involved potential losses was found both for lottery pairs with the same probabilities and different quantities and for lottery pairs with the different probabilities and same quantities. These behavioral results therefore suggest that asymmetry in the processing of gains and losses during decision making in non-human primates is not only observable through choice, but is also reflected in the vigor of arm reaching movements.

ACCUMULATION OF EVIDENCE DURING PERCEPTUAL DECISION-MAKING IN MICE

POSTER SESSION 05 - SECTION: DECISION-MAKING

Alexis Cerván, Carles Sindreu, Jaime De La Rocha
Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Brain Circuits And Behavior Lab, Barcelona, Spain

During perceptual decision-making, neural circuits must faithfully represent relevant stimulus features, transform them into decision evidence, accumulate this evidence along the stimulus duration and commit to a choice. However, despite the central role that this computation has in decision-making, the dynamics of evidence accumulation are not yet well understood. Here, we have developed a novel auditory two-alternative forced-choice (2AFC) task, in which head-fixed mice listen to two concomitant, intensity-fluctuating stimuli, each presented through a speaker on either side of the head. Mice have to infer which sound (left or right) was louder on average and lick in the associated spout to receive a water reward. We find that mice can learn the task and show a sigmoid probability of a rightward choice. However, the temporal weighting of the evidence is not generally uniform and can be idiosyncratic as revealed by reverse correlation analysis (i.e. psychophysical kernels). Moreover, we find that mice exhibit a tendency to repeat their previous response and that this trial history bias is best explained as repeating lapses rather than a bias term that alters the decision criteria of the categorization, that is an upward rather than horizontal shift of the psychometric curve (repeating lapse = 0.21 ± 0.04, alternating lapse = 0.05 ± 0.01; p=0.001, n=7 mice, data are mean ± s.e.m., two-tailed paired-samples t-test). Together, our results show that evidence integration is heterogeneous across individuals and that is affected by non-sensory biases that limit subjects' performance.

Higher Order Visual Areas Enhance Stimulus Responsiveness in Mouse Primary Visual Cortex.
Over the past few years, the various areas that surround the primary visual cortex (V1) in the mouse have been associated with many functions, ranging from higher order visual processing to decision-making. Recently, some studies have shown that higher order visual areas influence the activity of the primary visual cortex, refining its processing capabilities. Here, we studied how in vivo optogenetic inactivation of two higher order visual areas with different functional properties affects responses evoked by moving bars in the primary visual cortex. In contrast with the prevailing view, our results demonstrate that distinct higher order visual areas similarly modulate early visual processing. In particular, these areas enhance stimulus responsiveness in the primary visual cortex, by more strongly amplifying weaker compared with stronger sensory-evoked responses (for instance specifically amplifying responses to stimuli not moving along the direction preferred by individual neurons) and by facilitating responses to stimuli entering the receptive field of single neurons. Such enhancement, however, comes at the expense of orientation and direction selectivity, which increased when the selected higher order visual areas were inactivated. Thus, feedback from higher order visual areas selectively amplifies weak sensory-evoked V1 responses, which may enable more robust processing of visual stimuli.

RULE AWARENESS IN MICE PREDICTS CAPACITY TO GENERALIZE RULES TO NEW STIMULI.

POSTER SESSION 05 - SECTION: DECISION-MAKING

Bas Van Gorp[1], Tim Schröder[2], Anna Beltramini[3], Paul Tiesinga[4], Richard Van Wezel[5], Martha Havenith[6]
[1]Radboud University, Donders Institute For Brain, Cognition And Behaviour, Nijmegen, Netherlands, [2]Radboud University Nijmegen, Donders Center For Neuroscience, Nijmegen, Netherlands, [3]Maastricht University, Faculty Of Psychology And Neuroscience, Maastricht, Netherlands, [4]Radboud University Nijmegen, Neuroinformatics, Donders Institute, Nijmegen, Netherlands, [5]Donders Institute for Brain, Cognition and Behaviour, Biophysics, Nijmegen, Netherlands, [6]Ernst Strüngmann Institute for Neuroscience in Cooperation with Max Planck Society, Zero Noise Lab, Frankfurt am Main, Germany

The ability to apply acquired knowledge to new contexts brings clear advantages - when it is confined to appropriately similar situations. Successful behaviour must therefore balance utilizing known rules and acquiring new ones. Here we show that mice apply one of two learning strategies when faced with a visual dicrimination task featuring increasingly varied stimuli: While some mice applied a learned rule to new stimuli without delay (generalizers), others repeatedly acquired a new rule for each new stimulus pair (re-learners). To characterize these different learning strategies, we trained head-fixed mice to approach either horizontal or vertical grey-scale stimuli in a virtual environment, with the range of stimuli increasing gradually. The animals' capacity to generalize their learned orientation preference to new stimuli was predicted by their ability to predict trial outcomes for the original stimuli: Animals that behaved more hesitantly in incorrect than in correct trials, signaling uncertainty about their stimulus choice, were also better able to generalize their behaviour to new stimuli. This suggests that the degree to which different animals adhere to learned rules is a stable cognitive processing style that appears to apply across different contexts. Finally, we connect these two learning styles to neuronal response preferences in primary visual cortex.

A COMPUTATIONAL AND EXPERIMENTAL FRAMEWORK FOR TESTING THEORIES OF LEARNING

POSTER SESSION 05 - SECTION: DECISION-MAKING

Samuel Liebana Garcia[1], Aeron Laffere[1], Peter Zatka-Haas[1], Rafal Bogacz[2], Armin Lak[1], Andrew Saxe[3]
[1]University of Oxford, Department Of Physiology, Anatomy, And Genetics, Oxford, United Kingdom, [2]University of Oxford, Mrc Brain Network Dynamics Unit, Oxford, United Kingdom, [3]UCL, Gatsby Computational Neuroscience Unit & Sainsbury Wellcome Centre, London, United Kingdom

Learning to make decisions underlies many aspects of our behavior. As such, understanding the neural mechanisms of learning is a fundamental goal in systems neuroscience. However, despite proliferating theories and large datasets, testing theories of learning remains challenging. Experiments often only approximately control the learning epoch, making the interpretation of learning trajectories difficult; and modern theories of learning (such as deep RL networks) are often complex and hard to fit to data. Here we address this gap with a three-fold approach: first, we introduce a perceptual decision-making paradigm for mice that remains unaltered across the whole learning epoch, such that the learning period is well-controlled (see poster by Laffere et al.). Second, we develop a software toolbox that leverages the automatic differentiation, Just-in-time (JIT) compilation, and GPU acceleration enabled by the JAX software library to enable fast trial-by-trial fitting of diverse and reasonably complex models to behavior. And third, we employ model reduction methods to introduce a class of models that retain key features of more complex theories of learning, such as ‘depth’, while remaining tractable. We describe learning trajectories of tens of mice trained in the task, and show that a `deep’ model with a combined goal-directed (reward-dependent) and habitual (action-dependent) learning rule best fits the data. More broadly, our framework takes a step towards linking modern theories of learning to large-scale data being generated by systems neuroscience, offering a potential route to testing theories of learning in the brain and mind.

Bilateral Intracranial Beta Activity During Forced and Spontaneous Movements in a 6-OHDA Hemi-PD Rat Model.
Cortico-basal ganglia beta oscillations (13-30 Hz) are assumed to be involved in motor impairments in Parkinson's Disease (PD), especially in bradykinesia and rigidity. Various studies have utilized the unilateral 6-hydroxydopamine (6-OHDA) rat PD model to further investigate PD and test novel treatments. However, a detailed behavioral and electrophysiological characterization of the model, including analyses of popular PD treatments such as DBS, has not been documented in the literature. We hence challenged the 6-OHDA rat hemi-PD model with a series of experiments (i.e., cylinder test, open field test, and rotarod test) aimed at assessing the motor impairments, analyzing the effects of Deep Brain Stimulation (DBS), and identifying under which conditions excessive beta oscillations occur. We found that 6-OHDA hemi-PD rats presented an impaired performance in all experiments compared to the sham group, and DBS could improve their overall performance. Across all the experiments and behaviors, the power in the high beta band was observed to be an important biomarker for PD as it showed differences between healthy and lesioned hemispheres and between 6-OHDA-lesioned and sham rats. This all shows that the 6-OHDA hemi-PD model accurately represents many of the motor and electrophysiological symptoms of PD and makes it a useful tool for the pre-clinical testing of new treatments when low β (13-21 Hz) and high β (21-30 Hz) frequency bands are considered separately.
