FENS Forum 2022
9-13 July 2022 | Paris, France

Table of contents:

- **Poster Session 03**:
  - Poster Session 03 - Section: Functional Connectivity and Cognition
  - Poster Session 03 - Section: The Social Brain: From Genes to Behavior
  - Poster Session 03 - Section: Midbrain and Forebrain Function in Stress and Emotion
  - Poster Session 03 - Section: Development of Cortical Circuitry
  - Poster Session 03 - Section: Neurons and Glia: Cell Excitability
  - Poster Session 03 - Section: Synaptic Function and Neurotransmission
  - Poster Session 03 - Section: Glutamate Receptors and Their Modulation
  - Poster Session 03 - Section: Astrocytes and Microglia
  - Poster Session 03 - Section: Multiple Sclerosis: Biomarkers, Pathogenesis and Therapies
  - Poster Session 03 - Section: Amyotrophic Lateral Sclerosis
  - Poster Session 03 - Section: Neuroimmune Mechanisms Mediating Dysfunction in Autism
  - Poster Session 03 - Section: Gut-Brain Axis and the Modulation of Appetite
  - Poster Session 03 - Section: Brain Computer Interface
  - Poster Session 03 - Section: Cochlear & Subcortical Auditory Processing
  - Poster Session 03 - Section: Coding in Visual Cortex
  - Poster Session 03 - Section: Oscillations in the Brain

- **Poster Session 04**:
  - Poster Session 04 - Section: Mental Health, Addiction and Obsessive-Compulsive Disorder
  - Poster Session 04 - Section: Neural Correlates of Social Interactions
  - Poster Session 04 - Section: Attention and Perception
  - Poster Session 04 - Section: Neurostimulation and Neurofeedback
  - Poster Session 04 - Section: Novel Neural Interfaces for Stimulation & Tracking
  - Poster Session 04 - Section: Ion Channels & Excitability
  - Poster Session 04 - Section: Astrocyte Function and Dysfunction
  - Poster Session 04 - Section: Epigenetics of the Nervous System
  - Poster Session 04 - Section: The Brain and Metabolism
  - Poster Session 04 - Section: Brain Hypoxia-Ischemia and Inflammation
  - Poster Session 04 - Section: Spinal Cord, Peripheral Nerve Injury and Regeneration
  - Poster Session 04 - Section: Traumatic Brain Injury
  - Poster Session 04 - Section: Cerebellar Computation and Motor Learning
  - Poster Session 04 - Section: Cluster 90: Movement: spinal cord and motor neurons
  - Poster Session 04 - Section: Somatosensory Processing
  - Poster Session 04 - Section: Visual System, From Retina to Cortex
  - Poster Session 04 - Section: Alzheimer's Disease and Neurodegeneration
  - Poster Session 04 - Section: Risk Factors and Treatment of Mood Disorders
  - Poster Session 04 - Section: Epilepsy and Epileptogenesis
  - Poster Session 04 - Section: Neurodevelopmental Disorders

- **Poster Session 05**:
  - Poster Session 05 - Section: Spatial Navigation and Memory
  - Poster Session 05 - Section: Temporal Cognition, Rhythms & Attention
  - Poster Session 05 - Section: Decision-Making
  - Poster Session 05 - Section: Reward & Addiction Mechanisms
  - Poster Session 05 - Section: Animal Models of Psychiatric Disorders and Preclinical Pharmacology
  - Poster Session 05 - Section: Alzheimer's Disease: From NeuroInflammation to Neuroprotection
  - Poster Session 05 - Section: Neuroinflammation and Autoimmunity
  - Poster Session 05 - Section: Glial Cells and Myelination
  - Poster Session 05 - Section: Evo-Devo - Evolutionary Developmental Neuroscience
  - Poster Session 05 - Section: Pluripotent Stem Cells in Disease Modeling
  - Poster Session 05 - Section: Cellular Architecture of the Brain
  - Poster Session 05 - Section: Interneurons and Dendrites
  - Poster Session 05 - Section: Neuronal Interactions and Synchronization
  - Poster Session 05 - Section: Multisensory Integration
  - Poster Session 05 - Section: Modeling the Brain
  - Poster Session 05 - Section: Emerging Technologies & Methods
  - Poster Session 05 - Section: Neuropathic Pain, Analgesia, & Therapeutics

Mini Conference

FENS Forum 2022
9-13 July 2022 | Paris, France

PRESENTATION NUMBER: MC001

ESSENTIAL FOR THE SYNAPSE: ADNP IS A MAJOR REGULATOR OF DEVELOPMENT AND AGING

MINI CONFERENCE 02: MOLECULAR BASIS FOR SYNAPTIC FUNCTION HIGHLIGHTING DISEASE MECHANISMS. ORGANISED BY EUROPEAN SOCIETY FOR NEUROCHEMISTRY (ESN)

Illana Gozes
Tel Aviv University, Sagol School Of Neuroscience, Faculty Of Medicine, Tel Aviv, Israel

Activity-dependent neuroprotective protein (ADNP) and its smallest active fragment, drug candidate NAP (davunetide) were discovered and first characterized in our laboratory. *De novo* mutations in ADNP cause the autistic intellectual disability (ID) ADNP syndrome. Now, we showed that *ADNP* and related genes are somatically mutated in postmortem aged Alzheimer's disease (AD) brains correlating with increasing AD tau pathology (Ivashko-Pachima, Hadar et al., Molecular Psychiatry, 2021). We then revealed tauopathy in post-mortem 7-year-old ADNP syndrome boy (Grigg et al., Translational Psychiatry, 2020). Using CRISPR-Cas9 genome editing, we developed a mouse model carrying the most abundant ADNP syndrome mutation, showing early tauopathy and reversal by NAP treated (Karmon et al., Biological Psychiatry 2021). Mechanistically, ADNP/NAP fortify microtubules through NAP (amino acid sequence: NAPV**SIP**Q), containing a microtubule end binding proteins (EB1, EB3) domain **S**x**IP** (Ivashko-Pachima et al., J. Mol. Neurosci. 2021). NAP enhances microtubule dynamics, augmenting Tau-microtubule association and protecting against tauopathy. ADNP mutations, disrupt Tau-microtubule interaction, which is ameliorated by NAP treatment. We have further demonstrated NAP enhancement of Tau/sirtuin1(SIRT1)-microtubule interaction in human induced pluripotent stem cell-derived neural cells, with SIRT1 and its partner Forkhead Box O3 (FOXO3, also regulated by ADNP/NAP) being major controllers of healthy aging (Hadar, Kapitansky et al., Molecular Psychiatry, 2021). Lastly, STOP codon mutations in ADNP, implicated in the ADNP syndrome and in AD represent sites of natural caspase cleavage, hallmarking apoptosis (Gozes and Shazman, Frontiers in Endocrinology, 2022). Thus, NAP (davunetide) fortification of ADNP activity is predicted to be beneficial in autism and neurodegenerative diseases.

Plenary Lectures

FENS Forum 2022
9-13 July 2022 | Paris, France

PRESENTATION NUMBER: PL001

NEUROBIOLOGY OF SOCIAL AND SICKNESS BEHAVIOURS

PLENARY LECTURE 01: CATHERINE DULAC: NEUROBIOLOGY OF SOCIAL AND SICKNESS BEHAVIOURS (THE FRED KAVLI OPENING LECTURE)

Catherine Dulac
Harvard University, Mcb, Cambridge, United States of America

Social interactions are essential for animals to survive, reproduce, raise their young. Over the years, my lab has attempted to decipher the unique characteristics of social recognition: what are the unique cues that trigger distinct social behaviors, what is the nature and identity of social behavior circuits, how is the function of these circuits different in males and females and how are they modulated by the animal physiological status? In this lecture, I will describe our recent progress in understanding how different parts of the brain participate in the positive and negative control of parental behavior in males and females, providing a new framework to understand the regulation of adult-infant interactions in health and disease. I will also describe how new approaches in in situ single cell transcriptomics have enabled us to uncover specific hypothalamic cell populations involved in distinct social behaviors. Finally, I will describe our most recent work –fit for our current pandemic era—uncovering essential brain circuits underlying sickness symptoms in mice.

PRESENTATION NUMBER: PL002

FROM MEMORY TO GUT MICROBES: AN UNEXPECTED PATH TO DISCOVERY

PLENARY LECTURE 02: MAURO COSTA-MATTIOLI: FROM MEMORY TO GUT MICROBES: AN UNEXPECTED PATH TO DISCOVERY

Mauro Costa-Mattioli
Baylor College of Medicine, Department of Neuroscience, Houston, TX, United States of America

Before I describe the context of my lecture, I would ask you to consider the following question. What would be the impact on human society of a successful “universal” treatment for memory loss? Memory is essential for animal survival. For humans, memory is the ongoing, real-time narrative of our lives. When our capacity to remember is lost, we are lost to ourselves and lost to those who we love. Even with so much at stake, we still lack a therapy that can effectively reverse the effects of time and disease on human memory.
My presentation, which will focus on mechanism(s) underlying brain function and dysfunction, will be split into two parts. First, I will outline our identification of a protein homeostasis network that is crucially required for normal long-term memory formation. More importantly, I will describe how its dysfunction is emerging as the main causative mechanism underlying the cognitive decline in a wide range of memory and neurodegenerative disorders. While I will briefly describe some of our original findings, I will mainly focus on how we can now leverage this knowledge to identify new therapeutic approaches to promote brain health. Second, in a complementary line of research, I will explain how a serendipitous discovery led us to identify and dissect the causative mechanism(s) by which gut microbes impact brain development & function. I will also discuss our findings supporting an emerging concept: “targeting the brain through the gut”. We discovered that a selective non-invasive, microbial-based approach is beneficial in preclinical animal models or neurological dysfunction and more recently in human patients. Even though the talk is on a Sunday morning (8:30 am), you should consider joining us!

PRESENTATION NUMBER: PL003

HUNTINGTON'S DISEASE: FROM NEURODEVELOPMENT TO NEURODEGENERATION

PLENARY LECTURE 03: SANDRINE HUMBERT: HUNTINGTON'S DISEASE: FROM NEURODEVELOPMENT TO NEURODEGENERATION

Sandrine Humbert
Inserm U1216, Univ. Grenoble Alpes, Grenoble Institut Neurosciences, Grenoble, France

Huntington disease (HD) is a dominantly inherited neurological disorder characterized by the dysfunction and death of neurons from the cortex and the striatum. Striatal degeneration in HD is due, at least in part, to defective cortical signaling to the striatum. Symptoms in HD typically do not appear until mid-life or later. Yet huntingtin, the protein mutated in HD, and mutant huntingtin are expressed from the very beginning of life and huntingtin is essential for mouse development. Anyway, given the adult onset and dysfunction and death of adult neurons characterizing HD, most studies have focused on the toxic effects elicited by mutant huntingtin in adult post-mitotic neurons and the roles of the wild-type protein during development have been less studied. I will discuss how the huntingtin protein regulates several steps of mouse cortical development. Huntingtin maintains the pool of cycling progenitors, ensures the multipolar-bipolar transition of newborn neurons, their proper migration and maturation. In HD mice, mutant huntingtin causes mitotic spindle misorientation of dividing progenitors and decreases cortical thickness. Mutant huntingtin also interferes with the migration and maturation of post-mitotic neurons. I will also show that, as in HD mouse models, mutant huntingtin reduces the number of proliferating cells and triggers more neural progenitors to enter lineage specification prematurely in human HD mutation carrier fetuses. Finally, I will discuss how early axonal growth defects in the developing cortex contribute to presymptomatic HD signs and consider the viewing of HD with a neurodevelopmental component.

PRESENTATION NUMBER: PL004

ASSEMBLY AND OPERATION OF THE NEOCORTEX

PLENARY LECTURE 04: SONG-HAI SHI: ASSEMBLY AND OPERATION OF THE NEOCORTEX (THE HERTIE FOUNDATION LECTURE)

Song-Hai Shi
Tsinghua University, School Of Life Sciences；idg/mcgovern Institute For Brain Research, Beijing, China

The ability of the neocortex to command higher-order brain functions depends on the assembly and operation of intricate neural circuitries comprised of a vast number of diverse neurons and glia. Notwithstanding the progress made in our understanding of the initial specification and the general histology and information flow of the neocortex, the principles and mechanisms that instruct the assembly and operation of neocortical circuits remain largely elusive. The research in my laboratory has focused on searching for the common developmental commodities of neocortical circuits at both the structural and functional levels and linking them with animal behaviors under normal and disease conditions. We have analyzed the molecular and cellular mechanisms that control the production and positioning of neocortical excitatory and inhibitory neurons, as well as glia, with the premise that the origin and lineage relationship guide the formation of defined neuronal ensembles or substrates for effective functional circuit assembly. In this presentation, I will discuss our recent findings and ongoing efforts.

PRESENTATION NUMBER: PL005

THE MOLECULAR LOGIC OF SYNAPSE FORMATION

PLENARY LECTURE 05: THOMAS C. SüDHOF: THE MOLECULAR LOGIC OF SYNAPSE FORMATION (PRESIDENTIAL LECTURE)

Thomas C. Südhof
Stanford, Mcp, Stanford, United States of America

The brain processes information in million of parallel and intersecting neural circuits that compute information by transmitting and processing synaptic signals. Neural circuit computations critically depend on the number, locations and properties of their constituent synapses. We hypothesize that the construction of the neural circuits by formation of defines synapses is based on an overall simple molecular logic that is determined by interactions between pre- and postsynaptic impairments in the molecular logic of neural circuits, such that the input/output relations in affected circuits exhibit a skewed information processing capacity. In my presentation, I will discuss key drivers of the molecular logic of neural circuits, such as neurexins and their multifarious ligans or latrophilin- and BAI-adhesion GPCRs, to illustrate the broader concepts of how trans-cellular signaling drives synapse formation.

HUNGRY BRAINS AND CLEVER GUTS

PLENARY LECTURE 06: IRENE MIGUEL-ALIAGA: HUNGRY BRAINS AND CLEVER GUTS

Irene Miguel-Aliaga
MRC LMS, Imperial College London, Faculty of Medicine, London, United Kingdom

Our research group explores the idiosyncrasies of adult organs: how they differ between the sexes or across life stages, and why they engage in crosstalk with other organs. We were one of the first labs to tackle the study of the brain-gut axis using the powerful genetics of Drosophila: work that we have now extended to mouse and human models. We discovered that the brain-gut axes of males and females are very different, and that these intestinal sex differences impact food intake, gamete production and tumour susceptibility. We have also investigated how the intestine senses nutrients, revealing unexpected roles for metal sensing in the regulation of feeding and growth. I will present some of this work, as well as our ongoing attempts to shed some light on the molecular nature of this brain-gut communication and its spatiotemporal logic.

PRESENTATION NUMBER: PL007

LEARNING WITH DENDRITES IN BRAINS AND MACHINES

PLENARY LECTURE 07: PANAYIOTA POIRAZI: LEARNING WITH DENDRITES IN BRAINS AND MACHINES (TCCI PLENARY LECTURE)

Panayiota Poirazi
FORTH, Imbb, Heraklion, Crete, Greece

Dendrites are thin processes that extend from the cell body of neurons and receive the vast majority of synaptic input. Their biophysical, anatomical and plasticity properties allow them to shape incoming signals in complex ways and have thus been suggested to serve as key players in learning and memory functions. In my presentation I will discuss how computational modelling has helped us illuminate dendritic function and its role in cognitive processes. I will present the main findings of a number of projects in lab dealing with dendritic nonlinearities in excitatory and inhibitory neurons and their consequences on memory formation, the role of dendrites in solving nonlinear problems in human neurons and recent efforts to adopt dendritic features in order to improve learning in artificial systems. PRESENTATION NUMBER: PL008

DEVELOPMENTAL COGNITIVE NEUROSCIENCE IN THE ERA OF BIG DATA

PLENARY LECTURE 08: DAMIEN FAIR: DEVELOPMENTAL COGNITIVE NEUROSCIENCE IN THE ERA OF BIG DATA (THE ERA-NET NEURON LECTURE)

Damien Fair
University of Minnesota, Masonic Institute for The Developing Brain, Minneapolis, United States of America

Abstract:
Developmental cognitive neuroscience is being pulled in new directions by network science and big data. Brain imaging (e.g. functional MRI, functional connectivity MRI), analytical advances (e.g. graph theory, machine learning), and access to large computing resources have empowered us to collect and process neuro-behavioral data faster and in larger populations than ever before. The translational potential from these advances is unparallelled, as a better understanding of complex human brain function is best grounded in the onset of these functions during human development. However, the maturation of the developmental cognitive neuroscience has seen the emergence of new challenges and pitfalls, which have significantly slowed progress and need to be overcome to maintain momentum. Here I examine the state of developmental cognitive neuroscience in the era of networks and ‘big data’ and highlight the solid footing we can take forward into the future.

FENS Forum 2022

PRESENTATION NUMBER: PL009

ORGANISATION OF NEURAL ACTIVITY ACROSS THE BRAIN

PLENARY LECTURE 09: MATTEO CARANDINI: ORGANISATION OF NEURAL ACTIVITY ACROSS THE BRAIN (CLOSING PLENARY LECTURE)

Matteo Carandini
University College London, Ucl Institute Of Ophthalmology, London, United Kingdom

Neuroscience textbooks are typically arranged according to function (e.g., vision, movement, or navigation) or anatomy (e.g. visual cortex, spinal cord, or hippocampus), and often assume a relation between the two. However, new techniques that record the activity of thousands of neurons are revealing marked deviations from this view. In this talk I will provide examples of such deviations. First, I will discuss recordings from >30,000 neurons across the brain of mice involved in a simple visual decision task. Neurons that process images were found in restricted areas, including but not limited to the classical visual system; neurons predicting the animal's upcoming choices were rare, and found in a subset of these regions, with lateralized choice correlates particularly found in midbrain structures. In contrast, signals related to task engagement and to impending movements were distributed across the entire brain. Second, I will discuss recordings showing that neurons in the visual cortex carry not only visual signals but also signals encoding the animal's position in a virtual reality environment. These signals are absent in the thalamic afferents to the cortex and are coherent with those measured in the hippocampus. These results, and results from other laboratories, indicate that while some signals are encoded by localized brain circuits, others are much more distributed than one might assume from textbooks. Looking back, this suggests we should reevaluate some previous findings. Looking forward, this poses a new challenge: to understand what advantage is gained by broadcasting certain signals so widely across the brain.

FENS-EJN AWARD: IMMUNOTHERAPY TO BEAT ALZHEIMER'S DISEASE: A TRANSFORMATIVE UNDERSTANDING OF NEURODEGENERATIVE DISEASES

SPECIAL LECTURES 01: FENS - EJN AWARDS LECTURES

Michal Schwartz
The Weizmann Institute of Science, Brain Science, Rehovot, Israel

Since the time of Medawar and Burnet's Nobel prize in 1960, it has been widely accepted that the CNS cannot tolerate any immune activity under any circumstances. Our team initiated more than two decades ago a change in this dogma, by demonstrating that the brain requires support from innate and adaptive immune cells for its maintenance and repair, with implications to aging and neurodegenerative diseases. Deep understanding that neurodegenerative diseases like Alzheimer's disease (AD) encompass not only the brain but also the immune system, led us to propose that defeating such diseases could be accomplished by promoting the process of repair, by harnessing the immune system that is either exhausted or insufficient. We found that transient blocking the inhibitory PD-1/PD-L1 immune checkpoint pathway, initiates an immune response in the periphery that leads to disease modification within the brain. This approach was found to be effective regardless of disease etiology, and independent of TREM2 activity. In both models of AD and tauopathy, we found that the treatment improved behavior and reduced multiple parameters that contribute to disease escalation, including neural loss, local inflammation and phospho-tau and aggregated tau in tauopathy, soluble oligomers of amyloid beta in amyloidosis. The effect was found to be dependent on bone-marrow derived macrophages, and was also associated with homing of FoxP3 regulatory T cells. A brief intermitted treatment was found to be for long-term effect, with AD-optimized antibody. Together, these studies show that targeting the immune system provides new avenues for understanding and treating neurodegenerative diseases.

PRESENTATION NUMBER: SL002

FENS-EJN YOUNG INVESTIGATOR PRIZE: UNCOVERING HOW INHIBITORY BRAIN CIRCUITS REGULATE BEHAVIOUR

SPECIAL LECTURES 01: FENS - EJN AWARDS LECTURES

Sara Mederos
University College London, Sainsbury Wellcome Centre For Neural Circuits And Behaviour, London, United Kingdom

To pursue goal-directed behaviours, humans and animals have to select appropriate actions after evaluating all available information. Beyond their well-recognized homeostatic functions, astrocytes have emerged as relevant elements in brain physiology. Through their ability to regulate neuronal and synaptic activity, astrocytes influence neural networks. However, it is largely unknown how GABAergic interneurons and astrocytes interact and contribute to stable performance of complex animal behaviors. By combining optogenetics, gene ablation in astrocytes with electrophysiological recordings in behaving mice and ex vivo electrophysiology we have revealed interactions between astrocytes and cortical inhibitory cells, showing the significance of this pathway for sustained adaptive behaviours. We found that PV interneuron signaling recruits astrocyte networks through GABABRs activation enhancing inhibitory transmission. Additionally, the genetic ablation of GABAB receptors in medial prefrontal cortex astrocytes (GFAP/GABAB ablated mice) altered firing properties of cortical neurons, which affected decision-making. By optogenetic stimulation of astrocytes with melanopsin, a GPCRs optogenetic tool mimicking astrocytic activity, we were able to restore the cognitive disabilities shown by GFAP/GABAB ablated mice, demonstrating the ability of astrocytes to fine-tuning cortical circuits' activity, which underlies animal behavior. Therefore, our work identifies astrocytes as a hub for controlling inhibition in cortical circuits, providing a novel pathway for the behaviorally relevant midrange time-scale regulation of cortical information processing and consistent goal-directed behaviors.

FENS-EJN YOUNG INVESTIGATOR PRIZE: MAPPING NEURONAL AND VASCULAR NETWORKS IN TRANSPARENT BRAINS

SPECIAL LECTURES 01: FENS - EJN AWARDS LECTURES

Nicolas Renier
Paris Brain Institute, Sorbonne Universite, INSERM, CNRS, Laboratory Of Structural Plasticity, Paris, France

Over the past six years, there has been a convergence in the fields of optics, biochemistry, and computing, leading to dramatic improvements in light-sheet microscopy, tissue clearing protocols, and image analysis algorithms. The convergence of these different fields can streamline brain studies by accelerating data acquisition speed and reliability over the current whole-brain analysis pipelines based on serial sectioning methods. We previously developed the iDISCO+ (Renier et al., 2014) protocol for immunostaining and imaging intact adult mouse brains. As a companion tool, we also developed and distributed ClearMap (Renier et al., 2016, Liebmann et al., 2016, Kirst et al. 2020), an open-source environment to segment objects and map them onto reference atlases optimized for large 3D datasets. We used this pipeline as a discovery tool to find brain regions active in correlation with various behaviors by mapping neuronal activity landscapes derived from Fos expression (Renier et al. 2017, Nectow et al., 2017, Schneeberger Pane et al. 2019). Here, I will present how iDISCO+ and ClearMap 2 can help leverage data obtained from intact whole brain preparations. We hope that ongoing developments in light-sheet microscopy and image analysis pipelines will facilitate our understanding of individual variations in brain activity, connectivity, and structure.

FENS Forum 2022
9-13 July 2022 | Paris, France

PRESENTATION NUMBER: SL004

FENS-EJN YOUNG INVESTIGATOR PRIZE: SOMATOSENSORY NEUROPROSTHESES: CONNECT THE BRAIN TO BIONIC LIMBS

SPECIAL LECTURES 01: FENS - EJN AWARDS LECTURES

Giacomo Valle
ETH Zurich, D-hest, Zurich, Switzerland

In the recent past, several research groups are studyng the fascinating and futuristic research of connecting the human nervous system with bionic limbs. Striving to close the gap between humans and machines, this research combines the knowledge of neuroscience and medicine, as well as engineering and artificial intelligence, with the fundamentals of psychology. The research is now working to create prosthetic limbs that utilize the body's complex senses and nervous system to restore sensory-motor functions lost after an injury or a disease. Decades of technological developments have populated the field of brain-machine interfaces (BMI) and neuroprosthetics with several replacement strategies, neural modulation treatments, and rehabilitation strategies to improve the quality of life for patients affected by sensory and motor disabilities. Neuroprosthetics are implantable devices designed to replace or improve the function of a disabled part of the nervous system. Such approach has been expanded to many different applications, among which motor prosthetics, sensorimotor prosthetics, and cognitive prosthetics. The approaches for the restoration of sensory functions through neuroprostheses in amputees will be presented. This field is now quickly expanding thanks to advances in neural interfaces, machine learning techniques, and robotics. In the next future, the neurotechnologies will continue to grow thanks also to faster and more advanced computer simulations allowing to test and validate these technologies even faster. The transformation of neuro-technologies blurs the boundaries between human and machine and raises several ethical, social, and cultural questions.

PRESENTATION NUMBER: SL005

SITE OF ACTION OF DRUGS BLOCKING CGRP SIGNALING IN MIGRAINE

SPECIAL LECTURES 02: THE BRAIN PRIZE LECTURE

Lars Edvinsson
Institute of clinical sciences Lund, Department Of Medicine, Lund, Sweden

Site of action of drugs blocking CGRP signaling in migraine. Lars Edvinsson The trigeminovascular system (TGV) comprises of the trigeminal ganglion with neurons and satelitte glial cells, with sensory unmyelinated C-fibres and myelinated Aδ-fibres picking up information from different parts of the head and sending signals to the brainstem and the central nervous system (CNS). The presentation will discuss aspects of signalling at the distal parts of the sensory fibres, the extrasynaptic signalling between C-fibres and Aδ-fibres, and the contact between the trigeminal fibres at the nerve root entry zone where they transit into the CNS. We will adress the possible role of the neuropeptides calcitonin gene-related peptide (CGRP), the neurokinin family and pituitary adenylyl cyclase-activating polypeptide 38, all found in the TGV system together with their respective receptors. Elucidation of the expression and localization of neuropeptides and their receptors in the TGV system may provide novel ways to understand their roles in migraine pathophysiology and indicate novel ways for treatment of migraine patients.

CALCITONIN GENE-RELATED PEPTIDE IN CLUSTER HEADACHE
SPECIAL LECTURES 02: THE BRAIN PRIZE LECTURE

Peter Goadsby[1,2]
[1]King's College London, ., London, United Kingdom, [2]University of California, ., Los Angeles, United States of America

Cluster headache is a devastating primary headache disorder characterised by attacks of lateralised pain, a sense of restlessness and cranial autonomic features, such as lacrimation, conjunctival injection, nasal or aural symptoms. Cluster headache is one of the trigeminal-autonomic cephalalgias (TACs) (1). Calcitonin gene-related peptide (CGRP) is a neuropeptide that is found in the trigeminal (2) and sphenopalatine ganglia. CGRP is released during acute attacks of cluster headache: spontaneous (3) or nitroglycerin-evoked (4). CGRP pathway blockade with galcanezumab in patients with episodic cluster headache was effective at reducing attack frequency (5). CGRP is involved in the expression of attacks of cluster headache and has a role in some patients as an effective and well tolerated novel therapy.

PRESENTATION NUMBER: SL007

TRIGEMINOVASCULAR SYSTEM AS A MIGRAINE TARGET: HOW DID IT BEGIN AND WHEN WILL IT END?

SPECIAL LECTURES 02: THE BRAIN PRIZE LECTURE

Michael Moskowitz
MGH/Harvard, Center For Systems Biology/radiology, Charlestown, United States of America

Migraine entered the modern neuroscience era with a Lancet hypothesis in 1979. This hypothesis proposed that trigeminal meningeal afferents and their peptide neuromediators were important to the genesis of migraine headache, and as such, targets for therapy. Subsequent research on the trigeminovascular system (TV) led to mechanisms relevant to actions of ergots, triptans and 5-HT1F receptor agonists. They also identified other therapeutically relevant constituent molecules, receptors and channels that populate TV afferents including CGRP, SP, PACAP, PAR-2, prolactin, NGF and KATP and TRP ion channels, for example. Further research also identified an upstream trigger for headache in migraine with aura; cortical spreading depression (CSD), a slowly propagating intense depolarization of neurons and glia, is proinflammatory and releases noxious molecules that trigger overlying TV afferents and cause unilateral headache. It's also a target for some preventative drugs like anticonvulsants and a cause for the aura. Recently, inflammatory signals within the meninges and skull were found in migraine with aura patients. A second related discovery found CSF within dural perivascular spaces that extend from the subarachnoid space into the bone marrow via bony channels. These newly discovered channels provide a migration route for CSF-containing inflammatory signals from brain via meninges to bone. Hence, skull marrow may act as a reservoir for activated inflammatory cells and signaling molecules as recently shown in other neuroinflammatory disorders (e.g.,MS, stroke and trauma). This new body of information, inspired initially by interrogating the TV system, portends a bright future for novel migraine discoveries and therapeutic targets.

TRANSLATING MIGRAINE MOLECULAR MECHANISMS FROM MAN TO ANIMAL

SPECIAL LECTURES 02: THE BRAIN PRIZE LECTURE

Jes Olesen
University of Copenhagen, Neurology, Copenhagen, Denmark

Translational research usually means that discoveries in basic science are translated to humans. For migraine the opposite has mostly been the case. Animal models of migraine have uncertain validity, but migraine poses the unique possibility that attacks can be provoked in patients in a fully ethical fashion. Provocation experiments revealed that histamine induces migraine attacks, but antihistamines were ineffective in the treatment of migraine. Nitric oxide (NO) donors induced migraine and a non-selective nitric oxide synthase (NOS)-inhibitor was affective in migraine treatment. Selective antagonists of steps in the NO-cGMP cascade have not yet been tested. Calcitonin gene-related peptide (CGRP) induced migraine attacks and this was crucial for the development of modern CGRP antagonistic treatments of migraine that now revolutionize migraine treatment. Pituitary adenylate cyclase activating peptide (PACAP) induced migraine and a monoclonal antibody against PACAP is currently in trial. Prostanoids and several other signaling molecules, most importantly openers of ATP sensitive potassium channels (Katp) also induced migraine. Mechanisms of provoking molecules have been analyzed in detail in rodent models of migraine. They suggest that migraine induction as well as migraine treatment take place outside of the blood-brain-barrier, that CGRP antagonistic drugs and triptans are not additive, that NO mechanisms and CGRP mechanisms are closely interrelated and that PACAP is independent of CGRP. Katp channel blockers were effective in rodent models and may represent a new target for migraine treatment.

ORGANIZATION AND COMPUTATION IN NEURAL CIRCUITS DURING DEVELOPMENT

SPECIAL LECTURES 03: ERIC KANDEL PRIZE LECTURE & SCIENTIFIC AWARD CEREMONY

Julijana Gjorgjieva
Technical University of Munich, School Of Life Sciences, Freising, Germany

During early development, neural circuits in the brain generate precisely coordinated output without previous experience. This suggests that powerful developmental mechanisms drive substantial circuit organization and tuning as animals are still in the womb. These mechanisms need to be coordinated and appropriately timed at the molecular, single neuron and network level to enable animals to learn, establish a rich repertoire of computations and generate robust behaviors. I will discuss our recent theoretical and modeling work on understanding how neural circuits are built and organized during development, how they learn and adapt to sensory experience, and how they generate complex network dynamics to implement various computations. I will focus on mechanisms of synaptic plasticity that shape network connectivity and give rise to functional network dynamics. Our models are constrained by experimental data and yield new insights not only into normal brain development but also various developmental disorders.

NEUROETHICS AND AI ETHICS: TOWARDS A PRODUCTIVE INTERACTION

SPECIAL LECTURES 04: EDAB / SPECIAL LECTURE ON NEUROETHICS

Arleen Salles
Uppsala University, Center For Research Ethics And Bioethicse, Uppsala, Sweden

Beyond the important insights provided by the development of neuroscience and artificial intelligence and beyond their goal to serve society, each field raises a number of ethical, social, and regulatory issues that are generally explored by neuroethics and the ethics of AI respectively. Neuroethics and AI ethics have been gaining prominence in the last few decades but it is only recently that some neuroethicists have begun to call for their mutual collaboration. But what can neuroethics bring to the ethics of artificial intelligence? How can AI ethics contribute to the neuroethical discourse? I reflect on these questions, providing an overview of some conceptual and practical advantages of their collaboration and of foreseeable challenges.

DEVELOPMENT OF MULTICILIATED CELLS

SPECIAL LECTURES 05: HOST SOCIETY SPECIAL LECTURE

Nathalie Spassky
Institut de Biologie de l'Ecole Normale Supérieure, Biology And Neurogenesis, PARIS, France

Adult neural stem cells (NSCs) and post-mitotic multiciliated ependymal cells (E cells) are glial cells that compose the neurogenic niche in the mammalian brain. By clonal analysis of large numbers of radial glial progenitors (RGPs) using the Nucbow strategy or single-cell resolution of progenitor division patterns and fate, we and others recently showed that the vast majority of B1 and E cells are sister cells generated through sequential symmetric and asymmetric divisions. Interestingly, we also discovered that the Geminin family members, initially identified as regulators of DNA replication can modify the relative numbers of B1 and E cells in the resulting clones. More recently, we developed cellular and molecular approaches to decipher how cell cycle regulators drive the fate decision of neural progenitors during embryonic mouse brain development. I will present our current experimental evidences that the final fate decision of these glial cells occurs before their final cell cycle exit.

FROM PRIMATE ANATOMY TO HUMAN NEUROIMAGING: LINKING CIRCUITS TO PSYCHIATRIC DISEASE AND NEUROTHERAPEUTIC TARGETS

SPECIAL LECTURES 06: EDAB / MAX COWAN SPECIAL LECTURE

Suzanne Haber
University of Rochester, Pharmacology And Physiology, Rochester, United States of America

The cortico-basal ganglia networks are central to incentive-based learning and good decision making. There is growing consensus that obsessive-compulsive disorder (OCD), major depressive disorder, and addiction are manifestations of dysfunction of these networks. Deep brain stimulation (DBS), an effective therapeutic approach for several treatment resistant disorders, targets key circuits within these networks. This talk will first review the network connections most associated with psychiatric illnesses. Circuits include the cortico-striatal, cortico-thalamic, the cortico-subthalamic connections, and the ascending midbrain dopaminergic projection. Second, it will introduce the four most commonly targeted pathways; the anterior limb of the internal capsule (descending and ascending cortical fibers), the ventral striatum, the subthalamic nucleus, and midbrain ventral tegmental area (VTA). Here, using animal tracing experiments, I will outline the precise trajectory and location of fibers from different cortical regions through each target using animal tracing data. Combining this anatomy with diffusion magnetic resonance imaging (MRI) animals, I will demonstrate how accurate diffusion MRI reflects the anatomic organization. Using that analysis as a guide, connections through each target will be identified using diffusion MRI in humans. Finally, the circuits captured at the four surgical targets in humans with be compared.

THE EVOLUTION OF COMPUTATION IN THE BRAIN - INSIGHTS FROM STUDYING THE RETINA

SPECIAL LECTURES 07: BOEHRINGER INGELHEIM / FENS RESEARCH AWARD

Tom Baden
University of Sussex, Sussex Neuroscience, School Of Life Sciences, Brighton, United Kingdom

The retina is probably the most accessible part of the vertebrate central nervous system. Its computational logic can be interrogated in a dish, from patterns of lights as the natural input, to spike trains on the optic nerve as the natural output. Consequently, retinal circuits include some of the best understood computational networks in neuroscience. The retina is also ancient, and central to the emergence of neurally complex life on our planet. Alongside new locomotor strategies, the parallel evolution of image forming vision in vertebrate and invertebrate lineages is thought to have driven speciation during the Cambrian. This early investment in sophisticated vision is evident in the fossil record and from comparing the retina's structural make up in extant species. Animals as diverse as eagles and lampreys share the same retinal make up of five classes of neurons, arranged into three nuclear layers flanking two synaptic layers. Some retina neuron types can be linked across the entire vertebrate tree of life. And yet, the functions that homologous neurons serve in diffierent species, and the circuits that they innervate to do so, are often distinct to acknowledge the vast differences in species-specific visuo-behavioural demands. In the lab, we aim to leverage the vertebrate retina as a discovery platform for understanding the evolution of computation in the nervous system. Working on zebrafish alongside birds, frogs and sharks, we ask: How do synapses, neurons and networks enable 'function', and how can they rearrange to meet new sensory and behavioural demands on evolutionary timescales?

HETEROSYNAPTIC PLASTICITY EMERGING FROM MOLECULAR INTERACTIONS IN DENDRITES

SPECIAL LECTURES 07: BOEHRINGER INGELHEIM / FENS RESEARCH AWARD

Tatjana Tchumatchenko
University of Mainz Medical Center, University of Bonn Medical Center, Ag Tchumatchenko, Mainz, Germany

The dendrites of neurons evolved to maximize the amount of exposed surface available for intercellular communication. How do neurons distribute proteins across their dendrites such that all synapses get enough proteins and can respond to short-term changes in demand? Using a novel computational framework we made three key discoveries which we validated using fluorescently labeled proteins in vitro and 3D EM volumetric reconstructions. Our model predictions and in vitro measurements both show that soluble proteins preferentially move back toward the soma at branch points and surface proteins move forward distal sites. This surface protein bias in pyramidal morphologies is approximately 35%. Using 3D volumetric EM reconstructions of pyramidal neurons we show that the ratio of daughter radii in pyramidal neurons is selectively favoring protein diffusion lengths that overlap with the experimental reports of dendritic proteins. This suggests that dendritic morphology is optimized for long-range protein transport. Our results show that daughter radii optimization at branch points can reduce the total protein count a neurons needs to produce to serve all synapses by two orders of magnitude. In the next step, we are exploring how temporal features of the protein distributions impact synaptic plasticity rules.

FROM STEM CELLS TO BRAIN ASSEMBLOIDS: CONSTRUCTING AND DECONSTRUCTING THE HUMAN NERVOUS SYSTEM

SPECIAL LECTURES 09: IBRO – KEMALI PRIZE LECTURE

Sergiu Pasca
Stanford, The Bonnie Uytengsu & Family Director Of Stanford Brain Organogenesis, Stanford, United States of America

A critical challenge in understanding the programs underlying the development, assembly and dysfunction of the human brain is the lack of direct access to intact, functioning human neural tissue for direct investigation and manipulation. In this talk, I will describe efforts in my laboratory to build functional cellular models and to capture previously inaccessible aspects of human brain development and dysfunction. To achieve this, we have been using instructive signals to create, from pluripotent stem cells, self-organizing 3D cellular structures called regionalized brain organoids (or neural spheroids) that resemble domains of the developing central nervous system. We have shown that these cultures, such as the ones resembling the cerebral cortex, recapitulate features of neural development, can be derived with high reliability across dozens of cell lines and experiments, and can be maintained for years in vitro to capture advanced stages of neural and glial maturation and function. Moreover, we demonstrated that regionalized brain organoids can be put together to form functionally-integrated structures we named assembloids, which can be subsequently applied to investigate cell migration and formation of neural circuits. Lastly, I will illustrate how our modular, stem-cell derived 3D system can be used to study the cellular and molecular consequences of mutations or copy number variants associated with neuropsychiatric disorders.

FIRST CLINICAL TRIALS IN VISION RESTORATION

SPECIAL LECTURES 10: CHICA AND HEINZ SCHALLER FOUNDATION AWARD LECTURE

José-Alain Sahel[1,2], Botond Roska[3], Serge Picaud[1,4], Deniz Dalkara[1,5]
[1]Sorbonne-Université, INSERM, CNRS, Institut De La Vision, Paris, France, [2]The University of Pittsburgh School of Medicine, Department Of Ophthalmology, Pittsburgh, United States of America, [3]Institute of Molecular and Clinical Ophtalmology Basel, Basel, Basel, Switzerland, [4]Sorbonne Université, INSERM, CNRS, Institut de la Vision, Department Of Visual Information, PARIS, France, [5]Sorbonne Université, INSERM, CNRS, Institut de la Vision, Dept. Of Therapeutics, Paris, France

Rod-cone dystrophies, also termed Retinitis Pigmentosa, are a leading cause of heritable blindness. Mutations in photoreceptor cells or Retinal Pigment Epithelium lead to loss of function and eventually irreversible degeneration of photoreceptor cells. The number of known gene defects already identified and the late-stage diagnosis of the condition in many patients form challenges to therapeutic strategies aiming at preserving or restoring useful visual function. As part of a spectrum of therapeutic approaches developed over the past decades (gene therapy, neuroprotection, cell therapy, prosthetic vision), we designed and tested at the preclinical level an optogenetic therapy combining 1) gene-based expression of a red-shifted optogene, ChrimsonR, in Retinal Ganglion Cells, 2) a stimulation device comprising a neuromorphic camera and a projecting mirror in the corresponding amber wavelength, 3) vision rehabilitation protocols. The clinical trial, supported by GenSight Biologics, enrolled nine patients in Paris, London, and Pittsburgh using a dose-escalation protocol and demonstrated the safety of the procedure, gene product, and device as well as partial vision restoration in an initial subject (reported in Sahel et al., Nature Medicine, 2021) and subsequent patients. Multi-EEG recording demonstrated corresponding patterns of activation of the primary visual cortex. Ongoing studies include an extension cohort, refinement in the stimulation goggle design, the stimulation protocol, and the rehabilitation process. This initial demonstration of the potential of optogenetics paves the way to further programs aiming at improving cell selectivity, stimulation accuracy, and patterns. Optogenetics could potentially be applied to other blinding conditions (e.g., macular dystrophies, age-related macular degeneration).

A CIRCUIT MODEL FOR ADDICTION OPENING THE ROAD TO TRANSLATIONAL RESEARCH

SPECIAL LECTURES 10: CHICA AND HEINZ SCHALLER FOUNDATION AWARD LECTURE

Christian Lüscher
University of Geneva, Basic Neurosciences, Geneva, Switzerland

Addiction may be considered a disorder of dysfunctional motivation and decision circuits. We will review the empirical evidence that addiction starts with exposure to drugs that have in common to increase dopamine in the mesolimbic system. Adaptive behavior then arises from dopamine modulation of glutamatergic and GABAergic synaptic transmission, which alters circuit function, eventually leading to compulsive drug taking in vulnerable individuals. A special emphasis will be on the translational implication of the circuit model for addiction and the roadmap to novel therapies.

SLEEP-WAKE CYCLES SHAPE PROTEOME AND PHOSPHOPROTEOME DYNAMICS IN BRAIN

SPECIAL LECTURES 11: EJN SPECIAL FEATURE

Maria Robles
Ludwig Maximilian University of Munich, Institute Of Medical Psychology And Biomedical Center, Munich, Germany

Nearly all physiological processes in the body display circadian (close to 24 hours) oscillations. Brain processes, including memory and learning performance, are also shaped in a daily manner, however little is known about the molecular mechanisms driving this rhythmicity. Mass-spectrometry (MS) based quantitative proteomics is a powerful technique used to study tissue, cellular and sub-cellular proteomes as well as protein post-translational modifications (PTMs). This technology has revolutionized the quantification of protein levels and modifications in many biological fields, amongst them chronobiology. In my talk I will present our work using MS-based label free quantitative proteomics and phosphoproteomics to elucidate sleep- and circadian-driven cycling mechanisms in murine brains and synaptoneurosomes.

CALCIUM-INDEPENDENT ASTROCYTIC LIPID RELEASE MODULATES NEURONAL EXCITABILITY

SPECIAL LECTURES 11: EJN SPECIAL FEATURE

Nathan A. Smith
Unversity of Rochester School of Medicine and Dentistry, Department Of Neuroscience, The Del Monte Institute For Neuroscience, Rochester, United States of America

Accumulating data point to a key role of Ca^{2+}-dependent gliotransmitter release as a modulator of neuronal networks. Here, we tested the hypothesis that astrocytes in response to agonist exposure also release lipid modulators through activation of Ca^{2+}-independent phospholipase A_2 ($iPLA_2$) activity. We found that cultured rat astrocytes treated with selective ATP and glutamatergic agonists released arachidonic acid (AA) and/or its derivatives, including the endogenous cannabinoid 2-arachidonoyl-sn-glycerol (2AG) and prostaglandin E_2 (PGE_2). Surprisingly, buffering of cytosolic Ca^{2+} resulted in a sharp increase in agonist-induced astrocytic lipid release. In addition, astrocytic release of PGE_2 enhanced miniature excitatory post-synaptic potentials (mEPSPs) by inhibiting the opening of neuronal Kv channels in brain slices. This study provides the first evidence for the existence of a Ca^{2+}-independent pathways regulating the release of PGE2 from astrocytes, and furthermore demonstrates a functional role for astrocytic lipid release in the modulation of synaptic activity.

MOLECULAR BIOMARKERS FOR STROKE

SPECIAL LECTURES 12: ERA-NET NEURON/EXCELLENT PAPER IN NEUROSCIENCE AWARD

Steffen Tiedt
LMU Munich, Institute For Stroke And Dementia Research, Munich, Germany

Stroke is a leading cause of death and disability worldwide. Its heterogeneity poses a challenge for assigning patients to optimal treatment strategies and is a major reason for the large number of failed clinical trials, including those on neuroprotection. Current diagnostic algorithms are insufficient to capture the heterogeneity of stroke: stroke etiology remains undetermined in 40 % of patients, thus impeding the allocation of these patients to optimal secondary prevention regimens. Heterogeneity is also seen at the level of neuronal injury, which greatly varies between stroke patients, but can neither be assessed in the pre-hospital setting nor serially in the acute phase to monitor stroke progression. Circulating proteins and metabolites capture pathophysiological events in multiple organs including local and systemic events (e.g. stress) related to acute stroke and might thus inform on neuronal injury and the mechanisms causing stroke. Our work focuses on the discovery of such biomarkers for stroke using omics technologies and ultrasensitive targeted assays. Here, I will first present the awarded project that used a discovery-validation and global metabolomics approach across four independent cohorts to identify, validate, and replicate a set of four circulating metabolites that shows unprecedented utility and outperforms neuroimaging in identifying patients with stroke upon hospital arrival. Further, I will show recent data on how metabolomic data could be leveraged to improve our understanding of human stroke pathophysiology. The talk will end with an outlook on how molecular biomarkers can guide future precision medicine, in stroke, neurology, and beyond.

NEURAL CIRCUITS FOR MULTISENSORY INTEGRATION AND PERCEPTUAL DECISIONS

SPECIAL LECTURES 13: ALBA-ELSEVIER AWARD LECTURE ON BRAIN SCIENCES

Seung-Hee Lee
KAIST, Biological Sciences, Daejeon, Korea, Republic of

Cortical circuits process multiple sensory information and transform them into the motor decision in animals performing perceptual tasks. However, it is still unclear how sensory inputs are integrated and transformed into motor signals in the cortex to initiate goal-directed actions. We recently found cortical circuits that are important for multisensory integration and perceptual decision-making. First, we found that the posterior parietal cortex (PPC) integrates visual and auditory inputs and process multisensory decisions in a state-dependent manner. Parvalbumin-positive inhibitory neurons in the PPC receive strong inputs from the auditory cortex and exert feedforward inhibition, which leads to auditory-dominant decisions in head-fixed mice under audiovisual conflicts. Notably, locomotion suppresses auditory inputs to the PPC, switching mice under the same conflict conditions to make visually dominant decisions more often. Second, we found that visual inputs from the visual cortex to the anterior cingulate cortex (ACC) trigger gated feedforward inhibition to release goal-directed actions in mice performing Go/No-go tasks. Three different types of ACC neuronal activities—visual amplitudes of sensory neurons, suppression times of motor neurons, and network activity from other neurons—predicted response times of the mice. Moreover, optogenetic activation of visual neurons in the ACC prompted task-relevant actions in mice by suppressing ACC motor neurons, which disinhibited downstream striatal neurons. Collectively, our study illustrates how cortical circuits integrate and transform sensory information into flexible motor decisions. Our data demonstrate that feedforward inhibitory circuits in cortico-cortical projections play critical roles in perceptual decision-making.

POST-TRANSCRIPTIONAL REGULATION OF THE MICROTUBULE ASSOCIATED PROTEIN TAU: FUNCTIONAL CONSEQUENCES AND THERAPEUTIC PERSPECTIVES

SPECIAL LECTURES 13: ALBA-ELSEVIER AWARD LECTURE ON BRAIN SCIENCES

Maria Elena Avale, Ana Damianich, Carolina Facal, Javier Muñiz, Sonia Espindola
Consejo Nacional de Investigaciones Científicas y Técnicas, Instituto De Investigaciones En Ingeniería Genética Y Biología Molecular "dr Hector N Torres" (ingebi-conicet), Buenos Aires, Argentina

Tau is a microtubule-associated protein, predominantly expressed in neurons, that regulates a myriad of neuronal processes. Abnormal tau metabolism underly many neurodegenerative diseases, named tauopathies, such as Alzheimer's disease, frontotemporal dementia and progressive supranuclear palsy. The tau primary transcript undergoes highly regulated post-transcriptional modifications in the brain; and failures in such processing leads to disease. Particularly, in the normal adult brain, the alternative splicing of exon 10 (E10) produces equal amounts of tau protein isoforms with three (3R) or four (4R) microtubule binding repeats. Several mutations -and also other non-genetic factors- affecting E10 alternative splicing are associated with tauopathies. Targeting Tau RNA processing is therefore a promising avenue to develop effective therapies. In this talk I will outline our achievements using RNA based strategies to modulate either the tau 3R:4R ratio or total tau contents, in a mouse model of tauopathy (htau mice). We used lentiviral vectors to express molecules that modulate E10 inclusion/exclusion by RNA trans-splicing with the endogenous tau transcript. When delivered into the prefrontal cortex, these molecules improved cognitive deficit, restored neuronal firing patterns and reduced hyperphosphorylated tau contents. Moreover, shifting of 3R to 4R tau into the striatum rescued motor coordination deficits. Furthermore, we tested designed microRNAs to locally reduce tau contents in the adult htau brain. Tau knockdown in the htau prefrontal cortex rescued cognitive impairments and pathological phenotypes, even after phenotypic onset. Together, our results evidence the (dys)functional consequences of abnormal tau post-transcriptional regulation and highlight the potential of using RNA-based therapeutic strategies for tauopathies.

VIB, Center For Brain And Disease Research, Leuven, Belgium

Developmental programs are highly conserved across all vertebrates, although there are significant temporal variations in interspecies developmental processes. Changing the timing and rate of developmental processes can profoundly affect subsequent organogenesis and may also have been a critical factor in evolution. However, despite their potential importance, the cellular and molecular mechanisms that control interspecies differences in developmental timeline remain unclear. Neuronal development is considerably prolonged in the human cerebral cortex compared with other mammals, leading to brain neoteny. Moreover, changes in the maturation timing and rate were proposed to be associated with brain malformation and dysfunction. Here, we explore whether mitochondria influence the species-specific properties of cortical neuron maturation. By comparing human and mouse cortical neuronal maturation at high temporal and cellular resolution, we found a slower pattern of mitochondria development in human cortical neurons compared with the mouse, together with lower mitochondria metabolic activity, particular oxidative phosphorylation. Stimulation of mitochondria-dependent metabolism in human neurons resulted in accelerated maturation, leading to increased excitability and morphological complexity weeks ahead of time. Our data identify mitochondria as important regulators of the rate of neuronal development underlying human-specific features of brain evolution.

NEURAL SPECIFICATION IN THE DEVELOPING HUMAN CORTEX

SYMPOSIUM 01 - THE LINKS BETWEEN NEURAL CIRCUIT DEVELOPMENT, HUMAN BRAIN EVOLUTION AND DISEASES' - RYOHEI IWATA, APARNA BHADURI, ALESSANDRO VITRIOLO, EWOUD SCHMIDT

Aparna Bhaduri
University of California, Los Angeles, Biological Chemistry, Los Angeles, United States of America

The human brain is comprised of myriad cell types organized into distinct regions, including the cerebral cortex, the outermost layer of the human brain which enables aspects of cognition and other higher order processes. Compared to other mammals and even primates, the human cortex is substantially expanded. These size differences emerge during developmental timepoints and the cell types and gene expression programs enriched in humans at these developmental timepoints also make humans uniquely susceptible to neurodevelopmental and neuropsychiatric disorders. In order to study the emergence of these functional cortical regions, cell types, and gene expression networks, we have leveraged single-cell RNA-sequencing to identify cell types across developmental time. These data have highlighted the early specification of frontal and occipital poles of the cortex, and suggest that in between regions become further specified at later timepoints. We have also identified extremely dynamic gene expression programs, with the specific gene signatures that define cortical areas varying immensely both across developmental time and between cell types across the differentiation spectrum. In an effort to inventory and compare these gene signatures, we have compiled a meta-atlas of datasets from peak neurogenesis. This compendium of single-cell data enables us to identify biological pathways that driv these cell fate specification events. In turn, these data sets can be compared across species, *in vivo* and *in vitro* model systems, and across developmental epochs. Paired with experiments in primary tissue and cortical organoids, we can begin to decipher the logic of neural specification in the developing human cortex.

EMERGING INSIGHTS ON THE MODERN HUMAN BRAIN THROUGH THE PRISM OF NEURODEVELOPMENTAL DISORDERS

SYMPOSIUM 01 - THE LINKS BETWEEN NEURAL CIRCUIT DEVELOPMENT, HUMAN BRAIN EVOLUTION AND DISEASES' - RYOHEI IWATA, APARNA BHADURI, ALESSANDRO VITRIOLO, EWOUD SCHMIDT

Giuseppe Testa[1], Cedric Boeckx[2], Adrianos Skaros[1], Alessandro Vitriolo[1], Oliviero Leonardi[1], Nicolò Caporale[1], Emanuele Villa[1], Sebastiano Trattaro[1], Juan Moriano Palacios[2]
[1]Human Technopole, Neurogenomics, Milan, Italy, [2]ICREA and Universitat de Barcelona, Cognitive Biology Of Language, Barcelona, Spain

Anatomically modern humans have evolved facial and neural features that significantly differ from those of archaic hominins and plausibly underlie their cognitive-behavioral specificities. Their evolution has thus far been inferred from fossil records and through the comparison of modern and archaic genomes. The modern face, with its overall smaller size and retracted features, has been understood as an instance of self-domestication, a process hypothesized to have selected mild neural crest deficits, and for which we recently provided the first experimental evidence. Yet, the modern human brain does not meet the core predictions of the self-domestication hypothesis, either in size (not reduced, unlike with most domesticates) or temporal emergence and shape. It is in fact the growth reconfiguration in specific areas of the braincase (e.g. globularity) that sets us apart from our closest relatives, and this evolved much more recently than the modern face. Here, I discuss our latest inroads to make the evolutionary logic of the modern human brain experimentally tractable, by leveraging selected neurodevelopmental disorders whose neural phenotypes, aligned to novel paleogenomic datasets, illuminate the modern human condition. Specifically, we mobilize the latest advances from human developmental biology at single cell resolution and paleogenomics to enable an empirically tested, systems-level definition of the molecular logic underlying our recent evolution.

HUMANIZING THE MOUSE BRAIN: HOW A HUMAN-SPECIFIC MODIFIER OF CORTICAL CONNECTIVITY SHAPES BRAIN DEVELOPMENT, FUNCTION, AND DISEASE.

SYMPOSIUM 01 - THE LINKS BETWEEN NEURAL CIRCUIT DEVELOPMENT, HUMAN BRAIN EVOLUTION AND DISEASES' - RYOHEI IWATA, APARNA BHADURI, ALESSANDRO VITRIOLO, EWOUD SCHMIDT

Ewoud Schmidt
Medical University of South Carolina, Department Of Neuroscience, Charleston, United States of America

Human cortical pyramidal neurons (PNs) are characterized by increased synaptic density and prolonged synaptic maturation. These features are considered critical for the emergence of human cognition by enabling the formation of more densely connected cortical networks. However, we lack insight into how these features of cortical connectivity emerged during evolution and how they contribute to the cognitive capacity of humans. We previously identified a human-specific gene duplication, SRGAP2C, that when expressed in mouse cortical PNs induces traits characterizing human cortical PNs, including increased synapse density and delayed synaptic maturation. When we mapped connectivity of layer 2/3 PNs, we discovered that SRGAP2C selectively increases cortical connectivity, without affecting subcortical inputs. Moreover, *in vivo* 2-photon Ca^{2+} imaging revealed that SRGAP2C expression improves sensory coding of layer 2/3 PNs by increasing stimulus response probability, while reducing overall spontaneous activity. Strikingly, when we examined the impact of these circuit changes on behavior, we found that SRGAP2C mice display an increased ability to learn in a cortex-dependent sensory discrimination task. Our results suggest that the emergence of SRGAP2C in the human genome critically changed cortical circuit connectivity and function and provided a key evolutionary step towards improved cognition. We currently investigate how modified cortical connectivity drives improved learning by studying circuit dynamics at the cellular and cortex-wide level. Furthermore, given how human-specific traits of synaptic development impact the structural and functional makeup of cortical circuits, our work seeks to understand how human-specific genes shape the phenotypic expression of disease-causing mutations implicated in neurodevelopmental disorders.

MAPPING THE TRANSCRIPTIONAL DIVERSITY OF CELL TYPES IN THE DEVELOPING HUMAN BRAIN

SYMPOSIUM 02 - THE CEREBRAL CORTEX CHALLENGE: GENERATING MANY CELL TYPES FROM DISTINCT SOURCES IN A RESTRICTED TIME - ARNOLD KRIEGSTEIN, TANJA VOGEL, MATTHEW HOLT, KARINE LOULIER

Arnold Kriegstein
University of California, San Francisco, Ucsf School Of Medicine, San Francisco, United States of America

The human cerebral cortex is more than three times expanded compared to our closest non-human primate relatives. The cortex emerges from an initially pseudostratified neuroepithelium that gives rise to radial glia, the neural stem cells of the cortex. A number of subtypes of radial glia have been identified as the cortex matures, and single cell RNA sequencing (scRNAseq) has added substantially to our knowledge of these processes. However, the first trimester of cortical development has not been described at this level of molecular detail, and important questions remain about the timing of neurogenesis, the presumed uniformity of the neuroepithelium, and the signals that promote the transition to radial glia. We have begun to characterize the molecular populations of cellular subtypes that exist at the onset of neurogenesis across regions of the developing human brain. Our single-cell transcriptomic and *in-situ* data suggest that early cortical areal patterning is strongly defined by the mutual exclusion of strong frontal or occipital gene expression signatures, with the specification of areas between these two poles arising at later developmental timepoints. Thus, we find evidence supporting the existence of a cortical protomap at the extremities, but also support for the protocortex hypothesis to refine spatial identity between the poles. We find that major signaling pathways including Notch, Wnt, and mTOR drive the specification and maintenance of neuroepithelial stem cells and radial glia. Overall, we provide a comprehensive molecular and spatial atlas of early stages of human brain and cortical development at the onset of neurogenesis.

TEMPORAL AND SPATIAL REGULATION OF NEURONAL DIFFERENTIATION IN THE DEVELOPING MOUSE NEOCORTEX

SYMPOSIUM 02 - THE CEREBRAL CORTEX CHALLENGE: GENERATING MANY CELL TYPES FROM DISTINCT SOURCES IN A RESTRICTED TIME - ARNOLD KRIEGSTEIN, TANJA VOGEL, MATTHEW HOLT, KARINE LOULIER

Yukiko Gotoh[1], Yusuke Kishi[1], Tanja Vogel[2]
[1]The University of Tokyo, Department Of Pharmaceutical Sciences, Laboratory Of Molecular Biology, Tokyo, Japan, [2]Albert-Ludwigs-University Freiburg, Anatomy And Cell Biology, Molecular Embryology, Freiburg, Germany

Transcription factors play various roles in the process of neuronal differentiation during neocortical development. Recent studies have described the waves of activation of transcription factors and alterations in chromatin accessibility at the corresponding target loci in differentiating neurons. However, given that most of these studies analyzed a mixture of neuronal types born at different developmental time points from radial glial cells (a.k.a. neural stem-progenitor cells, NPCs) in the neocortex, fine and subtle temporal changes might have been missed in these studies. We therefore selectively labeled neurons born at around E16 in the mouse neocortex and traced their differentiation process for 4 days by performing single cell ATAC-sequencing analysis. A graph-based clustering identified cell clusters with distinct peaks of chromatin accessibility patterns along the differentiation axis (pseudotime). Importantly, a hierarchical clustering of the motif activity score of 884 transcription factors revealed waves of activation of transcription factor sets at specific temporal windows of differentiation. Some of such transcription factors showed a significant delay of motif activation after their gene expression along the differentiation pseudotime. This analysis also unveiled narrow temporal windows of motif activation for some transcription factors which have not so far been described as regulators of neuronal differentiation. These results thus highlight the advantage of pulse-labeling of a certain neuronal lineage, which leads to high temporal resolution of chromatin analysis and identification of putative factors involved in fine differentiation processes.

Astrocytes are a numerous cell type in the central nervous system. They perform many important functions in synapse formation and maintenance, control of local homeostasis and modulation of synaptic transmission. However, the degree to which specialist astrocyte subtypes fulfil these specific tasks is currently unclear. In this talk, I will present work using single cell transcriptomic and *in situ* hybridization approaches, which demonstrates that even astrocytes lying within the same region of mouse brain show distinct molecular and spatial profiles. Furthermore, I will provide evidence obtained from morphological analyses and Ca^{2+} imaging experiments that these subtypes also possess both distinct anatomies and physiologies. These findings are evidence for the existence of specialized astrocyte subtypes, residing both within and between brain regions, and strongly suggest that specific CNS functions, such as axon guidance, synaptogenesis and synaptic transmission, are differentially controlled by specialized astrocyte subtypes.

The functions of the mammalian cerebral cortex rely on the cooperation of distinct cell types, including neurons and astrocytes, which must be produced in defined proportions and whose imbalance can lead to severe pathologies. Astrocytes constitute an heterogeneous population and, while distinct molecular signatures of astrocyte subtypes are becoming better known, the developmental origin underlying this diversity in the mouse cerebral cortex and how it translates into specific functions remains unknown. Using combinatorial genetic markers and multicolor imaging techniques, we labeled adjacent cortical progenitors with rare color markers prior to gliogenesis and tracked their descent over long periods of time to characterize astrogliogenesis. We determined that cortical progenitors contribute both pre- and postnatally to the generation of the astrocyte 3D matrix and that cortical astrocyte clones exhibit high variability in terms of structural organization, localization, number and subtype of cells generated. Although we did not identify dedicated subpopulations of cortical progenitors responsible for astrocyte diversity, we nevertheless found an alternative embryonic source for cortical astrocytes. In addition to characterizing the cellular and molecular properties of these progenitors located in a restricted area of the developing brain, we compare the characteristics of cortical astrocytes derived from these two distinct sources and investigate whether they might be differentially affected in the context of neurodevelopmental disorders. Overall, our work highlights the unsuspected complexity of cortical astrocyte genesis and will lead to a better understanding of the critical cellular and molecular components of astrogliogenesis that may be altered in brain pathologies.

PSYCHEDELICS IN TINY AMOUNTS TO ENHANCE COGNITIVE AND EMOTIONAL PROCESSES: WHAT DOES SCIENCE SAY?

SYMPOSIUM 03 - PSYCHEDELIC EFFECTS WITHOUT PSYCHEDELIC EXPERIENCE - KIM KUYPERS, SCOTT THOMPSON, LINDSAY CAMERON, RAFAEL MOLINER

Kim Kuypers
Maastricht University, Neuropsychology And Psychopharmacology, Maastricht, Netherlands

Microdosing with psychedelics (MD) has gained popular and scientific attention in recent years. It is the practice of taking repeatedly small doses of substances like LSD and psilocybin, for a certain period which can be a few weeks, up to months, and years. People who engage in this are most typically motivated to gain cognitive, psychological, emotional, and/or health benefits. Most of the knowledge we have so far comes from questionnaire studies in which users report retrospectively or keep diaries of the effects they experience during MD. According to users, it leads to positive effects on mood, concentration, focus, and productivity. While there is little attention in the media for potential negative or unwanted effects, these also seem to occur including physical discomfort and heightened feelings of fear. The limited number of placebo-controlled studies in healthy people revealed that MD has subtle effects on cognitive processes and brain connectivity. The findings of placebo-controlled studies in combination with reports from users suggest that MD with psychedelics can be effective in controlling certain psychological symptoms. This means that this phenomenon deserves more attention, partly because psychedelics are relatively safe substances. In the future, placebo-controlled studies will provide more clarity for who (age, diagnosis) MD can be effective and for which (cognitive, emotional) processes. The purpose of this presentation will be to give an overview of the knowledge we have so far about MD and to identify which unanswered questions still exist.

HARNESSING PSILOCYBIN FOR NEUROPSYCHIATRIC DISORDERS: PRECLINICAL PERSPECTIVES ON PHARMACOLOGICAL AND PHYSIOLOGICAL MECHANISMS

SYMPOSIUM 03 - PSYCHEDELIC EFFECTS WITHOUT PSYCHEDELIC EXPERIENCE - KIM KUYPERS, SCOTT THOMPSON, LINDSAY CAMERON, RAFAEL MOLINER

Scott Thompson
University of Maryland, Department Of Physiology, Baltimore, United States of America

Psychedelics have the potential to revolutionize psychiatric pharmacotherapy. Dozens of companies are exploring hundreds of compounds as therapeutics. But how do they work and what are the ideal pharmacological properties these compounds should possess? Preclinical studies have the potential to suggest the pharmacology and physiology underlying their therapeutic actions, both during the induction phase, when the compounds are acting on the brain, and in the induction phase, when persistent beneficial changes result in lasting restoration of the normal state. This presentation will consider both aspects of the anti-anhedonic actions of psilocybin in mice subjected to chronic stress. We find that a single administration of psilocybin restored two behavioral measures of hedonic state: the preference of male mice for sucrose solution and the scent of female urine. We next tested the role of 5HT2ARs, known to underlie the mind-altering properties of psychedelics. We found that psilocybin remained effective when co-administered with the 5HT2R antagonist ketanserin. Following completion of behavioral testing, we prepared hippocampal brain slices and observed that the strength of stress-sensitive TA-CA1 synapses was greater in stressed mice administered psilocybin, compared to vehicle, and that this restoration of synaptic strength was also seen in mice co-administered ketanserin. We conclude that 1) the beneficial actions of psilocybin can be studied in mice, 2) restoration of stress-impaired synaptic function may underlie their therapeutic actions, and 3) neither the behavioral nor synaptic actions of psilocybin require 5HT2AR activation, at least in mice.

RETHINKING PSYCHEDELICS: NON-HALLUCINOGENIC ANALOGS OF PSYCHEDELICS AS TREATMENTS FOR NEUROPSYCHIATRIC DISORDERS

SYMPOSIUM 03 - PSYCHEDELIC EFFECTS WITHOUT PSYCHEDELIC EXPERIENCE - KIM KUYPERS, SCOTT THOMPSON, LINDSAY CAMERON, RAFAEL MOLINER

Lindsay Cameron
Stanford University, Psychiatry, Stanford, United States of America

The prefrontal cortex (PFC) is a critical brain structure that regulates mood, anxiety and reward. Atrophy of neurons in this brain region is implicated in the development of neuropsychiatric disorders, and thus, strategies to regrow these neurons are highly desirable. Classic psychedelics are potent psychoplastogens that have been shown to produce rapid and sustained antidepressant-like effects in both humans and rodents. Psychedelics target the serotonin 2A (5-HT2A) receptor, which is densely expressed in layer V pyramidal neurons of the PFC. By comparing the effects of hallucinogenic and non-hallucinogenic congeners, we demonstrate that both types of 5-HT2A ligands produce long-lasting changes in neuronal structure and function. Specifically, we demonstrate that these non-hallucinogenic analogs increase cortical neuron dendritic arbor complexity and spine density, comparable to psychedelic compounds. The effects of these compounds were further characterized using whole cell patch clamp, calcium imaging, and beta-arrestin recruitment assays. Mouse behavioral studies revealed that both psychedelics and non-hallucinogenic analogs facilitate anti-depressant-like effects in the tail suspension test. Additionally, psychedelics reverse anhedonia-like behaviour as measured in the sucrose preference test. By using both antagonists of the 5-HT2A receptor and 5-HT2A KO animals, we demonstrate that this receptor plays a critical role in the beneficial effects of non-hallucinogenic analogs of psychedelics. Our work suggests that the hallucinogenic effects of psychedelic compounds can be dissociated from their beneficial effects on neuronal growth and behavior. These data provide an important starting point for the design of safer next-generation therapeutics for treating depression and other stress-related disorders.

Psychedelics like LSD and psilocybin induce structural and functional neuroplasticity resembling the action of clinically approved antidepressants. They also show promise as fast-acting antidepressants with long-lasting therapeutic effects. Pharmacologically diverse antidepressants including fluoxetine and ketamine promote neuroplasticity through TrkB, the brain-derived neurotrophic factor (BDNF) receptor. BDNF and TrkB are also thought to play a central role in the action of psychedelics as effectors downstream of their canonical target, the serotonin 2A (5-HT_{2A}) receptor. In this presentation, we will discuss the short and long-term effects of psychedelics on receptor activation, signaling, plasticity and behavior. The roles of 5-HT_{2A} and TrkB in the hallucinogenic and plasticity-inducing effects of psychedelics will be addressed. Finally, we will compare the mechanisms of action of psychedelics with those of other conventional and rapid-acting antidepressants, highlighting the differences and commonalities that may underlie their therapeutic value.

A TRANSCRIPTIONAL RHEOSTAT IN OLFACTORY SENSORY NEURONS

SYMPOSIUM 04 - SMELL, CELL-BY-CELL - SANDEEP ROBERT DATTA, ALEXANDER FLEISCHMANN, MARCELA LIPOVSEK, KOEN VAN DEN BERGE

Sandeep Robert Datta
Harvard Medical School, Department Of Neurobiology, Boston, United States of America

Animals traversing different environments encounter both stable background stimuli and novel cues, which are thought to be detected by primary sensory neurons and then distinguished by downstream brain circuits. Here, we show that each of the ~1,000 olfactory sensory neuron (OSN) subtypes in the mouse harbors a distinct transcriptome whose content is precisely determined by interactions between its odorant receptor and the environment. This transcriptional variation is systematically organized to support sensory adaptation: expression levels of more than 70 genes relevant to transforming odors into spikes continuously vary across OSN subtypes, dynamically adjust to new environments over hours, and accurately predict acute OSN-specific odor responses. The sensory periphery therefore separates salient signals from predictable background via a transcriptional rheostat whose moment-to-moment state reflects the past and constrains the future; these findings suggest a general model in which structured transcriptional variation within a cell type reflects individual experience.

The mammalian cortex comprises ancient paleocortical structures, exemplified by the olfactory cortex, as well as more recently evolved neocortical areas. Neurons in the mouse olfactory cortex differ from neurons in neocortex in their developmental origin, morphology, functional properties and molecular identities. However, the mechanisms driving cell type diversification across these distinct cortical traits remain unknown. Here, we characterize the gene regulatory network (GRN) activity that defines cell type identity in the mouse olfactory cortex, and we compare GRN activity across paleo-, peripaleo- and neocortical areas. Using single cell ATAC and RNA sequencing, we reveal enhancer-gene interactions and identify transcription factors cross-repression as a key mechanism for cell type diversification. Finally, we propose semilunar cells of the olfactory cortex as the ancestral neuronal cell type of the mammalian cortex. Our data provide the first comprehensive molecular description of cell types in the mouse olfactory cortex and identify epigenetic mechanisms underlying cell type diversification during evolution.

Dopaminergic (DA) neurons in the olfactory bulb regulate the transmission of information at the earliest stages of sensory processing and are one of the few neuronal types in the mammalian brain continually generated throughout postnatal life. Here, we ask whether this continuous neuronal production results in a gradient of cell states within the resident population. Birthdating in 4-week old DAT-IRES-Cre/Flox-tdT mice revealed that resident DA neurons span an age range of at least 3 weeks. We next collected individual DA neurons by either manual sorting of tdT positive DA neurons, or aspiration after patch-clamp recordings in acute slices (Patch-seq), and performed deep single-cell RNA sequencing. Clustering analysis identified putative subpopulations of DA neurons, while cell trajectory analysis described a single, unbranched, trajectory that closely matched the clusters. Further analysis revealed differentially expressed genes, significantly enriched for GO terms related to neuronal and synaptic function, indicating that the identified trajectory may reflect a transcriptional maturational gradient. Ongoing analysis of electrophysiological properties along the identified trajectory will reveal whether it describes a gradient of functional states. In summary, we are exploring a hitherto unanticipated gradient of cell states within a specific neuronal subtype that could underpin the functional maturation of DA cells in the postnatal brain.

STATISTICAL METHODS FOR THE INTERROGATION OF SINGLE-CELL RNA-SEQ DATA ON THE OLFACTORY EPITHELIUM

SYMPOSIUM 04 - SMELL, CELL-BY-CELL - SANDEEP ROBERT DATTA, ALEXANDER FLEISCHMANN, MARCELA LIPOVSEK, KOEN VAN DEN BERGE

Koen Van Den Berge
University of California, Berkeley, Statistics, Berkeley, United States of America

The olfactory epithelium (OE) is one of the few sites in the nervous system that supports active neurogenesis throughout life. Since the olfactory neurons are exposed to the environment, cells must continuously be renewed in order to maintain and/or repair the tissue, from a source population of globose basal cells. In case of injury, however, the olfactory epithelium is capable of regeneration from an otherwise resting stem cell population of horizontal basal cells (HBCs). In this talk, we will introduce statistical methodology that allows us to characterize dynamic systems such as the olfactory epithelium. Specifically, we will introduce Slingshot to be able to characterize continuous developmental cell processes such as cell activation, cell cycle and cellular development. These processes can be summarized as a 'trajectory' including one or multiple lineages, each referring to a possible cellular differentiation path. Based on such a trajectory, we introduce tradeSeq to discover differential gene expression within and between such lineages, as demonstrated through an application on the olfactory epithelium. Finally, contemporary single-cell RNA-seq studies may focus on comparing such dynamic developments between experimental or biological conditions, such as treatment groups or genotypes. We introduce condiments, a novel framework to compare global characteristics of the trajectory, such as topology and cell fates, between conditions, as well as detailed differential gene expression analysis between conditions, within each lineage.

DOPAMINE SIGNALS FOR CONFIDENCE-DEPENDENT CHOICE UPDATING

SYMPOSIUM 05 - NEUROMODULATION OF PERCEPTUAL DECISION-MAKING - ARMIN LAK, KENNETH KISHIDA, KATHARINA SCHMACK, MATTHEW MCGINLEY

Armin Lak
University of Oxford, Dpag, Oxford, United Kingdom

Learning from successes and failures often improves the quality of subsequent decisions. Past outcomes, however, should not influence purely perceptual decisions after task acquisition is complete since these are designed so that only sensory evidence determines the correct choice. Yet, numerous studies report that outcomes can bias perceptual decisions, causing spurious changes in choice behaviour without improving accuracy. In this talk, I will show that the effects of reward on perceptual decisions are principled: past rewards bias future choices specifically when previous choice was difficult and hence decision confidence was low. I will identify this phenomenon in various species and sensory modalities. I will demonstrate that this choice updating can be explained by reinforcement learning models incorporating statistical decision confidence into their prediction errors. Lastly, I will provide three pieces of evidence indicating that midbrain dopamine neurons play critical roles in regulating confidence-dependent choice updating. a) Dopamine neural responses during perceptual decisions quantitatively match confidence-dependent prediction errors in both monkeys and mice. b) Dopamine neural responses predict the magnitude of the psychometric choice bias in the subsequent trial. c) Manipulation of dopamine neurons biases psychometric curves in a trial-by-trial fashion. Together, these results provide a framework for studying learning under sensory uncertainty, and indicate that dopamine signals are well-suited to guide this form of learning.

COORDINATION OF EXTRACELLULAR DOPAMINE AND SEROTONIN SIGNALS IN HUMAN STRIATUM DURING CONSCIOUS DECISION-MAKING.

SYMPOSIUM 05 - NEUROMODULATION OF PERCEPTUAL DECISION-MAKING - ARMIN LAK, KENNETH KISHIDA, KATHARINA SCHMACK, MATTHEW MCGINLEY

Kenneth Kishida
Wake Forest School of Medicine, Physiology And Pharmacology, Winston-Salem, United States of America

How the human brain generates conscious experience is a fundamental problem. In particular, it is unknown how highly variable and dynamic changes in subjective experience are driven by interactions with objective phenomena. We hypothesize a 'dynamic *affective* core' that requires not only dynamic representations of the contents and context of conscious experiences but also their value. The latter, 'representations of value', have begun to be well characterized by computational reinforcement learning models and empirical data that support the idea that dopamine neurons signal 'better (or worse) than expected' experiences by encoding 'reward prediction errors' in changes in their firing rate. However, whether first-person subjective experiences align with dopaminergic encoding of better or worse than expected 'reward prediction errors' has, to our knowledge, not been directly tested. Recently developed technology allows, for the first time ever, high temporal resolution (i.e., sub-second) measurements of the neurotransmitters dopamine and serotonin from deep within the human brain during conscious decision-making and behavior. I will present recent work that supports the hypotheses that dopamine and serotonin encode reward and punishment prediction errors, respectively; that these signals coordinate and drive human behaviors; and, that sub-second fluctuations in dopamine and serotonin levels may drive moment-to-moment changes in the valence of self-reported subjective experiences. Together, our results support the idea that dopamine and serotonin provide valuation update signals in the human brain that guide behavior and may also be critical modulators of subjective phenomenal experience.

STRIATAL DOPAMINE MEDIATES HALLUCINATION-LIKE PERCEPTION IN MICE

SYMPOSIUM 05 - NEUROMODULATION OF PERCEPTUAL DECISION-MAKING - ARMIN LAK, KENNETH KISHIDA, KATHARINA SCHMACK, MATTHEW MCGINLEY

Katharina Schmack[1], Marion Bosc[1], James Sturgill[2], Torben Ott[3], Adam Kepecs[4]
[1]The Crick Institute, Neuroscience, London, United Kingdom, [2]Cold Spring Harbor Laboratory, Neursocience, Cold Spring Harbor Laboratory, United States of America, [3]Humboldt University of Berlin, Bernstein Centre For Computational Neuroscience, Berlin, Germany, [4]Washington University School of Medicine, Neuroscience & Psychiatry, St. Louis, United States of America

Hallucinations, a central symptom of psychotic disorders, are attributed to excessive dopamine in the striatum. However, the neural circuit mechanisms by which dopamine produces hallucinations remain elusive, largely because hallucinations have been challenging to study in model organisms. Here, we aimed to establish a novel readout of hallucinations that easily translates from humans to mice. Our goal was to provide a circuit-level description of the suggested link between dopamine and hallucinations. We reasoned that hallucinations can be operationalized as false perceptions of non-existent signals that are experienced with high confidence. We developed a task to quantify hallucination-like perception in mice and humans alike. We found evidence across species that hallucination-like perceptions were a valid readout of hallucinations: In humans, self-reported hallucinations were correlated with hallucination-like perceptions. In mice, hallucinogenic manipulations using ketamine or prior expectations consistently induced hallucination-like perceptions. Neural circuit investigations in mice showed that elevated baseline dopamine in both ventral and tail of striatum preceded hallucination-like perceptions. Computational modelling suggested that ventral striatal dopamine was consistent with the encoding of reward expectations, whereas the tail of striatum dopamine signalled prior expectation of hearing a signal. In line with this, optogenetic stimulation of dopaminergic activity in the tail of the striatum induced more hallucination-like perceptions, and this was reversed by the antipsychotic haloperidol. Taken together, our findings reveal a causal role for dopamine-dependent striatal circuits in hallucination-like perception and open new avenues to develop circuit-based treatments for psychotic disorders.

TOWARDS NEUROMODULATORY MECHANISMS OF AROUSAL AND MOTIVATION IN SUSTAINED ATTENTION

SYMPOSIUM 05 - NEUROMODULATION OF PERCEPTUAL DECISION-MAKING - ARMIN LAK, KENNETH KISHIDA, KATHARINA SCHMACK, MATTHEW MCGINLEY

Matthew Mcginley[1,2], Jan Willem De Gee[3], Zakir Mridha[2]
[1]Baylor College of Medicine, Duncan Neurological Research Institute, Houston, United States of America, [2]Baylor College of Medicine, Neuroscience, Houston, United States of America, [3]Baylor College of Medicine, Houston, TX, USA., Department Of Neuroscience, Houston, United States of America

The expectation of reward can lead to heightened perceptual sensitivity and improved decision-making. This is sometimes referred to as ‘the arousal effect.’ However, it is not clear how reward expectancy relates to arousal in its underlying circuit mechanisms or precise behavioral impacts. We here developed a challenging auditory feature-based sustained attention task in head-fixed mice, called the ‘attentional intensity’ task. Mice respond to unpredictable emergence of temporal coherence in an otherwise incoherent tone cloud by licking for sugar-water reward, analogous to coherent motion in visual attention. Difficulty is parametrically varied by partially degrading the coherence. The task alternates between blocks of trials with large and small rewards, resulting in shifts in reward expectancy that manifest as shifts in performance. Arousal is monitored via pupil size. We find that mice exhibit >5 attentional shifts/session, tightly time-locked to transitions in reward block. These shifts in attention manifest as increase discriminatory licking, and multiple signatures in a drift diffusion model of improved target stimulus engagement. Contrary to the naive prediction that high reward expectancy increases arousal, baseline pupil size actually decreased on average in high reward blocks, moving towards an optimal middle size, accounting for a fraction of the effect of reward expectation on attentional intensity. In ongoing experiments, we use two-photon calcium imaging to determine the roles of frontal-sensory and neuromodulatory signals in mediating the adaptation of attentional intensity to task utility.

CHOROID PLEXUS AND NON-CELL AUTONOMOUS REGULATION

SYMPOSIUM 06 - GO WITH THE FLOW! CHOROID PLEXUS MECHANISMS SHAPE BRAIN FUNCTION IN HEALTH AND DISEASE - ANNARITA PATRIZI, JEAN-FRANCOIS GHERSI-EGEA, FIONA DOETSCH, ROOSMARIJN VANDENBROUCKE

Annarita Patrizi
German Cancer Research Center DKFZ, Neuronal Signaling And Morphogenesis, Heidelberg, Germany

The Choroid Plexus (ChP), a specialized epithelial membrane located in all ventricles of the brain, produces 60-70% of the total cerebrospinal fluid (CSF) and forms the blood-CSF barrier impacting CSF and brain homoeostasis. In addition, ChP carries out neuro-endocrine, excretory and neuro-immune actions that are most likely involved in multiple neurological diseases. Recently, great attention has been given to the ChP as a key structure contributing to brain-body communication by sensing and reacting to both internal and external stimuli. However, only a few selective stimuli have been identified and very little is known about how the ChP can sense and respond to them. In the last few years our group has been focusing on understanding whether and how the ChP epithelial cell primary cilia, located on the apical cellular membrane and bathed in the CSF, can act as bio-sensors detecting surrounding stimuli. We did, indeed, demonstrate that ChP is characterized by a unique process of multi-ciliation that is spatio-temporally controlled. Furthermore, we found that ChP cilia are highly dynamic organelles that adapt and change throughout lifetime. In fact, ChP primary cilia are formed during embryogenesis but are gradually lost in early postnatal life both in mice and human postmortem samples. Interestingly, the maintenance of the cilium can be modulated by the presence of selective growth factors, suggesting that they can adapt to and reflect selective and different needs of the brain.

THE CHOROID PLEXUS-CSF SYSTEM IN PERINATAL ADVERSE CONDITIONS

SYMPOSIUM 06 - GO WITH THE FLOW! CHOROID PLEXUS MECHANISMS SHAPE BRAIN FUNCTION IN HEALTH AND DISEASE - ANNARITA PATRIZI, JEAN-FRANCOIS GHERSI-EGEA, FIONA DOETSCH, ROOSMARIJN VANDENBROUCKE

Jean-Francois Ghersi-Egea
Lyon Neuroscience Research Center (CRNL), INSERM U1028, CNRS UMR5292, UCBL1, Fluid Team, Bron, France

The choroid-plexus CSF system plays an important role in protecting brain fluid environment during pre-and post-natal periods of development. It also synthetizes or transports important proteins and trophic factors necessary to the development and normal maturation of the brain. These functions can be challenged in the setting of perinatal injuries, which increases the risk of abnormal development. Such injuries include inflammatory/infectious diseases. The choroid plexuses are highly sensitive to cytokines and toll-like receptor ligands. They respond by secreting an array of cytokines and chemokines in the choroidal stroma and CSF, that can be followed by immune cell infiltration into the CSF. Independently of their function as inflammatory modulators, some of these bioactive molecules are present in CSF during the perinatal/postnatal period. Their physiological levels appear finely regulated, and following cytokine-specific developmental patterns, likely reflecting the role that these bioactive molecules play in the development of the neuronal and vascular networks. Changes in CSF cytokines that result from choroid plexus activation or from immune cells invading the CSF through the choroid plexuses may participate in the disorganization of brain development induced by perinatal injuries.

CHOROID PLEXUS REGULATION OF ADULT NEURAL STEM CELLS

SYMPOSIUM 06 - GO WITH THE FLOW! CHOROID PLEXUS MECHANISMS SHAPE BRAIN FUNCTION IN HEALTH AND DISEASE - ANNARITA PATRIZI, JEAN-FRANCOIS GHERSI-EGEA, FIONA DOETSCH, ROOSMARIJN VANDENBROUCKE

Fiona Doetsch
University of Basel, Biozentrum, Basel, Switzerland

Specialized niches support the lifelong maintenance and function of tissue-specific stem cells. Stem cells in the adult ventricular-subventricular zone (V-SVZ) adjacent to the lateral ventricles give rise to olfactory bulb neurons, as well as different types of glia. Adult V-SVZ neural stem cells contact the cerebrospinal fluid, which flows through the brain ventricles, and depending on their spatial location generate different types of cells. They continuously integrate extrinsic signals to either maintain their quiescent state or to become activated and generate progeny.We have found that different physiological states and long-range signals regulate regionally distinct pools of V-SVZ stem cells. A key niche compartment is the choroid plexus, a vascularized epithelial structure in the brain ventricles that forms the blood-CSF barrier. The choroid plexus also secretes diverse factors into the CSF that differentially regulate adult neural stem cells. The choroid plexus is uniquely poised to sense signals in the blood and the CSF and in turn change its secretome in response to different states. Here we show that the choroid plexus transcriptome exhibits circadian changes, sex differences, and changes during the estrous cycle. Females have more macrophages than males, and male and female choroid plexus-secreted factors elicit different effects on adult neural stem cells. Given the multiple roles of the choroid plexus, our findings highlight that dynamic fluctuations in the choroid plexus transcriptome and secretome may have important impact on adult neural stem cells, as well as brain physiology in both health and disease.

Icahn School of Medicine at Mount Sinai, Psychiatry, NEW YORK, United States of America

Background: Prior literature has documented multiple biological and social factors that influence both brain development and mental health outcomes in adolescence. The current presentation discusses the role of the biosocial context of adolescent brain development and its association with psychopathology. Methods: A range of computational methods was applied to data pooled from multiple cohorts of adolescents to derive normative measures of regional brain development and to quantify the contribution of environmental exposures to brain morphometry, myelination and synaptic density in healthy adolescents and those with affective psychopathology. Results: The presentation introduces CentileBrain (www.centilebrain.org), an online tool for normative modeling of morphometric data and demonstrates its utility in quantifying the degree of morphometric deviance in adolescents with affective psychopathology. Application of clustering approaches to neuroimaging data and social exposures identified clusters of adolescents with advanced, delayed or atypical maturation. Conclusion: The availability of large datasets and computational tools is opening new avenues in the study of adolescent brain development.

Adolescence is a period of increased vulnerability to mental health conditions, particularly internalising difficulties such as depression. Earlier-onset is often associated with a more severe illness course and a range of psychosocial and physical difficulties which perpetuate across the lifespan. Given the emergence of depression during the adolescent period, the role that pubertal development may play in this heightened vulnerability has garnered increasing attention. Earlier pubertal timing (relative to same-age, same-sex peers) has been associated with higher rates of depressive disorders, particularly in females. Further, genetic studies have found that earlier age of menarche is implicated in depression. Adolescence is also a time of immense neurobiological change and brain structural differences have been found in both adults and adolescents with depression. However the role that neural mechanisms may play in the relationship between pubertal timing and depression risk remains unknown. Here, we present findings examining whether brain structure mediates the association between early pubertal timing and depressive symptoms in a large sample of early adolescents (aged 9-13 years) from the Adolescent Brain and Cognitive Development (ABCD) Study®.

LONGITUDINAL STRUCTURAL BRAIN DEVELOPMENT AND EXTERNALIZING BEHAVIOR IN ADOLESCENCE

SYMPOSIUM 07 - NEUROIMAGING APPROACHES TO UNDERSTANDING ADOLESCENT MENTAL HEALTH: OPPORTUNITIES FOR INTERVENTION - SOPHIA FRANGOU, HEATHER WHALLEY, MARIEKE BOS, RYAN MUETZEL

Marieke Bos
Leiden University, Developmental & Educational Psychology, Leiden, Netherlands

BACKGROUND AND AIMS: Most adolescents take part in some kind of antisocial behavior, such as rule-breaking, aggression, curving, or underage drinking. Antisocial behavior is marked by individual differences, not only in extent and severity but also in stability over time. Specifically, the transition between adolescence and young adulthood has long been recognized as a potential turning point for the development of antisocial behavior, due to changes in social contexts and ongoing psychological and neurobiological maturation. To increase our understanding of developmental trajectories of antisocial behavior, longitudinal study designs are pivotal. METHODS: I will present data of two longitudinal studies focusing on neurodevelopment of aggressive behavior. In the first study, we examined the relation between structural brain development and aggressive behavior in a population sample (N=299; age 8-28). In the second study, we examined brain activity in a social aggression task in a high-risk sample of young adults (N=55; age 20 - 28). RESULTS: (1) decrease of hippocampal volume was associated with increase in aggressive behavior (2) individuals with persistent or desistent trajectories of antisocial behavior showed dissociable patterns of neural activity when receiving social feedback in a social aggression task: desisting and persisting trajectory groups showed higher activity in the insula compared to controls, and the desisting trajectory group showed higher activity in dlPFC. CONCLUSION: In this talk, I will emphasize the value of studying different neurobiological mechanisms and using an individual differences approach to better understand the complexity of antisocial behavior and its diverse trajectories.

Neuroimaging offers a unique window into the developing brain, providing important insights into emergent mental illness. Identification of reproducible neurobiological signatures of psychopathology with strong predictive value remains a priority. However, relatively modest effect sizes from univariate statistical techniques combined with heterogenous symptom presentation may impede the detection of such clinically-relevant imaging biomarkers. Multivariate statistical techniques show promise in identifying complex patterns in high dimensional data and in aggregating across many small effects. For example, techniques such as canonical correlation analysis have demonstrated utility in identifying maximally-correlated features from both neuroimaging and behavioral data. This approach allows for the delineation of brain-based dimensions of psychiatric problems which are not constrained by traditional diagnostic nosology and potentially yield better clinical predictive value. This presentation will cover the application of canonical correlation analysis to identify maximally correlated features of resting-state functional connectivity and dimensional psychiatric symptoms in children 9-to-11 years old. Using data from two large, population-based cohorts (Generation R, ABCD), we present different brain-based dimensional features of psychiatric problems which may offer insights into transdiagnostic neurobiological signatures of mental illness. Importantly, we also highlight several caveats and potential limitations related to the application of canonical correlation analysis in high-dimensional resting-state functional connectivity data.

MACHINE LEARNING APPROACHES FOR UNRAVELING HUMAN MECHANISMS OF BRAIN DYSFUNCTION IN MICE.

SYMPOSIUM 08 - NEURONAL NETWORK AND SYNAPTIC DYSFUNCTION IN ALZHEIMER'S DISEASE - JORGE PALOP, SILVIA VIANA DA SILVA, MARTIN FUHRMANN, ANNABELLE SINGER

Jorge Palop
University of California, San Franscisco, Department Of Neurology,glasdtone Institutes, San Francisco, United States of America

New molecular approaches of genome editing are creating a paradigm shift in modeling neurodegenerative disorders by humanizing mouse genes carrying disease-associated genomic changes. These exquisite disease-induced manipulations – often affecting only a few amino acids – mimic closely human disease mechanisms, yet represent a tremendous challenge for assessing their behavioral and functional manifestations that define neurological disorders because standard behavioral approaches often lack the required sensitivity and breadth. We approached this technological barrier by implementing machine learning platforms for assessing diseased-induced behavioral manifestations of humanized models of Alzheimer's disease (AD). We found that machine learning approaches reveal prominent behavioral manifestations and cognitive dysfunction in humanized AD mice with an unprecedented level of quantitative precision and insights into behavioral organization.

SUB-CIRCUIT SPECIFIC DEFICITS UNDERLYING SPATIAL MEMORY IMPAIRMENTS IN ALZHEIMER'S DISEASE

SYMPOSIUM 08 - NEURONAL NETWORK AND SYNAPTIC DYSFUNCTION IN ALZHEIMER'S DISEASE - JORGE PALOP, SILVIA VIANA DA SILVA, MARTIN FUHRMANN, ANNABELLE SINGER

Silvia Viana Da Silva
DZNE, Berlin, Berlin, Germany

Deficits in spatial navigation are among the early symptoms in Alzheimer's disease (AD) patients, consistent with the hippocampal formation being necessary for spatial computations and with disease onset in the hippocampal formation. Although it is recognized that early symptoms correspond to brain regions that are affected early in the disease, it is not clear whether further cognitive decline is solely caused by a spreading cellular pathology, or whether a focal pathology can by itself cause aberrant neuronal activity in a larger network. These possibilities cannot be distinguished in standard disease models, which broadly express AD-related proteins across brain regions. We therefore generated a mouse model in which the expression of mutant human APP was limited to hippocampal CA3 cells (CA3-APP mice). We first asked whether the limited pathology in CA3 can result in memory deficits and found memory impairments in CA3-APP mice. By recording neuronal activity in the hippocampus, during the memory task, we asked to what extent pathological neuronal activity patterns emerged in different hippocampus sub-regions. We found that early circuit dysfunction did not include differences in the spatial firing patterns of place cells, but were rather encompassed by a reduced theta oscillation frequency and disruption in sequential firing of CA1 place cells during the task. This underlines the influence that altered network function has on the memory deficits associated with AD, indicating that the disease progression can be driven by altered network mechanisms rather than changes at the level of individual cells.

MEMORY TRACE DISTURBANCES UNDER AD-LIKE CONDITIONS

SYMPOSIUM 08 - NEURONAL NETWORK AND SYNAPTIC DYSFUNCTION IN ALZHEIMER'S DISEASE - JORGE PALOP, SILVIA VIANA DA SILVA, MARTIN FUHRMANN, ANNABELLE SINGER

Martin Fuhrmann
German Center for Neurodegenerative Diseases (DZNE), Neuroimmunology And Imaging, Bonn, Germany

Memory impairment is a characteristic of Alzheimer's disease (AD). The hippocampus is important for memory processes and primarily affected in AD. Ensembles of neurons in the hippocampus are thought to be active during encoding and retrieval of a memory. These reactivated ensembles of neurons are called a memory trace or engram. We hypothesized that memory traces would be disturbed under AD-like conditions in a mouse model. To test this hypothesis, we visualized hippocampal memory traces under AD-like conditions over the course of a hippocampus-dependent memory test – contextual fear conditioning. Surprisingly, we detected intact memory traces even in mice with AD-like pathology. However, these memory traces were superimposed by other active ensembles of neurons that most likely encoded novelty-like information. These results indicated that memory trace interference could be the basis for memory impairment. We used chemogenetic experiments to manipulate novelty-like neuronal ensemble activity, either artificially activating or inhibiting novelty-like ensembles. We found that artificial silencing of novelty-like neuronal activity improved memory under AD-like conditions, suggesting that memory trace interference might be a neuronal network mechanism affecting memory in AD.

NEW APPROACHES TO ALZHEIMER'S: FROM NEURAL DEFICITS TO STIMULATION THAT BOOSTS IMMUNE FUNCTION

SYMPOSIUM 08 - NEURONAL NETWORK AND SYNAPTIC DYSFUNCTION IN ALZHEIMER'S DISEASE - JORGE PALOP, SILVIA VIANA DA SILVA, MARTIN FUHRMANN, ANNABELLE SINGER

Georgia Institute of Technology and Emory University, Coulter Department Of Biomedical Engineering, Atlanta, United States of America

In this talk I will describe how discovering deficits in neural activity in Alzheimer's disease (AD) led to the development of new neural stimulation approaches to treat the disease. Spatial navigation deficits are one of the earliest symptoms of AD and the hippocampus is one of the areas first affected by the disease. First, we discovered how neural codes underlying memory-based spatial decisions fail in animal models Alzheimer's disease (AD). Using a virtual reality behavior paradigm to record and manipulate neural activity in transgenic mice, the primary animal model of AD, we found deficits in synaptic efficacy during behavior and in patterns of activity that are required for spatial memory. The neural deficits we found inspired us to stimulate specific frequencies of activity that are lacking in the Alzheimer's model mice. To achieve this, we developed new non-invasive sensory stimulation to drive rhythmic neural activity at different frequencies. Driving gamma frequency (40Hz) activity non-invasively mobilized the immune system and reduced pathogenic proteins in mouse models of Alzheimer's disease. Investigating the biochemical mechanisms involved, we discovered a unique immune signaling cascade by which gamma neural activity recruits neuroimmune function. Interestingly, other frequencies have distinct effects on neuroimmune signaling and cells. Finally in humans with Alzheimer's disease, gamma sensory stimulation altered neuroimmune signaling in the cerebral spinal fluid and stengthened connectivity of neural circuits important for memory. These discoveries could lead to new therapies for Alzheimer's disease by driving specific patterns of neural activity to impact cognitive, cellular, and molecular dysfunction.

The transition from early stages in which neurons display highly synchronous activity patterns to a mature state in which neural activity is sparse and decorrelated, is poorly understood. This transition has important functional consequences, as the latter state allows for more efficient storage, retrieval and processing of information. Here, we show that in the developing mouse prefrontal cortex (PFC), neural activity decorrelates across timescales spanning more than three orders of magnitude. This developmental phenomenon is accompanied by a concomitant tilting of excitation/inhibition (E-I) ratio towards inhibition. Using optogenetic manipulations and neural network modeling, we provide extensive evidence revealing how the two processes are causally linked, and how, across the first two postnatal weeks, in the mouse PFC, a relative increase of inhibition drives the decorrelation of neural activity. Accordingly, in two mouse model of neurodevelopmental disorders, subtle alterations in E-I ratio are associated with specific impairments in the correlational structure of spike trains. Finally, we show that an analogous transition takes place also in the developing human brain. We conclude that changes in E-I ratio control the sparseness of neural activity, and that developmental imbalances in this process might be relevant for understanding the pathogenesis of neurodevelopmental disorders.

GABAERGIC INPUTS AND THE FUNCTIONAL INTEGRATION OF PYRAMIDAL NEURON SUBTYPES IN THE SOMATOSENSORY CORTEX

SYMPOSIUM 09 - THE EMERGENCE OF FUNCTION IN DEVELOPING CORTICAL CIRCUITS - ILEANA HANGANU-OPATZ, NATALIA DE MARCO GARCIA, CARLOS PORTERA-CAILLIAU, OSCAR MARIN

Natalia De Marco Garcia
Weill Cornell Medical College, Brain And Mind Research Institute, New York, United States of America

Dysfunction of gamma-aminobutyric acid (GABA)-mediated inhibitory circuits isstrongly associated with neurodevelopmental disorders. However, it is unclear how genetic predispositions impact circuit assembly. Using in vivo two-photon and widefield calcium imaging in developing mice, we study how early GABAergic dysfunction impacts neuronal development and circuit assembly. Using longitudinal in vivo two-photon and widefield calcium imaging in developing mice, we show that altered interneuron function and $GABA_A$ receptor signaling lead to a long-lasting increase in correlated activity in the somatosensory cortex. This aberrant network pattern impacts interneuron survival and neuronal development including the assembly of long-range circuits.

Cortical circuit dysfunction is a primary pathophysiology in neurodevelopmental disorders (NDDs). Considering how symptoms in NDDs/autism become apparent in toddlers, circuit changes must emerge very early in cortical development. Over the last decade, developmental differences in cortical synaptic dynamics, neuronal adaptation, and network synchrony have been reported in the *Fmr1* knockout (KO) mouse model of Fragile X Syndrome (FXS), a prototypical NDD. In addition, the density, maturity and activity of parvalbumin cortical interneurons (PV INs) are all reduced in *Fmr1* KO mice and in other autism mouse models. Here, we will present our latest research on PV cells and their precursors from the medial ganglionic eminence (MGE) and how their dysfunction in *Fmr1* KO mice within feedforward circuits in the primary somatosensory cortex (S1) contributes to atypical sensory processing. We find that the density of PV INs in S1 is reduced in both juvenile and adult *Fmr1* KO mice, as well as in post-mortem tissue from human FXS cases. Furthermore, the density and the firing of Nkx2.1-expressing precursors of PV INs are both reduced in *Fmr1* KO mice by postnatal day (P) 6. Remarkably, increasing their activity from P5 to P9 using excitatory DREADDs significantly increases the density of PV cells at P15. Moreover, increasing the activity of PV cells in *Fmr1* KO mice with a novel allosteric modulator of Kv3.1 channels (responsible for fast-spiking characteristics of PV INs) improves deficits in the tuning and the adaptation of excitatory neurons in S1 to repetitive whisker stimulation.

MOLECULAR MECHANISMS REGULATING THE MATURATION OF CORTICAL GABAERGIC INTERNEURONS

SYMPOSIUM 09 - THE EMERGENCE OF FUNCTION IN DEVELOPING CORTICAL CIRCUITS - ILEANA HANGANU-OPATZ, NATALIA DE MARCO GARCIA, CARLOS PORTERA-CAILLIAU, OSCAR MARIN

Oscar Marín
King's College London, Centre For Developmental Neurobiology And Mrc Centre For Neurodevelopmental Disorders, London, United Kingdom

GABAergic interneurons play crucial roles in the regulation of neural circuit activity in the cerebral cortex. A hallmark of cortical interneurons is their remarkable structural and functional diversity, yet the molecular determinants and the precise timing underlying their diversification remain largely unknown. The search for mechanisms controlling the diversity of GABAergic interneurons has primarily focused on the analysis of transcriptional programs driving the initial specification of different types of interneurons. However, relatively little is known about the mechanisms regulating their terminal differentiation. In this talk, I will describe molecular mechanisms regulating the maturation and plasticity of PV+ interneurons, which allow their functional integration into neuronal assemblies in the neocortex.

REGULATION OF ADULT NEURAL STEM CELL CYCLING HETEROGENEITY

SYMPOSIUM 10 - NEURAL STEM CELLS IN THE ADULT VERTEBRATE BRAIN - ISABEL FARIñAS, LUCA BONFANTI, LAURE BALLY-CUIF, DIEGO GARCíA-GONZáLEZ

Isabel Fariñas
University of Valencia, Instituto De Biotecnología Y Biomedicina, Burjassot, Spain

Most mammalian tissues harbor long-lived stem cells (SCs), which balance their self-renewing proliferation with the production of differentiated progeny to compensate for physiological cell loss. Subsets of SCs can spend long periods in quiescence, but the molecular regulation of this state as well as the reversible transitions between dormancy and activation have started to be understood only recently. Furthermore, subsets of non-cycling SCs in a particular tissue can be found at varying depths of quiescence. While all these cells share a transcriptional program of quiescence, some of them are more prone to engage proliferation upon mitogen stimulation. This state of shallow quiescence has been described in muscle SCs, hematopoietic SCs, and neural SCs (NSCs). Recent refinements of the procedures to isolate NSCs from the adult mouse subependymal zone (SEZ) by fluorescence-activated cell sorting together with deep sequencing and cycling analysis now allows to recognize NSCs in three states: quiescent (q), quiescent-primed (p), and activated (a). Molecularly defined primed-like and activated-like NSCs dividing at different rates can detected in neurospheres growing under mitogenic stimulation suggesting intrinsic properties. The existence and interchangeability of these states suggest finely tuned mechanisms of cycling regulation, the molecular details of which, however, remain unknown. The combination of the molecular knowledge about these states with ways to label quiescent NSCs since mid-gestation by in utero electroporation is helping unravel physical interactions between quiescent NSCs and their niche with impact on cell transitions.

BEYOND STEM CELL-DRIVEN ADULT NEUROGENESIS: THE COMPLEX ISSUE OF “IMMATURE” NEURONS

SYMPOSIUM 10 - NEURAL STEM CELLS IN THE ADULT VERTEBRATE BRAIN - ISABEL FARIñAS, LUCA BONFANTI, LAURE BALLY-CUIF, DIEGO GARCíA-GONZáLEZ

Luca Bonfanti
University of California San Francisco (UCSF), School Of Medicine, San Francisco, United States of America

Research in adult neurogenesis has revealed some general trends: a progressive reduction across the animal lifespan (due to stem cell depletion); remarkable interspecies differences (with reduction from non-mammalian vertebrates to mammals, and from mouse to gyrencephalic species).
In mammals, “canonical” neurogenic processes (stem cell-driven neurogenesis) are restricted to small stem cell niches persisting from embryonic germinal layers. The genesis of new neurons has also been reported in parenchymal brain regions, their outcome being mostly “incomplete”. Whichever the process involved, several populations of “young” neurons can be found at various locations of the brain.
Across the last few years, further complexity emerged: i) molecules of immaturity can also be expressed by pre-natally generated cells, then maintaining immature features later on (“immature” or “dormant” neurons); ii) interspecies differences exist concerning the types, location, amount of undifferentiated neurons; iii) re-expression of immaturity can occur in aging (dematuration). These twists are introducing a somewhat different definition of neurogenesis than normally assumed, in which our knowledge of the “immature” neurons is less sharp. Moreover, a mix of newlyborn and non-newly generated immature cells expressing common markers of immaturity can exist (maybe coexist).
In this emerging complexity, there is a need for complete mapping of the different “types” of young neurons, considering their role in postnatal development, plasticity, functioning, and interspecies differences. Important aspects are at stake: the possible role(s) that these neuronal populations may play in maintaining brain efficiency and in prevention/repair of neurological disorders; nonetheless, the correct translation of results obtained from laboratory rodents.

SINGLE-CELL AND POPULATIONAL CONTROL OF ADULT NEURAL STEM CELL MAINTENANCE

SYMPOSIUM 10 - NEURAL STEM CELLS IN THE ADULT VERTEBRATE BRAIN - ISABEL FARIñAS, LUCA BONFANTI, LAURE BALLY-CUIF, DIEGO GARCíA-GONZáLEZ

Laure Bally-Cuif
Institut Pasteur, Developmental And Stem Cell Biology, Paris, France

We aim to understand how single cell and population events interplay to ensure the maintenance of neural stem cell (NSC) pools in the adult brain. We focus on the dorsal telencephalon (pallium), which hosts NSCs in all adult vertebrates. In the zebrafish, pallial NSCs are a monolayer of tightly juxtaposed radial glia. These cells are mostly quiescent but can transiently activate (ie. enter the cell cycle) to divide and generate other NSCs and/or neurons. The NSC decision to activate, and the fate choices it makes at division, are two key events conditioning NSC maintenance. These events are controlled at both the single-cell and the population levels, and we are taking quantitative and dynamic approaches to understand these processes in time and space. For this, we developed an intra-vital imaging method to record, over weeks and with single cell resolution, the behavior of all NSCs in their niche. With this, we generated a 4D map of NSC activation and division events. Using spatial statistics and mathematical modeling in an NSC lattice, we showed that NSC activation events are spatiotemporally correlated by local and temporally delayed interactions that occur between brain germinal cells and generate self-propagating dynamics. We also observed that NSC apical size is highly predictive of NSC fate decisions at division, and are analyzing the mechanisms involved and their cell- and non-cell-autonomous impact. Together, this work will highlight how NSCs across the germinal sheet coordinate their state and fate decisions for the harmonious and long-lasting maintenance of the NSC pool.

An ample range of interneuron subtypes are generated during brain development. In the mammalian brain, specification of interneuron identity is thus a highly controlled process that emerges in the ventricular-subventricular zone (V-SVZ) around the lateral ventricles. There, a population of heterogeneous neural stem cells (NSCs) give rise to intermediate progenitor cells (IPC), which in turn, produce neuroblasts that migrate along the rostral migratory stream (RMS) to the olfactory bulb (OB). Once within the OB, neuroblasts integrate into specific layers where they become distinct subtypes of mature interneurons, which are involved in the processing of olfactory information. The V-SVZ-OB system is thus an excellent model to study interneuron identity specification during brain development. Here we present a comprehensive analysis of V-SVZ-OB interneuron lineages in postnatal mouse brain development with the help of single-cell transcriptomics. We provide further evidence for the existence of different subsets of NSCs, depending on their spatial localisation within the V-SVZ, and we show a deep characterisation of mature OB interneuron supopulations. In addition, we employ virus-mediated gene expression modification to provide functional evidence of how the specific expression of transcription factors modulates the number of OB interneurons.

CO-TRANSMISSON OF ACH AND GABA THROUGH DEVELOPMENT

SYMPOSIUM 11- REVISITING DALE'S PRINCIPLE- NEUROTRANSMITTER PLASTICITY AND CO- TRANSMISSION IN HEALTH AND DISEASE - ADAM GRANGER, JING REN, THOMAS STEINKELLNER, SWETHA GODAVARTHI

Adam Granger
Harvard Medical School, Stanley Center At The Broad Institute, Boston, United States of America

The cholinergic system plays a crucial role in a variety of cognitive processes, including maintaining attention, learning and memory, and sensory processing. However, our understanding of how cholinergic neurons influence cortical activity is incomplete. Specifically, we have recently learned that many cholinergic neurons of the basal forebrain, medial septum, and cortex can also release the neurotransmitter GABA. Because acetylcholine is typically excitatory and GABA is inhibitory, co-transmission of both of these molecules appears contradictory. In addition, we found that that while an integrated genetic measure of GABA release indicates that nearly all cholinergic neurons are able to release GABA, *in situ* labeling of GABAergic markers at a single adult time point finds GABA release machinery in only a subset of neurons. To explain this discrepancy, we characterized GABAergic marker expression in cholinergic neurons throughout development, and found that at each stage, a subset of cholinergic neurons are capable of GABA release. These results suggest a model of pulsatile GABA release from cholinergic neurons, whereby different subset of cholinergic neurons are able to release GABA at different time points.

CO-TRANSMISSION IN THE MID-BRAIN CHOLINERGIC AND SEROTONERGIC SYSTEMS

SYMPOSIUM 11- REVISITING DALE'S PRINCIPLE- NEUROTRANSMITTER PLASTICITY AND CO- TRANSMISSION IN HEALTH AND DISEASE - ADAM GRANGER, JING REN, THOMAS STEINKELLNER, SWETHA GODAVARTHI

Jing Ren
The Medical Research Council Laboratory of Molecular Biology (MRC LMB), Neurobiology Division, Cambridge, United Kingdom

Cotransmission was proposed in 1976 and found in the peripheral nervous system. More recently it is recognized that, in the mammalian central nervous system (CNS), neurons not only contain multiple transmitter substances like neuropeptides, co-released with small-molecule transmitters; but also can co-release two or more small molecule transmitters. The midbrain contains multiple neuromodulatory systems, and almost all of them possess complex contransmission organization. The habenulo-interpeduncular projection is a major cholinergic pathway in the brain. In 2011, we found that the habenula cholinergic neurons co-release glutamate and acetylcholine. In addition, glutamatergic responses are fast and likely mediated by synaptic ionotropic glutamate receptors, whereas slow cholinergic effects are triggered only by tetanic stimuli and likely produced by the volume transmission of acetylcholine. These results suggest dual modes of signal transmission by cholinergic neurons in the brain. In 2017, we found that the terminals of projection from dorsal raphe (DR) to orbital frontal cortex (OFC) co-release serotonin and glutamate to modulate OFC network activity. Our data further suggested that these neurons are mainly located at the ventral DR, expressing Vglut3. In 2019, we profiled the transcriptomic properties of the serotonin neurons in the midbrain, revealing the extremely complex organization of multiple transmitter substances in the serotonin system. Recently, we also generated the transcriptomic profile of the DR dopamine system to reveal its cotransmission properties. These data confirmed that cotransmission is a core signalling mechanism in the CNS, operating in remarkable diversity.

DOPAMINE NEURONS EXHIBIT EMERGENT GLUTAMATERGIC IDENTITY IN PARKINSON'S DISEASE

SYMPOSIUM 11- REVISITING DALE'S PRINCIPLE- NEUROTRANSMITTER PLASTICITY AND CO- TRANSMISSION IN HEALTH AND DISEASE - ADAM GRANGER, JING REN, THOMAS STEINKELLNER, SWETHA GODAVARTHI

Thomas Steinkellner
Medical University of Vienna, Institute Of Pharmacology, Center For Physiology And Pharmacology, Vienna, Austria

Loss of midbrain dopamine neurons causes the cardinal symptoms of Parkinson's disease. However, not all dopamine neurons are equally vulnerable and a better understanding of the cell-type specific properties relating to selective dopamine neuron degeneration is needed. Most midbrain dopamine neurons express the vesicular glutamate transporter VGLUT2 during development and a subset continue to express low levels of VGLUT2 in adulthood, enabling the co-release of glutamate. Moreover, VGLUT2 expression in dopamine neurons can be neuroprotective since its genetic disruption was shown to sensitize dopamine neurons to neurotoxins. Here, we show that in response to toxic insult, and in two distinct models of alpha-synuclein stress, VGLUT2 dopamine neurons were resilient to degeneration. Dopamine neurons expressing VGLUT2 were enriched whether or not insult induced dopamine neuron loss, suggesting that while VGLUT2 dopamine neurons are more resilient, VGLUT2 expression can also be transcriptionally upregulated by injury. Finally, we observed that VGLUT2 expression was enhanced in surviving DA neurons from postmortem Parkinson's disease subjects. These data indicate that emergence of a glutamatergic identity in dopamine neurons may be part of a neuroprotective response in Parkinson's disease.

Robust communication systems include an acknowledgement signal from the receiver to the sender indicating that the sender's message has been received. We have tested this organization at the synapse, with loss-of-function (LOF) and gain-of-function experiments (GOF). Using the *Xenopus* neuromuscular junction (NMJ), we find that LOF with focal blockade of endogenous acetylcholine receptors by pancuronium results in loss of ChAT in presynaptic motor neurons (MNs). Ectopic expression of GABA receptors ($GABA_AR\alpha\beta\gamma$) in myocytes in a GOF during development leads to expression of GABA in presynaptic cholinergic MNs. GABA expression is seen in innervating axon terminals and in cell bodies in the spinal cord. Co-expression of the MN markers Hb9, ChAT and Lim3 confirms their primary MN identity. Consistent with the appearance of GAD67 and VGAT in these MNs, GABAergic miniature endplate potentials at the NMJs are recorded from the myocytes. Misexpression of a single $GABA_AR\alpha$ subunit, resulting in a non-functional GABAR that is not trafficked to the postsynaptic membrane, does not produce these changes. Expressing the GABA-insensitive mutant $GABA_AR\alpha\beta_{E179Q}\gamma$ reveals that $GABA_AR$ channel activity is not necessary for presynaptic expression of GABA. Because these MNs normally express GABA transiently at earlier stages of development, exogenous $GABA_AR\alpha\beta\gamma$ likely prevents the loss of GABA expression. Our GOF results suggest that ectopically expressed postsynaptic receptors promote presynaptic neurotransmitter stability. Our LOF results suggest that blockade of endogenous receptors destabilizes presynaptic neurotransmitter expression. Receptor-mediated retrograde signaling at the synapse may be an acknowledgment signal for maintaining transmitter expression.

PATTERN DETECTION IN SUBCORTICAL AND CORTICAL AUDITORY STRUCTURES

SYMPOSIUM 12 - STATISTICAL LEARNING AND PATTERN RECOGNITION FOR NATURAL BEHAVIOUR IN MICE - LIVIA DE HOZ, ROBERT FROEMKE, JEFFREY GAVORNIK, CATHERINE PERRODIN

Livia De Hoz
Charité-Universitätsmedizin Berlin, Neuroscience Research Center, Berlin, Germany

Detecting the spatiotemporal structure that threads external stimuli together is an essential function of the brain. It facilitates subsequent distinction between background and foreground, familiar and novel, or salient and neutral information. This is particularly true for the auditory soundscape, which our brain detects continuously and pre-attentively. The detection and learning of a soundscape's structure begins already in sensory subcortical stations. This processing both feeds and is modulated by cortical structures, through feedforward and feedback projections respectively. Using a combination of behaviour and electrophysiology, we study the emergence of activity patterns that code both neutral and behavioural relevant soundscape patterns across auditory subcortical and cortical processing stations, as well as across mental states.

Oxytocin is important for social interactions and maternal behavior. However, little is known about when, where, and how oxytocin modulates neural circuits to improve social cognition. Here I will discuss recent results and unpublished data from our lab on how oxytocin enables maternal behavior in new mother mice. I will focus on experience-dependent plasticity in auditory cortex related to recognizing the significance and statistical structure of pup distress calls, which are important for mother mice retrieving lost pups back to the nest. Surprisingly, this behavior, neural responses, and oxytocin receptor expression were lateralized to the left side of the auditory cortex, perhaps similar to the lateralization of language abilities in humans. I will also describe a new system we have built to combine neural recordings from the auditory cortex and oxytocin neurons of the hypothalamus in vivo, synchronized with days-to-weeks long continuous video monitoring of homecage behavior to identify when oxytocin release and cortical plasticity might occur during natural social and maternal experience.

LEARNING TO ANTICIPATE TEMPORAL RELATIONSHIPS IN VISUAL INFORMATION

SYMPOSIUM 12 - STATISTICAL LEARNING AND PATTERN RECOGNITION FOR NATURAL BEHAVIOUR IN MICE - LIVIA DE HOZ, ROBERT FROEMKE, JEFFREY GAVORNIK, CATHERINE PERRODIN

Jeffrey Gavornik
Boston University, Department Of Biology, Boston, United States of America

The last decade has produced unequivocal evidence that the primary visual cortex (V1) is not simply a simple feature detector. There are cells in V1 that detect edges and other simple features of visual space, but V1 dynamics are also affected by non-visual information associated with movement, auditory activity, hippocampal place fields, and cholinergic projections from the forebrain. Visual experience can also drive local plasticity that allows V1 to represent time, spatial patterns, and to predict expected inputs. In addition to raising interesting questions about V1's precise function in the visual hierarchy, these findings also make clear that V1 is a model system that can be used to study more general aspects of cortical computation and inter-area integration. In this talk, I will focus on what V1 reveals about how cortical circuits learn to encode ordinal and temporal relationships, and how neural circuits use this coding to anticipate expected events. I will focus particularly on the role of muscarinic acetylcholine receptors in selecting plasticity to represent either spatial or temporal information and also how V1 circuits are modified to make predictions at various timescales.

BEHAVIOURAL RELEVANCE OF VOCAL TEMPORAL REGULARITY FOR MOUSE COURTSHIP

SYMPOSIUM 12 - STATISTICAL LEARNING AND PATTERN RECOGNITION FOR NATURAL BEHAVIOUR IN MICE - LIVIA DE HOZ, ROBERT FROEMKE, JEFFREY GAVORNIK, CATHERINE PERRODIN

Catherine Perrodin
University College London, Ear Institute, London, United Kingdom

Animals navigating the real world continuously face large amounts of complex sensory information. One of the strategies used by the brain to perceptually compress multidimensional input is to selectively extract the features relevant for behaviour. Like many other animals, mice communicate using acoustically complex vocal sequences. However, little is known about what acoustic information in these sensory streams listeners monitor to guide their social interactions. Here, we utilized C57Bl/6 female mice's natural behavioural response to ultrasonic songs emitted by conspecific males to identify socially-relevant acoustic dimensions in mouse communication. Using competing playbacks of intact and artificial version of male songs, we quantified whether and how different acoustic manipulations affected the females' place preference. This allowed us to evaluate the behavioural relevance of several candidate acoustic features for mouse communication. In this ethologically-relevant laboratory assay, we found that females listeners were highly sensitive to disruptions of song temporal regularity and preferentially approached playbacks of intact male songs over rhythmically irregular versions of the songs. In contrast, female behaviour was invariant to manipulations affecting the global song structure, such as randomization of syllable order and song temporal reversal. Similarly, female approach behaviour was robust to the removal of syllable spectro-temporal dynamics such as phase-scrambling or pure tone approximation. The results highlight temporal structure as a key acoustic cue monitored by female listeners during vocal-driven mate selection, and suggest vocal regularity as a potential acoustic signature of singer fitness. This behavioural work informs ongoing electrophysiological investigations into the neuronal substrates supporting the perception of vocal sequences for mate choice.

TIME AND NEURAL POPULATION ACTIVITY IN ENTORHINAL CORTEX

SYMPOSIUM 13 - EPISODIC TIME - EDVARD MOSER, CHRISTIAN DOELLER, CORNELIA MCCORMICK, VIRGINIE VAN WASSENHOVE

Edvard Moser
NTNU, Kavli Institute For Systems Neuroscience And Centre For Neural Computation, Trondheim, Norway

The representation of time is a critical component of episodic memories encoded in the hippocampal formation. We showed four years ago in tetrode recordings in freely foraging rats that temporal information is robustly and specifically encoded in the overall neural population activity of lateral entorhinal cortex (LEC), across time scales from seconds to hours. We have now used Neuropixels recordings from hundreds to more than a thousand simultaneously recorded cells, along with dimensionality reduction approaches, to describe the evolution of neural activity in LEC during performance in tasks with different event structures. In LEC there was a strong tonic drift in population activity during individual behavioral trials, independently of whether the animals were pretrained. Only minimal change was observed in parallel recordings from MEC, CA1 or V1. Discrete events were associated with phasic jumps in the state space, possibly proportional to the novelty of the event, supporting the notion that the representation of episodic time in the LEC is discretized, with progression through state space scaled to the density and salience of events. We hypothesize that these event-driven dynamics of population activity in LEC is stored in hippocampal memory and may be used both during ongoing task performance to estimate how much time has passed and subsequently in order to estimate retrospectively the duration of the entire experience. The correlation with event structure suggests that estimates of duration must be non-linear, not merely reflecting the difference in population state between beginning and end of a block of experience.

STRUCTURING TIME IN THE HIPPOCAMPAL-ENTORHINAL SYSTEM

SYMPOSIUM 13 - EPISODIC TIME - EDVARD MOSER, CHRISTIAN DOELLER, CORNELIA MCCORMICK, VIRGINIE VAN WASSENHOVE

Christian Doeller
Max Planck Institute for Human Cognitive and Brain Sciences, Department Of Psychology, Leipzig, Germany

The hippocampal-entorhinal system supports the representation of task regularities. A critical function may be the encoding of temporal context, i.e., forming integrated relational representations of co-occurring events and stimuli. In my talk, I will present data from two fMRI studies. In one study, participants mnemonically constructed times of events from multiple sequences (see Bellmund et al, bioRxiv 2022). Here, temporal relations were generalized across sequences, revealing distinct representational formats in the hippocampus for events from the same or different sequences. Furthermore, structural knowledge about time patterns across different sequences biased the construction of specific event times. In another study (cf. Polti, Nau et al, bioRxiv 2021), we used a time-to-contact estimation task to test whether temporal context modulates grid-like coding in the entorhinal cortex. In addition, we characterized in detail the relationship between trial-wise entorhinal fMRI activity and participants' task performance. Critically, we found that entorhinal activity reflected biases in timing behaviour, and that the strength of grid-like signals depended on the timing errors, consistent with temporal-context encoding. In sum, our findings demonstrate that the human hippocampal-entorhinal system contributes to adapting internal timing mechanisms to the temporal statistics of the environment and supports the generalization of temporal relations across experiences.

THE NEURAL CONSTRUCTION OF IMAGERY-RICH MENTAL EVENTS

SYMPOSIUM 13 - EPISODIC TIME - EDVARD MOSER, CHRISTIAN DOELLER, CORNELIA MCCORMICK, VIRGINIE VAN WASSENHOVE

Cornelia Mccormick
University Medical School Bonn, Department Of Neurodegenerative Diseases And Geriatric Psychiatry, Bonn, Germany

Most people can voluntarily play out vivid, detail-rich mental events from their past, envision various scenarios set in the future or imagine never-experienced events in a fictitious setting. These imagery-rich events seem ubiquitous in our mental life, underlying autobiographical memory retrieval and episodic future thinking, and spatial navigation. However, there is still a dearth of evidence, whether people actively use imagery-based strategies in these cognitive tasks and which neural substrates support their initiation and elaboration. In this talk, I will synthesize evidence that imagery-rich mental events may be the modus operandi of our minds. Moreover, I suggest that these mental movies are constructed by a functional neural hierarchy spanning from the ventromedial prefrontal cortex (vmPFC), anterior and posterior segments of the hippocampus to the posterior neocortex. The vmPFC represents the apex of this hierarchy, initiating and coordinating extended, movie-like events that are supported by hippocampal-dependent snapshot-scenes and enriched by short-lasting visual-perceptual details of the posterior neocortex. The implications of this neural model of event construction urge to rethink traditional medial temporal lobe memory systems, and open goal-directed questions of why we rely on this system.

BUILDING MENTAL CHRONOLOGIES IN THE HUMAN BRAIN

SYMPOSIUM 13 - EPISODIC TIME - EDVARD MOSER, CHRISTIAN DOELLER, CORNELIA MCCORMICK, VIRGINIE VAN WASSENHOVE

Virginie Van Wassenhove
CEA DRF-Joliot, INSERM, CNRS, Université Paris-Saclay, Neurospin, Cognitive Neuroimaging Unit, Gif sur Yvette, France

"The representation of a sequence is not a sequence of representations" (Friston & Buzsáki, 2016) captures the non-isomorphism between the serial ordering of world events, neural sequences, and experienced chronologies (e.g. Lashley, 1951; Gallistel, 1990; Kinsbourne & Dennett, 1992). How then can we study mental timelines generated in the human brain? In a series of behavioral, fMRI and MEG experiments (Gauthier et al., 2016a, 2016b, 2017, 2019, 2020), we explored "mental time travel" by manipulating the context in which participants recalled and organized learned historical events. Participants imagined themselves away from the here and now and subsequently reported as correctly and as fast as possible whether a learned historical event (*what*) occurred before or after (*when*), or west or east (*where*) of their mental self-positioning. Behavioral outcomes (reaction times and error rates) were comparable in the temporal and spatial dimensions of the task: participants took longer and made more errors when they were self-projected, and when events were closer to the location of their imagined self. fMRI findings showed that despite behavioral similarities, brain regions mediating self-projection, distance, and ordinality in time and space were partially distinct. Crucially, classifying MEG activity as a function of the imagined location of the self, revealed neural indices of both absolute and signed symbolic distances: how far in past/future or west/east a memory was to the mental self also engaged hippocampal activity. Our results suggest that, temporal cognitive maps, like spatial ones, are flexibly and endogenously generated using allocentric and egocentric coordinate systems.

University of Edinburgh and NHS Lothian, Neuroimaging Sciences, Centre For Clinical Brain Sciences And Uk Dementia Research Institute, Edinburgh, United Kingdom

This talk will provide an overview of the evidence from clinical research linking cerebral small vessel disease with cognitive decline and dementia. It will also briefly present information on small vessel disease and vascular dysfunctions, considering not just cerebral blood flow, but cerebral vasoreactivity, pulsatility and vascular stiffness, and briefly blood-brain barrier dysfunction in clinical studies. It will consider whether any of these vascular dysfunctions influence longitudinal lesion change or cognition, and finally also discuss small vessel lesion regression, the potential influences and whether lesion regression might delay or even reverse cognitive decline.

Blood brain barrier (BBB) disruption is a critical component of the pathophysiology of cognitive impairment of vascular etiology (VCI) and associated with Alzheimer's disease (AD). The Wnt pathway plays a crucial role in BBB maintenance, but there is limited data on its role in cognitive pathologies. The E3 ubiquitin ligase PDZRN3 is a regulator of the Wnt pathway. In a murine model of VCI, overexpressing *Pdzrn3* in endothelial cell (EC) exacerbated BBB hyperpermeability and accelerated cognitive decline. We extended these observations, in both VCI and AD models, showing that EC-specific depletion of *Pdzrn3,* reinforced the BBB, with a decrease in vascular permeability and a subsequent spare in cognitive decline. We found that in cerebral vessels, Pdzrn3 depletion protects against AD-induced Wnt target gene alterations and enhances endothelial tight junctional proteins. Our results provide evidence that Wnt signaling could be a molecular link regulating BBB integrity and cognitive decline under VCI and AD pathologies.

Cerebral small vessel diseases (SVDs) are a central link between stroke and dementia—two co-morbidities without specific treatments. Despite the emerging consensus that SVDs are initiated in the endothelium, the early mechanisms remain largely unknown. Deficits in on-demand delivery of blood to active brain regions (functional hyperemia) are early manifestations of the underlying pathogenesis. The capillary endothelial cell strong inward-rectifier K^+ channel Kir2.1, which senses neuronal activity and initiates a propagating electrical signal that dilates upstream arterioles, is a cornerstone of functional hyperemia. Using a genetic SVD mouse model, we show that impaired functional hyperemia is caused by diminished Kir2.1 channel activity. We link Kir2.1 deactivation to depletion of phosphatidylinositol 4,5-bisphosphate (PIP_2), a membrane phospholipid essential for Kir2.1 activity. Systemic injection of soluble PIP_2 rapidly restored functional hyperemia in SVD mice, suggesting a possible strategy for rescuing functional hyperemia in brain disorders in which blood flow is disturbed.

DYSFUNCTION OF THE BLOOD-BRAIN BARRIER IN DEMENTIA

SYMPOSIUM 14 - VASCULAR HYPOTHESES FOR UNDERSTANDING AND RESTORING MEMORY IMPAIRMENTS - JOANNA WARDLAW, CECILE DUPLAà, FABRICE DABERTRAND, AXEL MONTAGNE

Axel Montagne
University of Edinburgh, Uk Dementia Research Institute, Centre For Clinical Brain Sciences, Edinburgh, United Kingdom

Our brain is an energy-hungry organ surrounded by a rich network of blood vessels supplying the oxygen and nutrients required to function. It is essential that the microenvironment in the brain is finely controlled, and this is achieved through the specialist blood-brain barrier (BBB) structure. However, dysfunction of the BBB is recognised as one of the earliest events in the progression of brain disorders that cause dementia. We have previously discovered that one type of cell within the BBB, the pericyte, is particularly affected during disease and we aim to fully understand the consequences to the BBB and brain health as a whole. Using a combination of advanced molecular and imaging techniques including MRI, we seek to uncover the disease mechanisms at play and identify therapeutic targets for intervention.

FAST CLOSED LOOP OPTICAL BRAIN COMPUTER INTERFACES TO STUDY NEURAL PLASTICITY

SYMPOSIUM 15 - HYBRID AND MULTIFUNCTIONAL APPROACHES TO STUDY NEURALCIRCUITS - BERNARDO SABATINI, DUYGU KUZUM, ILKA DIESTER, FILIPPO PISANO

Bernardo Sabatini, Richard Hakim
Howard Hughes Medical Institute - Harvard Medical School, Department Of Neurobiology, Boston, MA, United States of America

In standard behavioral tasks, mice adapt their action selection in order to achieve positive outcomes, such as access to water and food. Learning to perform these tasks requires adaptations in neural circuits that are driven by action-outcome associations. Brain-machine interfaces (BMI), in which neural activity is read directly from the brain to control devices or set environmental contingencies, allow direct testing of the possible mechanisms of neural plasticity that underly learning. Here we teach mice to move the activity of their primary motor cortex in specific directions in neural state space in order to achieve reward. We control the BMI by rapidly reading and analyzing activity of neurons expressing Ca-sensitive fluorophores with a 2-photon laser scanning microscope. Furthermore, we analyze movements associated with performing the task using a novel method. We examine the ability of the animal to discover and move neural activity along complex trajectories in order to achieve reward and the consequences of this plasticity on the activity of neurons that are not explicitly selected as part of the reward-guided ensemble.

TRANSPARENT NEURAL PROBE TECHNOLOGIES FOR MULTIMODAL, MULTI-REGION RECORDINGS

SYMPOSIUM 15 - HYBRID AND MULTIFUNCTIONAL APPROACHES TO STUDY NEURALCIRCUITS - BERNARDO SABATINI, DUYGU KUZUM, ILKA DIESTER, FILIPPO PISANO

Duygu Kuzum
University of California San Diego, Department Of Electrical And Computer Engineering, La Jolla, CA, United States of America

The complexity of neural activities has challenged both neuroscience research and clinical practice for decades. Understanding neuronal dynamics and information processing performed by neural populations requires advanced technologies with high-resolution sensing and stimulation capability. Conventional neural interfaces offering electrical, optical, or chemical signals have greatly advanced our understanding of neural functions, however, most of these technologies are based on a single functionality and limited to recording local activity in specific brain regions. Combining multiple functionalities in a single system has recently been pursued as an integrative approach to achieve high resolution monitoring of neural activity across multiple spatial and temporal scales. Graphene has recently emerged as a neural interface material offering several outstanding properties, such as optical transparency, flexibility, high conductivity, and biocompatibility. In this talk, I will present our recent work on graphene-based neural interfaces, highlight key applications, and demonstrate examples of in vivo multimodal imaging and recording experiments utilizing optical transparency of the microelectrodes. I will also present a Flexible, Insertable, and Transparent Microelectrode array technology (‘Neuro-FITM’) and discuss how this technology can be applied to investigate coordination and interactions between the cortex and subcortical structures.

NEURAL PROBES FOR OPTIMIZED IN VIVO OPTOGENETIC MANIPULATIONS AND ELECTROPHYSIOLOGICAL MEASUREMENTS

SYMPOSIUM 15 - HYBRID AND MULTIFUNCTIONAL APPROACHES TO STUDY NEURALCIRCUITS - BERNARDO SABATINI, DUYGU KUZUM, ILKA DIESTER, FILIPPO PISANO

Ilka Diester
University of Freiburg, Optophysiology - Optogenetics And Neurophysiology, Freiburg, Germany

Optogenetics involves delivery of light-sensitive opsins to the target brain region, combined with the introduction of optical and electrical devices to manipulate and record neural activity. Combining these functionalities in a single implantable device is of relevance for a precise investigation of neural networks while minimizing tissue damage. We report on the development, characterization, and in vivo validation of a multifunctional optrode that combines a silicon-based neural probe with an integrated microfluidic channel, and an optical glass fiber in a compact assembly. The size and position of fluidic channels, electrodes, and optical fiber can be precisely tuned according to the in vivo application. With a total system weight of 0.97 g, our multifunctional optrode is suitable for chronic in vivo experiments requiring simultaneous drug delivery, optical stimulation, and neural recording. In comparison to conventional multi-step surgeries, our approach achieves higher spatial specificity while minimizing tissue damage. In a second approach, we developed a technique for simultaneous multi-side, large-scale recordings and optogenetic interventions. The approach is based on unprecedentedly thin Lambertian side-emitting optical fibers combined with silicon probes to achieve high quality recordings and ultrafast multichannel optogenetic inhibition in freely moving animals. Our new framework paves the way for large-scale photo tagging and controlled interrogation of rapid neuronal communication in any combination of brain areas. Lastly, we established a setup for training the required surgical techniques underlying opto- and electrophysiology. It can be adapted to serve in testing and optimizing newly developed tools as the ones described above.

Capturing the dynamics of brain activity in its multifaceted components is a longstanding challenge in neuro-technology. To achieve this aim, we propose a new class of multifunctional implants based on Tapered optical fibers (TF). TF have recently emerged as a versatile, minimally invasive tool for depth-resolved optogenetic stimulation and fiber photometry (Pisanello *et al.*, *Neuron* 2014; Pisanello *et al.*, *Nat. Neurosci.*2017; Pisano *et al.*, *Nat. Methods,* 2019). Here, we will present recent efforts to extend this approach to electrical and biochemical monitoring in the deep brain. Taking advantage of the inherently light-coupled tip, we used an unconventional two-photon lithography approach to develop a *fibertrode* that combines multiple optical windows with artifact-free extracellular microelectrodes. As demonstrated *in vivo*, the *fibertrode* allows for simultaneous optical control and electrical readout of custom-designed brain volumes. At the same time, we pushed on the photonic properties of the TFs to achieve implantable label-free biomolecular monitoringe. Using implantable Raman spectroscopy, we observed biomolecular alterations linked with cancer invasion label-free. Finally, we investigated the potential of harnessing nanoscale light-matter interactions in the deep brain by decorating TF implants with plasmonic nanostructures. This lead us to a proof-of-principle of surface enhanced Raman scattering (SERS) detection of neurotransmitters as well as of novel perspectives in spectrally-modulated light delivery and collection through subwavelength apertures (Pisano *et al.*, *Adv. Opt. Mater* 2022). We view multifunctional TF as a promising complement to existing technologies for multimodal brain evaluation.

CORTICOSTRIATAL CIRCUITS FOR REWARD LEARNING AND DECISION-MAKING

SYMPOSIUM 16 - CAUSAL INTERACTIONS BETWEEN NEUROMODULATORS AND CORTICOSTRIATAL CIRCUITS IN DECISION MAKING - ILANA WITTEN, DOUGAL TERVO, NIMA KHALIGHINEJAD, HANNEKE DEN OUDEN

Ilana Witten
Princeton University, Princeton Neuroscience Institute, Princeton, United States of America

A classic view of the striatum holds that activity in direct and indirect pathways oppositely modulates motor output. Whether this involves direct control of movement, or reflects a cognitive process underlying movement, remains unresolved. We have found that both the demands imposed by a task, as well as the internal state of mice when performing a task, determine whether striatal pathways provide strong and opponent control of behavior. We are in the process of idenfying state-dependent correlates of decision-making.

The ability to rapidly adjust one's strategy in complex environments depends on computations in frontal cortical circuits. In addition, perturbations of the more slowly changing neuromodulatory tone in frontal cortical regions have detrimental effects on the ability to behave strategically, pointing to the importance of the interaction between the neuromodulatory systems and the cortical circuits. How this interplay is accomplished mechanistically and its connection to decision-making in volatile and adaptive environments remains poorly understood. We had previously established that increasing noradrenergic tone in the ACC decreases commitment to the default strategy in a task that models a game-theoretic interaction. More recently, we tied the balance between persistence with the default strategy and a choice to commit to an alternative one to an interplay between the intratelecenphalic (IT)- and the pyramidal tract (PT)- subcircuits within the ACC. Specifically, we demonstrated that the output of the ACC's PT sub-circuit drives the pursuit of alternative learned strategies but is kept clamped by the IT pathway through local opponent interaction until evidence grows in favor of deviating from the ongoing strategy. Combined, our two studies are intriguing considering the earlier findings that highlight the increased responsiveness of the PT neurons under high noradrenergic tone to long-range inputs. As such, an interesting possibility is that one mechanism by which the more slowly-acting noradrenergic input interacts with the otherwise cortically-computed strategy selection process is through lowering the threshold for deviating from the default strategy typically informed by the often incomplete understanding of the environment's structure.

NEUROMODULATION OF DECISIONS ABOUT 'IF' AND 'WHEN' TO ACT

SYMPOSIUM 16 - CAUSAL INTERACTIONS BETWEEN NEUROMODULATORS AND CORTICOSTRIATAL CIRCUITS IN DECISION MAKING - ILANA WITTEN, DOUGAL TERVO, NIMA KHALIGHINEJAD, HANNEKE DEN OUDEN

Nima Khalighinejad
University of Oxford, Department Of Experimental Psychology, Oxford, United Kingdom

Decision making not only involves deciding about which action to choose but when and whether to initiate an action in the first place. Here, I present results from three experiments investigating the role of neuromodulatory systems in decisions about when to act. In experiment 1, we recorded blood-oxygen-level-dependent (BOLD) indices of activity from the dorsal raphe nucleus (DRN) and basal forebrain (BF). Brain data from fMRI showed that while the effect of immediate context on action timing was mediated by BF, the broader, general features of the environment – environmental richness -- and its effect on action timing was mediated by activity in DRN. DRN and BF are major sources of serotonin (5-HT) and acetylcholine (ACh) in the brain, respectively. In experiment 2, systemic 5-HT levels were manipulated by protracted administration of a selective serotonin reuptake inhibitor (SSRI). Increasing 5-HT levels prolonged the time animals would wait before making a response. This effect was more evident during blocks with long inter-trial intervals (ITI), where good opportunities were sparse, a similar pattern to the effect of average value of the environment observed in the first study. In experiment 3 we manipulated systemic levels of ACh by protracted administration of a cholinesterase inhibitor and evaluated its effects on decision time to act. Increasing ACh levels invigorated movements so that animals acted faster in response to features in their immediate context. These findings suggest complementary roles for serotonin/DRN and acetylcholine/BF in decisions about when to initiate an action.

DISSOCIATING FRONTAL AND STRIATAL DOPAMINERGIC CONTROL OF MOTIVATION-ACTION COUPLING

SYMPOSIUM 16 - CAUSAL INTERACTIONS BETWEEN NEUROMODULATORS AND CORTICOSTRIATAL CIRCUITS IN DECISION MAKING - ILANA WITTEN, DOUGAL TERVO, NIMA KHALIGHINEJAD, HANNEKE DEN OUDEN

Hanneke Den Ouden
Radboud University, Donders Institute For Brain, Cognition And Behaviour, NIJMEGEN, Netherlands

Motivations shape our behaviour: the promise of reward invigorates, while in the face of punishment, we hold back. Abnormalities of motivational processing are implicated in clinical disorders characterised by excessive habits and loss of top-down control, notably substance and behavioural addictions. Striatal and frontal dopamine have been hypothesised to play complementary roles in the respective generation and control of these motivational or 'Pavlovian' biases. However, while dopaminergic interventions have indeed been found to modulate motivational biases, these previous pharmacological studies used regionally non-selective pharmacological agents. Here, I will present two recent studies, testing the following hypotheses: i) We can overcome maladaptive motivational biases through frontal cognitive control. To test this hypothesis, we use a combination of EEG and computational modelling. ii) Frontal dopamine controls the balance between Pavlovian, bias-driven automated responding and instrumentally learned action values. Specifically, we examined whether selective enhancement of cortical dopamine enables adaptive suppression of Pavlovian control when biases are maladaptive, where we modulate frontal dopamine with COMT inhibitor tolcapone.

GABA-MEDIATES THE SENSORY DEPENDENT DEVELOPMENT OF INTERHEMISPHERIC CIRCUITS OF THE CORPUS CALLOSUM

SYMPOSIUM 17 - DEVELOPMENT AND EVOLUTION OF BILATERAL SENSORY CIRCUITS - MARTA NIETO, OLIVIER COLLIGNON, ELOISA HERRERA, FILIPPO DEL BENE

Marta Nieto
CNB-CSIC, Dpt Molecular And Cellular Biology, Madrid, Spain

Bilateral sensory circuits provide complex representations of the external world by computing overlapping information. In this workshop, we will present complementing perspectives of how bilateral sensory circuits built and function during development and evolution, from fish to humans, and from vision to crossmodal perception. In mammals, an ulterior exchange of information occurs through the corpus callosum (CC), which enables the addition of novel brain functions. The developmental and evolutionary mechanisms mediating the appearance of this structure are unknown. According to predominant views, callosal and non-callosal fates are predetermined early after neuronal birth. Certain populations are born pre-programmed as callosal projecting neurons while others, such as cortical layer (L) 4 excitatory neurons of the primary somatosensory (S1) barrel, invariably project ipsilaterally. Using a novel axonal-retrotracing strategy and GFP-targeted visualization of young neurons, we instead demonstrate the opposite in L2/3 and 4 neurons. Virtually all these neurons develop transient interhemispheric axons, and local-projecting fates emerge as a postnatal alternative when exuberant callosal axons refine in an area- and layer-specific under the influence of sensory-specific inputs. This developmental exuberance during CC formation appears a strategy that enables plasticity and robust stereotyped wiring of complex circuits during evolution. Furthermore, I will show that inhibitory interneurons select callosal fates and diversify area-specific circuits through their control of CC refinement.

ARTIFICIAL REWIRING OF THE EARLY VISUAL PATHWAY LEADS TO THE EMERGENCE OF OCULAR DOMINANCE COLUMNS IN MICE

SYMPOSIUM 17 - DEVELOPMENT AND EVOLUTION OF BILATERAL SENSORY CIRCUITS - MARTA NIETO, OLIVIER COLLIGNON, ELOISA HERRERA, FILIPPO DEL BENE

Eloisa Herrera
Instituto de Neurociencias CSIC-UMH, Developmental Neurobiology, Alicante, Spain

Species with good binocular vision, as cats or primates, have ocular dominance columns and other well-organized cortical features while mice have poorly organized visual cortices and are essentially monocular. Ocular dominance columns are defined in the visual cortex previous to eye-opening, but it remains unknown to what extent cortical circuits are intrinsically imprinted of haphazardly wired by the influence of the early emerging features in the thalamus, such as eye-specific lamination. As a test-bed to investigate the connection between early-emerging retinothalamic features and cortical properties such as ocular dominance columns, we created a mouse line with a rewired retinothalamic pathway that have a number of ipsilateral projections similar to those species with good binocular vision. Strikingly, adding extra numbers of ipsilateral retinal fibers in mice modifies cortical integration and generates ectopic microdomains resembling the columns of higher mammals. The consequences of these results will be discussed in my talk.

EVOLUTION AND FUNCTIONAL ORGANISATION OF BILATERAL VISUAL CIRCUITS IN FISH

SYMPOSIUM 17 - DEVELOPMENT AND EVOLUTION OF BILATERAL SENSORY CIRCUITS - MARTA NIETO, OLIVIER COLLIGNON, ELOISA HERRERA, FILIPPO DEL BENE

Filippo Del Bene
Institut de la Vision, Sorbonne Université, Inserm, Cnrs, Paris, France

Binocular stereopsis requires the convergence of visual information from corresponding points in visual space seen by two different lines of sight. This may be achieved by superposition of retinal input from each eye onto the same downstream neurons via ipsi- and contralaterally projecting optic nerve fibers. Zebrafish larvae can perceive binocular cues during prey hunting but have exclusively contralateral retinotectal projections. We report brain activity in the tectal neuropil ipsilateral to the visually stimulated eye, despite the absence of ipsilateral retinotectal projections. This activity colocalizes with arbors of commissural neurons, termed intertectal neurons (ITNs), that connect the tectal hemispheres. ITNs are GABAergic, establish tectal synapses bilaterally and respond to small moving stimuli. In zebrafish and presumably other teleost an intertectal circuit controls execution of the prey-capture motor program following binocular localization of prey, without requiring ipsilateral retinotectal projections. Conversely, bilateral visual projections exist in non-teleost fishes and that the appearance of ipsilateral projections does not correlate with terrestrial transition or predatory behavior. We have also reported that the developmental program that specifies visual system laterality differs between fishes and mammals, as the Zic2 transcription factor, which specifies ipsilateral retinal ganglion cells in land vertebrates, appears to be absent from the ganglion cells of ray finned fish species. However, overexpression of human ZIC2 is able to induce ipsilateral visual projections in zebrafish. Therefore, we propose that the existence of bilateral visual projections preceded the emergence of binocular vision in land vertebrates.

To model developmental disorders of the human brain, we used induced pluripotent stem cell (iPSC)-derived brain organoids derived from a cohort of individuals with idiopathic autism spectrum disorder (ASD) and their unaffected first-degree family members. Our main goal was to overcome the heterogeneity in genetic risk for ASD and identify a convergent pathophysiology. Differences in cellular composition and cell type-specific gene expression were evaluated by single-cell RNA-sequencing (scRNA-seq) over a 3-month time course. The scale of the dataset allowed an investigation of the sources of variation influencing human neurogenesis in the organoid system over multiple genetic backgrounds and culture batches. We found that organoids were patterned into regional and cellular identities similar to those present in human fetal brains. Analyses of gene expression comparing probands and unaffected relatives revealed alterations in genes driving the tempo of cortical excitatory neurogenesis from undifferentiated progenitors. Macrocephalic ASD probands showed a delay in initial excitatory neuron differentiation and an increase in the progenitor pool. This resulted in an increased proportions of excitatory neurons of the dorsal cortex, whereas normocephalic ASD probands showed a diametrically opposite phenotype. This difference in gene expression and imbalance in excitatory neuron subtypes reveals intrinsically different subtypes of ASD, with head circumference as a biomarker, that could be used as potential stratifying factors in clinical or genetic studies of the disorder. Overall, omics studies in organoid allow to understand heterogeneity of human brain development across individuals and delineate altered trajectories in developmental disorders.

HUMAN BRAIN DEVELOPMENT IN CEREBRAL ORGANOIDS

SYMPOSIUM 18 - CAPTURING HUMAN BRAIN CIRCUIT DEVELOPMENT AND DISEASE MECHANISMS WITH STEM CELL-BASED TECHNOLOGIES - FLORA VACCARINO, MADELINE LANCASTER, SILVIA CAPPELLO, VINCENZO DE PAOLA

Madeline Lancaster
MRC Laboratory of Molecular Biology, Cell Biology, Cambridge, United Kingdom

The human brain sets us apart as a species, with its size and complexity unrivaled in the animal kingdom. Brain size is largely determined during development as vast numbers of neurons and supportive glia are generated, followed by a highly coordinated process of axonal outgrowth to set up the intricate connectome. In an effort to better understand the events that determine human brain cellular makeup, size, and connectivity, we use a human model system in a dish, called cerebral organoids. These 3D tissues are generated from pluripotent stem cells through neural differentiation and a supportive 3D microenvironment to generate organoids with the same tissue architecture as the early human fetal brain. Such organoids are allowing us to tackle questions previously impossible with more traditional approaches. Indeed, our recent findings provide insight into regulation of brain size and neuron number across ape species, identifying key stages of early neural stem cell expansion that set up a larger starting cell number to enable the production of increased numbers of neurons. We are also investigating the roles of extrinsic regulators in determining numbers and types of neurons produced in the human cerebral cortex. Overall, our findings are pointing to key, human-specific aspects of brain development and function, that have important implications for neurological disease.

HUMAN CELLULAR MODELS FOR BRAIN INJURY OF PREMATURITY

SYMPOSIUM 18 - CAPTURING HUMAN BRAIN CIRCUIT DEVELOPMENT AND DISEASE MECHANISMS WITH STEM CELL-BASED TECHNOLOGIES - FLORA VACCARINO, MADELINE LANCASTER, SILVIA CAPPELLO, VINCENZO DE PAOLA

Silvia Cappello
Max Planck Institute of Psychiatry, Developmental Neurobiology, Munich, Germany

Cellular crosstalk is an essential process during brain development and it is influenced by numerous factors, including the morphology of the cells, their adhesion molecules, the local extracellular matrix and the secreted vesicles. Inspired by mutations associated with neurodevelopmental disorders, we focus on understanding the role of extracellular mechanisms essential for the correct development of the human brain. Hence, we combine the in vivo mouse model and the in vitro human-derived neurons, cerebral organoids, and dorso-ventral assembloids in order to better comprehend the molecular and cellular mechanisms involved in progenitors' proliferation and fate as well as migration and maturation of inhibitory and excitatory neurons during human brain development and tackle the causes of neurodevelopmental disorders. We particularly focus on mutations in genes influencing cell-cell contacts, extracellular matrix, and secretion of vesicles and therefore study intrinsic and extrinsic mechanisms contributing to the formation of the brain. Our data reveal an important contribution of cell non-autonomous mechanisms in the development of neurodevelopmental disorders.

Central nervous system (CNS) axons fail to regenerate or recover synaptic connectivity leading to permanent disability in many brain and spinal cord injury patients. Work in model organisms has revealed that CNS axon regeneration is dependent on both the microenvironment and the intrinsic growth state of the damaged neuron itself. Mechanistic insights from these models need to be validated in humans to advance translational therapies. Therefore, there is a pressing need for new preclinical systems that can mimic human-specific features to (i) characterise axon regeneration of major CNS neuronal subclasses e.g. the cortico-spinal tract, and (ii) develop strategies to enhance axon regeneration of mature human neurons. I will present recent work to establish a new *in vivo* system to study human cortical axon degeneration and regeneration using transplanted donor-derived stem cell grafts and 2-photon time-lapse *in vivo* imaging. This model recapitulates many important features of the physiological axon response to injury including fragmentation, the loss of regeneration potential with maturity, progressive die-back, as well as sprouting and branching, and can be used to test strategies to enhance human axon regeneration after nerve damage.

FEEDFORWARD AND FEEDBACK PATHWAYS IN VISUAL CORTEX

SYMPOSIUM 19 - INTEGRATION OF TOP-DOWN INFORMATION IN CORTICAL LAYER 1 AND ITS CONTRIBUTION TO BEHAVIOR - ANDREAS KELLER, LEOPOLDO PETREANU, JOHANNES LETZKUS, MATTIA AIME

Andreas Keller
IOB, University of Basel, Molecular Research Center, Basel, Switzerland

We hardly notice when there is a speck on our glasses, the obstructed visual information seems to be magically filled in. The mechanistic basis for this fundamental perceptual phenomenon has, however, remained obscure. What enables neurons in the visual system to respond to context when the stimulus is not available? While feedforward information drives the activity in cortex, feedback information is thought to provide contextual signals that are merely modulatory. We have made the discovery that mouse primary visual cortical neurons are strongly driven by feedback projections from higher visual areas when their feedforward sensory input from the retina is missing. This drive is so strong that it makes visual cortical neurons fire as much as if they were receiving a direct sensory input. These signals are likely used to predict input from the feedforward pathway. Preliminary results show that these feedback projections are strongly influenced by experience and learning.

The neocortex is organized in a hierarchy of functionally specialized areas. This architecture influences our understanding of sensory, motor and cognitive processes and inspires machine learning algorithms. However, the precise computations that the hierarchical organization of the neocortical network endows us with remain largely unknow. A mayor hub of hierarchical interactions is Layer 1, where descending feedback projections from multiple high order cortical areas contact interneurons and the apical dendrites of pyramidal cells. Thus, understanding hierarchical cortical interactions requires unveiling the organizing rules of feedback inputs in Layer 1. Using optogenetic circuit mapping methods and two-photon imaging we studied how the connectivity of feedback inputs from higher visual areas in primary visual cortex (V1) depends on the projection type and functional properties of its target neurons. Using different visual deprivation paradigms, we also measured how the organization of feedback inputs is shaped by visual experience. We found that feedback inputs to L1 are selectively wired to engage in recurrent inter-area computations between retinotopically aligned neurons. The extent of the retinotopic alignment depends on the laminar position of the source of the inputs. The selectivity of feedback for reciprocating neurons also varies depending on the laminar depth of the innervated neurons. While the overall organization of cortical feedback inputs in Layer 1 does not require vision, their fine scale connectivity, and functional properties reflect experienced spatio-temporal correlations between areas. Our observations shine light on the computations implemented by long-range cortical networks, constraining existing theories of cortical computation.

PROCESSING OF TOP-DOWN INFORMATION IN LAYER 1 OF THE AUDITORY CORTEX

SYMPOSIUM 19 - INTEGRATION OF TOP-DOWN INFORMATION IN CORTICAL LAYER 1 AND ITS CONTRIBUTION TO BEHAVIOR - ANDREAS KELLER, LEOPOLDO PETREANU, JOHANNES LETZKUS, MATTIA AIME

Johannes Letzkus
University of Freiburg, Institute For Physiology, Dept. I, Freiburg, Germany

Top-down projections convey a family of signals encoding previous experiences and current aims to sensory neocortex, where they converge with bottom-up information from the environment to produce perception. Whereas several excitatory afferent systems for top-down control of neocortex have been identified, the existence, connectivity and information content of inhibitory top-down projections remains elusive. Here we use a combination of circuit tracing, connectivity mapping, chemogenetics, cortex-dependent learning and synaptic 2-photon calcium imaging to identify GABAergic afferents from the subthalamic zona incerta as a major source of memory-related top-down input to neocortex. Incertocortical projections transmit integrated information from many sources preferentially to auditory cortex layer 1, where they connect selectively to inhibitory interneurons to disinhibit the cortical circuit. This pathway encodes both auditory stimuli and primary reinforcers, and undergoes robust plasticity during learning that improves information transfer and facilitates behavioural memory. Unlike excitatory top-down pathways, incertocortical afferents engage in two distinct plasticity regimes with different temporal dynamics and response properties. A unique hallmark is the rapid *de novo* appearance of negative responses as the major driver of learning-related changes in stimulus representation. Our results therefore uncover the distinctive contribution of long-range (dis)inhibitory afferents to the computational flexibility of neocortical circuits.

PARADOXICAL SOMATO-DENDRITIC DECOUPLING SUPPORTS CORTICAL PLASTICITY DURING REM SLEEP

SYMPOSIUM 19 - INTEGRATION OF TOP-DOWN INFORMATION IN CORTICAL LAYER 1 AND ITS CONTRIBUTION TO BEHAVIOR - ANDREAS KELLER, LEOPOLDO PETREANU, JOHANNES LETZKUS, MATTIA AIME

Mattia Aime
University of Bern, Department Of Neurology, Bern, Switzerland

REM sleep is associated with the consolidation of emotional memories encoded by neuronal circuits from the limbic system and prefrontal cortex in mammals. Yet, the underlying neocortical circuits and synaptic mechanisms remain unclear. Here, we found that REM sleep is associated with a somato-dendritic decoupling in pyramidal neurons of the prefrontal cortex, using simultaneous 2-photon calcium imaging and electrophysiological recordings in sleeping mice. This decoupling reflects a shift of inhibitory balance between PV neurons-mediated somatic inhibition and VIP-mediated dendritic disinhibition, mostly driven by neurons from the central medial thalamus. We further showed that REM-specific optogenetic suppression of dendritic activity led to a loss of danger versus safety discrimination during associative learning and a lack of synaptic plasticity, whereas optogenetic release of somatic inhibition resulted in enhanced discrimination and synaptic potentiation. Collectively, our results demonstrated that somato-dendritic decoupling during REM sleep promotes opposite synaptic plasticity mechanisms that optimize emotional response to future behavioral stressors.

NEURON CLASS-SPECIFIC RESPONSES GOVERN ADAPTIVE MYELIN REMODELING IN THE NEOCORTEX

SYMPOSIUM 20 - NOT JUST INSULATION: OLIGODENDROCYTE FUNCTION AND MYELINATION IN BRAIN PLASTICITY AND BEHAVIOR - PAOLA ARLOTTA, IIRIS HOVATTA, HANNELORE EHRENREICH, MARIA-CECILIA ANGULO

Paola Arlotta
Harvard University, Department Of Stem Cell And Regenerative Biology, Cambridge, United States of America

Myelin plasticity is critical for neurological function, including learning and memory. However, it is unknown whether this plasticity reflects uniform changes across all neuronal subtypes, or whether myelin dynamics vary between neuronal classes to enable fine-tuning of adaptive circuit responses. We performed in vivo two-photon imaging of myelin sheaths along single axons of excitatory callosal neurons and inhibitory parvalbumin-expressing interneurons in adult mouse visual cortex. We found that both neuron types show homeostatic myelin remodeling under normal vision. However, monocular deprivation results in adaptive myelin remodeling only in parvalbumin-expressing interneurons. An initial increase in elongation of myelin segments is followed by contraction of a separate cohort of segments. This data indicates that distinct classes of neurons individualize remodeling of their myelination profiles to diversify circuit tuning in response to sensory experience.

MYELIN PLASTICITY IN CHRONIC PSYCHOSOCIAL STRESS AND ANXIETY

SYMPOSIUM 20 - NOT JUST INSULATION: OLIGODENDROCYTE FUNCTION AND MYELINATION IN BRAIN PLASTICITY AND BEHAVIOR - PAOLA ARLOTTA, IIRIS HOVATTA, HANNELORE EHRENREICH, MARIA-CECILIA ANGULO

Iiris Hovatta
University of Helsinki, Sleepwell Research Program, Helsinki, Finland

Chronic stress, a major risk factor for anxiety disorders, has been associated with changes in myelin gene expression and thickness in multiple mouse models. Our unbiased genetic screen of stress resilient, stress susceptible and control mice from two inbred mouse strains (C57BL/6NCrl and DBA/2NCrl) suggested that myelin plasticity is one of the major responses to chronic psychosocial stress in mammals, varies across brain regions, and is genetically controlled. Myelin plasticity also encompasses changes in the nodes of Ranvier, which have not been extensively studied in stress. Our new data indicates mouse strain-dependent alterations in the paranode length after chronic stress. These changes are likely mediated by neuronal activity because chemogenetic activation of the ventral hippocampus to medial prefrontal cortex pathway specifically influenced paranode length of stimulated, but not unstimulated, axons, while also affecting anxiety-like behavior. To investigate whether white matter structural differences are associated with anxiety symptoms in humans, we carried out diffusion tensor imaging in young adults. We found larger mean diffusivity in the forceps minor in individuals with subclinical anxiety symptoms compared to those without, suggesting alterations in myelination. Thus, myelin plasticity may be involved in anxiety disorders via regulation of spatial connectivity. Identification of the mechanisms underlying the myelin response will provide mechanistic insight into the molecular basis of anxiety, a critical step in developing targeted therapy.

ISOLATED CATATONIA-EXECUTIVE DYSFUNCTION COMPLEX IN AGED MICE INDUCED BY FOREBRAIN-SPECIFIC LOSS OF MYELIN INTEGRITY

SYMPOSIUM 20 - NOT JUST INSULATION: OLIGODENDROCYTE FUNCTION AND MYELINATION IN BRAIN PLASTICITY AND BEHAVIOR - PAOLA ARLOTTA, IIRIS HOVATTA, HANNELORE EHRENREICH, MARIA-CECILIA ANGULO

Hannelore Ehrenreich
Max Planck Institute of Multidisciplinary Sciences, Clinical Neuroscience, Göttingen, Germany

The etiology of catatonia, an executive 'psychomotor' syndrome seen across diseases, has remained mysterious. We studied humans and myelin mutant mice, using microglia depletion as therapeutic strategy. In schizophrenic patients (N>2000), we uncovered >25% of subjects with catatonic signs. *CNP* rs2070106-AA, a *loss-of-function* genotype of a myelin-specific gene, was associated with catatonia in schizophrenia cohorts, and white matter hyperintensities in the general population. Subtle myelination defects in mouse mutants of *Cnp*, but also *Plp* or *Mbp,* led to catatonia and microgliosis. We hypothesized that neuroinflammation of myelinated tracts might cause catatonia and be alleviated by microglia depletion. Indeed, the CSF1 receptor inhibitor, PLX5622, attenuated catatonia in *Cnp* mutants, whereas executive dysfunction and brain atrophy failed to improve. Next, we wondered which brain areas might be causative of catatonic phenotypes. We generated mice lacking *Plp1*, encoding the major integral myelin membrane protein, selectively from ventricular zone stem cells of the forebrain. In contrast to conventional *Plp1* mutants, subtle myelin defects were restricted to the cortex and underlying callosal tracts. Forebrain-specific *Plp1* mutants exhibited no defect of basic motor-sensory performance. Behavioral alterations reported for conventional *Plp1* null mice were absent and even social interactions appeared normal. However, we determined catatonia-like symptoms and isolated executive function defects in both genders at progressed age, suggesting that a gradual loss of myelin integrity affects cortical connectivity and underlies specific defects of executive function, emerging only with increasing age. These observations are likewise relevant for human brain aging and neuropsychiatric conditions.

Background: Understanding molecular changes associated with major depression at single-cell resolution is key to better understand the illness and develop new treatments. In this study, we aimed to study single-nucleus transcriptomic and open-chromatin states of individuals affected with major depression. **Methods:** We isolated N~80,000 nuclei from the prefrontal cortex (PFC) of cases and controls for single nucleus RNA sequencing. We used single-cell fluorescence in situ hybridization to validate the gene expression changes in given cell types of interest, as well as a high-throughput fluorescence assisted nuclei sorting to validate changes in broader cell types. We then used a droplet based single nucleus snATAC-seq approach to profile chromatin accessibility in the same samples. **Results:** Our transcriptomic results implicate 96 genes differentially expressed in 16 cells types, particularly lower layer excitatory neurons and immature oligodendrocytes. The addition of a modality—chromatin accessibility, improved and refined the transcript-only based clustering. Our data showed an enrichment of open chromatin at functional non-coding regions, while enhancer regions showed the most cell specific patterning. Differential open chromatin regions between cases and controls showed enrichment for gene regulatory regions and transcription factor binding motifs associated with disease-related biological pathways. We also identified gene regulators with cell-type specificity, and disease-specific epigenetic signatures of differential gene expression patterns. **Conclusion:** Leveraging the power of single cell technologies has allowed us to produce cell-type specific epigenetic signature. Specifically, we have identified cell types mostly affected in depression, as well as chromatin accessibility architecture that partly explains expression patterns associated with this illness.

ALTERED SOCIAL LEARNING AND ECONOMIC INVESTMENT BEHAVIOR IN HUMANS WITH BILATERAL BASOLATERAL AMYGDALA DAMAGE AS A RESULT OF URBACH WIETHE DISEASE

SYMPOSIUM 21 - GENETICALLY DISSECTING NEUROBIOLOGY OF SOCIAL COLLABORATION IN HUMANS, MACAQUES AND RODENTS - JACK VAN HONK, CHENGYU LI, RON STOOP, SARA FREDA

Jack Van Honk[1,2]
[1]Utrecht University, Psychology, Utrecht, Netherlands, [2]University of Cape Town, Dept. Psychiatry And Mental Health, Cape Town, South Africa

According to the leading computational framework, organisms learn the value of actions and outcomes via punishment and reward algorithmically. A model-free (or action-based) algorithm, rigidly assigns actions based upon immediate intrinsic value (value > action), and a model-based (or outcome-based) algorithm flexibly derives value from a causal model of the environment and is instrumentally guided by action-outcome probabilities (outcome > action). The amygdala conveys a translational obstacle for the cross-species applicability of this framework of value-based learning and choice. That is, the human amygdala is typically researched and discussed as a single unit despite the fact that the mammalian amygdala consists of sub-regions different in structure and function. Most prominently, the basolateral amygdala (BLA) and the central-medial amygdala (CMA), which consist of respectively cortical-type and striatal-type neural structures. Rodent research has determined that by parallel actions on the striatum, the CMA sub-serves habitual (which is action-based) choice behavior, while the BLA sub-serves goal-directed (which is outcome-based) choice behavior. Reconceptualized in terms of the computational framework, the CMA subserves the model-free algorithm, while the BLA subserves the model-based algorithm. At the symposium, research in human subjects with selective bilateral basolateral amygdala damage will be presented. In this research, which focuses on social learning, and social-economic and moral decision-making, it is established that role of the human BLA in value-based learning and choice behaviors translates seamlessly to the rodent BLA. The value-based learning and choice behaviors of our BLA-damaged subjects are entirely action-based and thus model-free.

CRITICAL ROLE OF PREFRONTAL-RELATED CIRCUITS IN PROSOCIAL BEHAVIOR REVEALED BY ACUTE GENETIC MANIPULATION IN NON-HUMAN PRIMATES

SYMPOSIUM 21 - GENETICALLY DISSECTING NEUROBIOLOGY OF SOCIAL COLLABORATION IN HUMANS, MACAQUES AND RODENTS - JACK VAN HONK, CHENGYU LI, RON STOOP, SARA FREDA

Chengyu Li, Chengfeng Wu
Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Institute Of Neuroscience, Shanghai, China

Social behavior is one of the most important driving forces of human society evolution. This has allowed us to reach major achievements in which many individuals are involved with each fulfilling a specialized task. An insight in how and why the brain can organize individual efforts at such large scale would therefore represent an important goal for brain research. In the monkey brain a number of regions, including prefrontal cortices and amygdala, have been identified to play important roles in social behavior, mostly through electrophysiological recording, and pharmacology and lesion techniques with limited social interactions. Here we established three groups of cynomolgus macaques, each group with 8-10 female individuals free ranging in a 30 m^2 room. Chronic behavioral monitoring and AI-assisted analysis revealed detailed social-interaction patterns in the groups. We perturbed neuronal activity of dorsolateral prefrontal cortex while observing changes in social behaviors in manipulated monkeys and other group members. In future electrophysiological recordings will also be performed in these free ranging and group housed monkeys with close monitoring of behavioral states. Our results will shed new insights to neural mechanism underlying social organization.

Social support can help to reduce fear, but much is unknown about the neurobiological mechanisms underlying this "social buffering of fear" (SBF). Here we show, by chemogenetic and optogenetic manipulations, as well as *in vivo* single-unit recordings, that the neuropeptide oxytocin, originating from the hypothalamic paraventricular nucleus (PVN) and acting in the central nucleus of the amygdala (CeA), mediates SBF in fear-conditioned rats. The reduced freezing during fear memory recall in the presence of a companion is strong and immediate and maintained during a second fear recall 24h later without the companion. This is accompanied by acute and long-lasting changes in spiking patterns in oxytocinergic neurons in the PVN and three different neuron types in the CeA. Our findings reveal how acute and long-lasting SBF is mediated by an oxytocinergic signaling pathway between PVN and CeA that is completely subcortical, and thereby different from classical cortical-basolateral amygdala fear extinction pathways.

Aims: Central release of oxytocin modulates a wide range of social behaviors including pair bond formation, mating, and parental care. Long-standing research links oxytocin to neural processing of reward, primarily via actions in the ventral striatum. Our recent studies, among others, extend the oxytocin-dopamine interaction landscape to encompass dopamine-synthesizing circuits of the ventral tegmental area and substantia nigra pars compacta, with medial prefrontal cortex emerging as a recent critical element in this distributed network mediating aspects of social interactions and resilience. Methods: Anterograde and retrograde projections, receptor mRNA studies, and electrophysiology combine with wired and wireless opto- and pharmacogenetics with fiber photometry and 2-photon imaging, to characterize the relevant pathways of oxytocin and dopamine system convergence and function. Results and Conclusions: To dissect convergence sites for oxytocinergic system connectivity with reward circuitry, we performed whole-brain anterograde and retrograde tracing of oxytocin neurons in the paraventricular nucleus. We found oxytocin terminals widely distributed in the mesocorticolimbic dopamine system and neighboring hypothalamic and thalamic nuclei. The atlases provide a detailed mapping of cortical projections, revealing unexpected areas of strong connectivity, including medial prefrontal cortex (mPFC). Optogenetically induced release of oxytocin from local neuronal fibers increases tonic activity of ventral tegmental area dopamine neurons, linked to reward processing. Besides controlling the activity of DA neurons, oxytocin changes how they respond to their inputs, by dampening excitatory synaptic transmission onto DA neurons via endogenous cannabinoids. In the mPFC, dopamine mediates neuroplasticity and supports motivational resilience, also potentially facilitating neural synchrony during social interactions.

MICROGLIAL CLOCKS: FRIENDS OR FOES OF CIRCADIAN TIMEKEEPING?

SYMPOSIUM 22 - GLIA: CRUCIAL REGULATORS OF CIRCADIAN RHYTHMS AND SLEEP - MARCO BRANCACCIO, OLGA BARCA MAYO, RUNE ENGER, LAUREN HABLITZ

Marco Brancaccio
UK DRI at Imperial College, Dept Of Brain Sciences, London, United Kingdom

Circadian timekeeping regulates daily behaviour and physiology, including sleep/wake cycles, cognition and inflammatory process. The suprachiasmatic nucleus (SCN) is responsible for internally coordinating circadian activities and aligning them to light-dark cycles in mammals. SCN astrocytes can generate circadian patterns of behaviour and neuronal activity in mice genetically ablated of clock function. In revealing an unexpected functional reservoir of circadian resilience in glia, this work has also highlighted an unforeseen vulnerability of timekeeping in brain disease. Astrocyte transformation from a homeostatic to a reactive phenotype may disrupt central timekeeping and drive alterations of circadian function associated with early neurodegeneration. Microglia play a key role in turning astrocyte behaviour from neuroprotective to neurotoxic, but their circadian properties are poorly understood, mainly because limited availability of tools to genetically target and manipulate them. We have developed new intersectional genetic approaches to target microglia in SCN tissue, by using AAV-based genetically-encoded reporters of clock gene expression and microglia activation. Microglial circadian activities were monitored by live imaging, together with neurons and astrocytes, in physiological conditions and upon challenge with pro-inflammatory and proteotoxic stimuli. This has revealed highly dynamic properties of microglial timekeeping in the SCN. While unchallenged microglia show circadian oscillations that are less robust and coherent than astrocytes and neurons, this is rapidly transformed by proteotoxic and proinflammatory challenges, which can either reduce, or enhance, coherence of microglial timekeeping. Further work is underway investigating the role of astrocytes-microglia neuro-immune circadian coupling in physiological and pathological conditions and will be discussed at the meeting.

CLOCKS, GLIA, BRAIN AND METABOLISM

SYMPOSIUM 22 - GLIA: CRUCIAL REGULATORS OF CIRCADIAN RHYTHMS AND SLEEP - MARCO BRANCACCIO, OLGA BARCA MAYO, RUNE ENGER, LAUREN HABLITZ

Olga Barca Mayo
Universidade de Santiago de Compostela, Center For Research In Molecular Medicine And Chronic Diseases, Santiago de Compostela, Spain

In mammals, endogenous circadian clocks sense and respond to daily feeding and lighting cues, adjusting internal ~24 h rhythms to resonate with, and anticipate, external cycles of day and night. This ensures a temporal partitioning of catabolic and anabolic reactions synchronizing organism metabolism to the feeding-fasting cycle. The mechanism underlying circadian entrainment to feeding time is critical for understanding why mistimed feeding, as occurs during shift work, disrupts circadian physiology, a state associated with increased incidence of chronic diseases such as type 2 diabetes. Metabolic state sensing pathways can alter the molecular clock in anticipation of the environmental light-dark cycles. During feeding, anabolic processes are triggered by the activation of the Insulin (INS)-AKT-mTOR signaling pathway. On the other hand, during fasting, AMPK activation triggers catabolic processes and inhibits mTOR activity. As astrocytes are at the interface between vessels and neurons, they are in a privileged position to act as metabolic sensors of systemic cues that entrain the peripheral clocks linking the periphery and brain clocks. Here, we will discuss the role of INS and AMPK signaling pathways in the entrainment of astrocyte clocks and their impact in regulating daily rhythms in physiology and behavior.

Astrocytes inextricably influence neuronal physiology by providing structural and trophic support, extracellular homeostasis, and by active signaling. With such essential functions astrocytes are consequential to many different behaviors. Sleep is no exception, and astrocytes have been shown to influence sleep state maintenance, sleep drive and waste clearance. Disentangling the roles of astrocytes in sleep is challenging, as it requires subcellular resolution imaging of natural sleep. We have developed a model for two-photon microscopy of naturally sleeping head fixed mice, and have employed this model to describe astrocytic signaling in sleep. We have shown that astrocytic Ca^{2+} signals exhibit distinct features across the sleep-wake cycle and are reduced during sleep compared to wakefulness. Moreover, an increase in astrocytic Ca^{2+} signaling precedes transitions from slow wave sleep to wakefulness, with a peak upon awakening exceeding the levels during whisking and locomotion. Finally, attenuated astrocytic Ca^{2+} signaling impairs slow wave sleep and results in an increased number of microarousals, abnormal brain rhythms, and an increased frequency of slow wave sleep state transitions and sleep spindles. We are currently working on disentangling the relationship between astrocytic Ca^{2+} signals and memory function, by studying sleep spindles and sharp wave ripple dynamics. Moreover, we are investigating the roles of astrocytic endfoot Ca^{2+} signaling and potential effects on blood flow dynamics and perivascular fluid flow in sleep.

SLEEP, CIRCADIAN CLOCKS AND THE GLYMPHATIC SYSTEM

SYMPOSIUM 22 - GLIA: CRUCIAL REGULATORS OF CIRCADIAN RHYTHMS AND SLEEP - MARCO BRANCACCIO, OLGA BARCA MAYO, RUNE ENGER, LAUREN HABLITZ

Lauren Hablitz
University of Rochester, School Of Medicine, Rochester, United States of America

The glymphatic system is a network of perivascular spaces through the brain that enables movement of cerebrospinal fluid into, and interstitial fluid through the brain. Glymphatic fluid movement is regulated by the circadian system and increased during sleep, enabling clearance of metabolic waste from the brain parenchyma. This talk will cover the basics of sleep and circadian regulation of the glymphatic system, explore the contribution of astrocytic circadian molecular clocks to glymphatic fluid movement, and present novel findings on the regulation of glymphatic flow.

THE ANTERIOR CLAUSTRUM ENCODES MOTOR PLANNING

SYMPOSIUM 23 - THE FUNCTION(S) OF THE CLAUSTRUM: ATTENTION, SALIENCE, SLEEP, ALL OF THE ABOVE, OR SOMETHING ELSE? - SOLANGE BROWN, ALAN CARLETON, MAR REUS-GARCIA, LORENZ AUGUST FENK

Solange Brown[1,2]
[1]Johns Hopkins School of Medicine, Solomon H. Snyder Department Of Neuroscience, Baltimore, United States of America, [2]Johns Hopkins University School of Medicine, Kavli Neuroscience Discovery Institute, Baltimore, United States of America

The claustrum, a thin, elongated subcortical nucleus located between the neocortex and striatum, forms extensive reciprocal connections with the neocortex and has been implicated in sensory selection. It has been proposed that claustrum activity evoked by sensory input modulates the neocortex's context-dependent responses to sensory stimuli. Recording from neurons in anterior claustrum while mice performed a crossmodal sensory-selection task, we found that claustrum neurons, including claustrocortical neurons projecting to primary somatosensory cortex, rarely responded to tactile or visual input alone. We found instead that claustrum neurons exhibited direction-tuned motor responses and encoded upcoming movement during intertrial intervals. Chemogenetic inhibition of claustrocortical neurons decreased lick responses to inappropriate sensory stimuli. These data indicate that the claustrum is integrated into higher-order premotor circuits recently implicated in decision-making.

THE CLAUSTRUM-MEDIAL PREFRONTAL CORTEX NETWORK CONTROLS COGNITIVE FLEXIBILITY

SYMPOSIUM 23 - THE FUNCTION(S) OF THE CLAUSTRUM: ATTENTION, SALIENCE, SLEEP, ALL OF THE ABOVE, OR SOMETHING ELSE? - SOLANGE BROWN, ALAN CARLETON, MAR REUS-GARCIA, LORENZ AUGUST FENK

Alan Carleton
University of Geneva, Department Of Basic Neuroscience, GENEVE, Switzerland

In various psychiatric disorders, prefrontal cortex dysfunction is thought to induce cognitive deficits. Here we studied how the claustrum (CLA), a nucleus sharing dense reciprocal connections with the cortex, may contribute to cognitive impairments. We molecularly characterized CLA neurons using single cell RNA sequencing and used a Cre-driver transgenic mouse line to specifically study CLA glutamatergic projection neurons. We show that CLA projection neurons exert a direct excitatory input on medial prefrontal cortex (mPFC) neurons. Furthermore, specific ensembles of CLA and of mPFC neurons are activated during a task requiring cognitive flexibility such as attentional set-shifting (i.e. the ability to shift attention towards newly relevant stimulus-reward associations while disengaging from irrelevant ones. Perturbing the recruitment of specific CLA assemblies through opto/chemogenetic manipulations impairs the activation of mPFC ensembles and alters cognitive flexibility. Our results emphasize a potential role of the CLA-mPFC network in cognitive dysfunctions observed in some mental disorders.

Finding an unassailable definition for *learning* might be as challenging as describing the function of the claustrum. Nonetheless, most authors will agree on the following: 1. Learning is a mechanism by which organisms acquire behaviours that improve their adaptation to the environment; and 2. Claustral activity supports numerous cognitive-related processes, mainly filtering out irrelevant information to focus attention on significant or salient stimuli. My recent publication examined claustrum neuronal activity during classical conditioning. Claustral neurons, usually silent in awake, resting state, became significantly active while the animals learned the task.Inhibiting claustral activity during the acquisition of conditioned responses disrupted the learning process, while no effect was observed when claustral cells were silenced after learning was achieved. This suggests that claustrum activity is required for the acquisition of learning, but not for the expression of the learned behaviour.Concurrently, several authors have revealed that claustral cells are also active in behavioural experiments in which animals not only learn a cognitive task but also adjust their behaviour constantly to succeed. Furthermore, during slow-wave sleep -when consolidation of learning occurs- claustrum cells are particularly active. Learning is essential for adaptation, survival and evolution; undoubtedly many brain structures are recruited in proper learning. Is the claustrum responsible for identifying information that needs to be stored and generating a suitable brain state for learning-related processes? To answer that, I will revisit what we know so far regarding how the claustrum could support learning. **This research/project is supported by the Ministry of Education, Singapore, under its MOEAcRF Tier 3 Award MOE2017-T3-1-002.**

THE ROLE OF ASTROGLIA-NEURON INTERACTIONS IN GENERATION AND SPREAD OF SEIZURES

SYMPOSIUM 24 - NEURAL MECHANISMS OF EPILEPSY - EMRE YAKSI, LAURA EWELL, ESTHER KROOK-MAGNUSON, GABRIELE LIGNANI

Emre Yaksi
Norwegian University of Science and technology, Kavli Institute For Systems Neuroscience, Trondheim, Norway

Astroglia-neuron interactions are involved in multiple processes, regulating development, excitability and connectivity of neural circuits. Accumulating number of evidences highlight a direct connection between aberrant astroglial genetics and physiology in various forms of epilepsies. Using multiple zebrafish seizure models, we showed that neurons and astroglia follow different spatiotemporal dynamics during transitions from pre-ictal to ictal activity. We observed that during pre-ictal period neurons exhibit local synchrony and low level of activity, whereas astroglia exhibit global synchrony and high-level of calcium signals that are anti correlated with neural activity. Instead, generalized seizures are marked by a massive release of astroglial glutamate release as well as a drastic increase of astroglia and neuronal activity and synchrony across the entire brain. Furthermore, using a combination of genetic and pharmacological perturbations, we revealed that astroglial glutamate signalling and astroglial gap junctions plays a major role in generation and spreading of epileptic seizures across the brain. Knocking out astroglial glutamate transporters leads to recurrent spontaneous generalized seizures accompanied with massive astroglial glutamate release. Whereas perturbing astroglial gap junctions leads to more complex alterations of neural activity and excitability, mitigating the impact of PTZ induced seizures. Our results highlight astroglial glutamate transporters and gap junctions as potential targets for developing novel anti-seizure therapies.

NETWORK MECHANISMS OF IMPAIRED MEMORY CODING IN EPILEPSY

SYMPOSIUM 24 - NEURAL MECHANISMS OF EPILEPSY - EMRE YAKSI, LAURA EWELL, ESTHER KROOK-MAGNUSON, GABRIELE LIGNANI

Laura Ewell
University of California – Irvine, Department Of Anatomy & Neurobiology, Irvine, United States of America

A common and devastating comorbidity of temporal lobe epilepsy (TLE) is impaired learning and memory. Strikingly, few studies have performed awake neural recordings *during* memory tasks, which would facilitate discovery of the physiological basis of such memory problems. To this end, we tested working memory performance in a mouse model of focal TLE, and found two types of impairment: (1) impaired learning of a constant reference frame, and (2) dynamic, intermittent impairment in working memory depending on real-time pathophysiology. Single unit and LFP recordings from various sub-regions of the hippocampus during the task revealed that mice were experiencing frequent sub-threshold (so called 'clinical') seizures during the task – and that such seizures occurred reliably at particular locations on the maze. Despite showing no overt behavioral phenotype during seizures, we suspect that such synchronized activity is interfering with normal hippocampal coding at key phases of the memory task – such as real-time replay of recent reward visits. The 'place' component of the seizure activity is indicative of heightened attractor dynamics in area CA3 of the hippocampus – and ongoing experiments in the lab are testing this hypothesis.

IN VIVO MANIPULATION OF NEURONAL CIRCUITS IN EPILEPSY

SYMPOSIUM 24 - NEURAL MECHANISMS OF EPILEPSY - EMRE YAKSI, LAURA EWELL, ESTHER KROOK-MAGNUSON, GABRIELE LIGNANI

Esther Krook-Magnuson
University of Minnesota, Department Of Neuroscience, Minneapolis, United States of America

In vivo perturbation of neuronal circuits, including selectively during spontaneous seizures, can provide important insight into which circuits and circuit components may contribute to epileptiform activity, and, importantly, which elements may be able to curtail seizures. Using on demand optogenetics, we have explored the key role of circuit elements near the seizure focus in a mouse model of temporal lobe epilepsy, and show that engagement of the dentate gyrus is critical for such seizures. Selective in vivo manipulation techniques also allow exploration of cell-types and circuits remote from the seizure focus. Somewhat surprisingly, we find that strong modulation of hippocampal seizures is achieved by cerebellar-directed interventions. Pathway dissection coupled with selective modulation indicates that cerebellar-mediated inhibition of hippocampal seizures rests on excitation of excitatory cerebellar nuclear neurons which project to a particular nucleus of the thalamus. An in-depth exploration of the parameter space further indicates that robust seizure inhibition can be achieved when targeting this circuitry via more traditional electrical stimulation approaches. These findings highlight how circuit dissection via selective in vivo manipulation can provide new insights into seizure networks and provide new avenues for potential intervention strategies.

MANIPULATION OF EPILEPTIC NEURONAL ACTIVITY USING ACTIVITY-DEPENDENT GENE THERAPY

SYMPOSIUM 24 - NEURAL MECHANISMS OF EPILEPSY - EMRE YAKSI, LAURA EWELL, ESTHER KROOK-MAGNUSON, GABRIELE LIGNANI

Gabriele Lignani
UCL Queen Square Institute of Neurology, Clinical And Experimental Epilepsy, London, United Kingdom

Epilepsy remains one of the commonest serious neurological diseases, affecting 1% of the world's population. 30% of people with epilepsy are refractory to pharmacological treatment and for these patients, surgical resection of the focal brain area where the seizures arise remains the best hope to achieve seizure freedom, but this procedure is often precluded by proximity to eloquent regions. Gene therapy is the most promising candidate replacement for surgical treatment. However, current experimental gene therapies do not discriminate between neurons involved in seizure generation and 'healthy' surrounding neurons. There is an urgent need to develop methods that identify and treat only the neurons involved in the generation of seizures. The possibility to target only the neurons actively involved in seizures by modifying their activity would be an important step towards to a rational treatment of epilepsy. This project is based on the use of activity-dependent promoters to drive a therapeutic transgene that attenuates neuronal excitability. Pathological hyperactivity triggers expression of the transgene in transduced neurons, which then reduces their likelihood to fire and release neurotransmitter. Once seizures resolve, the gene therapy tool automatically turns off, until excessive activity occurs again (if it does). Importantly, transgene expression only occurs in neurons that are recruited to fire in excess, and neighbouring or intermingled neurons not involved in the seizure are unaffected. Self-time-limited expression of the transgene and specificity for over-active neurons argue that the treatment is better tolerated than an indiscriminate and permanent reduction in excitability in the epileptic focus.

GENERALIZED NEOHEBBIAN SYNAPTIC PLASTICITY RULES FOR LEARNING CORTICAL REPRESENTATIONS

SYMPOSIUM 25 - ENCODING IN NEURONS AND BEYOND: APPLICATIONS IN MACHINE LEARNING - WULFRAM GERSTNER, ANDREW SAXE, MIGUEL ANGEL NUNEZ, JONATHAN CORNFORD

Wulfram Gerstner, Bernd Illing, Guillaume Bellec
EPFL, School Of Computer And Communication Sciences And School Of Life Sciences, Lausanne, Switzerland

Learning in the brain is based on synaptic plasticity rules, but learning rules that respect biological constraints pose challenges if the aim is to build deep hierarchical representations. Here, we propose a generalized NeoHebbian learning rule that depends on five factors: pre- and postsynaptic activity, a layer-wide broadcast signal of surprise, information about presence or absence of a saccade, and dendritic membrane potential the encodes learned predictions. We apply this rule in a multi-layer neural network where each layer can be interpreted as one cortical area. The learning rule applies contrastive predictive learning from machine learning to a causal, biological setting using saccades (ie rapid shifts in gaze direction). The learning rule is derived by minimizing an area-specific loss function and does not need to back-propagate error signals between cortical areas. We show that with such a local rule, the usefullness of cortical representations increases over several cortical areas.

RICH AND LAZY LEARNING OF TASK REPRESENTATIONS IN BRAINS AND NEURAL NETWORKS

SYMPOSIUM 25 - ENCODING IN NEURONS AND BEYOND: APPLICATIONS IN MACHINE LEARNING - WULFRAM GERSTNER, ANDREW SAXE, MIGUEL ANGEL NUNEZ, JONATHAN CORNFORD

Andrew Saxe
UCL, Gatsby Computational Neuroscience Unit & Sainsbury Wellcome Centre, London, United Kingdom

How do neural populations code for multiple, potentially conflicting tasks? We undertake a combination of computational simulations and mathematical analyses involving neural networks to define “lazy” and “rich” coding solutions to context-dependent tasks, which trade off learning speed for robustness. During lazy learning the input dimensionality is expanded by random projections to the network hidden layer, whereas in rich learning hidden units acquire structured representations that privilege relevant over irrelevant features. For context-dependent decision-making, one rich solution is to project task representations onto low-dimensional and orthogonal manifolds. Using behavioral testing and neuroimaging in humans and analysis of neural signals from macaque prefrontal cortex, we report evidence for neural coding patterns in biological brains whose dimensionality and neural geometry are consistent with the rich learning regime.

UNDERSTANDING INVARIANT TEXTURE CODING IN MOUSE VISUAL CORTEX THROUGH NEURAL NETWORKS

SYMPOSIUM 25 - ENCODING IN NEURONS AND BEYOND: APPLICATIONS IN MACHINE LEARNING - WULFRAM GERSTNER, ANDREW SAXE, MIGUEL ANGEL NUNEZ, JONATHAN CORNFORD

Carsen Stringer[1], Fengtong Du[2], Marius Pachitariu[2]
[1]Howard Hughes Medical Institute, Janelia Research Campus, Ashburn, United States of America, [2]Howard Hughes Medical Institute, Janelia Research Campus, ASHBURN, United States of America

The discrimination of visual textures, irrespective of rotation, scale and viewpoint, can help animals perform a variety of visual tasks such as object recognition and object segmentation. The neural basis of such invariant texture recognition is largely unknown. We recorded ~40,000 neurons simultaneously in mouse visual cortex while presenting ~14,000 visual stimuli sampled from 32 texture classes via random rotation, scaling and cropping. We found that the neural responses encoded the texture class robustly and a linear classifier trained on the neural data achieved test performance on single trials of 81.67% ± 2.74% (stddev, n=4 recordings, chance=0.03). Furthermore, we found that the patterns of errors in the task were highly-consistent across mice, and classification accuracy improved slightly in higher-order visual areas. These computations were supported by a subset of texture-coding neurons which formed 10% of the population and were spread throughout visual areas. Classification accuracy from the texture-coding neurons was similar to that from the entire population. To determine the computational operations leading to texture invariance, we next analyzed the responses of artificial neurons from a pretrained AlexNet model. These artificial neurons performed well in the texture classification task, but their pattern of errors did not match the patterns from the neural data. To better model the neural data, we next fit a CNN encoding model directly to the responses of the neurons. The model explained additional variability of the response patterns in individual images, but it did not fully reproduce the pattern of errors in the texture classification task.

THE ROLE OF RECURRENCE IN NOISE-ROBUST VISUAL PROCESSING

SYMPOSIUM 25 - ENCODING IN NEURONS AND BEYOND: APPLICATIONS IN MACHINE LEARNING - WULFRAM GERSTNER, ANDREW SAXE, MIGUEL ANGEL NUNEZ, JONATHAN CORNFORD

There is strong evidence that animals use top-down and local recurrent connections to help resolve ambiguous visual stimuli, but there are also surprisingly few ANN architectures that explicitly take advantage of such recurrent connections to generate robust visual perception. Here, we explore sequential visual tasks designed to require higher-order and sequential information to resolve ambiguities. We show that on these tasks recurrent convolutional networks that are more brain-like in their architecture perform better than networks with more traditional convolutional architectures. This work helps to identify task designs that could be used to examine robust visual processing with non-feedforward circuits, both in experiments on living subjects, and benchmarks for artificial intelligence agents.

[1]Charité – Universitätsmedizin Berlin, Institute For Medical Psychology, Berlin, Germany, [2]University of California Irvine, Pediatrics, Irvine, United States of America, [3]Oregon Health and Science University, Psychiatry, Portland, United States of America, [4]University of Rochester, Psychiatry, Rochester, United States of America, [5]Magee-Women's Hospital, Obstetrics, Gynecology And Reproductive Sciences, Pittsburgh, United States of America, [6]University of Minnesota, Pediatrics, Minneapolis, United States of America

The origins of alterations in brain anatomy and connectivity, that may underlie cognitive impairment and mental illness, can often be traced back to the fetal period of life when the developing embryo/fetus responds to suboptimal conditions during critical periods of brain development (“Fetal Programming”). Maternal inflammation is among such conditions that can alter fetal brain development and consequently have an impact on her child’s cognitive function and mental health. Animal models support a key role for cytokines, inflammatory signaling proteins, as *sensors*, *transducers,* and *effectors* of maternal inflammation and other environmental conditions on the developing embryonic and fetal brain. Results from prospective longitudinal studies in mother-fetal/infant dyads will be presented. Concentrations of the pro-inflammatory cytokine Il-6 were measured serially in early, mid and late pregnancy. Multimodal brain MRI scans were acquired in neonates, who were followed up with developmental assessments across infancy. Evidence will be presented in support of higher maternal IL-6 concentrations to be associated with variation in neonatal brain anatomy and connectivity that predict cognitive function and behavioral problems in infancy. Furthermore, variation in maternal inflammatory mediators during pregnancy will be discussed as potential mediators underlying intergenerational transmission of maternal preconceptual and prepartum stress. These findings suggest that the origins of variation in cognitive ability and mental health may, in part, trace back to the intrauterine period of life and support variation in brain anatomy and connectivity related to prenatal inflammation as a putative pathway.

FINDINGS FROM A NON-HUMAN PRIMATE MODEL OF MATERNAL IMMUNE ACTIVATION

SYMPOSIUM 26 - VULNERABILITIES OF THE DEVELOPING NEOCORTEX TO MATERNAL INFLAMMATION: FROM PROGENITORS TO CIRCUITS - CLAUDIA BUSS, MELISSA BAUMAN, ANTHONY C VERNON, NAVNEET VASISTHA

Melissa Bauman
University of California, Davis, Department Of Psychiatry & Behavioral Sciences, Sacramento, United States of America

Children born to women who experience infection during pregnancy have an increased risk of neurodevelopmental disorders, including schizophrenia and autism spectrum disorder. Rodent models of maternal immune activation (MIA) have identified the maternal immune response as the critical link between maternal infection and altered neurodevelopment. The nonhuman primate model provides an opportunity to maximize translational utility in a species more closely related to humans. Here we report data from the first longitudinal behavior and neuroimaging study conducted in a rhesus monkey (*Macaca mulatta*) MIA model. A modified form of the viral mimic, Polyinosinic-polycytidylic acid (PolyIC), was delivered to pregnant monkeys (N=14) in the late first trimester to stimulate maternal immune response. Control dams received saline injections (N=10) or were untreated (N=4). The offspring underwent behavioral assessments paired with longitudinal magnetic resonance imaging (MRI) from birth to four years to evaluate the long-lasting consequences of prenatal immune challenge. Although offspring born to control or MIA-treated dams did not differ on measures of physical growth and early developmental milestones, the MIA-treated animals exhibited subtle changes in cognitive development and deviated from species-typical brain growth trajectories. Longitudinal MRI revealed significant gray matter volume reductions in the prefrontal and frontal cortices of MIA-treated offspring at 6 months that persisted through the final time-point at 45 months, along with smaller frontal white matter volumes at 36 and 45 months. Comprehensive assessments of social development paired with an evaluation of the developing immune system will be presented to further explore the impact of prenatal immune challenge.

Background: Converging lines of evidence support a link between elevated levels of pro-inflammatory cytokines such as interferon-γ (IFN-γ) and interleukin (IL)-6 during neurodevelopment and increased risk for psychiatric disorders. The cellular basis of these effects in the brain however remains unclear. We tested the hypothesis that exposure to either cytokine would contribute to molecular and cellular phenotypes associated with neurodevelopmental disorders in two different cell types. **Methods:** Neural progenitor cells (NPCs) and microglia-like cells (MGLs) were differentiated from hiPSC collected (n=3 neurotypical male donors, n=3 clones per donor) and exposed to either IFN-γ (25 ng/ml) or IL-6 (100 ng/ml). Molecular phenotypes were assessed by RNA sequencing and cellular phenotypes by cell-specific assays including neurite outgrowth, motility and secretion of cytokines and chemokines. **Results:** At the cellular level, transient exposure of NPCs to IFN-γ increased neurite outgrowth dependent on up-regulation of major histocompatibility class (MHC)-I and promyelocytic leukemia (PML) nuclear bodies (Warre-Cornish et al. Science Advances, 2020). By contrast, transient exposure to IL-6 increased Y705-STAT-3 phosphorylation in MGLs but not in NPCs. In MGLs transient exposure to IL-6 triggered increases in cell/process motility and secretion of pro- and anti-inflammatory cytokines. At the molecular level, we provide evidence that transient exposure of NPCs to IFN-γ and MGLs to IL-6 disproportionately alter the expression of genes associated with either schizophrenia or autism, suggestive of an interaction between genetic and environmental risk factors. **Conclusion:** These data provide evidence for putative cell-specific effects of IFN-γ and IL-6 signalling in the eitiology of neurodevelopmental disorders.

TIME AND SUBTYPE-DEPENDENT IMPAIRMENT OF CORTICAL INTERNEURONS BY MATERNAL IMMUNE ACTIVATION

SYMPOSIUM 26 - VULNERABILITIES OF THE DEVELOPING NEOCORTEX TO MATERNAL INFLAMMATION: FROM PROGENITORS TO CIRCUITS - CLAUDIA BUSS, MELISSA BAUMAN, ANTHONY C VERNON, NAVNEET VASISTHA

Navneet Vasistha
University of Copenhagen, Biotech Research And Innovation Center, Copenhagen N, Denmark

Infections during pregnancy are associated with an increased risk for disorders such as autism and schizophrenia. Virus infections induce maternal immune system activation (MIA) and the release of several cytokines that cross the placental barrier and severely impact the development of the cerebral cortex. We have previously shown that MIA has a non-uniform impact on cell types in the developing brain. Specifically, MIA displays a developmental time and neuronal subtype-dependent impairment on progenitors that give rise to inhibitory neurons. Progenitor proliferation in the medial (MGE) and caudal ganglionic eminence (CGE) is affected during early- and mid-neurogenesis stages respectively. Furthermore, despite the acute nature of MIA, the impact on neuronal lineages is enduring and continues even after birth leading to physiological dysfunction. Finally, using high-throughput single-nuclei RNA sequencing (snRNA-seq) technology, we describe the possible mechanisms underlying the differential vulnerability due to MIA. We show that receptors for key cytokines are unequally expressed between MGE and CGE progenitors. Furthermore, non-canonically and canonical Wnt signaling is disrupted in MGE and CGE progenitors respectively. Finally, using RNA dynamics to study cell lineages, we show that MIA induces precocious differentiation of dorsal cortical progenitors to novel cell states. Our study hence emphasizes the fundamental differences between neural progenitor cells and how this shapes the development of the neocortex. Understanding the mechanistic basis behind such differential vulnerability is also crucial for resolving the pathogenesis of neurodevelopmental disorders.

NEW FUNCTIONAL PROPERTIES OF HIPPOCAMPAL NEURAL STEM CELLS IN EPILEPSY

SYMPOSIUM 27 - ADULT HIPPOCAMPAL NEUROGENESIS IN PHYSIOLOGY AND PATHOLOGY - JUAN ENCINAS, THOMAS LARRIEU, NORA ABROUS, MARIA LLORENS-MARTíN

Juanma Encinas
Achucarro Basque Center for Neuroscience, Laboratory Of Neural Stem Cells And Neurogenesis, Leioa, Spain

In normal conditions, **neural stem cells (NSCs)** dwelling in the dentate gyrus **of the hippocampus generate neurons and astrocytes**. **After seizures**, however, NSCs enter massively into the cell cycle and change their morphology drastically, **transforming into reactive-NSCs (React-NSCs), which ultimately differentiate into reactive astrocytes.** As a result, very little neurogenesis, and with abnormal properties, remains in the epileptic hippocampus. React-NSCs are distinct form normal NSCs, astrocytes and reactive astrocytes. Importantly, **React-NSCs contribute to reactive gliosis and are pro-inflammatory.** React-NSCs overexpress **interleukin 1β (IL-1β),** one of the major mediators of neuroinflammation in the brain. The seizure-induced **transformation of NSCs into pro-inflammatory React-NSCs is mediated** through the activation of **purinergic 2X receptors (P2XR)** and of **epidermal growth factor receptor (EGFR)**. By blocking these pathways, the induction of React-NSCs can be prevented and thus NSCs and neurogenesis can be preserved.

BLOOD CIRCULATING FACTORS REGULATE ADULT NEUROGENESIS IN THE CONTEXT OF ANXIETY

SYMPOSIUM 27 - ADULT HIPPOCAMPAL NEUROGENESIS IN PHYSIOLOGY AND PATHOLOGY - JUAN ENCINAS, THOMAS LARRIEU, NORA ABROUS, MARIA LLORENS-MARTíN

Thomas Larrieu
Lausanne University Hospital, Department Of Psychiatry, Center For Psychiatric Neurosciences, Prilly, Switzerland

Adult hippocampal neurogenesis, which consists in the continuous formation of neurons throughout adulthood, confers stress resilience but is also inhibited by stress and anxiety. Thus, mechanisms of regulation of adult neurogenesis are relevant to mood disorders. Using an in vitro assay, we found that blood-circulating molecules regulate adult neural stem cell proliferation and are necessary and sufficient to mediate the stress- or anxiety-mediated reduction of adult neurogenesis in mice. In a cohort of patients at high risk of developing psychiatric diseases, we found that some of these molecules are correlated with levels of anxiety and may participate to disease mechanisms. Together, our results show that blood-circulating molecules regulate adult neurogenesis and may represent biomarkers or drug targets relevant to stress and anxiety-related diseases.

Neurogenesis was traditionally believed to occur only during embryonic stages in the mammalian brain. However, over the last 30 years, research has firmly established that active neurogenesis persists throughout adult life in discrete areas of the brain such as the hippocampal dentate gyrus (DG). In fact, the DG is predominantly formed after birth, and it exhibits a permanent remodeling through continuous addition of new neurons throughout the life-span. Because of this continuous addition of new cells, the DG appears as a highly heterogeneous structure composed of different generations of granule neurons. I will provide some examples of this heterogeneity and will show that the temporal origin of DGNs dictates their morphology, their properties in response to learning and their role in hippocampal-dependent function. I will conclude on the potential implication of these different cohorts of neurons in establishing resilience/vulnerability to mental disorders.

HUMAN ADULT HIPPOCAMPAL NEUROGENESIS AND NEURODEGENERATIVE DISEASES

SYMPOSIUM 27 - ADULT HIPPOCAMPAL NEUROGENESIS IN PHYSIOLOGY AND PATHOLOGY - JUAN ENCINAS, THOMAS LARRIEU, NORA ABROUS, MARIA LLORENS-MARTíN

Maria Llorens-Martín
Spanish Research Council (CSIC), Centro De Biología Molecular "severo Ochoa" Cbmso, Madrid, Spain

The hippocampus hosts one of the most unique phenomena of the adult mammalian brain, namely the addition of new neurons throughout lifetime. While synapse loss and consequent death of mature neurons may be responsible for much of the hippocampal malfunctioning in neurodegenerative diseases, studies in mice suggest that the disease could also target the generation of new neurons – or adult hippocampal neurogenesis (AHN). In my talk, I will provide evidence from our lab that supports the occurrence of continued neurogenesis in the human hippocampus of aged healthy subjects and patients with distinct neurodegenerative diseases, using brain material obtained under tightly controlled conditions and applying state-of-the-art tissue processing methods. Our data evidence that AHN is a robust phenomenon in the human brain, and point to the impairment of adult neurogenesis and the homeostasis of the hippocampal neurogenic niche as a potentially relevant mechanism underlying hippocampal malfunctioning that may be amenable to novel therapeutic strategies.

Grasping requires translating object geometries into appropriate hand shapes. How the brain computes these transformations remained widely unclear. We investigated three key areas of the macaque cortical grasping circuit in a delayed grasping task with microelectrode arrays in primates and found cooperative but anatomically separated visual and motor processes. The parietal area AIP operated primarily in a visual mode. Its neuronal population revealed a specialization for shape processing, even for abstract geometries, and processed object features ultimately important for grasping. Premotor area F5 acted as a hub that shared the visual coding of AIP only temporarily and switched to highly dominant motor signals towards movement planning and execution. We visualize these non-discrete premotor signals that drive the primary motor cortex M1 to reflect the movement of the grasping hand. In addition to these active tasks, we collected neural activity during observation tasks in search of mirror neurons in this network. F5 and AIP responded substantially during this observation context, but there was no categorically distinct class of mirror neurons. In fact, even at the population level, there was little evidence for processing of the observed grip *per se*, only of passive visual processing of object features. Our results reveal visual and motor features encoded in the grasping circuit and their communication to achieve transformation for grasping. They also suggest that, whatever the putative mirror mechanism may be, it does not involve the processing of motor features of grasps which are merely observed.

Accurate movements require correct multisensory integration, a complex function performed by different brain areas including the posterior parietal cortex (PPC). The PPC of the monkeys contains area V6A, which receives different sensory input, namely visual and somatosensory, uses these signals to estimate the state of the arm and communicates with the frontal cortex to perform correct movements. Moreover, V6A is active before and during arm movements because it contains reach-related cells modulated by the depth and by the direction of reaching. In humans, V6A (hV6A) is in the posterior part of Brodmann's area 7 and shares many functions with monkey V6A, such as the processing of sensory stimuli and the activation during reaching. Recently, in our lab, the causal role of hV6A was investigated using transcranial magnetic stimulation (TMS): after TMS during reach planning, impairments in the encoding of depth of reaching were observed, in keeping with the presence of cells modulated by the depth of reaching targets during reach planning in monkey V6A. Furthermore, we have also proved the functional connectivity between hV6A and the frontal cortex at rest using a dual-site paired-pulse TMS protocol. We found inhibitory effects of hV6A on the frontal cortex excitability at longer inter-stimulus intervals (12 and 15ms). All these experiments support a strict homology between monkey V6A and hV6A and suggest that this region subserves crucial sensorimotor integration functions to interact with the external world.

REFERENCE FRAMES AND TASK REPRESENTATION FOR TACTILE-SPATIAL PROCESSING IN HUMAN POSTERIOR PARIETAL CORTEX

SYMPOSIUM 28 - MULTISENSORY INTEGRATION AND SPACE REPRESENTATION IN HUMANS AND MONKEYS - STEFAN SCHAFFELHOFER, ROSSELLA BREVEGLIERI, TOBIAS HEED, SULIANN BEN HAMED

Tobias Heed
University of Salzburg, Psychology, Salzburg, Austria

When humans have to reach or saccade towards a visual target, spatial information is coded in different reference frames anchored to the eyes, head, and world. When one wants to act towards a tactile stimulus, the target's location on the skin cannot sufficiently inform the movement, because the body's limbs can be flexibly configured, so that posture must be taken into account to aim for a skin location. To elucidate which brain regions contribute to transforming tactile information into a location in space and in planning the respective movement, 16 participants pointed towards, or away from, tactile stimuli presented to uncrossed and crossed feet in a delayed movement paradigm. Multi-voxel pattern decoding revealed that bilateral rostral regions of posterior parietal cortex (PPC) differentiated tactile stimuli based on the anatomical foot on which they had occurred. A caudal PPC region, in contrast, coded whether a stimulus had occurred in left or right space, independent of the anatomical foot on which it had been presented. The transformation rule, i.e. whether the pointing was towards or away from the stimulus, was decodable in caudal PPC, partly overlapping with the regions that coded stimuli anatomically and in space. Thus, the different reference frames relevant to tactile-motor processing appear to be integrated in the context of an overarching task representation.

The macaque ventral intraparietal area (VIP) in the fundus of the intraparietal sulcus has been implicated in a diverse range of sensorimotor and cognitive functions such as motion processing, multisensory integration, processing of head peripersonal space, defensive behavior, and numerosity coding. These functional properties have been used in order to identify VIP in the human parietal cortex as well as in other species. I will however show that human VIP research has consistently identified three, rather than one, bilateral parietal areas that each appear to subsume some, but not all, of macaque VIP's functionality. These three human areas are dominated, roughly, by coding the head or self in the environment, visual heading direction, and the peripersonal environment around the head, respectively. Based on cross-species functional comparison, I will suggest that VIP has evolved as a progressive expansion and specialization of a parietal area, from prosimians to new-world and old-world monkeys to humans. Based on this new understanding of human VIP, focusing on the visual and touch modalities, I will present data suggesting that some precursory specialization within macaque VIP, arising from specific functional brain connectivity patterns as well as from inter-individual differences, has been previously overlooked. I will then propose prediction in space and time, linking VIP to state estimation, as a unifying functional principle for the diversity of seemingly unrelated functions associated with area VIP. Last, I will propose that VIP's expansive differentiation of head and self-related processing may have been key in the emergence of human bodily self-consciousness.

ELECTROPHYSIOLOGICAL PROPERTIES OF DOPAMINE NEURONS PROJECTING TO TAIL OF THE STRIATUM

SYMPOSIUM 29 - THE BASAL GANGLIA SENSORY DOMAIN THROUGH TAIL OF THE STRIATUM: REWARD, THREAT AND SENSORY FILTERING - ROEPER JOCHEN, EMMANUEL VALJENT, MITSUKO WATABE-UCHIDA, SEBASTIAN KRUETTNER

Jochen Roeper
Goethe University Frankfurt, Neuroscience Center Institute For Neurophysiology, Frankfurt, Germany

The biophysical differences of dopamine midbrain neurons with defined axonal projections have been well characterized by in vitro slice patch-clamp experiments on retrogradely characterized and neurochemically identified cells. In contrast, little is known about those dopamine neurons in the pars lateralis of the substantia nigra (SNpl) that project to the tail of the striatum, a caudal part of the dorsal striatum. Therefore, combining in vivo retrograde tracing and in vitro patch-clamping we set out the characterize this subtype of dopamine neurons involved in fear responses. In contrast to those DA neurons residing in the lateral part of the substantia nigra (i.e. medial of the pars lateralis) that project to the more rostral dorsolateral stiatum, SNpl DA neurons had smaller somato and fired a higher baseline frequencies. The possessed intermediate sag levels and short rebound delays. We currently study these neurons in vivo to better capture their specific electrcophysiological properties.

SPATIOMOLECULAR HETEROGENEITY OF D1R AND D2R NEURONS OF THE TAIL OF THE STRIATUM

SYMPOSIUM 29 - THE BASAL GANGLIA SENSORY DOMAIN THROUGH TAIL OF THE STRIATUM: REWARD, THREAT AND SENSORY FILTERING - ROEPER JOCHEN, EMMANUEL VALJENT, MITSUKO WATABE-UCHIDA, SEBASTIAN KRUETTNER

Emmanuel Valjent
IGF, Université Montpellier, CNRS, Inserm, Molecular And Neural Coding Of Behavior (mncb)lab, Montpellier, France

The striatum is the gateway to the basal ganglia, an ensemble of subcortical structures involved in motor planning, procedural and reinforcement-based behaviors. In mammals, three functional domains have been characterized based on differences spanning across mediolateral and dorsoventral axis. Increasing evidences indicate however that the extreme caudal part of the striatum, also referred to as the tail of striatum (TS), constitutes a fourth functional domain. Here, I will discuss recent findings suggesting that the TS displays heterogeneous cell-type-specific organization and unique input-output connectivity. I will illustrate how the use of transgenic mice expressing reporters driven by specific promoters enables the delimitation of distinct TS domains, which are highly conserved across the *Muridae* family. Finally, I will provide evidence that the spatiomolecular heterogeneity of TS neurons expressing dopamine D1 and D2 receptors, and the peculiarity of TS-projecting DA neurons contribute to make this fourth striatal domain particularly responsive to psychostimulants.

Harvard University, Molecular And Cellular Biology, Center For Brain Science, Cambridge, United States of America

Animals adaptively learn to repeat rewarding actions and refrain from dangerous actions. Although our understanding of reward learning and threat learning has advanced tremendously in recent years, these are mostly studied independently of one another. However, in the natural world, it is critical to consider both reward and threat. Especially in case of threat, it is important to utilize information of potential threat, not only the ultimate outcomes such as pain, injury and death. What is the brain mechanism for balancing potential reward and threat? On the other hand, computational models often treat reward and threat as a single dimension. Does the brain map both potential reward and threat onto a single axis for behavioral choice? In this talk, I will introduce a series of our studies using both classical and naturalistic behavioral paradigms where mice must navigate threats to obtain water rewards. This talk will focus on the tail of the striatum (TS, or sensory striatum), which we found receive input from a unique subpopulation of dopamine neurons that encodes threat (but not reward) prediction errors. I will discuss why it is critical for survival that value and threat are represented in separate systems along two axes. Finally, from our preliminary data, I will share our working hypothesis that animals integrate reward and threat using multi-layered competing systems in the brain, both within local basal ganglia circuits and globally across cortico-striatal loops.

PREFRONTAL CORTICAL OUTPUTS TO THE TAIL OF STRIATUM TRANSLATE TASK RULES TO CONTROL SENSORY FILTERING

SYMPOSIUM 29 - THE BASAL GANGLIA SENSORY DOMAIN THROUGH TAIL OF THE STRIATUM: REWARD, THREAT AND SENSORY FILTERING - ROEPER JOCHEN, EMMANUEL VALJENT, MITSUKO WATABE-UCHIDA, SEBASTIAN KRUETTNER

FENS Forum 2022
9-13 July 2022 | Paris, France

To make adaptive decisions, organisms must appropriately filter sensory inputs, augmenting relevant signals and suppressing noise. It has been known that the prefrontal cortex (PFC) plays a critical role in guiding sensory filtering but how the PFC influences sensory processing remains poorly understood. Using multiple approaches, I find that engagement of the PFC projections to the tail of striatum are critical for the suppression of distracting sensory inputs, enhancing behaviorally relevant signals over noise. In addition, I identified distinct subnetworks of PFC neurons which project to visual or auditory domains of the tail of striatum and control the corresponding sensory modality. These subnetworks acted to decode sensory filtering rules encoded in the PFC, providing outputs capable of differentially controlling the gain of sensory inputs depending on task-demands. The outputs of these subnetworks were anatomically fixed, placing a fundamental constraint on the internal dynamics of the PFC. Overall, my results identify a key interaction between the PFC and the tail of striatum responsible for the control of sensory processing and introduce important principles that provide a framework for understanding how this circuit adaptively controls sensory processing.

GLUCOCORTICOID SPINE PLASTICITY IN STRESS

SYMPOSIUM 30 - NOVEL INSIGHTS INTO THE NEUROBIOLOGY OF STRESS VULNERABILITY AND RESILIENCE - FREDDY JEANNETEAU, LAURENCE COUTELLIER, VIRGINIE RAPPENEAU, STEFAN REBER

Freddy Jeanneteau
University of Montpellier, CNRS, Inserm, Institut De Génomique Fonctionnelle, Montpellier, France

In vivo microscopy of dendritic spines in pyramidal neurons of the mouse brain provided imaging correlates for the robust but complex physiological and behavioral effects of glucocorticoids in the context of learning and memory. Glucocorticoids enhance spine formation and elimination within distinct time domains. It takes minutes for glucocorticoids to promote spine formation while it takes hours to elicit spine elimination because it requires new gene products. Consolidation of newly formed spines depends on the mobilization of AMPA receptors through glucocorticoid-induced trafficking and synthesis. Glucocorticoid spine remodeling occurs in clusters physically gathering connectivity from projections neurons encoding the associative contents of the learning experience. Clustering is not random and could reduce the cost of plasticity. Dual imaging of mitochondrial function and spine turnover in the living mouse brain seems to support this model. It is possible that functional connectivity is sustained by the metabolism locally allocated to spine clusters. This adds to the current framework for better understanding the detailed accuracy of memories.

GABA-MODULATED SEX-SPECIFIC VULNERABILITY TO STRESS

SYMPOSIUM 30 - NOVEL INSIGHTS INTO THE NEUROBIOLOGY OF STRESS VULNERABILITY AND RESILIENCE - FREDDY JEANNETEAU, LAURENCE COUTELLIER, VIRGINIE RAPPENEAU, STEFAN REBER

Laurence Coutellier
The Ohio State University, Psychology, Columbus, United States of America

Women are twice as likely as men to develop an anxiety disorder after exposure to stress. The underlying mechanisms behind this sex-specific vulnerability to stress remains unknown. Our work in mice revealed that parvalbumin (PV)-expressing neurons of the prefrontal cortex (PFC) are more sensitive to chronic stress in females than in males. Indeed, we observed that female prefrontal PV cells develop a hyperactive phenotype not seen in males after four weeks of unpredictable chronic mild stress (UCMS). We further showed that chemogenetically driving the activity of these cells enhances anxiety in females but not males identifying a novel mechanism that can explain female vulnerability to stress-induced anxiety. We then aimed to understand how female prefrontal PV neurons become more sensitive to stress. These neurons undergo important maturation during adolescence, and the higher rate of diagnosis of stress-related neuropsychiatric disorders in women is observed after puberty. This led us to hypothesize that the surge of hormones during puberty drives the maturational processes that render PV neurons increasingly responsive to stress in adult females. We used a prepubertal ovariectomy approach in mice, followed by adult exposure to UCMS. We observed that ovariectomy prevents not only the development of an anxious phenotype after stress in adulthood, but also the stress-induced increase in detectable PV neurons in the PFC that is seen in control mice and reflects their increased level of activity. Altogether, these findings identified puberty as a critical period for the development of sex-specific vulnerability to stress.

Major depression (MD) has a high rate of comorbidity with metabolic diseases. Both involve alterations in the hypothalamic-pituitary-adrenal (HPA) axis. However, our knowledge of the precise molecular mechanisms by which the HPA axis contributes to their association remains limited. In this study, we used an animal model of MD to determine the behavioural and metabolic consequences of a short-term high-fat diet (HFD) treatment. Juvenile male mice of the 'Stress Reactivity' model, consisting of three independent lines selectively bred for high (HR), intermediate (IR) or low (LR) HPA axis reactivity, were fed for 4 weeks with either a HFD (45% kcal from fat) or a control diet (10% kcal from fat). Our results showed that the HFD treatment had a major impact on morphometric measures in the LR and IR lines, as indicated by marked increase in the body weight gain, overall adiposity and ectopic fat deposition. At the behavioural level, the HFD treatment did not alter locomotion in the open-field test. However, it significantly increased the floating duration of LR mice in the forced swim test, further increasing their passive stress-coping behaviour. Surprisingly, HR mice were seemingly resistant to the diet-induced behavioural and metabolic alterations. In both the adipose tissue and the brain, the HFD treatment produced major changes in gene expression related to glucose homeostasis and insulin signalling. The present work highlights the 'Stress Reactivity' model as a promising tool for improving our understanding of the involvement of HPA axis dysregulation in susceptibility vs. resilience to diet-induced metabolic dysfunction.

OLD FRIENDS, IMMUNOREGULATION, AND STRESS RESILIENCE

SYMPOSIUM 30 - NOVEL INSIGHTS INTO THE NEUROBIOLOGY OF STRESS VULNERABILITY AND RESILIENCE - FREDDY JEANNETEAU, LAURENCE COUTELLIER, VIRGINIE RAPPENEAU, STEFAN REBER

Stefan Reber
University of Ulm, Department Of Psychosomatic Medicine And Psychotherapy, Ulm, Germany

Immunodysregulation and subsequent chronic low-grade inflammation are risk factors for the development of stress-related somatic and psychiatric disorders, including inflammatory bowel disease (IDB) and posttraumatic stress disorder (PTSD). Thus, immunoregulatory approaches that counterbalance basal and/or stress-induced immune activation are expected to be protective in this context. In this talk Prof. Reber will discuss evidence indicating that increases in immune (re-)activity and inflammation, potentially promoted by a reduced exposure to immunoregulatory microorganisms (“Old Friends”) in today’s modern society, may be causal factors in mediating the vulnerability to development and persistence of stress-related pathologies. Moreover, he will discuss bioimmunoregulatory approaches, as for instance facilitating the contact with immunoregulatory Old Friends, as novel and promising strategies for the treatment and/or prevention of stress-related disorders.

TARGETING TAU AT PRESYNAPTIC TERMINALS

SYMPOSIUM 31 - INTRACELLULAR DYNAMICS AND NEURODEGENERATION - PATRIK VERSTREKEN, SUSANNE WEGMANN, SUBHOJIT ROY, CLOTILDE LAGIER-TOURENNE

Patrik Verstreken
VIB-KU Leuven Center for Brain and Disease Research, Laboratory For Neuronal Communication, Leuven, Belgium

Synaptic dysfunction is an early pathological feature of neurodegenerative diseases associated with Tau, including Alzheimer's disease. Interfering with early synaptic dysfunction may be therapeutically beneficial to prevent cognitive decline and disease progression, but the mechanisms underlying synaptic defects associated with Tau are unclear. In disease conditions in patients and in mouse and fly Tau-disease-models, the protein mislocalizes into pre- and postsynaptic compartments and we show that presynaptic Tau induces synaptic vesicle trafficking defects. I will present work that shows that interfering with this presynaptic function of Tau, by lowering the levels of the synaptic vesicle associated protein Synaptogyrin-3, rescues Tau-induced synaptic loss and cognitive decline in mice. Our work not only identifies new presynaptic roles for Tau but it also opens a new therapeutic window to tackle early synaptic dysfunction and cognitive decline in neurodegenerative disease.

THE MULTIPLE PHASES OF THE MICROTUBULE BINDING PROTEIN TAU

SYMPOSIUM 31 - INTRACELLULAR DYNAMICS AND NEURODEGENERATION - PATRIK VERSTREKEN, SUSANNE WEGMANN, SUBHOJIT ROY, CLOTILDE LAGIER-TOURENNE

Susanne Wegmann
German Center for Neurodegenerative Diseases, Berlin, Berlin, Germany

The microtubule associated protein Tau (MAPT) binds and stabilizes microtubules (MTs) in the axons of the central nervous system. It is best known, however, for its role in neurodegenerative brain diseases, such as Alzheimer's disease and forms of Fronntotemporal Dementia. In these diseases, the highly soluble and abundant protein forms amyloid-like intraneuronal aggregates and leads to neurotoxicity. Interestingly, from the protein physicochemical point of view, Tau is an intrinsically disordered protein that can adopt multiple protein conformations and assembly states, such as monomeric, oligomeric, liquid condensed, and aggregated. Since these "phases" of Tau have different biochemical and physical properties, they can encode different functions and misfunctions of Tau. The most recent discovered assembly form of Tau are liquid-like condensates, for which both physiological and pathologcical functions have been suggested, e.g. in MT binding and in aggregation. The concept and role of condensed Tau phases will be introduced in this presentation.

Despite much effort, the physiologic role of alpha-synuclein – a small presynaptic protein with established roles in the pathogenesis of Parkinson's and related disorders – is unclear. Phenotypes in alpha-synuclein knockout mice are mild, precluding definitive conclusions, and though mice lacking all synucleins (alpha/beta/gamma synuclein "triple knockout" mice) have given some insight into function, it has been difficult to parse out the specific effects of alpha-synuclein in this setting. Other studies have made conclusions based on over-expression of alpha-synuclein, but it has been unclear if these phenotypes are due to mis-localization of alpha-synuclein and gain of abnormal function. We will report updates from studies where we used CRISPRs to systematically and selectively delete each synuclein in mouse and human neurons, followed by experiments evaluating synaptic physiology.

Alteration of RNA metabolism has emerged as a central theme in neurodegenerative diseases with mutations and/or mislocalization of RNA binding proteins, including TDP-43 and FUS, in amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). TDP-43 and FUS are involved in fundamental RNA processing activities including RNA transcription, splicing, and transport. Following the recognition of their crucial role in neurodegeneration, we have used genome wide approaches to define their role in regulating expression and splicing of their RNA targets. We recently demonstrated that the human RNA most affected by reduction in TDP-43 is encoding the neuronal growth-associated factor called stathmin-2 (also known as SCG10), an essential component for neuronal regeneration and axonal maintenance. Reduced nuclear TDP-43 results in abnormal usage of cryptic splice and polyadenylation sites in pre-mRNAs from the *STMN2* gene, leading to loss of stathmin-2 protein. Remarkably, although TDP-43 affects the levels or splicing of many RNAs, restoration of stathmin-2 alone was sufficient to rescue regeneration after axotomy of iPSC-derived TDP-43 depleted motor neurons. Reduced levels in stathmin-2 is a hallmark in sporadic and familial ALS/FTD, and restoration of stathmin-2 expression emerges as an attractive therapeutic strategy in the vast majority of patients with ALS/FTD. We developed approaches to block cryptic splicing of stathmin-2 by targeting dCaRx or antisense oligonucleotides (ASOs) to stathmin-2 pre-mRNA leading to rescue of axonal regeneration capacity of human motor neurons with TDP-43 deficiency. Finally, using “humanized” stathmin-2 mice with constitutive misplicing, we establish that ASO injection into cerebral spinal fluid is a therapeutically viable approach to rescue stathmin-2 mRNA levels in TDP-43 proteinopathies.

THE HIPPOCAMPUS CONVERTS VOLATILE ENTORHINAL INPUTS INTO STABLE SPATIAL MAPS

SYMPOSIUM 32 - UNDERSTANDING THE FORMATION OF SPATIAL REPRESENTATIONS: FROM SYNAPSES TO CIRCUITS - MARLENE BARTOS, JUDIT MAKARA, MATTHEW NOLAN, CHRISTINE GRIENBERGER

Marlene Bartos
University of Freiburg, Institute For Physiology I, Freiburg, Germany

The medial entorhinal cortex (MEC)-hippocampal network plays a key role in the processing, storage and recall of spatial information. However, how the spatial code provided by MEC inputs relates to spatial representations generated by principal cell assemblies within hippocampal subfields remains enigmatic. To investigate this coding relationship, we employed two-photon calcium imaging in mice navigating through dissimilar virtual environments. Imaging large MEC bouton populations revealed spatially tuned activity patterns. MEC inputs drastically changed their preferred spatial field locations between environments, whereas hippocampal cells showed lower levels of place field reconfiguration. Decoding analysis indicated that higher place field reliability and larger context-dependent activity-rate differences allow low numbers of principal cells, particularly in the DG and CA1, to provide a more rapid and accurate information about location and context than MEC inputs. Thus, conversion of dynamic MEC inputs into stable spatial hippocampal maps may enable fast encoding and efficient recall of spatio-contextual information.

Spatially selective activity of hippocampal pyramidal neurons provides a representation of the environment supporting navigation and memory; however, the cellular mechanisms of the formation of hippocampal representations are incompletely understood. The activity of pyramidal neurons is shaped by the thousands of excitatory synaptic inputs arriving onto their dendritic tree. The spatiotemporal pattern of the active inputs, together with the active and passive properties of the targeted dendrites determine the integration of synaptic voltage signals in dendritic segments and may induce local forms of synaptic plasticity. Although synaptic long term potentiation has been proposed to contribute to the establishment of place coding, the fine-scale input pattern requirements to induce potentiation remained unclear. I will present our recent results demonstrating that local synaptic plasticity rules in thin perisomatic dendrites of CA1 pyramidal neurons depend on several factors, including the location of the input within the dendritic branch, the fine spatial organisation of the active synapses, the capacity of the input pattern to evoke dendritic spikes, and the activity of non-synchronous neighbouring synapses. The diversity of pattern-dependent cooperative synaptic plasticity rules can support fine-scaled discrimination of storage of information carried by input patterns, contributing to the versatility of hippocampal network coding.

Neurons in the retrohippocampal cortices, which include the entorhinal cortex, presubiculum and parasubiculum, play crucial roles in spatial memory. Many retrohippocampal neurons, for example grid cells and border cells, have firing fields associated with specific locations. These representations are thought to be building blocks for spatial localisation and memory. However, they are usually investigated in tasks in which relationships between locations and reward are absent. Whether these discrete codes are the sole strategy for representing spatial memories is therefore unclear. We investigated this using a memory task in which locations on a virtual track are associated with rewards. When mice solve this task we find that neurons in the retrohippocampal cortices encode location through ramping activity within discrete regions of the track. Rewarded locations were represented by offsets or switches in the slope of the ramping activity. These representations were maintained after removal of cues that mark reward locations indicating that they result from recall of the track structure. We find that similar representations emerged in recurrent neural networks trained to navigate to a rewarded location, suggest they may be part of a general computational strategy for spatial memory. We suggest that retrohippocampal ramping activity and its interruption mediates is well suited to readout of learned models for goal-directed navigation.

A crucial function of the brain is to produce useful representations of the external world. Previous results demonstrate that a non-Hebbian type of synaptic plasticity, behavioral timescale synaptic plasticity (BTSP), has a fundamental role in place field formation in hippocampal area CA1. BTSP has several distinct characteristics, including that it is driven by dendritic plateau potentials (plateaus) instead of APs. As axons from layer 3 entorhinal cortex (EC) impinge onto the site of plateau initiation and their activity regulates plateau probability, we hypothesized that this EC input might shape CA1 representations during learning. To test this hypothesis, we used two-photon calcium imaging in mice exploring a novel linear track. We observed the experience-dependent development of place cell representations in CA1, which featured an increased place field density (2-3x) around the reward location. Several findings implicated BTSP: (1) the abrupt appearance of new place cells; (2) the width of the new fields was correlated with the animal's running speed during induction; (3) new fields were shifted back in space with respect to their induction; (4) the development of the representation was severely attenuated by plasticity and calcium spike blockers. Using two-photon calcium imaging and optogenetic silencing of layer 3 EC axons we found that EC3 activity provides a signal to CA1 capable of increasing plateau probability and BTSP driven place field formation around the reward location. Taken together, our results identify the layer 3 entorhinal cortex input as a key signal that instructs CA1 neurons in how to represent an environment.

Coordinated activity across networks of neurons is a hallmark of both resting and active behavioral states in many species. These global patterns alter energy metabolism in the brain, making oxygen consumption and glucose uptake widely used proxies of neural activity. However, how changes in neural activity are causally related to changes in metabolic flux in intact circuits on sub-second timescales is unclear. We combine two-photon microscopy across the fruit fly brain with sensors that allow simultaneous measurements of neural activity and metabolic flux, across both resting and active behavioral states. We demonstrate that neural activity drives changes in metabolic flux, creating a tight coupling between these signals that can be measured across large-scale brain networks. Further, using local optogenetic perturbation, we demonstrate that even transient increases in neural activity result in rapid and persistent increases in cytosolic ATP, suggesting that neuronal metabolism predictively allocates resources to meet the energy demands of future neural activity. These studies reveal that the initiation of even minimal behavioral movements causes large-scale changes in the pattern of neural activity and energy metabolism, revealing unexpectedly widespread engagement of the brain. Moreover, the availability of the fruit fly connectome allows direct comparisons of functional measurements with anatomical constraints, revealing the extent to which specific functional networks can be predicted. As the relationships between neural activity, energy metabolism and anatomy are likely evolutionarily ancient, these studies provide a critical foundation for using metabolic proxies and connectomes to predict changes in neural activity.

Resting-state fMRI (rsfMRI) has been widely used to map brain network organization in healthy and pathological states. However, the neural underpinnings and dynamic rules governing brain-wide rsfMRI coupling remain unclear. Filling this knowledge gap is of crucial importance, given our current inability to decipher and relate clinical signatures of aberrant functional connectivity to interpretable neurophysiological events that can help understand or diagnose brain disorders. Towards this goal, my laboratory has recently combined chemogenetics, rsfMRI and *in vivo* electrophysiology to investigate how excitatory and inhibitory perturbations of brain activity causally affect whole-brain patterns of functional connectivity in the mouse. In my talk, will summarize some key results from this recent line of inquiry. Specifically, I will highlight how our approach can be used to identify the fundamental elements of rsfMRI coupling, challenging long-held assumptions regarding the relationship between rsfMRI connectivity and its underlying axonal determinants. I will also illustrate how disease-related signatures such as increased excitatory/inhibitory imbalance can generate clinically-relevant network signatures of dysconnectivity. These examples outline a novel research platform that is poised to shed light on the basis and determinants of macroscale rsfMRI coupling, offering opportunities to physiologically decipher signatures of atypical connectivity in human brain disorders.

Connectome projects worldwide have contributed enormously to our understanding of network-based brain function. However, little is known about brain connectivity at the scale of fundamental submillimeter functional domains that characterize human and nonhuman primate brains. This mesoscale understanding is critical as primate brains are functionally organized at this scale. Here, we present a novel method for studying connectivity in the macaque monkey. By combining focal (~0.5mm) near infrared neural stimulation at single brain sites and ultrahigh-field 7T fMRI (INS-fMRI), we map evoked activations at connected sites thereby providing maps of a single-site based mesoscale networks. Data collection is rapid, whole brain scale, and *in vivo*. This novel method uniquely enables comparison of many mesoscale networks within a single individual. Our data show that single site stimulation leads to activation of focal mesoscale nodes in multiple areas across the brain, including sensory, motor, cognitive, and limbic sites. Activated nodes are functionally specific, surprisingly sparse, and topographically organized (reflecting shifting connectivities). We suggest that each mesoscale brainwide network underlies a highly specific multi-dimensional behavior. These findings lead to a conceptual change in our understanding of the organization of behavioral networks in the brain. We are using this approach to develop a functional mesoscale connectome of the primate brain.

AXON-DENDRITE POLARITY ESTABLISHMENT IN C. ELEGANS, A MICROTUBULE BALANCING ACT

SYMPOSIUM 34 - CYTOSKELETON DYNAMICS IN NEURONAL DEVELOPMENT - MARTIN HARTERINK, CORALIE FASSIER, ANA RITA COSTA, MONIKA LEISCHNER-BRILL

Martin Harterink
Utrecht University, Department Of Cell Biology, Utrecht, Netherlands

Neurons are highly polarized cells that extend axons and dendrites to mediate information flow through the nervous system. The microtubule cytoskeleton is crucial to form these specialized cell extensions. It provides structural support and enables for cargo transport through the neuron. Whereas microtubules are organized plus-end out in axons, dendrites are characterized by minus-end out microtubues. This difference in organization between axons and dendrites allows for selective cargo transport into either neurite to establish neuronal polarity. However, the mechanisms that organize and maintain the neuronal microtubule cytoskeleton are still poorly understood. To study this, we used the in vivo model *C. elegans* in combination with advanced microscopy techniques. We found that during neuron development the establishment of this microtubule organization relies on local microtubule nucleation in dendrites in combination with stabilization by the microtubule minus-end binding CAMSAP protein. In addition, we identified and characterized the Ankyrin/UNC119/CRMP complex that connects the microtubule cytoskeleton to the cortex, to maintain this microtubule organization. In the absence of these mechanisms, neuronal polarity is lost leading to defects in neuron morphology and animal locomotion.

The mature nervous system is an intricate network in which the precise connectivity between neurons is critical for the optimal functioning of the system. Neuronal circuit wiring critically relies on the accurate navigation of developing axons towards their appropriate targets. Aberrant connections during development can lead to major neurological disorders. While the repertoire of guidance cues that wire the nervous system is mostly known, our understanding of the intracellular mechanisms that regulate axon responsiveness to these guidance signals is far from being complete. Notably, how these extracellular chemical signals are integrated and translated into cytoskeleton-driven growth cone mechanical behaviours remains largely unknown. We recently identified the microtubule-associated ATPase Fidgetin-like 1 (Fignl1) as a key player in zebrafish motor circuit wiring and larval locomotion. We showed that Fignl1 controls growth cone morphology and steering behaviours at guidance choice points through its versatile regulation of microtubule plus-end dynamics and bidirectional axonal transport. Using a combination of biological systems and cutting-edge imaging techniques, we showed that Fignl1 is also required for zebrafish retinal axon pathfinding at the optic chiasm and identified novel molecular links between this microtubule-depolymerizing enzyme, repulsive guidance pathways and the actin cytoskeleton. Altogether, these preliminary results suggest that Fignl1 acts as a key integrator of repulsive guidance signals coordinating microtubule/actin remodelling to steer developing axons.

Neurons present a unique arrangement of the axonal cytoskeleton unveiled by super-resolution microscopy, consisting of periodically distributed actin rings interconnected by spectrin tetramers - the membrane periodic skeleton (MPS). The MPS was initially considered to mechanically support the axons. Our previous data contributed to better understanding the role of the MPS in the regulation of axonal diameter by showing that it is an actomyosin network. Since there is still a lack of understanding regarding the biology of this structure, it is our aim to fully comprehend its biogenesis and function. Currently, actin nucleation and arrangement within the actin rings, as well as how non-muscle myosin II engages with actin rings to provide for axonal expansion and contraction, remains to be fully understood. To explore the role of different actin nucleators in the formation, maintenance and function of MPS actin rings, we are using complementary drugs and genetic approaches, together with single molecule localization microscopy. Our current data indicate that Arp2/3, that is involved in the nucleation of branched actin filaments, is essential for the initial formation but not for the maintenance of the MPS. Conversely, formins that promote the polymerization of linear actin filaments are essential for both the formation and maintenance of the MPS. The emerging picture is that a complementary action of actin nucleators is needed to provide for the timely MPS assembly, as is the case of actin rings that exist in other biological contexts.

Microtubules are dynamic cytoskeletal structures build from tubulin dimers, which can carry a range of post-translational modifications (PTMs). Together with associated proteins, post-translational modifications establish a ‘code’, endowing the microtubule scaffoldmwith specific and local functionality, such as regulating microtubule length andmdynamics and microtubule-dependent transport. However, how this codemtranslates into shaping cell- or tissue-level events, remains largely unexplored. We investigate how polyglutamylation, a post-translational modification enriched on neuronal microtubules, regulates postnatal motor axon remodelling: a regressive process in which ~90% of terminal branches prune, involving spastin-mediated loss of microtubules. While spastin is known to preferentially sever polyglutamylated microtubules, it remains elusive whether branch-specific polyglutamylation drives pruning.
Consistent with an instructive role of polyglutamylation, motoneurons ablated of deglutamylases CCP1&6 accelerate axon dismantling, while deletion of chainelongating glutamylase TTLL1, delayed axonal remodelling. Further measurements of polyglutamylation, microtubule mass and dynamics corroborate the predicted branch-specific regulation of microtubule stability, hinting at a rheostatic regulation of spastin-mediated severing and hence axonal remodelling. Surprisingly, deleting TTLL7, which ‘seeds’ the first glutamate residue, had no effect on polyglutamylation, suggesting several layers of regulation that are engrained in parallel or consecutive steps of editing the tubulin code. Together, a specific tubulin post-translational modification—polyglutamylation—acts as an instructive signal for spastin-mediated severing, which in turn paces developmental axon pruning. The ‘tubulin code’ could thus control specific morphogenetic events during nervous system development. Future work tries to unravel if synaptic activity coordinates glutamylases and deglutamylases and whether similar mechanisms determine axon stability in central neurons and during disease-related remodelling.

AUTOIMMUNE ENCEPHALITIS WITH ANTIBODIES AGAINST NMDA, AMPA OR KAINATE RECEPTORS: DISTINCT MECHANISMS AND PHENOTYPES

SYMPOSIUM 35 - AUTOANTIBODIES IN BRAIN PATHOPHYSIOLOGY - JOSEP DALMAU, ANA LUISA CARVALHO, LONNIE WOLLMUTH, LAURENT GROC

Josep Dalmau
Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Hospital Clínic, Universitat de Barcelona, ICREA, 1. neuroimmunology Program, Barcelona, Spain

The autoimmune encephalitides associated with antibodies against glutamate receptors (NMDAr, AMPAr, or GluK2) form part of a new category of diseases in which symptoms are antibody-mediated. Whereas anti-NMDAr (GluN1) encephalitis manifests with predominant psychiatric symptoms accompanied by severe neurological alterations (seizures, dyskinesias, coma, hypoventilation), anti-AMPAr (Glu2A>GluA1) encephalitis predominantly manifests with limbic dysfunction (memory deficits, seizures), and anti-GluK2 encephalitis associates with cerebellar dysfunction. For each of these diseases the pathogenicity of the antibody has been demonstrated in cultured neurons or animal models of passive antibody transfer or active immunization. For all 3 diseases, a fundamental pathogenic effect of the antibodies is the specific binding and internalization of the corresponding targets and the disruption of the surface interaction with synaptic partners (e.g., NMDAr with ephrinB2 or dopamine 1 receptor; AMPAr withTARP) resulting in alterations in synaptic transmission and plasticity. These alterations, which are antibody specific, associate with symptoms and downstream effects similar to those of diseases in which the same targets are affected by other mechanisms (e.g., schizophrenia and hypofunction of NMDAr). In some instances, synaptic scaling-like mechanisms (e.g., enhanced incorporation of inwardly rectifying non-GluA2 containing AMPArs) likely contribute to some of the symptoms. The reversibility of the behavioral and synaptic alterations caused by patients' antibodies is in line with the substantial improvement of patients after immunotherapy. Recent work focused on a better understanding of the underlying mechanisms may lead to treatment strategies that enhance or accelerate this improvement (e.g., positive allosteric modulation of NMDAr in anti-NMDAr encephalitis).

Contactin-associated protein 2 (CASPR2) is a cell adhesion molecule that is expressed both in the peripheral and central nervous system. Autoantibodies targeting surface epitopes of CASPR2 have been associated with neuromyotonia and autoimmune synaptic encephalitis, and patients with anti-CASPR2 autoantibodies (CASPR2-Abs) present a wide clinical spectrum ranging from acquired peripheral nerve hyperexcitability to CNS dysfunction, including cognitive impairments, memory loss and seizures. Notwithstanding the well-established pathogenic potential of CASPR2-Abs, the mechanisms triggered by antibody-mediated perturbations in CASPR2 function are still largely explored. Given the recently-described role for CASPR2 in the regulation of glutamate AMPA receptors (AMPAR) and cortical excitatory synaptic transmission, we explored whether patient CASPR2-Abs disrupt excitatory synapse function. We found that purified IgGs from patients with anti-CASPR2 synaptic encephalitis lead to dose-dependent changes in the dendritic and synaptic expression of Caspr2, and impact AMPAR trafficking by affecting receptor internalization and cell surface diffusion. Both IgGs purified from patients as well as patient-derived monoclonal antibodies targeting different domains in CASPR2 decrease the amplitude of AMPAR-mediated miniature excitatory postsynaptic currents. Moreover, CASPR2-Abs interfere with the synaptic incorporation of AMPARs following chemically-induced long-term potentiation. Finally, we found that excitatory synaptic transmission in the mouse visual cortex is perturbed following *in vivo* incubation with CASPR2-Abs. Collectively, our data show that CASPR2-Abs perturb the function of CASPR2 in regulating AMPAR trafficking and synaptic plasticity, pointing to the glutamatergic system as a target for pathogenesis in CASPR2 synaptic encephalitis.

AUTOANTIBODIES TARGETING THE NMDA RECEPTOR IN LUPUS

SYMPOSIUM 35 - AUTOANTIBODIES IN BRAIN PATHOPHYSIOLOGY - JOSEP DALMAU, ANA LUISA CARVALHO, LONNIE WOLLMUTH, LAURENT GROC

Lonnie Wollmuth
Stony Brook University, Department Of Neurobiology And Behavior, Stony Brook, United States of America

Systemic lupus erythematosus (SLE) or Lupus is an autoimmune disorder characterized by numerous pathologies including brain dysfunction. SLE patients suffer from diverse neuropsychiatric symptoms, ranging from the subtle (spatial memory deficits) to the severe (epilepsy, depression, & psychosis). A subset of SLE autoantibodies, referred to as DNRAbs, cross-react with DNA and the NMDA receptor (NMDAR), a glutamate-gated ion channel central to brain function. In patients, DNRAbs are associated with brain dysfunction, and in murine models with cell death, microglia activation, dendritic remodeling, and brain dysfunction. NMDARs are composed of two obligate GluN1 and typically two GluN2 subunits. DNRAbs bind to a pentapeptide amino acid sequence DWEYS within the GluN2A and GluN2B subunits. We find that DNRAbs act as positive allosteric modulators (PAMs), enhancing glutamate-induced channel opening. This action occurs preferentially at GluN2A-containing NMDARs, even NMDARs containing a single copy of GluN2A. Given this gain-of-function action, GluN2A-specific antagonists provide greater protection from DNRAb-mediated neuronal cell death than GluN2B antagonists. We also find, using transgenic mice to perturb expression of either GluN2A or GluN2B *in vivo*, that GluN2A mediates all DNRAb-induced pathologies. Hence, the PAM action is a key factor driving brain dysfunction. Notably, we find that the extent of this PAM action varies between DNRAbs derived from different SLE patients. We propose that clonal variations in DNRAbs may be a key factor leading to the diversity of clinical symptoms in SLE patients expressing DNRAbs.

The identification of autoimmune encephalitis in which patients express autoantibodies directed against neurotransmitter receptors has generated great hope to shed new light on the molecular mechanisms underpinning neurological and psychiatric conditions. Among these autoimmune encephalitis, the discovery of autoantibodies directed against the glutamatergic NMDA receptor (NMDAR-Ab), in the anti-NMDAR encephalitis, has provided some key information on how clinical symptoms can be caused by altered NMDAR signalling. Here, I will discuss recent advances on the molecular action of NMDAR-Ab on their targets and associated receptors at the single molecule level, unveiling unsuspected effects of such an autoantibody on the functional cross-talk between neurotransmitter systems.

NEURAL CIRCUIT MECHANISMS FOR NAVIGATING TO SHELTER DURING INSTINCTIVE ESCAPE

SYMPOSIUM 36 - NEURAL CIRCUITS FOR CONTEXT-DEPENDENT DEFENSIVE BEHAVIORS IN MICE AND FLIES - TIAGO BRANCO, TIHANA JOVANIC, PHILIP TOVOTE, CLARA FERREIRA

Tiago Branco
Sainsbury Wellcome Centre, Sainsbury Wellcome Centre, London, United Kingdom

When faced with predatorial threats the most adaptive action is to escape towards a shelter that offers long term protection against the attacker. Achieving this requires knowing where shelter is and using this knowledge to execute shelter-directed escape actions. Here we have investigated how information about shelter location is encoded in the mouse brain, and how this information is transmitted to neural circuits that control escape execution. We find that neurons in the retrosplenial cortex (RSP) and the lateral superior colliculus (lSC) specifically encode the angular distance to shelter in body-centered coordinates - the key variable for orienting and running along a direct vector to the shelter. Neurons in the RSP and lSC are monosynaptically connected and when this synapse is inactivated mice cannot find the shelter - escape is initiated, but the flight action is towards random places in the arena. In constrast, inactivating this synaptic connection does not impair sensory-guided orientation or navigation-to-reward tasks, indicating that the RSP to lSC pathway is specifically recruited during urgent navigation to safety. Recordings from cell type- and projection-specific neural dynamics combined with theoretical modelling sugest that the RSP maps shelter direction onto the lSC network using a centre-surround inhibition mechanism. These results identify a new circuit mechanism for representing instinctive goals and executing goal-directed actions during defensive behavior.

In face of an aversive stimulus animals need to decide whether to avoid and how to avoid them. In addition, they constantly need to balance their decisions to avoid dangers and threats with their drive to pursue food search. These decisions are modulated by animal's internal state and animals lacking nutrient were shown to be more likely to ignore aversive stimuli. However, how feeding states affect esacpe decisions and the neural circuit mechanisms underlying their state-dependent modulation are not well known. In order to adress this question we take advantage of *Drosophila* larva as a model system and combine automated behavioral detection, neuronal manipulation, functional imaging and electron microscopy reconstruction of synaptic connectivity We have previously described a circuit that controls the decision between startle and escape-like behavior following a mechanical stimulus. We hypothesized that integration of other information about the feeding state, might occur through long-range projections that connect to this circuit. We characterize how feeding state affect behavioral responses following a mechanical stimulus. Then, we describe how the activity of the already known neuronal substrates of decision making are differentially modulated by animal's state using 2-photon Calcium imaging in intact larvae. Understanding how the neural circuit mechanisms underlying escape decisions of whether and how these decisions can be modulated by the internal state in *Drosophila* larva where we can study neural circuit mechanisms with single cell and synaptic resolution across the nervous system, might shed light on principles underlying this process across species

INTEGRATED DEFENSE STATES AND THEIR NEURONAL SUBSTRATES IN THE PERIAQUEDUCTAL GREY

SYMPOSIUM 36 - NEURAL CIRCUITS FOR CONTEXT-DEPENDENT DEFENSIVE BEHAVIORS IN MICE AND FLIES - TIAGO BRANCO, TIHANA JOVANIC, PHILIP TOVOTE, CLARA FERREIRA

Philip Tovote
University Hospital Würzburg, Institute Of Clinical Neurobiology, Wuerzburg, Germany

Fear and anxiety are brain states that evolved to mediate defensive responses to threat. Brainstem neuronal circuits including the periaqueductal grey (PAG) play major roles in mediating behavioural and autonomic components of defensive states, yet their integrative nature is poorly understood. In particular, threat has been associated with various cardiac changes, but a clear consensus on their relevance for the integrated defense reaction is missing. This hinders our understanding of the neuronal underpinnings of dynamic defensive states. Novel analyses of concomitant behavioural, HR and thermal measures during various behavioural paradigms in freely moving mice, enable us to define transient microstates, including the notorious fear-induced freezing response and its interaction with longer-lasting macrostates. Applying integrated cardio-behavioural analyses to optogenetic perturbational approaches enable assignment of particular ‘state generator’ roles to individual neural circuit elements within the PAG. Our novel framework also guides descriptive calcium-imaging approaches that reveal PAG neuronal correlates for cardiac interoception under threat conditions. This talk will introduce characterization of integrated cardio-behavioural defensive states as the basis for a comprehensive understanding of complex neuronal mechanisms underlying aversive emotions such as fear and anxiety.

BEHAVIOURAL AND NEURONAL BASIS OF SAFETY IN NUMBERS

SYMPOSIUM 36 - NEURAL CIRCUITS FOR CONTEXT-DEPENDENT DEFENSIVE BEHAVIORS IN MICE AND FLIES - TIAGO BRANCO, TIHANA JOVANIC, PHILIP TOVOTE, CLARA FERREIRA

Clara Ferreira
Champalimaud Foundation, Chapalimaud Research, Lisboa, Portugal

A major benefit of being in a group is the possibility of adding social information to directly-perceived information about the environment to guide behaviour. Across the animal kingdom, social information acquired via specific signals or cues animals produce as they engage in their daily activities are used for decisions in reproduction, foraging and protection against predation. Acute fitness benefits of the usage of this information are flagrant in the context of a response to a potential threat: failure to detect a predator can lead to an animal's immediate demise whereas needless engagement in metabolically costly defence responses can, unnecessarily, negatively impact survival. We previously showed that Drosophila melanogaster display a graded decrease in freezing behaviour, triggered by an inescapable visual threat, with increasing group sizes. Crucially we identified that the movement of others is used as a cue of threat and safety, and that group responses are primarily guided by a safety in numbers effect. We have now further manipulated group composition, titrating the levels of the motion cues of safety, and uncovered that flies show chronometric (freezing bout length) and psychometric (probability of exiting freezing) curves similar to those observed in learned-choice decision-making tasks. Interestingly, simultaneously manipulating group composition and threat imminence, revealed that the social cue of safety has a preponderant role, overriding differences in perceived threat levels. These findings set the stage for uncovering the circuitry underlying the integration of motion cues from others, predators and conspecifics, in the deployment of responses to threat in groups.

CIRCUITS AND THE ENGRAMS FOR SYSTEMS CONSOLIDATION OF MEMORY

SYMPOSIUM 37 - ENGRAMS, CIRCUITS AND BIOCHEMICAL REORGANIZATION FOR REMOTE MEMORY CONSOLIDATION - TAKASHI KITAMURA, GISELLA VETERE, MICHEL VAN DEN OEVER, LAURA DENARDO

Takashi Kitamura
University of Texas Southwestern Medical Center, Psychiatry, Dallas, United States of America

Episodic memories initially require rapid synaptic plasticity within the hippocampus for their formation and are gradually consolidated in neocortical networks for permanent storage. However, the engrams and circuits that support neocortical memory consolidation have thus far been unknown.In my talk, I will present that neocortical prefrontal memory engram cells, which are critical for remote contextual fear memory, are rapidly generated during initial learning through inputs from both the hippocampal–entorhinal cortex network and the basolateral amygdala by using contextual fear conditioning as well as observational contextual fear conditioning. After their generation, the prefrontal engram cells, with support from hippocampal memory engram cells, become functionally mature with time. Whereas hippocampal engram cells gradually become silent with time, engram cells in the basolateral amygdala, which are necessary for fear memory, were maintained. Our study provides new insights into the functional reorganization of engrams and circuits underlying systems consolidation of memory.

THALAMIC INVOLVEMENT IN THE STABILIZATION OF LONG LASTING MEMORIES

SYMPOSIUM 37 - ENGRAMS, CIRCUITS AND BIOCHEMICAL REORGANIZATION FOR REMOTE MEMORY CONSOLIDATION - TAKASHI KITAMURA, GISELLA VETERE, MICHEL VAN DEN OEVER, LAURA DENARDO

Gisella Vetere
ESPCI, Brain Plasticity Unit, Paris, France

Understanding how memories are created and maintained over time is a fundamental problem in neuroscience. In this talk, I will explore how neural networks of co-active brain regions support memory recall. Within such networks, highly connected hub regions are assumed to disproportionately influence behavioural output. I will focus on the role of 2 thalamic regions, the anterodorsal and laterodorsal thalamus as key regions for fear memory stabilization and I will explore their contribution within the hippocampal-prefrontal cortex network. Ca^{2+} imaging and optogenetic manipulations suggest that the switch between recent to remote memory state requires a different engagement of these thalamic regions through direct control of the hippocampal and cortical ensembles. Finally, the role of head direction cells, present in both anterodorsal and laterodorsal thalamic nuclei, will be identified in representing spatial information as well as in processing emotional long-lasting memories.

Memory storage and retrieval is thought to depend on the consolidation of physical changes by sparsely distributed neurons that are highly activated during an experience, so-called engram cells. Recent data by us and others demonstrate that retrieval of remote (e.g. 1-month-old) contextual fear memory requires time-dependent maturation of engram cells in the medial prefrontal cortex (mPFC). Moreover, we found that the engagement of these neurons depends on memory strength, meaning that learning-activated mPFC neurons are required for remote memory expression after mild, but not strong, contextual fear conditioning (CFC). Based on this, we hypothesized that CFC-activated mPFC neurons undergo a time-dependent maturation process as a function of the intensity of conditioning. To investigate this, we made use of the TRAP2 mouse line to tag and identify mPFC neurons that are activated (*Fos*-expressing) during mild or strong CFC, or during context exposure only (no foot-shock). We compared changes in intrinsic excitability, synaptic and structural properties of tagged versus non-tagged mPFC neurons at a recent (≤ 1 week) and remote (≥ 4 weeks) timepoint after conditioning. Our findings demonstrate that following both mild and strong CFC, tagged mPFC neurons progressively develop adaptations in synaptic properties, however, these are most pronounced after mild CFC. Temporal changes in the structural properties of tagged mPFC neurons developed selectively after mild CFC. These observations support our hypothesis that time- and memory strength-dependent adaptations mirror the engagement of cortical engram cells in remote memory expression.

THE ORGANIZATION OF CORTICO-CORTICAL CIRCUITS UNDERLYING REMOTE MEMORY RETRIEVAL

SYMPOSIUM 37 - ENGRAMS, CIRCUITS AND BIOCHEMICAL REORGANIZATION FOR REMOTE MEMORY CONSOLIDATION - TAKASHI KITAMURA, GISELLA VETERE, MICHEL VAN DEN OEVER, LAURA DENARDO

Laura Denardo
University of California, Los Angeles, Department Of Physiology, Los Angeles, United States of America

Memories of emotional experiences can last a lifetime, guiding behavior from minutes to years after learning. In the clinic, remote memories of trauma are more treatment resistant than recent ones, linking memory evolution with memory resilience and highlighting the urgent need to understand the neurobiology of remote memory. As memories age, they are reorganized into a distributed cortical network, yet our understanding of this network at the cellular and synaptic level is incomplete. Activity in the prelimbic cortex (PL), part of the dorsomedial prefrontal cortex, is essential for both recent and remote fear memory recall, but accumulating evidence indicates that distinct PL output circuits control memory recall over time. In recent studies, we found that PL neurons involved in remote cued fear memory preferentially activate high order auditory association areas. Of these, the temporal association area (TeA), a major target of PL projections, is specifically required for remote memory recall. Yet the role of PL>TeA projections in memory recall and consolidation is unexplored. Using circuit-specific optogenetics and calcium imaging in freely behaving mice, we are examining the time-dependent functions of the PL-TeA connection. Our ongoing work will uncover the organizing principles and behavioral functions of key cortical networks underlying remote fear memories and can build foundations for new clinical interventions for trauma-based disorders.

BINGE DRINKING DURING ADOLESCENCE: MICROBIOME, IMMUNE AND COGNITIVE ALTERATIONS

SYMPOSIUM 38 - UNRAVELLING THE ROLE OF THE GUT MICROBIOME IN ADDICTION - CARINA CARBIA, BENJAMIN BOUTREL, LORENZO LEGGIO, NATHALIE DELZENNE

Carina Carbia, John Cryan
University College Cork, Apc Microbiome, Cork, Ireland

Binge drinking (BD) is defined as the consumption of six or more standard drinks in one session. This pattern of consumption is highly prevalent during adolescence, which is considered to last up to 25 years of age. This developmental period involves ongoing neuromaturation that results in greater vulnerability to disruptive events in the brain such as excessive alcohol consumption. BD has been associated with both neuroanatomical impairments and neuropsychological deficits. Accumulating evidence indicates that chronic alcohol consumption induces inflammation, both from a direct interaction with the brain and the periphery, particularly from the gut. Recently, chronic alcoholism has been linked with increased intestinal permeability and alteration of microbial profile that correlated with craving levels. However, no study to date has investigated the gut microbiota in young people with a repeated pattern of alcohol intoxication. The aim of this study is to investigate the potential link between alcohol-induced altered microbial profile, neurocognitive functioning and craving in healthy young BDs. Additionally, blood inflammatory markers will be measured. We will characterize both composition and functionality of the gut microbiome. The Cambridge Neuropsychological Test Automated Battery (CANTAB) will be used to assess neurocognitive performance. We will propose and discuss the results within a neuro-immuno-affective framework to integrate recent evidence on how central and peripheral alterations might affect the still developing young brain.

FECAL MICROBIOTA TRANSFER REVERSES EXCESSIVE ALCOHOL SEEKING IN STRESSED RATS

SYMPOSIUM 38 - UNRAVELLING THE ROLE OF THE GUT MICROBIOME IN ADDICTION - CARINA CARBIA, BENJAMIN BOUTREL, LORENZO LEGGIO, NATHALIE DELZENNE

Benjamin Boutrel
Lausanne University Hospital, University of Lausanne, Psychiatry, Lausanne, Switzerland

Although only a small proportion of individuals develop persistent alcohol used disorder, unhealthy alcohol use represents a significant public health concern, accounting for 4.5% of global disease burden. Identifying biological markers predicting vulnerability to develop excessive alcohol consumption may lead to real improvement of prevention strategies and possibly clinical care.
Considering that gut microbiota is capable of influencing immunity, brain and behavior, we investigated gut microbiome and signs of peripheral inflammation in rats exhibiting uncontrolled alcohol seeking behaviors. We monitored 1) the inability to abstain during a signaled period of reward unavailability, 2) the increased motivation assessed in a progressive effortful task and 3) the persistent alcohol seeking despite aversive foot shocks (Jadhav et al., 2017, 2018). After a long-training for alcohol (10%weight/volume) self-administration, all rats were screened according to the 3 criteria defined above and were identified as resilient versus vulnerable to uncontrolled alcohol seeking. All rats were then given access to 2 sources of reward: 0,1mL 10% w/v ethanol and 0.1mL saccharine (0.2 %, 0.00625%, 0%), 2 consecutive sessions for each concentration, during which vulnerable rats exhibited a clear-cut preference for alcohol compared to controls. Strikingly, we identified signs of peripheral inflammation in vulnerable rats, and not only fecal microbiota transfer lowered vulnerable rats' motivation and preference for alcohol but it restored inflammation modulators levels to those observed in controls. In the near future, manipulation of the gut microbiome may represent an original strategy to alleviate the overwhelming urge for compulsive alcohol drinking in human patients.

GUT MICROBIOME AND HARMFUL ALCOHOL DRINKING: FINDINGS FROM NON-HUMAN PRIMATE AND HUMAN STUDIES

SYMPOSIUM 38 - UNRAVELLING THE ROLE OF THE GUT MICROBIOME IN ADDICTION - CARINA CARBIA, BENJAMIN BOUTREL, LORENZO LEGGIO, NATHALIE DELZENNE

Lorenzo Leggio
National Institutes of Health, Nida And Niaaa, Baltimore, United States of America

Rodent studies report that chronic alcohol use leads to a loss in the diversity of the fecal microbial community, and in changes in the relative abundance of microbial taxa. Human studies also show an association between gut dysbiosis and chronic alcohol use. Non-human primate models provide a degree of experimental control that is not possible in humans, while, compared to rodents, are evolutionarily closer to humans. We conducted a study in a unique baboon model of chronic excessive alcohol drinking (Papio Anubis; N=14 males). Baboons were studied in controlled conditions, with consistent and reliable alcohol self-administration and blood alcohol levels, controlled food/caloric intake, and identical housing and exposure to stimuli. We compared three groups: L = Long-term alcohol drinking (12.1 years), S = Short-term alcohol drinking (2.7 years), and C = Control group, drinking an isocaloric, non-alcoholic reinforcer (8.2 years). We found that fecal microbial α- and β-diversity were significantly lower in the L group, vs. the other two groups. Members of the commensal bacterial families Lachnospiraceae and Prevotellaceae showed a relative decrease, whereas the opportunistic pathogen Streptococcus genus showed a relative increase, in the L group, vs. the other two groups. Microbiota-related metabolites of aromatic amino acids, tricarboxylic acid cycle, and pentose increased in the L group, vs. the other two groups, suggesting high energy metabolism and enhanced glycolysis in the gut lumen in response to alcohol. We are currently analyzing the results of a human gut microbiome and metabolome study.

Our recent data unravelled how the gut microbiome can participate to metabolic and behavioural disorders in obesity and alcohol disorders. In a cohort of obese individuals supplemented with prebiotic dietary fibers (DF), that modulate the gut microbiota, the presence of specific bacteria prior the nutritional intervention influenced both metabolic and behavioral outcomes. The potential relevance of nutritional disorders and intervention have been evaluated in alcohol use disorders (AUD). We have previously shown that depressive and social behavioural alterations of AUD patients was associated with gut microbial dysbiosis (changes in gut microbiota composition and activity). Dysbiotic patients had a lower sociability score and a smaller/less connected social network. Data obtained in mice transferred with the gut microbiome from AUD patients allowed to show that gut microbiota from AUD may drive inflammatory processes and hepatic metabolism, leading to decreased ketogenesis that may affect brain function. More recently, we found that among nutritional disorders that characterize AUD patients, DF intake, which is associated with anxiety and sociability, was lower in AUD than in healthy subjects. However, the supplementation with inulin as prebiotic DF versus placebo during a 3-weeks period of alcohol detoxification program, had only minor effect on behavioral and biological alterations as compared to alcohol withdrawal itself. Those data, obtained on a limited number of patients, could be extended to larger cohorts in order to unravel the multiple systems biology involved in behaviour related to beverage and food addiction, that remains very difficult to treat and has a tremendous consequence on health.

HOW ATTENTION AND NEUROMODULATORS CONTROL SYNAPTIC PLASTICITY IN DEEP CORTICAL NETWORKS

SYMPOSIUM 39 - REVISITING SENSORY CORTICES: IMPLICATIONS FOR DIVERSE COGNITIVE PROCESSING - PIETER ROELFSEMA, NATHALIE ROCHEFORT, ALEXANDRA LIBBY, ABHISHEK BANERJEE

Pieter Roelfsema
Netherlands Institute for Neuroscience, Department Of Vision & Cognition, Amsterdam, Netherlands

Humans and many other animals have an enormous capacity to learn about sensory stimuli and to master new skills. However, many of the mechanisms that enable us to learn remain to be understood. One of the greatest challenges of systems neuroscience is to explain how synaptic connections change to support maximally adaptive behaviour. I will provide an overview of factors that determine the change in the strength of synapses, with a focus on synaptic plasticity in sensory cortices. I will highlight the influence of neuromodulators and feedback connections in synaptic plasticity and suggest a specific framework in which these factors can interact to improve the functioning of the entire network.

Information processing is energetically expensive. In the mammalian brain, it is unclear how information coding and energy use are regulated during food scarcity. Using whole-cell recordings and two-photon imaging in layer 2/3 mouse visual cortex, we found that food restriction reduced AMPA receptor conductance, reducing synaptic ATP use by 29%. Neuronal excitability was nonetheless preserved by a compensatory increase in input resistance and a depolarized resting potential. Consequently, neurons spiked at similar rates as controls but spent less ATP on underlying excitatory currents. This energy-saving strategy had a cost because it amplified the variability of visually-evoked subthreshold responses, leading to a 32% broadening of orientation tuning and impaired fine visual discrimination. This reduction in coding precision was associated with reduced levels of the fat mass-regulated hormone leptin and was restored by exogenous leptin supplementation. Our findings reveal that metabolic state dynamically regulates the energy spent on coding precision in neocortex.

ROTATIONAL DYNAMICS REDUCE INTERFERENCE BETWEEN SENSORY AND MEMORY REPRESENTATIONS

SYMPOSIUM 39 - REVISITING SENSORY CORTICES: IMPLICATIONS FOR DIVERSE COGNITIVE PROCESSING - PIETER ROELFSEMA, NATHALIE ROCHEFORT, ALEXANDRA LIBBY, ABHISHEK BANERJEE

Alexandra Libby
Princeton University, Department Of Neuroscience, Buschman Lab, Princeton, United States of America

Behavior relies on the ability to make predictions. To form predictions, the brain must associate sensory information with the memory of recent stimuli. Because information is distributed within populations of neurons, interference can occur between these sensory and memory representations. To study the neural dynamics that underlie sensory processing, memory maintenance, and the formation of predictions, we recorded from the auditory cortex of mice, while they experienced sequences with statistical regularities. Exposure to predictable sequences aligned the sensory codes in auditory cortex, such that the first sensory event triggered the representation of later expected events. However, because predictions were embedded in the sensory codes, they could not be used as reliable memory readouts; unexpected trials resulted in overwriting of short-term memories. Interestingly, the memories were not lost; sensory information rotated over time into an orthogonal representation, where memories were accurately maintained. Multiple mechanisms can support this kind of orthogonal neural code. One mechanism simply keeps the sensory and memory representations in two separate populations of neurons. Alternatively, both sensory and memory information could be represented orthogonally in a single neural population. Our results support the latter hypothesis; we found the sensory representation rotated into an orthogonal dimension within the same population, protecting the memory from interference when new stimuli were presented. This rotation was supported by a combination of 'stable' and 'switching' neurons, which either maintained or inverted their selectivity over time. Theoretical modeling showed that such structured rotational dynamics are efficient, compared against alternative mechanisms for generating orthogonal representations.

BUILDING A FLEXIBLE SENSORY CORTEX

SYMPOSIUM 39 - REVISITING SENSORY CORTICES: IMPLICATIONS FOR DIVERSE COGNITIVE PROCESSING - PIETER ROELFSEMA, NATHALIE ROCHEFORT, ALEXANDRA LIBBY, ABHISHEK BANERJEE

Abhishek Banerjee
Newcastle University, Adaptive Decisions Lab, Biosciences Institute, Newcastle upon Tyne, United Kingdom

Animals adapt their behaviour in response to variable changes in reward reinforcement. The prefrontal areas of the mammalian neocortex, especially the orbitofrontal cortex (OFC), play an important role in invoking rule-based strategies to enable flexible learning. However, the neural circuit mechanisms in OFC and its interactions with different hierarchical cortical areas underlying such processes remain elusive. In my talk, I will discuss interactions between orbitofrontal and somatosensory cortices that implement flexible decision-making in a tactile reversal-learning task in mice. The talk will shed light on the circuit mechanisms underlying behavioural flexibility, indicating a crucial role of mouse OFC neurons in encoding predictive ‘teaching signals’ that drive adaptive changes in sensory cortices and in behaviour.

SPERM SMALL RNA-MEDIATED INTERGENERATIONAL INHERITANCE OF PATERNAL DIETARY EFFECTS

SYMPOSIUM 40 - TRANSGENERATIONAL EPIGENETIC INHERITANCE: IS THERE A CONNECTION BETWEEN THE LEARNED AND THE INNATE? - UPASNA SHARMA, KEVIN MITCHELL, ISABELLE MANSUY, ODED RECHAVI

Upasna Sharma
University of California Santa Cruz, Department Of Molecular, Cell And Developmental Biology, Santa Cruz, United States of America

Although there is mounting evidence from worms to humans suggesting that parental environment can influence phenotypes in offspring, the mechanism of such transgenerational inheritance remains deeply mysterious. Male mice fed a low protein diet sire offspring with altered lipid and cholesterol biosynthesis. We examined the mechanistic basis of epigenetic inheritance of paternal dietary effects. We show that protein restriction affects small RNA levels in mature sperm, including specific tRNA-derived small RNAs or tRNA fragments (tRFs). Specific tRFs can regulate early embryonic gene expression. These studies suggest that sperm small RNAs potentially mediate epigenetic inheritance of paternal dietary effects. Intriguingly, our studies revealed surprising dynamics of small RNA biogenesis during sperm maturation in the epididymis. We find that a subset of sperm small RNAs are synthesized in the somatic epididymis epithelial cells and shipped to sperm via extracellular vesicles. These studies revealed a role for soma-to-germline trafficking in shaping the RNA payload of mammalian sperm. Current studies are focused on elucidating the mechanism of this RNA-mediated soma-germline communication and its consequences on offspring development.

THE TROUBLE WITH EPIGENETICS

SYMPOSIUM 40 - TRANSGENERATIONAL EPIGENETIC INHERITANCE: IS THERE A CONNECTION BETWEEN THE LEARNED AND THE INNATE? - UPASNA SHARMA, KEVIN MITCHELL, ISABELLE MANSUY, ODED RECHAVI

Kevin Mitchell
Trinity College, Smurfit Institute Of Genetics, Dublin, Ireland

The concept of epigenetics - that gene expression can be modified by experience and that this provides a mechanism of cellular memory - has entered the mainstream of public consciousness. Despite a lack of clarity on usage of the term, it seems to offer a way to escape the perceived threat of genetic determinism, a means of rewriting our own psychological traits through experience. Moreover, the idea that the effects of such experiences might be transmitted across generations has truly gripped the public imagination, with studies of transgenerational psychological effects of famine or trauma – even the Holocaust – making headlines in newspapers across the world. There is strong evidence for transgenerational epigenetic inheritance in plants and simple animals like nematodes, with an understandable rationale for why such phenomena would exist and well worked out mechanisms. Neither the evidence nor the rationale is as convincing in mammals, however. This talk will explore methodological issues in seminal studies in rodents and humans, and examine the principles of genotype-phenotype relations and behavioural adaptation and flexibility in larger, more complex organisms. In particular, it will examine the idea that epigenetic mechanisms can provide a generational bridge between learning and instinct.

NEUROEPIGENETICS: HOW CHILDHOOD TRAUMA IS PASSED TO DESCENDANTS VIA THE GERM LINE

SYMPOSIUM 40 - TRANSGENERATIONAL EPIGENETIC INHERITANCE: IS THERE A CONNECTION BETWEEN THE LEARNED AND THE INNATE? - UPASNA SHARMA, KEVIN MITCHELL, ISABELLE MANSUY, ODED RECHAVI

Isabelle Mansuy
University & ETH Zurich, Laboratory Of Neuroepigenetics, Zurich, Switzerland

Behavior and physiology in mammals are strongly influenced by the environment and life experiences, particularly in childhood. While positive factors can favor proper development and good mental and physical health later in life, childhood adversity and traumatic events increase the risk for cancer and psychiatric, metabolic and autoimmune diseases. Such disorders can affect exposed individuals directly and in some cases, impact the offspring across generations. The biological mechanisms underlying transmission are thought to involve epigenetic factors. We developed a transgenerational mouse model of postnatal stress that recapitulates trauma symptoms including increased risk-taking, depressive behaviors, cognitive and social deficits, and metabolic and cardiovascular dysregulation in adulthood. The symptoms persist throughout life and are transmitted to the offspring, in some cases, up to the 5th generation. Comparable symptoms affect traumatized children, indicating conserved effects in mouse and human. Symptoms are associated with molecular changes involving RNA in germ cells, that in mice, are causally linked to symptoms transmission. MiRNAs are also affected in extracellular vesicles in the reproductive tract. Circulating factors were identified as mediators of alterations in germ cells. Chronic injection of serum from trauma-exposed mouse males into controls recapitulates metabolic phenotypes in the offspring, suggesting information transfer from serum to germ cells. Circulating factors involving peroxisome proliferator-activated receptor (PPAR) pathways are causally involved, and pharmacological PPAR activation *in vivo* affects sperm transcriptome and metabolic functions in the offspring and grand-offspring. These results suggest an ensemble of mechanisms from the periphery to germ cells for the inheritance of acquired traits.

CHALLENGING THE BASIC DOGMAS OF EVOLUTION: HERITABLE SMALL RNA

SYMPOSIUM 40 - TRANSGENERATIONAL EPIGENETIC INHERITANCE: IS THERE A CONNECTION BETWEEN THE LEARNED AND THE INNATE? - UPASNA SHARMA, KEVIN MITCHELL, ISABELLE MANSUY, ODED RECHAVI

Oded Rechavi
Tel Aviv University, Department Of Neurobiology, Wise Faculty Of Life Sciences & Sagol School Of Neuroscience, Tel Aviv University, Tel Aviv, Israel

In *C. elegans* nematodes, small RNAs enable transmission of epigenetic responses across multiple generations, independently of changes to the DNA sequence. Different environmental challenges, including exposure to viruses, starvation, and heat stress generate heritable small RNA responses, that in certain cases could be adaptive. Recently we have shown that neuronal activity can also produce small RNA-mediate heritable responses, and that the decisions that the progeny makes are affected by whether their ancestors' experienced stress or not. Our results indicate that specific processing of small RNAs in the parents leads to marked differences in the physiology of the progeny. I will discuss the underlying mechanisms, and the potential of small RNA inheritance to affect the worm’s fate and perhaps even evolution.

STRUCTURAL AND FUNCTIONAL ANNOTATION OF THE MOUSE PREFRONTAL CORTEX

SYMPOSIUM 41 - DECODING THE PREFRONTAL CIRCUITS OF COGNITIVE FLEXIBILITY - MARIE CARLEN, KATHLEEN CHO, JULIO MARTINEZ, DANIEL DURSTEWITZ

Marie Carlen
Karolinska Institutet, Neuroscience, Stockholm, Sweden

The structure and function of the prefrontal cortex (PFC) across species remain unresolved. Taking advantage of the technological toolbox available to studies in rodents, our studies aim to outline the mouse PFC through integration of structural, molecular, and functional characteristics. Whole-brain tracing of connectivity and spatial transcriptomics give a novel and unbiased view of the structure of the mouse PFC. The connectivity tracing outlines the mouse PFC as a module with dense intraconnectivity, questioning independent processing in discrete prefrontal subregions. In line with this, higher cognitive functions are considered to be integrative rather than localized. Non-localized functions of the PFC can only be revealed by studies focusing on the PFC as a whole, and high-density Neuropixels recordings have opened up for massive and concurrent sampling of neuronal activities across the subregions of the PFC. I will in my talk present our current work focused on large-scale recording of neuronal activities across the PFC subregions and what our investigations reveal about functional hierarchy and local versus non-local functions in prefrontal subterritories.

PREFRONTAL PARVALBUMIN INTERNEURON FUNCTION IN COGNITIVE CONTROL

SYMPOSIUM 41 - DECODING THE PREFRONTAL CIRCUITS OF COGNITIVE FLEXIBILITY - MARIE CARLEN, KATHLEEN CHO, JULIO MARTINEZ, DANIEL DURSTEWITZ

Kathleen Cho
Paris Brain Institute (ICM), INSERM, -, Paris, France

Changes in patterns of activity within the medial prefrontal cortex enable rodents, non-human primates, and humans to update their behavior to adapt to changes in the environment, e.g., during cognitive tasks. Within medial prefrontal cortex, inhibitory neurons expressing parvalbumin are important for updating strategies in a rule shift task. Nevertheless, causal mechanisms through which parvalbumin neurons recruit specific circuits to produce prefrontal network dynamics that switch from maintaining to updating task-related patterns of activity remain unknown. Here, I will discuss the role of gamma synchrony in cognitive flexibility, specifically cross-hemispheric gamma synchrony of prefrontal parvalbumin interneurons, and how long-range GABAergic projections support and affect synchrony in prefrontal cortex-dependent cognitive tasks.

MENTAL REPRESENTATIONS FOR COGNITIVE CONTROL IN THE MACAQUE LATERAL PREFRONTAL CORTEX

SYMPOSIUM 41 - DECODING THE PREFRONTAL CIRCUITS OF COGNITIVE FLEXIBILITY - MARIE CARLEN, KATHLEEN CHO, JULIO MARTINEZ, DANIEL DURSTEWITZ

Julio Martinez-Trujillo
Western University, Schulich School of Medicine and Dentistry, Physiology, Pharmacology And Psychiatry, London, Canada

Humans and other anthropoid primates can represent and manipulate complex information in the mind. A brain area that has been deemed critical to such cognitive ability is the lateral prefrontal cortex. We study the neural substrates of mental representations and learning in the lateral prefrontal cortex of non-human primates using naturalistic virtual reality associative learning and working memory tasks. During the tasks the animals are required to maintain and manipulate information about spatial and no spatial features of objects and their associations while navigating through virtual environments using a joystick. We used multielectrode arrays and pharmacological manipulations to record the activity of neurons and neuronal populations in the lateral prefrontal cortex (areas 9/46 of Brodmann). We found that single neurons and populations encode complex combinations of space and features (e.g., context-stimulus response associations) while animals navigate through the virtual environments. When the task contingencies change (e.g., introduction of new associations), neuronal populations become tuned for the new contingencies over a few trials reflecting changes in the animals' behavioral performance. Tuning was robust to changes in visual scenes produced by exploratory saccades during navigation but was disrupted by administration of the NMDA antagonist Ketamine. We conclude that the lateral prefrontal cortex flexibly encodes complex mental representations and their associations during naturalistic behavior providing a neural substrate for primates' remarkable adaptability to changes in the environment.

Recurrent Neural Networks (RNNs) are deep learning tools for processing and predicting time series data. They can also be used to identify, or reconstruct, the nonlinear dynamical system that underlies observed data, thus providing mechanistic insight into the system dynamics. In fact, RNNs are known to be computationally and dynamically universal, i.e., in theory they can represent and emulate any other computational or dynamical system, like the brain. By directly training RNNs on neural recordings and behavioral observations we can therefore formally examine the computational processes behind these experimental observations, thus linking cellular ensembles and behavior to computation. In my talk, I will first discuss recent advances in RNN models and training algorithms that were designed for the specific purpose of dynamical systems reconstruction, including the identification of limit sets like attractors and their geometrical or topological structure. Such techniques enable not only out-of-sample, but also out-of-distribution generalization to novel experimental settings. I will particularly focus on methodological approaches for identifying dynamical systems from multiple data modalities simultaneously. This enables, for instance, to link simultaneously recorded neurophysiological and behavioral observations to the same underlying latent dynamical process model, and thereby to elucidate their functional relationships. It will be illustrated on multiple-single-unit recordings from the rodent prefrontal cortex and behavioral responses during rule learning tasks how these techniques can be applied to faithfully reconstruct the underlying system with its observed physiological and behavioral properties, to decipher prefrontal computations, to detect cell assemblies, and to quantify inter-regional information transfer.

The molecular mechanisms involved in the organization and regulation of chemical synapses are central questions in neuroscience. Apart from synaptic adhesion molecules that engage trans-synaptic interactions in the synaptic cleft, some secreted proteins behave as 'synaptic scaffolders', *i. e.* proteins that interact with pre- or postsynaptic components within the synaptic cleft and organize the synapse without necessarily triggering a signal transduction cascade. Some extracellular scaffolders can position neurotransmitter receptors at the synapse by interacting with receptor-associated scaffolds in the synaptic cleft. Others bridge presynaptic adhesion molecules with the extracellular domains of neurotransmitter receptors or with adhesion receptors. Ce-Punctin/MADD-4 was initially identified in the nematode *C. elegans* as an extracellular matrix protein secreted by neuronal boutons and controlling the excitatory vs inhibitory identity of postsynaptic domains (*Nature*, 2014, 511, 466-70). Its vertebrate ortholog, ADAMTSL3/Punctin-2, is expressed in the central nervous system but its function has not been characterized so far. Specific combinations of Ce-Punctin isoforms are expressed by cholinergic and GABAergic motoneurons and trigger the clustering of acetylcholine- or GABA-gated ion channels at *C. elegans* excitatory and inhibitory neuromuscular junctions, respectively. This involves the postsynaptic positioning of transmembrane scaffolding molecules and the activation of the netrin receptor DCC. In turn, these proteins recruit intracellular scaffolding molecules that interact with the receptors. In addition, we recently discovered that Ce-Punctin is processed into discrete proteolytic fragments with distinct localization and function. These results shed light on novel mechanisms controlling the molecular organization of chemical synapses, with potential implications for neuropsychiatric diseases.

Trans-synaptic adhesion complexes organize synapse development. Their molecular diversity offers a profound cooperative potential to guide neuronal connectivity. Yet, it is only known for a few of these proteins whether they act in concert. We investigated the prefrontal cortex, a region impacted in multiple brain disorders, and analyzed the postsynaptic adhesion molecule LRRTM1 that is associated with schizophrenia and forms a complex with presynaptic Neurexins. Biochemical studies determined that loss of LRRTM1 elevates the synaptic amounts of the immunoglobulin adhesion molecule SynCAM 1, which promotes excitatory synapse number similar to LRRTM1 but does not bind it. To abrogate possible redundancy, we generated double knock-out mice lacking LRRTM1 and SynCAM 1. Their combined KO reduced the number of dendritic spines more than the sum of single KO losses and impacted presynaptic sites, making Neurexin puncta less spatially restricted. On a functional level, we used in vivo recordings and fMRI to determine that LRRTM1 and SynCAM 1 jointly control neuronal firing in the prefrontal cortex and synchronized brain activity. Moreover, behavioral tasks involving the prefrontal cortex were impacted in double but not single KO mice. We obtained no evidence in the hippocampus for a synaptic cooperation of these molecules. Our results provide evidence that LRRTM1 and SynCAM 1 act together in the prefrontal cortex to organize synapses and together modulate neuronal firing and cognition-relevant functions. These findings support that molecularly distinct trans-synaptic complexes can cooperate in a brain region-selective manner.

Triggering Receptor Expressed on Myeloid cells 2 (Trem2), is an immunoglobulin superfamily transmembrane receptor, expressed exclusively by microglia in the brain. Trem2 engages with membrane-bound or soluble ligands and interacts with the adaptor proteins DAP10 and DAP12, which recruit the intracellular signal transduction machineries. The known ligands of Trem2 comprise a large spectrum of anionic molecules, such as phospholipids, lipoproteins, DNA, and bacterial products. Further, membrane-bound Trem2 can be cleaved into its soluble form by the α-secretases ADAM10 and ADAM17, leading to the release into the extracellular environment of soluble Trem2 (sTrem2), which maintains its biological activity. We have found that Trem2 controls the process of synapse elimination during development. When this process is defective due to the lack of the trem2 gene, altered functional brain connectivity and defective behavioral phenotype emerge in the adult (Filipello, Morini et al., Immunity 2018). We also showed that externalized phosphatidylserine (PS) represents a neuronal “eat-me” signal recognized by Trem2 (Scott-Hewitt, Perrucci et al., EMBO J 2020). Using a fusion protein between the extracellular domain of Trem2 and the IgG Fc fragment, immobilized onto a solid support, we identified Trem2 ligands from brain synaptosomes. We are in the process of characterizing these receptors and defining whether they can be bound also by sTrem2. These data will shed a light on the mechanisms which control glia-mediated circuit sculpting.

REGULATION OF SYNAPSE CONNECTIVITY AND STABILITY

SYMPOSIUM 42 - SPECIFYING NEURONAL CONNECTIVITY ACROSS SPECIES - JEAN-LUIS BESSEREAU, THOMAS BIEDERER, MICHELA MATTEOLI, CAMIN DEAN

Camin Dean
German Center for Neurodegenerative Disease / Charité University of Medicine, Synaptic Dysfunction, Berlin, Germany

Synapses form, strengthen, weaken, and dissociate not only for proper development of the nervous system, but also to modulate circuit function. Synaptic dynamics are especially important during learning, remembering, and forgetting, for example, since memories are encoded by adjusting strength of specific synapses. The impairment of these dynamics can lead to neurodegenerative and psychiatric diseases. To follow synapse formation and dissociation from the initial point of contact between a pre and postsynaptic neuron, we are using GRASP (GFP Reconstitution Across Synaptic Partners), initially developed for circuit mapping. GRASP consists of two non-fluorescent parts of GFP, each fused extracellularly to a pre or postsynaptic membrane-targeted molecule. When a cell expressing the presynaptic split GFP forms a synapse with a cell expressing the postsynaptic split GFP, the GFP parts become close enough to reconstitute and produce a fluorescent signal indicating contact. Using this technique, we can detect synapse formation and dissociation in primary neuronal cultures transduced with pre and postsynaptic GRASPs by time-lapse imaging. In addition, synapse stability can be assessed by fluctuations in fluorescence over time. Fluorescence intensity, and magnitude of fluctuations, is increased or decreased by compounds that strengthen or weaken synapses to affect learning or forgetting. In addition, GRASP expression does not affect neuronal health and synaptogenesis, making it a powerful tool to investigate synaptic dynamics. We aim to apply this technique to human induced pluripotent stem cell (hIPSC)-derived neuronal networks to assay synapse formation, stability, and dissociation upon addition of compounds that influence synapse strength and memory.

PROCESSING OF FEEDFORWARD AND FEEDBACK SIGNALS IN MOUSE VISUAL THALAMUS

SYMPOSIUM 43 - MORE THAN A RELAY: NEURONAL CIRCUIT DYNAMICS IN THE VISUAL THALAMUS ACROSS INTERNAL STATES - LAURA BUSSE, JUDITH HIRSCH, MARK ANDERMANN, SANTIAGO ROMPANI

Laura Busse
Ludwig-Maximilians-Universität München, Division Of Neurobiology, Faculty Of Biology, Planegg-Martinsried, Germany

Traditionally, the dorsolateral geniculate nucleus (dLGN) of the thalamus has been considered a feedforward relay station for retinal signals to reach primary visual cortex. The local and long-range circuits of dLGN, however, have long suggested that this view is not correct. Indeed, besides the thalamo-cortical relay cells, dLGN contains local inhibitory interneurons, and receives not only feedforward input from the retina, but also anatomically massive direct and indirect feedback from primary visual cortex. Furthermore, it is one of the earliest processing stages in the visual system that integrates visual information with neuromodulatory signals.

In my talk, I will present recent findings from the mouse visual system regarding the impact of corticothalamic (CT) feedback on visual processing of synthetic and naturalistic visual stimuli. Here, I will focus on the role and circuits of CT feedback in modulating contextual spatial integration. In addition, I will consider the impact of behavioral state on dLGN activity across several temporal scales. Together, the results will highlight that dLGN is more than just a simple relay, offering opportunities for feedforward convergence of retinal inputs and being modulated by feedback and behavioral state.

The sensory thalamus was once viewed as a relay, serving to communicate information from the periphery to cortex during waking and halting this downstream flow during sleep. It has become increasing clear, however, that thalamus actively integrates sensory information and, most recently, that inhibitory circuits are central to this process. Indeed, inhibitory cells dominate intrinsic circuits in thalamus. Specifically, thalamocortical cells make few local connections but are embedded in two dense inhibitory networks. First, local interneurons supply feedforward inhibition; second, neurons in the adjacent thalamic reticular nucleus provide feedback inhibition. Our work focuses on visual components of the sensory thalamus, including the dorsal lateral geniculate nucleus and the visual compartment of the thalamic reticular nucleus. We use anatomical approaches to explore the structure of inhibitory networks in concert with with physiological, optogenetic, and computational tools to learn how intrathalamic inhibition might influence vision. Moreover, we compare results across species to resolve evolutionarily conserved aspects of thalamic circuitry and function.

Throughout the brain, the processing of sensory information is modulated to guide adaptive behaviors. Here, we investigate how serotonergic axons may specifically gate visual inputs at the level of retinal ganglion cell (RGC) axon terminals, prior to further integration and processing of sensory information in the thalamus. Bulk recordings of RGC axons showed that baseline and visually evoked calcium activity and glutamate release were suppressed by serotonin axon stimulation. Two-photon calcium imaging revealed that retinal axons preferring fullfield changes in luminance were more suppressed than those driven selectively by spatially localized stimuli, even when accounting for differences in each axon's baseline activity. Slice electrophysiology confirmed that serotonergic axon-evoked suppression of retinal glutamate release depends on presynaptic 5-HT1B receptors. Using single-cell sequencing, whole-mount electrophysiology and immunohistochemistry, we demonstrate differences in 5-HT1B receptor gene expression and axonal protein expression between RGCs that prefer fullfield changes in luminance vs. local stimuli. These data suggest a mechanism by which serotonin axons selectively gate specific visual information channels.

Image-forming visual information is transmitted from the retina to the lateral geniculate nucleus (LGN) of the thalamus, which is the principal driver of the primary visual cortex and thus conscious vision. The retina encodes the visual scene an organism sees into over 40 different features, such as motion in a particular direction or sharp edges. Previously, it was thought that these simple features were relayed by the LGN to the cortex without substantial combination or modulation. In this seminar, I will talk about recent work using single-cell initiated transsynaptic rabies in the mouse showing that LGN cells receive far more types of retinal input than was previously appreciated. Furthermore, I will present the more recent efforts from our lab in understanding the functional and structural convergence of different visual features in the thalamus using a combination of *in vivo* calcium imaging, optogenetics, and 3D electron microscopy, among other tools. Altogether, we hope to elucidate not only the early circuits of vision, but the mechanisms whereby simple neuronal features are combined to form complex representations.

SOCIAL DECISION-MAKING IN FORAGING CONTEXTS

SYMPOSIUM 44 - SOCIAL COGNITION… BEYOND SOCIAL INTERACTIONS - CRISTINA MARQUEZ, CHRISTIAN KEYSERS, EWELINA KNAPSKA, FRANCESCO PAPALEO

Cristina Marquez
Instituto de Neurociencias de Alicante (CSIC-UMH), Neural Circuits Of Social Behavior Lab, Alicante, Spain

Prosocial behaviours are actions that benefit others. They are thought to be evolutionary conserved across different mammal species however, the behavioural and neural mechanisms that explain this type of actions are yet poorly understood. In this talk we will focus on how animals perceive rewarding states from others and incorporate these into social decision-making. Using novel behavioural paradigms that allow for deep analysis of social behaviour, calcium imaging, closed-loop optogenetic experiments and computational modelling, we will explore how social hierarchy and the perception of the well-being of others guide the decision to help or not to help others.

In humans, the mid/anterior cingulate cortex (Brodmann Area 24) is one of the most consistently activated in neuroimaging studies while witnessing the distress of others. Many have speculated that this region plays a causal role in empathy and, because it is also recruited during pain experience, that it does so by mapping the pain of others onto the witness' own via mirror neurons. Testing these speculations in humans is difficult, and we therefore developed rat models. Recording from cingulate area 24 in rats, we showed that it indeed contains neurons that respond both while the animal experiences pain and witnessing others receive footshocks, demonstrating the presence of pain mirror neurons. Rats typically freeze while witnessing a conspecific receive footshocks, deactivating area 24 dramatically reduces this sign of emotional contagion and establishes the causal role of this region in emotional contagion. To assess whether it also contributes to social harm aversion, we developed a paradigm in which a rat can choose between two levers delivering food, one of which also delivers a footshock to an adjacent conspecific. Rats were found to avoid using this shock lever, even if the alternative lever provided less food or required more effort, confirming the presence of a prosocial motivation to avoid harming others. Deactivating area 24 abolished that harm aversion. Together, these rodent paradigms therefore allow us to gain insights into the cellular and causal mechanisms linking cingulate area 24 to emotional contagion and harm aversion.

SOCIAL LEARNING ABOUT REWARDS AND THREATS – HOW INFORMATION FROM OTHERS HELPS TO ADAPT TO CHANGING ENVIRONMENT.

SYMPOSIUM 44 - SOCIAL COGNITION… BEYOND SOCIAL INTERACTIONS - CRISTINA MARQUEZ, CHRISTIAN KEYSERS, EWELINA KNAPSKA, FRANCESCO PAPALEO

Ewelina Knapska
Nencki Institute of Experimental Biology, Centre Of Excellence For Neural Plasticity And Brain Disorders (braincity), Warsaw, Poland

In social species, emotions displayed by others influence the cognition and behavior of the interacting individuals. The capacity to be affected by or share emotional states is observed both in humans and rodents. It is believed that this capacity facilitates building relationships because it fosters emotional synchrony between individuals. However, the utility of sharing emotion surpasses a purely social function. Since to survive, an animal must continuously learn about challenges and opportunities in its environment, the emotions of other individuals can also be a source of valuable information. Thus, our rodent studies focus on the neuronal circuits underlying socially perceived emotions and their role in adaptation to the environment. In particular, we show that social cues convey information about the imminence of threat and that socially triggered responses recruit different neuronal circuits in the central amygdala. Further, we show that rodents socially transfer information about a distant food source through direct interaction with an individual who encountered the food reward or with a scent thereof. We also show that socially acquired knowledge modifies the exploration patterns of familiar and novel environments. Thereby, perceiving affective states of others evoked by a threat or a reward helps the individual adapt its behavior and thus avoid harm and maximize rewards. Perceiving others' emotions carries informational value, which offers a new perspective on the evolutionary origins of socially shared emotions.

CIRCUITS OF EMOTION DISCRIMINATION

SYMPOSIUM 44 - SOCIAL COGNITION… BEYOND SOCIAL INTERACTIONS - CRISTINA MARQUEZ, CHRISTIAN KEYSERS, EWELINA KNAPSKA, FRANCESCO PAPALEO

Francesco Papaleo
Istituto Italiano di Tecnologia, Neuroscience Area, Genova, Italy

Emotion recognition and consequent social reaction are important for a wealthy animal life. These socio-cognitive processes are supposed to rely on evolutionary conserved long-range brain networks, regulated by an inhibitory/excitatory balance. We found that inhibitory somatostatin (SOM) neurons within the medial prefrontal cortex (mPFC) are a fundamental biological substrate of emotion discrimination. However, it is unclear how cell-specific long-range circuits might process socially derived information for reliable emotion recognition. Here, we show the specific involvement of atypical long-range SOM projections from the mPFC to the retrosplenial cortex (RSC), and an excitatory feedback loop from the RSC to mPFC in emotion discrimination. Using human imaging and rodent anatomical tracing, we highlight the involvement of the mPFC-RSC network in emotion recognition and the existence of a subpopulation of SOM GABAergic neurons projecting from the mPFC to the RSC. Our findings demonstrate a specific cortico-cortical inhibitory/excitatory circuit subtending emotion recognition.

EARLY PATTERNS OF ACTIVITY IN CEREBRAL CORTEX OF NEONATAL RATS

SYMPOSIUM 45 - THE NEWBORN BRAIN: UNRAVELING THE INTERPLAY BETWEEN EARLY ACTIVITY AND NETWORK DEVELOPMENT - ROUSTEM KHAZIPOV, CHARLIE DEMENé, REBECCAH SLATER, PETRA HüPPI

Roustem Khazipov[1,2]
[1]Kazan Federal University, Laboratory Of Neurobiology, Kazan, Russian Federation, [2]Inserm, Aix-Marseille University, Inmed, Marseille, France

Development of thalamocortical sensory maps during the neonatal period in rodents is characterized by particular intermittent network activity patterns, which are implicated in the activity-dependent formation of the topographic thalamocortical circuits. Several developmental rules determine cortical functions during these stages. Firstly, thalamocortical maps develop from a crude protomap and refine through the competition between sensory inputs for the cortical territories. Temporal binding of thalamic and cortical neurons by virtue of the early thalamocortical oscillations is instrumental for the enforcement and stabilization of the topographic synapses and elimination of the non-topographic synapses. Secondly, early operation of the immature cortex is fundamentally reflexological and it is largely driven by the thalamic input. Intracortical circuits at these stages are yet poorly developed to support internally organized activities. The ability of cortical networks to generate internally organized activities and a transition to the adult-like mode of cortical function emerges only with acquisition of sustained neuronal firing patterns by cortical neurons and the formation of the intracortical excitatory and inhibitory circuits. Thirdly, natural stimulus to the thalamocortical circuits is provided by spontaneous activity at the sensory periphery (retinal waves in visual system, cochlear bursts in auditory system and sensory feedback from twitches in somatosensory system). Thus, both rodents possess the internal mechanisms driving activity within the developing sensory systems independently on external inputs.

Neonatologists have long been interested in functional brain monitoring, as reversible functional losses often precedes the observable irreversible structural insults. By characterizing neonatal functional cerebral networks, resting-state functional connectivity is envisioned to provide early markers of cognitive impairments. Here we present a pioneering deep brain resting-state functional connectivity imaging on human neonates using functional ultrasound (fUS). fUS leverages in-depth cerebral blood volume high sensitivity, beside portability, 250µm spatial resolution and <1s temporal resolution, making it unique in the landscape of neonatal brain imaging. Using a micro-motorized and miniaturized probe facing the anterior fontanel, it enables to acquire 3D images of the neonate's brain that can be registered with an MRI neonate atlas. Signal correlations between cerebral regions revealed interhemispheric connectivity at an early stage in very preterm newborns. Furthermore, fUS high spatial resolution enabled to build fine-grain homotopic connectivity maps, based on correlations between mirror pixels, which revealed underlying structures, such as the white/grey matter boundary in the cortex. Finally, resting-state connectivity could be assessed dynamically showing a significant occurrence decrease of thalamo-cortical networks for very preterm neonates (N=6) as compared to control term newborns (N=4), a subtle difference that would have staid concealed with a more classical static connectivity analysis. The same method also showed abnormal patterns in a congenital seizure disorder case compared with the control group. We hope fUS can help to quickly identify and quantify atypical connectivity patterns at bedside and to study the emergence of functional networks in the early days of life.

NEONATAL PAIN PERCEPTION: BEHAVIORAL AND BRAIN EXPLORATIONS BY ELECTROENCEPHALOGRAPHY AND MAGNETIC RESONANCE IMAGING

SYMPOSIUM 45 - THE NEWBORN BRAIN: UNRAVELING THE INTERPLAY BETWEEN EARLY ACTIVITY AND NETWORK DEVELOPMENT - ROUSTEM KHAZIPOV, CHARLIE DEMENé, REBECCAH SLATER, PETRA HüPPI

Rebeccah Slater
University of Oxford, Department Of Paediatrics, Oxford, United Kingdom

The human brain has a central role in pain perception, and individual differences in brain structure and function underpin differences in pain sensitivity and pain tolerance. Humans display wide variation in their response to painful events, and even infants of a few days old differ dramatically in their evoked pain-related behavioural, physiological and cerebral activity. In adults, the emergence of pain experience is considered to arise when a set of brain networks, that are not individually unique to pain, become active together, and there is a high degree of correspondence between brain activity patterns observed at rest and patterns of activity evoked by salient events or tasks. Although the newborn infant brain is highly immature, it has many functional properties that are similar to that observed in adults. A key question is how does the structural and functional organisation of the infant brain give rise to the individual variability that is observed between infants during pain experience? I will describe a series of studies conducted in newborn infants that will show how resting-state brain activity recorded in the first few days of life can be used to predict individual differences in pain-related cerebral activity evoked by a controlled experimental noxious stimuli. I will also discuss underlying differences in white matter microstructural complexity that can explain between-subject differences in pain-related brain activity and discuss how responses to noxious stimulation mature during early development. This work provides insight into the structural and functional differences that underpin normal variability in response to noxious input in newborn infants.

THE INFLUENCE OF PRETERM BIRTH AND EARLY ENVIRONMENT ON STRUCTURAL AND FUNCTIONAL BRAIN DEVELOPMENT EXPLORED BY MAGNETIC RESONANCE IMAGING

SYMPOSIUM 45 - THE NEWBORN BRAIN: UNRAVELING THE INTERPLAY BETWEEN EARLY ACTIVITY AND NETWORK DEVELOPMENT - ROUSTEM KHAZIPOV, CHARLIE DEMENé, REBECCAH SLATER, PETRA HüPPI

Petra Hüppi
University of Geneva, Department Of Pediatrics Obstetrics And Gynecology, Geneva, Switzerland

Preterm birth is one of the leading causes for neurodevelopmental delay in surviving infants, and has been associated with a wide range of behavioural and cognitive problems from childhood to adult life. Studies by us and others have helped to uncover the underlying neural mechanisms of these difficulties, which is paramount to identify potential avenues for interventions to improve outcome. MR imaging studies have allowed to identify altered global brain tissue growth rates in preterm infants and have identified microstructurally altered brain white matter networks in the associative and limbic cortico-basal ganglia-thalamocortical circuits, involving the dorsolateral prefrontal cortex, the orbitofrontal cortex and the amygdala (Sa de Almeida et al., 2021). Recently we we have further evidence for altered salience (anterior insula to anterior cingulate) network functionality already in the newborn period, a network that allows to adapt behavior according to the predictive value of stimuli, positive (reward) or negative (punishment)(Lordier et al., 2019). Predictive relations between stimuli and outcome are learned through experience and preterm infants clearly have very different early life experiences with extreme situations of non-predictability. These findings raise the question of how to induce resilience through more predictable stimuli in the newborn period. Our recent research has engaged in introducing interventions, in the newborn period by maternal voice and music (Adam-Darque et al., 2020; Lordier et al., 2019; Loukas et al., 2021). The combination of fMRI and high density EEG are shown to be valid methods to study early functional competence of the developing brain.

[1]University of California, Berkeley, Department Of Chemical And Biomolecular Engineering, Berkeley, United States of America, [2]University of California, Berkeley, Helen Wills Neuroscience Institute, Berkeley, United States of America, [3]UC Berkeley, Center For Computational Biology, Berkeley, United States of America

Restoration of CNS tissue function and neuronal death following traumatic injury requires the regeneration of hundreds of diverse neuronal types interconnected via orderly and specific synapses. Moreover, different neuronal types can exhibit a wide range of susceptibility to injury, and differ in their capacity to respond to interventions. A systematic investigation of this diversity is necessary to identify viable strategies to promote the functional restoration of disrupted circuits. I will describe our efforts to use single-cell genomic approaches to study the diversity, development and response to injury of the projection neurons of the retina, the retinal ganglion cells (RGCs). Using single-cell transcriptomic profiling, we identified 46 types of RGCs in mice, which collectively parcellate visual input. We have also now unified molecular definitions with morphology and physiology (rgctypes.org). We then used this molecular atlas as a foundation for three lines of investigation: (1) Identifying selectively resilient RGC types following axotomy as a screen to identify molecular factors that may promote neuroprotection/regeneration, (2) Studying the natural developmental process of diversification of RGC types, and (3) Studying the impact of early activity on molecular aspects of RGC development and maturation. Together, these studies are providing us new insights into the developmental processes that guide the establishment and maintenance of a diverse neuronal class in the CNS.

LOCAL AND SYSTEMIC RESPONSES TO INJURY IN AXOLOTL

SYMPOSIUM 46 - BARRIERS AND HOPES FOR FUNCTIONAL RESTORATION AFTER TRAUMATIC CNS INJURY - FRANK BRADKE, KARTHIK SHEKHAR, JESSICA WHITED, AYA TAKEOKA

Jessica Whited
Harvard University, Department Of Stem Cell And Regenerative Biology, Cambridge, United States of America

Regenerative abilities vary dramatically across animal lineages. Yet, how systems-level injury responses in individual species shape ultimate regenerative outcomes is not well understood. We recently discovered a body-wide stem cell activation response that occurs following amputation in the highly-regenerative axolotl salamander. Here, we present evidence that this systemic activation primes appendages distant to the original injury for their own future regeneration events. We hypothesize that stem cell priming may have evolved due to cannibalism faced by juvenile salamanders. We investigated the mechanism of systemic activation in axolotls and found the process requires innervation by the peripheral nervous system at distant responding sites. Using transcriptomic studies, we identified gene expression changes in nerve processes and responding tissues underlying systemic activation, which led us to consider adrenergic signaling. We found inhibiting adrenergic signaling is sufficient to block systemic activation. Inspired by previous reports of mTOR activity being required for systemic stem cell activation following injury in both highly-regenerative species and species with modest regenerative abilities, we also tested mTOR signaling in axolotl. Our studies also implicate mTOR signaling as required for axolotl systemic activation following amputation. Together, these results demonstrate a direct link between systemic stem cell responses and localized regeneration of an appendage, and they also highlight roles for peripheral nerves, adrenergic signaling, and the mTOR pathway in systemic injury responses in axolotls. They also suggest a model whereby common initial injury responses are used as a foundation across species, while species-specific life history constraints shape differing downstream responses that ultimately drive the regenerative outcome.

NEUROTRANSMITTER SWITCH BY SPINAL EXCITATORY INTERNEURONS DEFINES AGE OF INJURY-DEPENDENT LOCOMOTOR CIRCUIT PLASTICITY AFTER SPINAL CORD INJURY

SYMPOSIUM 46 - BARRIERS AND HOPES FOR FUNCTIONAL RESTORATION AFTER TRAUMATIC CNS INJURY - FRANK BRADKE, KARTHIK SHEKHAR, JESSICA WHITED, AYA TAKEOKA

Aya Takeoka
VIB, Neuroelectronics Research Flanders, Leuven, Belgium

Age is one of the defining factors for functional outcomes after a traumatic injury to the central nervous system. Both neuronal intrinsic and extrinsic factors contribute to age of injury-dependent plasticity. Immature neurons are more resilient to trauma and exhibit robust regeneration capabilities than mature neurons. In addition, the scar environment of juvenile animals is more permissive to growth than that of adults, supporting the sprouting and regeneration of neurons to establish novel connections. While these findings highlight the regenerative ability of injured cells themselves, our recent work reveals that circuits located at a distance from the injury site also undergo reorganization depending on the age of injury. Severe spinal cord injury to the mature nervous system leads to irreversible paralysis below the lesion. In contrast, a complete thoracic lesion just after birth leads to proficient hindlimb locomotion without brain input as an adult. How the spinal cord achieves such striking functionality remains unknown. We uncover age of injury-dependent divergent synaptic connectivity from interneurons to motor neurons. Adult injury prompts neurotransmitter switching of spatially defined excitatory interneurons to inhibitory phenotype, promoting inhibition at synapses interfacing motor neurons. In contrast, neonatal injury causes synaptic sprouting of identical populations to facilitate excitation. Furthermore, genetic manipulation to mimic inhibitory phenotype observed after adult injury by excitatory interneurons abrogates autonomous locomotor functionality in neonatally injured mice. In comparison, attenuating inhibitory phenotype improves locomotor recovery after adult injury. Together, our study demonstrates that flexible neurotransmitter phenotype of defined excitatory interneurons steers locomotor capacity after injury.

THE INVOLVEMENT OF ASTROCYTE CALCIUM-DEPENDENT SIGNALING IN BEHAVIOR

SYMPOSIUM 47 - ASTROCYTES CONTROL BRAIN CIRCUITS UNDERLYING BEHAVIOR - JOãO FILIPE OLIVEIRA, MARTA NAVARRETE, ALFONSO ARAQUE, INBAL GOSHEN

João Filipe Oliveira[1,2,3]
[1]ICVS/3B's - PT Government Associate Laboratory, Neuroscience, Braga, Portugal, [2]IPCA-EST-2Ai, Polytechnic Institute of Cávado and Ave, Applied Artificial Intelligence Laboratory, -, Barcelos, Portugal, [3]ICVS, School of Medicine - University of Minho, Neuroscience, Braga, Portugal

Astrocytes are critical players in the regulation of brain development and function. They sense and respond to neuronal activity by elevating intracellular calcium levels, which derive from different sources and display complex spatiotemporal properties. Calcium elevations appear spatially distributed in global (soma and main processes) and focal regions (microdomains). Such astrocytic calcium activity is expected to underlie the astrocyte involvement in synaptic transmission, metabolism, and brain homeostasis. In this work, we studied the IP3 receptor type 2 knockout (IP3R2 KO) mouse model that lacks global calcium elevations in astrocytes to disclose its implications in cognitive function. We found an influence of global astrocyte calcium long-term memory performance. Thus, we performed a structural and molecular analysis of cortico-limbic regions that revealed a shift to immature spines in pyramidal neurons of the dorsal hippocampus that could support the changes in synaptic plasticity underlying our behavioral observations. The characterization of the IP3R2 KO mouse model provided new insights into the importance of astrocytic calcium-dependent signaling in the modulation of neural activity. These findings broaden the scope of astrocytic modulation of brain circuits.

Unraveling the principles of information processing in complex cellular circuits requires techniques capable of specifically targeting and modulating the activity of the elements involved. Neuro-astrocyte networks display a surprising degree of complexity and state-of-the-art complementary tools are required to understand astrocyte involvement in circuit modulation and behavior. Although the evolution of genetic tools to study and control these circuits has focused mainly on neuronal activity, in this talk, I will show newly developed techniques to specifically dissect the active astrocyte circuits with spatio-temporal precision, i.e. *CaMPARI*$_{GFAP}$ (calcium-modulated photoactivatable ratiometric integrator under GFAP promoter) and *Astro-Light* (calcium- and light-gated switch to induce gene expression in activated astrocytes). Furthermore, I will discuss our recent data about mapping the functional astrocytic-circuitries within the Nucleus Accumbens (NAc) that reveal the existence of specific-astrocyte circuits in the NAc. In short, I will present data, acquired using cutting-edge tools, which supports the idea that NAc astrocytic networks are critical players in understanding the way that the NAc integrates information. Astrocytes, a major type of glial cells, are recognized as key supportive elements in neuronal function, providing structural and metabolic support for neurons, and controlling brain homeostasis mechanisms. Historically, they were ignored as being active players in cellular processes underlying brain function. However, accumulating evidence indicate that astrocytes and neurons establish bidirectional communication. Astrocytes respond to synaptically-released neurotransmitters and, in turn, release gliotransmitters that influence neuronal and synaptic activity. This evidence has led to the establishment of the tripartite synapse concept, a novel view of synaptic physiology in which astrocytes are integral elements involved in synaptic function. I will present and discuss current evidence revealing the specific mechanisms of astrocyte-neuron signaling in different brain areas. I will also present the functional consequences of astrocyte-neuron signaling at different levels of analysis, from cellular and synaptic levels to network and behavioral levels. Finally, I will discuss how this evidence supports a paradigm shift in our understanding of the cellular basis of brain function, which would result not solely from the neuronal activity, but from the coordinated activity of astrocytes and neurons.

Recent studies, including ours, have implicated hippocampal astrocytes in memory processes; e.g. they can improve memory when activated, and have a projection specific effect on the acquisition of remote memory. Astrocytic calcium dynamics are involved in sensory information encoding, but their real-time calcium activity in awake mice has not been investigated as of yet. We chronically imaged dozens of CA1 astrocytes using 2-photon microscopy when head-fixed mice run on a linear treadmill and proceed in a virtual environment to obtain water rewards. We find that astrocytic activity persistently ramps towards the reward location in a familiar environment. However, when mice were introduced to a novel context, the ramping was not apparent. Following additional training, as the mice were familiarized with the novel context, the ramping was reestablished, suggesting that spatial modulation of astrocytic activity is experience dependent. Similarly, when mice were tested in the familiar environment, and the reward location was changed (in the same environment), the ramping was no longer apparent. When, after learning, the mice learned the new reward location, the ramping reappeared, suggesting again that astrocytic activity is learning dependent. This is the first indication that astrocytes can encode position related information in learnt spatial contexts, thus broadening their known computational abilities, and their role in cognitive functions.

Emerging evidence suggests that there is a relative reduction in glutamatergic neurotransmission in major depressive disorder (MDD), which afflicts approximately 14-20% of individuals. Pyramidal arborization and dendritic spine abundance are reduced with this disorder. Of interest, functional changes in parvalbumin-expressing interneurons have also been observed in rodent models of MDD. In particular, enhanced deposition of perineuronal net (PNN) components occurs with social defeat-inducing persistent stress. Since parvalbumin-expressing interneurons are the predominant cell population that is enveloped by PNNs, which enhances their ability to release GABA, excess PNN deposition likely increases pyramidal cell inhibition. In the present study we investigate the potential for matrix metalloprotease-9 (MMP-9), an endopeptidase secreted in response to neuronal activity, to contribute to the antidepressant efficacy of venlafaxine, a serotonin/norepinephrine reuptake inhibitor. Herein we observe that PNN expression is increased in a corticosterone-induced stress model of disease and reduced by venlafaxine in wild type but not MMP-9 null animals. Corticosterone treated mice also display reduced *ex vivo* gamma power and impaired working memory, with normalization by venlafaxine. This is a relevant endpoint because gamma power is increased with pyramidal cell disinhibition and with remission from MDD. Consistent with our murine studies, autopsy-derived prefrontal cortex samples show elevated MMP-9 levels in anti-depressant treated MDD patients as compared to controls. These preclinical and postmortem findings highlight a link between extracellular matrix regulation and MDD.

Synapses are surrounded by extracellular matrix (ECM) molecules composed of glycoproteins of the tenascin gene family and the lectican chondroitinsulfate proteoglycans (CSPGs) aggrecan, neurocan and brevican. Around a subpopulation of inhibitory CNS interneurons the ECM condenses to superstructures termed perineuronal nets (PNNs). PNNs regulate synaptic plasticity, are implicated in several forms of memory formation and modified in the context of addiction and neuropsychiatric disease. We have developed a system that allows to cultivate embryonic hippocampal neurons in the presence of primary astrocytes of distinct genetic backgrounds. We could show that the elimination of tenascins and lecticans shifts the balance of excitatory and inhibitory synapses. Activation of the maternal immune system (MIA) during gestation is linked to neuropsychiatric diseases like schizophrenia. Pregnant mice were treated with polyinosinic-polycytidylic acid (Poly I:C), embryonic hippocampal neurons were cultivated and a significant reduction of PNN area, aggrecan staining intensity and neuronal soma size could be documented. Applying multielectrode array analysis (MEA) a remarkable increase of the spontaneous network activity in neuronal networks was detected. Activated microglia can cause the loss of PNNs. We analyzed the impact of Poly I:C stimulated activated microglia on hippocampal neuronal networks. Immunocytochemistry of the PNN component Aggrecan revealed a clear disruption of PNNs accompanied by an increase of glutamatergic synapse numbers and a significantly increased spontaneous network activity using MEA. In conclusion, we could demonstrate a strong impact of microglial secreted factors on PNN integrity, synaptic plasticity, and electrophysiological properties of cultured hippocampal neurons. In the hippocampus, the highest density of perineuronal net (PNN) is observed in area CA2. In addition to surrounding PV+ interneurons, as seen in other hippocampal areas, the PNN also encompasses CA2 pyramidal neurons. As reported in other brain regions, maturation of the PNN in CA2 prevents the induction of long-term potentiation at CA3-CA2 excitatory synapses. However, we have found that the PNN is also permissive for the plasticity induction at inhibitory synapses between parvalbumin-expressing (PV+) interneurons and CA2 pyramidal neurons. This plasticity of inhibitory transmission emerges during adolescence in parallel with an increase in PNN density, the control of PV transmission by Neuregulin/ErbB4 signaling and the maturation of social recognition memory. Degradation of the PNN or blockade of PV-CA2 synaptic plasticity in vivo impairs social memory. Interestingly, these changes occur during the same age as PV+ interneuron loss and plasticity reduction in area CA2 in a mouse model of the 22q11 deletion syndrome, suggesting that adolescence is a period of high susceptibility for PV+ interneurons. We also found that the PNN density is reduced and PV+ interneuron physiology is altered in the Tg2576 mouse model of Alzheimer's disease. By injecting neuregulin 1 injection in CA2, we were able to restore PV and PNN expression as well as social memory. These data indicate that area CA2 plays a critical role in the social cognition impairments observed during neurodegenerative and psychiatric diseases and the peculiar PNN expression in this region may be a key component in this process.

Schizophrenia is a devastating psychiatric disorder that is associated with three main symptom clusters: positive symptoms that are well treated with antipsychotic drugs, and emotional and cognitive disruptions that are harder to treat, and represent an urgent clinical need (Green and Nuechterlein, 2004). Clinical neuroimaging studies and rodent models of schizophrenia have implicated dysfunction in the prefrontal cortex (PFC), and glutamatergic overactivity within the anterior hippocampus (aHipp) in the mechanisms underlying schizophrenia symptoms (Schobel et al., 2013). In addition, disruption of hippocampal parvalbumin-positive inhibitory GABAergic interneurons, and their surrounding perineuronal net (PNN), induce schizophrenia-like changes in rodent models (Shah and Lodge, 2013). However, while the role of aHipp hyperfunction has been considered in the positive symptoms, aHipp-PFC projections may also underlie the cognitive symptoms. We therefore evaluated how selective PNN degradation within the aHipp of marmoset monkeys altered performance of a probabilistic discrimination learning task known to depend on orbitofrontal-striatal circuitry. We also investigated how aHipp PNN degradation altered stereotypy in a marmoset version of the amphetamine-induced hyperlocomotion test. Probabilistic discrimination learning was impaired by aHipp PNN degradation, with animals more likely to respond to misleading, probabilistic feedback. Compared to pre-aHipp PNN degradation behaviour, amphetamine increased the amount of stereotypical behaviours, while microdialysis indicates these behavioural changes were accompanied by increased tonic catecholamine levels in the orbitofrontal cortex. Thus aHipp PNN degradation not only alters PFC neurochemistry, but also alters behaviours of relevance to both the positive and cognitive symptoms of schizophrenia, and links such deficits to aberrant aHipp-PFC circuitry.

DISSECTING THE MOLECULAR CONNECTOME IN DEVELOPING NEURAL CIRCUITS

SYMPOSIUM 49 - BUILDING CORTICAL NETWORKS FROM DEVELOPMENT TO ADULTHOOD - JORIS DE WIT, BEATRIZ RICO, SIMON BUTT, CéCILE CHARRIER

Joris De Wit
VIB Center for Brain & Disease Research, Ku Leuven, Department Of Neurosciences, Leuven, Belgium

Neural circuits are composed of distinct neuronal cell types connected in highly specific patterns. Unraveling how neurons form appropriate synaptic connections during development is a key challenge in neuroscience and is essential to understand brain function and disease. Neural circuit formation critically relies on cell-cell recognition and communication mediated by cell-surface ligands and receptors. The complexity of the cell-surface interactions that pattern precise synaptic connectivity is only beginning to emerge. In this talk, I will discuss our recent work dissecting the cell-surface interaction networks that control connectivity, structure and function of specific synapses in the hippocampal circuit.

MECHANISMS ORCHESTRATING THE ASSEMBLY OF INTERNEURON-PYRAMIDAL CELL NETWORKS

SYMPOSIUM 49 - BUILDING CORTICAL NETWORKS FROM DEVELOPMENT TO ADULTHOOD - JORIS DE WIT, BEATRIZ RICO, SIMON BUTT, CéCILE CHARRIER

Beatriz Rico
King's College London, Centre For Developmental Neurobiology, Centre For Neurodevelopmental Disorders, London, United Kingdom

The function of neural networks in the mammalian cerebral cortex relies on the interaction between two main classes of neurons, excitatory projection neurons (pyramidal cells) and inhibitory neurons (interneurons). In these circuits, the output of excitatory neurons is fine-tuned and synchronised by the activity of interneurons. Recent work suggests that distinct classes of interneurons preferentially target pyramidal cells with specific projection patterns to gate information flows in cortical circuits, but the mechanisms controlling this sophisticated form of interneuron specialisation are unknown. Furthermore, integration between pyramidal cells and interneurons requires independent control at multiple subcellular compartments. The local translation is ubiquitous in neuronal pre- and postsynaptic compartments. However, to what extent local translation is differentially regulated at the level of specific synapses during wiring or in mature neural circuits is unknown. In my talk, I will discuss our last findings on synaptic specificity, what are the cellular rules and molecular codes that interneurons use to make synapses into pyramidal cells. Our work deciphers a molecular mechanism by which these synapses are formed, segregate into different pyramidal cell types and some have synapse-specific control of local translation.

CONTRIBUTION OF TRANSIENT GABAERGIC NETWORKS TO EMERGENT SENSORY PROCESSING ACROSS NEONATAL SENSORY CORTICES

SYMPOSIUM 49 - BUILDING CORTICAL NETWORKS FROM DEVELOPMENT TO ADULTHOOD - JORIS DE WIT, BEATRIZ RICO, SIMON BUTT, CéCILE CHARRIER

Simon Butt
Oxford University, Physiology, Anatomy And Genetics, Oxford, United Kingdom

GABAergic interneurons (INs) are necessary for normal information transfer in both the developing and adult mammalian neocortex. Somatostatin-expressing (SST+) INs are ideally placed to be the main source of GABAergic signalling during postnatal development as they integrate early into cortical networks. In mouse somatosensory barrel cortex (S1BF), thalamo-recipient layer (L)5b SST+ INs establish a transient, translaminar, reciprocal circuit with L4 spiny stellate neurons during the critical period for plasticity. This network plays a role in timing the emergence of sensory-driven, feed-forward architecture in L4. Despite this critical role, the L5b-L4 circuit is not present in primary visual cortex (V1) through postnatal life. Moreover, layer 5 SST+ INs in V1 do not receive monosynaptic thalamic input. Comparison of known markers of layer 5 SST+ interneurons revealed similar transcriptomic subtypes across both areas, with the exception of those defined by expression of *Lpar1-EGFP* transgene which were found in reduced numbers in V1. *In vivo* optogenetic spike-tagging of either SST+ INs alone or *Nkx2-1*-derived INs, that capture both SST+ and parvalbumin-expressing (PV+) IN subtypes, allowed us to investigate the contribution of both SST+ and putative PV+ INs to emergent sensory processing. We observed distinct recruitment of SST+ INs in S1BF versus V1 over early ages. We conclude that local GABAergic circuits differ across these two primary sensory areas and that the function of GABAergic INs – and resultant control of information transfer, is tuned to modality-specific needs early in life, with consequences for understanding of both normal and dysfunctional circuit development.

MOLECULAR CROSSROAD IN SYNAPSE DEVELOPMENT AND DEGENERATION

SYMPOSIUM 49 - BUILDING CORTICAL NETWORKS FROM DEVELOPMENT TO ADULTHOOD - JORIS DE WIT, BEATRIZ RICO, SIMON BUTT, CéCILE CHARRIER

Cécile Charrier
Ecole Normale Supérieure, CNRS, INSERM, Université PSL, Institut De Biologie De L'ens (ibens), Paris, France

Synaptic connections of the human neocortex present species-specific features often altered in brain disorders. Yet, little is known about the molecular pathways that link human brain evolution and diseases. Here, we identify catenin delta-2 (CTNND2) as a binding partner of the human-specific protein and synapse regulator SRGAP2C. CTNND2 is a cadherin-binding protein whose mutations cause intellectual disability in the Cri-du-Chat syndrome and severe autism. We demonstrate that CTNND2 deficiency in sparse layer 2/3 cortical pyramidal neurons disrupts excitation/inhibition coordination and increases intrinsic excitability in juvenile mice. These effects are followed by premature loss of dendritic spines in adults. We further show that (1) CTNND2 forms a postsynaptic protein complex that acts as a brake on excitatory activity and synaptic maturation, and (2) human-specific SRGAP2C enhances CTNND2 synaptic accumulation. Thus, while CTNND2 loss of function causes failure of neuronal homeostasis, its regulation by SRGAP2C may contribute to synaptic neoteny and long-term maintenance in humans.

CEREBELLAR CONTROL OF LOCOMOTOR COORDINATION

SYMPOSIUM 50 - CIRCUITS FOR MOTOR CONTROL: MOVING FROM THE CORTEX TO THE SPINAL CORD AND BACK - MEGAN CAREY, IAN DUGUID, ARIEL LEVINE, GRAZIANA GATTO

Megan Carey
Champalimaud Centre for the Unknown, Neuroscience, Lisbon, Portugal

Whole-body movements require precise coordination across the body. The cerebellum is critical for coordinating movement; during locomotion it is particularly important for interlimb coordination. Decades of recordings have consistently shown that cerebellar Purkinje cell output is broadly correlated with the locomotor stride cycle. However, much of the firing rate variability has remained unexplained; moreover, previous analyses do not provide a clear model for how Purkinje cell activity could be read out to control coordination. I will describe our recent work demonstrating that a substantial proportion of Purkinje cells simultaneously encode movements of multiple body parts to provide precise representations of temporal coordination across diverse combinations of behavioral events. These findings resolve long-standing controversies surrounding the role of Purkinje cells in locomotor control and could allow for efficient readouts of whole-body coordination by a simple linear decoder.

SYMPOSIUM 50 - CIRCUITS FOR MOTOR CONTROL: MOVING FROM THE CORTEX TO THE SPINAL CORD AND BACK - MEGAN CAREY, IAN DUGUID, ARIEL LEVINE, GRAZIANA GATTO

Dexterous movements serve the major functions of the brain, perception and manipulation of the world. Considering the range of possible actions and the complexity of musculoskeletal arrangements, control of the hand is an amazing achievement of the nervous system. Dexterous behavior involves understanding objects in the world, developing appropriate plans, converting those plans into appropriate motor commands, and adaptively reacting to feedback. The myriad of these underlying operations is likely performed by a diverse set of neural circuits. By combining anatomy, physiology, and specific (genetic and temporal) manipulations, we are identifying the neural elements responsible for dexterous motor control. Currently, we focus on the role of the cortico-cerebellar loop in a skilled reach-grab-eat task in the rodent.

SPINAL CORD CELLS AND CIRCUITS FOR MOTOR CONTROL

SYMPOSIUM 50 - CIRCUITS FOR MOTOR CONTROL: MOVING FROM THE CORTEX TO THE SPINAL CORD AND BACK - MEGAN CAREY, IAN DUGUID, ARIEL LEVINE, GRAZIANA GATTO

Ariel Levine
NIH, Ninds, Bethesda, United States of America

The mammalian spinal cord links the brain and the body to enable voluntary movements and disruption of this critical role through spinal cord injury or neurodegeneration can lead to paralysis and death. My lab seeks to understand how spinal neurons encode simple movements and how they are integrated into larger networks throughout the nervous system to execute, refine, and learn broad motor behaviors. Here, I will focus on the direct descending and ascending pathways that connect the spinal cord and the cerebellum. First, I will present our recent work characterizing the structure and function of the CerebelloSpinal Tract (CeST), which we found is required for aspects of online motor control and motor learning. Second, I will present our new work on Spinocerebellar Tract (SCT) neurons and how they undergo structural plasticity and remodeling after spinal cord injury, raising the hope that these cells could support re-learning of motor skills and recovery. Together, these findings highlight the importance and bidirectional nature of communication between the spinal cord and cerebellum.

THE FUNCTIONAL CONTRIBUTION OF SPINAL NEURON HETEROGENEITY TO SENSORIMOTOR BEHAVIORS

SYMPOSIUM 50 - CIRCUITS FOR MOTOR CONTROL: MOVING FROM THE CORTEX TO THE SPINAL CORD AND BACK - MEGAN CAREY, IAN DUGUID, ARIEL LEVINE, GRAZIANA GATTO

Graziana Gatto
Uniklinik Köln, Department Of Neurology, Köln, Germany

The spinal cord comprises networks of interconnected neuron types, dedicated to the generation of movement and the processing of sensory input. Despite the great advances in identifying the molecular identity of the heterogeneous populations making up the spinal networks, we are still far from understanding the role of the distinct cell types and their synergistic or antagonistic interactions in the execution of sensorimotor behaviors. Therefore, even the spinal neural circuits that underlie simpler movements, like reflex responses, remain poorly characterized. To dissect the neural circuit that patterns the coordination of flexor and extensor muscles, we undertook an intersectional genetic approach to modulate the activity of distinct neuron types during the execution of the scratch reflex. We identified a core circuit composed of excitatory and inhibitory interneurons that synergistically cooperate to titrate the rhythm of scratching and to coordinate antagonistic muscle pairs for the smooth execution of the movement trajectory. Our model, built on the scratch experimental data, is also capable to recapitulate the dynamics of flexor and extensor muscle coordination during locomotion. Taken together, we identified and modeled the synergistic interactions of specialized spinal neuron types, which coordinate the recruitment of flexor and extensor muscles during rhythmic motor behaviors. Interestingly, this specialized network seems to be a convergence point for diverse motor responses, functioning as a malleable substrate under the modulation of sensory and descending inputs.

CHILDHOOD ADVERSITY AND BRAIN ADAPTATION: IMPACT ON SOCIAL FUNCTIONING AND MENTAL HEALTH VULNERABILITY

SYMPOSIUM 51 - BRAIN ADAPTATION AND MENTAL HEALTH THROUGH A SOCIAL TRANSACTIONAL LENS - EAMON MCCRORY, CHARLOTTE CECIL, CARMEN SANDI, BERNET ELZINGA

Eamon Mccrory
University College London, Psychology And Language Sciences, London, United Kingdom

Childhood trauma, in the form of maltreatment and neglect, is one of the strongest predictors of later mental health problems across the lifespan. However, the neurobiological mechanisms by which childhood adversity 'gets under the skin' remain poorly understood. Prof McCrory will highlight the complex relationship between the brain, childhood trauma, the social world and mental health. He will argue that mental health and wellbeing are intrinsically relational phenomena, and it is erroneous to think of them as ‘located’ within an individual or their brain. Rather, we need to think of the brain as a socially embedded organ. The domains of threat, reward and autobiographical memory processing will be briefly reviewed. The concepts of Stress Generation and Social Thinning will also be introduced to illustrate this argument, and implications for prevention and intervention will be noted.

Although it is well-established that both genetic and the environmental factors influence brain development, these are typically examined separately. Here, we prospectively investigated the interactive effects of genetic variants – from a genome-wide approach – and early life stress (ELS) on child subcortical brain structures, and their association with subsequent mental health problems. Primary analyses were conducted using data from the Generation R Study (N=2,257), including genotype and cumulative prenatal and postnatal ELS scores. Neuroimaging data were collected at 10 years, including total and subcortical brain volumes (accumbens, amygdala, caudate, hippocampus, pallidum, putamen, thalamus). Genome-wide-by-environment interaction analyses (GWEIS) were conducted, from which polygenic scores (PGS) were calculated for validation in an independent cohort (ABCD Study; N=10,751), in relation to subcortical volumes and mother-reported mental health problems. One GWEIS-prenatal stress locus significantly associated with caudate volume (rs139505895, mapping onto PRSS12 and NDST3) and two GWEIS-postnatal stress loci associated with the accumbens (rs2397823 and rs3130008, mapping onto CUTA, SYNGAP1, and TABP). Functional annotation revealed that these genes play a role in neuronal plasticity and synaptic function, and have been implicated in neurodevelopmental and psychiatric phenotypes such as intellectual disability, autism, and schizophrenia. In the validation sample, PGS_{GxE} associated with several subcortical volumes, including the caudate, and all $PGS_{genotype}$ associated with their respective brain volumes. A minority of PGS scores further associated with child mental health problems. Overall, our study lends novel insights into gene-environment interplay on the developing brain as well as pointing to promising candidate loci for future mechanistic studies.

NEUROENDOCRINE AND METABOLIC FACTORS REGULATING THE LONG-TERM IMPACT OF EARLY LIFE ADVERSITY ON SOCIAL BEHAVIOURS

SYMPOSIUM 51 - BRAIN ADAPTATION AND MENTAL HEALTH THROUGH A SOCIAL TRANSACTIONAL LENS - EAMON MCCRORY, CHARLOTTE CECIL, CARMEN SANDI, BERNET ELZINGA

Carmen Sandi
Ecole Polytechnique Federale de Lausanne (EPFL), Brain Mind Institute, Lausanne, Switzerland

The period comprising late childhood and puberty (i.e., peripuberty) is a critical time-window for brain development, and chronic stress during this period can lead in some individuals to protracted alterations in sociability and aggressive behavior. Using rodent models, we have underscored a differential regulation of the glucocorticoid responsiveness to stress as a critical factor explaining individual variation in social behaviors and aggression, particularly in individuals formerly exposed to peripubertal stress. In addition, our recent work underscores a link between increased fat mass at adulthood in individuals exposed to peripubertal stress and reduced sociability. We report a fat-to-brain pathway, involving the adipokine nicotinamide phosphoribosyltransferase (Nampt) and the nicotinamide adenine dinucleotide (NAD^+)/SIRT1 pathway in the nucleus accumbens in the mediation of sociability deficits of early life stress origin. Our work highlights nutritional interventions targeting NAD^+ as potential treatments to ameliorate social deficits of early life stress origin.

Adolescence is a key period for the development of a sense of self. Depression, a mental disorder typically related to low self esteem, also frequently emerges during this period. One of the key factors in the formation of adolescents' self-concept is socio-evaluative feedback from parents. How exactly parental feedback relates to adolescent depression is not clear, however. To elucidate the affective and neural responses to parental feedback in depressed (*n*=35) and healthy control adolescents (*n*=63), and how this relates adolescents own self views and to parental criticism in daily life, we developed a social feedback task. In this task, adolescents receive positive and negative feedback, supposedly provided by their mother or father in the form of appraisals about their personality (e.g., 'respectful' or 'lazy') during fMRI scanning. After each feedback word, adolescents reported their mood and adolescents rated whether these words match their self-views. In healthy controls, negative parental feedback worsened adolescents' mood, which was exacerbated when feedback did not match adolescents' self-views. Negative feedback increased activity in the neural 'saliency network' (incl. anterior insula, anterior cingulate cortex and dorsomedial prefrontal cortex), while positive feedback improved mood and increased activity in brain regions supporting social cognition (including TPJ, posterior superior temporal sulcus, and precuneus). Parental warmth (but not criticism in daily life) was associated with adolescent's positive self views and mood. Results in adolescents with depresson (*n*=35) on the role of parental criticism and aberrant affective and neural responses to parental feedback will be presented (analyses currenlty in prep) and clinical implications will be discussed.

HIPPOCAMPAL MECHANISMS OF FEAR RELAPSE AFTER EXTINCTION

SYMPOSIUM 52 - HIPPOCAMPAL PLASTICITY ALONG THE DORSOVENTRAL AXIS: IMPLICATIONS FOR PSYCHIATRIC DISEASES - MICHAEL DREW, CHRISTINE DENNY, DENIS DAVID, EERO CASTREN

Michael Drew
University of Texas at Austin, Neuroscience, Austin, United States of America

Learned fear often relapses after extinction, suggesting that extinction training generates a new memory that coexists with the original fear memory. Recent work from our lab has identified the hippocampal dentate gyrus (DG) as a region where such fear and extinction memories are generated. Specifically, using activity-dependent neural tagging in mice, we discovered that extinction training suppresses reactivation of contextual fear engram cells in DG while activating a second ensemble, a putative extinction engram. Here we investigate (1) whether these effects of extinction training on fear ensembles are limited to the DG or exist in other regions of the hippocampus and parahippocampal cortex, (2) whether fear and extinction ensembles in DG exhibit distinct patterns of gene expression, and (3) whether fear and extinction activate unique hippocampal output pathways. We used ArcCreErt2-eYFPflx mice injected tag neurons active during fear acquisition. Mice then received extinction training or were left undisturbed in their home cages. After a test of conditioned fear in the training context, we first assessed reactivation of eYFP-tagged fear acquisition neurons using immunohistochemistry against Arc and Fos proteins. Extinction training suppressed reactivation of YFP-tagged fear acquisition neurons in dorsal and ventral DG, dorsal CA1, and dorsal and ventral lateral entorhinal cortex. Next we used single-nuclei RNA Sequencing (snRNA-seq) to characterize gene expression profiles in eYFP+ and eYFP- cells in the dorsal DG of mice from Extinction and No-Extinction groups. We recovered the canonical DG cell types, examined how the transcriptomes of eYFP+, Fos+ and Arc+ fear acquisition neurons changed after extinction training, and identified the transcriptomes of extinction-activated neurons. Finally, we used cholera toxin retrograde tracing and immediate-early gene assays to characterize activity of hippocampal projections pathways during expression of fear and extinction. Our results show that fear recall favors activity in hippocampal projections to basolateral amygdala, whereas extinction recall favors activity in projections to prefrontal cortex. Together our results that extinction training has anatomically and molecularly robust effects on activity of fear acquisition neurons.

DRUG-DEPENDENT MODULATION OF STRESSFUL MEMORY TRACES IN HIPPOCAMPAL CA3

SYMPOSIUM 52 - HIPPOCAMPAL PLASTICITY ALONG THE DORSOVENTRAL AXIS: IMPLICATIONS FOR PSYCHIATRIC DISEASES - MICHAEL DREW, CHRISTINE DENNY, DENIS DAVID, EERO CASTREN

Christine Denny
Columbia University Irving Medical Center, Psychiatry, New York, United States of America

A memory trace or engram is a neural ensemble activated during learning (or during an individual experience) and whose reactivation by the original stimuli results in memory retrieval. In order to permanently tag activated neurons that are part of an engram, we previously generated the ArcCreER^{T2} mouse line. This line is unique in that it allows for an indelible label of previously activated neurons and thus, allows for a comparison of the cells activated during memory encoding with those activated during memory expression. Most notably, it allows for a brain-wide tagging of an individual memory with single-cell resolution. These activity-dependent tagging mice can be utilized in a number of studies to determine how external factors such as context, mood, stress, or drugs influence an individual memory trace, resulting in altered behavior. In this talk, I will summarize our recent work elucidating the neural mechanisms of drug administration on fear learning and memory utilizing the ArcCreER^{T2} mice.

Previously, we showed that vortioxetine (VORT) [a serotonin reuptake inhibitor combined with actions at serotonin receptors (5-HT_{1A}, 5-HT_{1B}, 5-HT_{1D}, 5-HT_3, 5-HT_7)] protected against stress reinstatement induced anxiety/depression-like phenotype and decreased adult hippocampal neurogenesis (AHN). In a mouse model of genetic ablation of AHN [glial fibrillary acidic protein (GFAP)-positive neural progenitor cells mouse line], we assessed whether AHN is required for VORT -induced prevention of anxiety/depression. Four weeks before the start of the corticosterone (CORT) treatment to induce depression-like behavior and until the end of the protocol, male GFAP-TK positive mice (TK+) and their littermates (TK-) were administered with valganciclovir in the chow to arrest AHN. After 4 weeks of chronic vehicle (VEH) or CORT, TK+ and TK- mice were administered with saline or VORT (10 mg/kg/day, i.p) treatment for 4 weeks. Behavioral assays (Elevated Plus Maze, EPM; the Novelty Suppressed Feeding, NSF; the Splash Test, ST) were chosen to assay anxiolytic-antidepressant-like activity during VORT treatment and 3 weeks after withdrawal. We confirmed that chronic VORT induced anxiolytic/antidepressant-like effects and protected against CORT reinstatement–induced anxiety/depression-like phenotype in both genotypes. In the EPM and the ST, ablation of AHN in TK+ mice did not alter anxiolytic/antidepressant-like response induced by VORT and prevention of stress reinstatement. However, in the NSF, chronic VORT treatment-induced decrease in latency to feed and prophylactic effects against stress reinstatement in TK- mice, is arrested in TK+ mice. In conclusion, AHN is required not only for VORT -induced antidepressant effects but also for the prevention of relapse.

CHOLESTEROL-DEPENDENT HIPPOCAMPAL PLASTICITY IS MEDIATED BY TRKB

SYMPOSIUM 52 - HIPPOCAMPAL PLASTICITY ALONG THE DORSOVENTRAL AXIS: IMPLICATIONS FOR PSYCHIATRIC DISEASES - MICHAEL DREW, CHRISTINE DENNY, DENIS DAVID, EERO CASTREN

Eero Castren, Plinio Casarotto
University of Helsinki, Neuroscience Center, Helsinki, Finland

Cholesterol is known to be required for the proper maturation and function of cortical and hippocampal synapses, but the molecular mechanisms underlying these effects have remained unclear. We recently found that cholesterol critically regulates the function of TrkB, the receptor for brain-derived neurotrophic factor (BDNF), a central regulator of neuronal connectivity and plasticity. Depletion of cholesterol in primary hippocampal cultures blocks the ability of BDNF to increase TrkB autophosphorylation and neurite sprouting, and, conversely, increase in cholesterol in the culture medium promotes the effects of BDNF in an inverted U-shaped manner. We found that the transmembrane domain (TMD) of TrkB possesses a cholesterol recognition consensus sequence (CRAC) and provided evidence that cholesterol directly binds to this site, as mutation of a central tyrosine (Y433F) within the TrkB TMD blocks cholesterol interaction. Atomistic molecular modeling revealed that the dimer of TrkB TMDs cross each other within the membrane and that the angle between the two domains is dependent on the thickness of plasma membrane, which in turn depends on cholesterol concentration. Our data indicate that the configuration of TrkB TMD dimers is optimal in membranes with moderate concentration of cholesterol, but the dimer structure is instable in very low as well as in high concentrations of cholesterol, such as found in synaptic membranes. Our data suggest that neuronal cholesterol is a critical regulator of TrkB function, which may at least partially explain the requirement for cholesterol in the maturation and plasticity of cortical and hippocampal synapses.

SPATIAL MAPS IN POSTERIOR PIRIFORM CORTEX DURING NAVIGATION

SYMPOSIUM 53 - OLFACTORY-DRIVEN BEHAVIORS AND THEIR REPRESENTATIONS IN THE BRAIN - CINDY POO, CARL SCHOONOVER, PRIYANKA GUPTA, VENKATESH MURTHY

Cindy Poo
Champalimaud Foundation, Champalimaud Neuroscience Programme, Lisbon, Portugal

Odors are a fundamental part of the sensory environment used by animals to inform behaviors such as foraging and navigation. Primary olfactory (piriform) cortex is thought to be dedicated to encoding odor identity. Using neural ensemble recordings in freely moving rats performing a novel odor-cued spatial choice task, we show that posterior piriform cortex neurons also carry a robust spatial map of the environment. Piriform spatial maps were stable across behavioral contexts independent of olfactory drive or reward availability, and the accuracy of spatial information carried by individual neurons depended on the strength of their functional coupling to the hippocampal theta rhythm. Ensembles of piriform neurons concurrently represented odor identity as well as spatial locations of animals, forming an “olfactory-place map”. Our results reveal a previously unknown function for piriform cortex in spatial cognition and suggest that it is well-suited to form odor-place associations and guide olfactory cued spatial navigation. We

Columbia University, Department Of Neuroscience, New York, United States of America

We have discovered that in the rodent primary olfactory cortex (piriform) the pattern of neural activity evoked by a smell changes with the passage of time. These changes, which unfold absent a task or learning paradigm, accumulate to such an extent that after just a few weeks odor responses bear little resemblance to their original form. The piriform has been traditionally hypothesized to establish the identity of odorants. Our observations have forced us to radically reconsider the role of this vast brain region in olfactory perception. We propose that the piriform operates instead as a flexible learning system, a ‘scratch pad’ that continually learns and continually overwrites itself. This poses the problem of how transient memory traces can subsequently be stored over long timescales.

Growing evidence suggests that sensory perception is better described as the continuous tally of actual inputs and predictions, than solely as a process of stimulus feature representation. To date, however, little is known about the mechanisms that facilitate the evaluation of sensory inputs against internally generated predictions. To study sensorimotor predictions both at behavioral and circuit-level, we developed a novel closed-loop behavioral task (*Smellocator*), wherein head-fixed mice learn to steer a lever to control the lateral location of an odor source. To obtain rewards, mice need to move the lever so as to bring the odor source, initialized in different trials at different starting locations, in front of their nose. Mice thus learn to link their motor action to well-defined sensory expectations (odor location). To *read-out the learnt sensorimotor predictions in expert mice*, we violate the learnt expectations by decoupling the stimulus from the current action and creating brief sensorimotor errors. Additionally, across longer timescales, we invert the sensorimotor mapping (direction of odor movement), so as to engage sensorimotor adaptation. Strikingly, we find that *expert mice readily counter these sensorimotor errors and display precise corrective movements which provide a behavioral read-out of their individual specific, learnt sensorimotor expectations*. Simultaneous recordings from olfactory cortex show that *odor-driven responses are strongly modulated by movement related expectations* about the stimulus arrival. Further, transient perturbations often drive olfactory cortex neurons stronger than any other variable in our task including odor onset, target entry and rewards.

There has been significant recent progress in understanding how odors are represented in the olfactory cortex, but how these representations are modified during learning is largely unknown. We investigated how learned smells are encoded and evolve in the olfactory cortex of mice while they learn to discriminate a unique target odor blend against hundreds of nontarget blends. A significant proportion of posterior piriform cortex neurons discriminate between target and nontarget odor blends. Neurons that prefer the target odor tend to respond with brief increases in firing rate at odor onset, whereas neurons preferring non-target odors tend to respond with sustained increases or decreases in firing rates. Mice trained on the target/non-target task are initially confused by morphed stimuli that contain a mixture of target and nontarget components, but quickly learn to categorize them as nontarget odors; the cortical representation of morphed stimuli evolves in parallel with learning. Although all non-target odors elicit the same behavioral choice, individual non-target mixtures maintain their identity by developing unique representations upon repeated presentations. These data show that populations of piriform cortex neurons can change their representation of complex stimuli in different ways to enable categorization, while preserving identity coding.

THE CONTRIBUTION OF VISCERAL SIGNALS TO BRAIN DYNAMICS AND COGNITION IN HUMANS

SYMPOSIUM 54 - COMMON MECHANISMS OF BRAIN-BODY INTERACTIONS ACROSS HUMANS AND ANIMAL MODELS - CATHERINE TALLON-BAUDRY, MICAH ALLEN, YOAV LIVNEH, MONICA DUS

Catherine Tallon-Baudry
Ecole Normale Supérieure, Inserm, Paris, France

The stomach is not only active when it mixes and grinds food during digestion, but continuously and intrinsically generates a slow electrical rhythm (0.05Hz) which could be relayed up to the central nervous system without giving rise to conscious gastric feelings. We thus asked whether the stomach could act as an electrical pacemaker constraining brain activity. In a series of experiments where we measured the gastric rhythm and brain activity using either fMRI or magneto-encephalography (MEG), we found that spontaneous brain activity is coupled with the stomach rhythm in a large, distributed network. The gastric network cuts across classical resting-state networks, and does not depend on fasting state nor anxiety. Both fMRI and MEG reveal that the gastric network encompasses all sensory cortices (known interoceptive cortices as well as visual, auditory, etc.) and motor and premotor regions, but includes only a very limited set of higher order brain areas. The anatomo-functional distribution of the gastric network holds true whether participants are passive or engaged in a visual task. Altogether, these results suggest a pervasive influence of the gastric rhythm on brain dynamics extending well beyond the circuits of interoceptive feelings or feeding behavior.

CORTICAL COMPUTATIONS OF CURRENT AND FUTURE INTEROCEPTION WITHIN THE BRAIN-BODY LOOP

SYMPOSIUM 54 - COMMON MECHANISMS OF BRAIN-BODY INTERACTIONS ACROSS HUMANS AND ANIMAL MODELS - CATHERINE TALLON-BAUDRY, MICAH ALLEN, YOAV LIVNEH, MONICA DUS

Yoav Livneh
Weizmann Institute of Science, Dept. Of Brain Sciences, Rehovot, Israel

The brain and body are in a continuous dialog that is essential for our physical and mental health. Little is known about how this dialog is achieved at the neurobiological level. A large corpus of work implicates the insular cortex as a central node for bi-directional brain-body communication. However, there is very little direct evidence for its functional role. We developed a microprism-based cellular imaging approach to monitor insular cortex activity in behaving mice across different physiological need states. We combine this imaging approach with manipulations of peripheral physiology and related circuits to investigate the underlying mechanisms. I will first present our recent data suggesting that insular cortex population activity represents both current bodily states, as well as future predicted ones. I will then describe our current efforts to further our understanding of these predictions, and their potential role in regulating bodily physiology.

Diet composition has a profound influence on brain physiology and behavior, but the mechanisms through which nutrient information is transmuted into neural changes remain elusive. Here we uncover how the metabolic enzyme O-GlcNAc Transferase (OGT) transforms information about the dietary environment into taste adaptations. We show that in the fly D. melanogaster, OGT decorates the chromatin of the sweet taste neurons and provides the nutrient context to drive changes in chromatin accessibility in response to high dietary sugar. Specifically, we found that OGT cooperates with the epigenetic silencer Polycomb Repressive Complex 2.1 (PRC2.1) to promote nutrient-sensitive variations in chromatin openness; these chromatin dynamics result in changes in gene expression and taste plasticity that are dependent on the catalytic activity of OGT. Parallel nutrigenomic signatures were also observed in the lingual epithelium of rats exposed to high dietary sugar, suggesting that this conserved metabolic-epigenetic pathway may also underlie diet-dependent taste changes in mammals. Together our findings reveal a novel role for nutriepigenetic signaling in the brain: amplifying nutrient perturbations into robust changes in chromatin accessibility and transcriptional output that shape neural and behavioral plasticity.

Expanded CAG/CTG repeats cause at least 15 different diseases, including Huntington's disease, myotonic dystrophy, and several spinocerebellar ataxias. They all remain without effective treatments. Disease severity scales with the size of the repeat tract and thus contracting them to non-pathogenic lengths is expected to remove the underlying cause of the disease and provide much needed relief. Here we show that the CRISPR-Cas9 nickase targeted to the CAG/CTG repeat itself leads to efficient contractions in multiple cellular systems. It appears to be safe, with undetectable levels of off-target mutations or changes in repeat sizes at other, non-expanded repeat loci. Moreover, sequencing analysis did not reveal rearrangements or mutations, other than the contraction of the repeat tract itself. We further found that contractions are transcription-dependent and they are prevented by FAN1, an endonuclease involved in repeat instability. Together, these results build a case for the translation of the Cas9 nickase approach *in vivo*.

The repeat expansion diseases (REDs) are a group of 40+ disorders that arise from the expansion of a disease-specific short tandem repeat (STR) tract. The expansion mechanism(s) is incompletely understood. Expansions in many of these diseases occur in both the germline and somatic cells. The STRs, which vary in sequence composition and repeat unit length—ranging from 3-12 nucleotides, are situated in different regions of the affected gene. Expansions situated in the coding sequence tend to be relatively small, while expansion of some STRs located outside the primary open reading frame of the gene can involve the gain of hundreds or even thousands of repeats. While some genetic modifiers of expansion risk differ in different mouse models of the REDs, a case can be made that these diseases all share a common expansion mechanism. We suggest that such mechanism likely involves a form of aberrant mismatch repair that proceeds via the production of a double-strand break, with common factors like FAN1 protecting against expansion similarly across all of these diseases. A common expansion mechanism raises the tantalizing possibility that a single treatment strategy could be effective against this entire group of diseases.

[1]Triplet Therapeutics, Inc., Chief Medical Officer, Head Of R&d, Cambridge, United States of America, [2]Triplet Therapeutics, Inc., R&d, Cambridge, United States of America

Triplet is harnessing the growing evidence that DNA damage response (DDR) genes are potent modifiers of onset and rate of progression of Repeat Expansion Diseases (REDs), such as Huntington's disease (HD), myotonic dystrophy, and spinocerebellar ataxias. DDR modifier genes act by modulating the rate of somatic expansion at disease causing gene loci, such as mutant Huntingtin (mHTT). The DDR gene *MSH3* has been strongly associated with disease progression in HD, including during premanifest disease. Only about 50% lowering of *MSH3* appears sufficient to halt or markedly slow somatic expansion of mHTT. As no untoward safety signals have been associated with this moderate level of *MSH3* lowering, *MSH3* has emerged as a prime target with the potential to treat HD and multiple other REDs by acting upstream of individual disease genes. Triplet is advancing its *MSH3*-lowering antisense oligonucleotide (ASO) TTX-3360 towards a Phase 1 trial by mid-2022. With a long duration of action in non-human primates (NHPs), TTX-3360 has the potential for infrequent clinical dosing. To support the Phase 1 trial, Triplet has initiated a natural history study, SHIELD HD, in 2020. Premanifest and early manifest people with HD have been enrolled in Europe and North America. SHIELD HD data allow to 1) perform trial simulations to design a robust Proof-of-Concept (PoC) trial, and 2) develop a novel target engagement assay based on measuring *MSH3* messenger RNA (mRNA) in CSF exosomes. Key data from NHPs and SHIELD HD, including the target engagement biomarker assay, will be presented.

THE SUBTHALAMIC NUCLEUS AS A TARGET FOR ADDICTION TREATMENT

SYMPOSIUM 56 - THINKING OUTSIDE THE BOX: ALTERNATIVE TARGETS AND STRATEGIES FOR ADDICTION - MICKAëL DEGOULET, PATRICIA JANAK, SERGE AHMED, MARCO VENNIRO

Mickaël Degoulet
Institut de Neurosciences de la Timone, UMR7289 CNRS & AMU, Team Bagamore, Marseille, France

Transition to addiction does not solely result from the mere consumption of a drug of abuse, but relies on the onset of complex behaviors, such as loss of control over drug intake and perseverance of drug seeking despite its negative consequences. Although critical advances in our understanding of neuronal processes leading to addiction have been made, it still remains a critical problem for the society, affecting both individual and public health. Our recent works indicate that the neuronal activity of the subthalamic nucleus, a small glutamatergic structure of the basal ganglia system, can be used as a proxy for the onset of addiction-like behaviors in rats. Indeed, escalation of cocaine intake, a behavioral model mimicking the loss of control over drug intake, induces changes in the subthalamic nucleus electrical activity, which can further predict which individual would subsequently display compulsive-like seeking behavior. Furthermore, manipulating activity of the subthalamic nucleus with deep brain stimulation can reduce, or worsen, addiction-like behaviors in a frequency-dependent manner. Our results thus emphasize the critical role played by the subthalamic nucleus in the onset and expression of addiction-like behaviors and further advocate for the use of deep brain stimulation in human suffering from addicted disorders.

THE VENTRAL PALLIDUM AS A CRITICAL ACTOR IN REWARD PROCESSING

SYMPOSIUM 56 - THINKING OUTSIDE THE BOX: ALTERNATIVE TARGETS AND STRATEGIES FOR ADDICTION - MICKAëL DEGOULET, PATRICIA JANAK, SERGE AHMED, MARCO VENNIRO

Patricia Janak
Johns Hopkins School of Medicine, The Solomon H. Snyder Department Of Neuroscience, Baltimore, United States of America

The governance of reward-seeking behavior requires coordination among multiple brain regions, with the ventral striatopallidal system playing a key role. We have identified an unexpected contribution for the ventral pallidum in reporting a dynamic history-dependent reward preference signal. This signal is sensitive to drive state and largely comports with reward prediction error encoding. Although the ventral pallidum receives a major projection from the nucleus accumbens, our data show that reward-specific neuronal firing in the ventral pallidum is present in a greater proportion of the neural population, and arises sooner following rewarding events, than in the accumbens. These findings challenge the existing model of information flow in the ventral basal ganglia and suggest a reevaluation of the contributions of the ventral pallidum to reward-seeking behavior and reward-based decisions.

NON-DRUG REWARDS AS ALTERNATIVE TO DRUG ADDICTION

SYMPOSIUM 56 - THINKING OUTSIDE THE BOX: ALTERNATIVE TARGETS AND STRATEGIES FOR ADDICTION - MICKAëL DEGOULET, PATRICIA JANAK, SERGE AHMED, MARCO VENNIRO

Serge Ahmed
CNRS/Université de Bordeaux, Incia - Umr 5287, Bordeaux, France

Since the first experimental hint for the existence of “an actual desire or striving for the drug” in nonhuman animals by Sidney Spragg in the late 1930s, much effort has been expended by researchers to try to model the key behavioral aspects and signs of addiction in animals, typically in rodents. Despite much advances, there still remains some lingering doubt about the disordered status of drug use in animals. This is mainly because drug use occurs in an artificial setting where animals have access to a drug for self-administration but without access to alternative nondrug reward options that could compete with and divert from continued drug use. I will review evidence showing how offering access to alternative nondrug rewards during drug access can under certain circumstances incite animals to quit using drugs and discuss the possible interpretations of this finding.

SOCIAL INTERACTIONS AS ALTERNATIVE REWARDS TO DRUGS

SYMPOSIUM 56 - THINKING OUTSIDE THE BOX: ALTERNATIVE TARGETS AND STRATEGIES FOR ADDICTION - MICKAëL DEGOULET, PATRICIA JANAK, SERGE AHMED, MARCO VENNIRO

Marco Venniro
University of Maryland, School of Medicine, Anatomy And Neurobiology, Baltimore, United States of America

The goal of our research, and of the addiction field in general, has not merely been to identify neuropharmacological and circuit mechanisms of drug addiction and relapse. The goal was to achieve *prospective predictive validity*—the ability to identify new treatments. As I will describe in the talk, the classical relapse model in its traditional form has not appreciably changed the options available to patients in need of relapse prevention. This shortcoming is not unique to relapse, but it is an increasing source of disappointment, and it calls for a regrouping. In our laboratory, we have regrouped by developing a set of approaches that begin with *reverse* translation. As a first step, we have mimicked behavioral treatments that are largely successful in humans such as the community-reinforcement approach where nondrug rewards (e.g., family, friends, employment) are given in exchange for being drug free to maintain abstinence. Our research has revelead three main findings: (1) rats strongly prefer operant social interaction over drugs, (2) social choice-induced abstinence (voluntary abstinence) prevents drug craving, and (3) the protective social-based effect on drug craving is associated with selective brain mechanisms in insula and amygdala. These reverse-translated “treatments” are an ecologically relevant platform from which we can move on to translation itself, using different methods to discover new relapse-related circuits and to identify new medications for relapse prevention in “treated” or post-“treated” rats. In the lecture, I will introduce these animal models, describe our initial pharmacological and circuit results, and discuss implications for treatment.

VOLTAGE IMAGING IN LIVE MICE

WORKSHOP 01 - VOLTAGE IMAGING AND BEYOND, NEXT-GENERATION MOLECULAR AND OPTICAL TOOLS FOR HIGH-SPEED BRAIN IMAGING - HE TIAN, ERIC SCHREITER, ROBERT CAMPBELL, XUE HAN, STéPHANE DIEUDONNE

He Tian
Harvard University, Chemistry And Chemical Biology, Cambridge, United States of America

The brain encodes and processes information through the dynamic membrane voltage of neurons. However, in vivo electrophysiology, i.e., the study of the membrane voltage of individual cells in live animals, has been a major challenge for neuroscience. I will present recent advances in molecular and optical voltage imaging tools to visualize the membrane voltage dynamics of cells in live animals. Imaging of near infrared Archaerhodopsin-derived voltage indicators can be combined with optogenetic stimulation to enable “all-optical electrophysiology”, opening a path for high-throughput characterization of single-cell excitability, synaptic connections, and microcircuit dynamics in live animals. I will discuss how to use voltage imaging and all-optical electrophysiology to understand network dynamics and cellular biophysics in the live mouse brain. Together, these molecular and optical methods greatly expand our ability to decipher mechanisms of brain function.

CHEMIGENETIC INDICATORS OF NEURONAL ACTIVITY

WORKSHOP 01 - VOLTAGE IMAGING AND BEYOND, NEXT-GENERATION MOLECULAR AND OPTICAL TOOLS FOR HIGH-SPEED BRAIN IMAGING - HE TIAN, ERIC SCHREITER, ROBERT CAMPBELL, XUE HAN, STéPHANE DIEUDONNE

Eric Schreiter
Howard Hughes Medical Instituite, Janelia Research Campus, Ashburn, United States of America

Fluorescent indicators of cell physiology have become ubiquitous tools for biology, especially neuroscience, because they allow sensitive monitoring of signals with high spatiotemporal precision over large areas of tissue. Many of the most popular indicators, like the calcium indicator GCaMP, are engineered from fluorescent proteins like GFP. During the last several years, we have collaboratively worked to develop new scaffolds for fluorescent indicators that combine engineered protein sensor domains with small molecule fluorophore reporters that have better photophysical properties than fluorescent proteins, such as higher brightness, improved photostability, and red-shifted emission. We call these hybrid protein-small molecule sensors ‘chemigenetic’ indicators. I will present the development and application of several such chemigenetic indicators, highlighting their advantages over existing sensors.

PUSHING THE WAVELENGTH FRONTIER FOR GENETICALLY ENCODED BIOSENSORS OF NEURAL ACTIVITY

WORKSHOP 01 - VOLTAGE IMAGING AND BEYOND, NEXT-GENERATION MOLECULAR AND OPTICAL TOOLS FOR HIGH-SPEED BRAIN IMAGING - HE TIAN, ERIC SCHREITER, ROBERT CAMPBELL, XUE HAN, STéPHANE DIEUDONNE

Robert Campbell
The University of Tokyo, Department Of Chemistry, Tokyo, Japan

Advances in microscopy and fluorescent probe development are revolutionizing biological research by enabling the normally achromatic world of the cell to be visualized in high resolution and with vivid colours. The Campbell research group uses protein engineering and chemical biology to expand the palette of biosensor colours and specificities, with the overall aim of enabling the visualization of cell signalling and metabolism. Protein engineering, using a combination of rational protein design and directed protein evolution, is the most effective and versatile approach for generating such biosensors. Accordingly, by exploiting structure-guided design, combined with iterative cycles of high-throughput fluorescence image-based screening of bacterial colonies, and lower throughput testing of promising variants in mammalian cells, we are developing a growing selection of fluorescent protein-based biosensors with improved properties. In this seminar I will present some of our most recent efforts to expand the colour and specificity palette of biosensors, focussing on metabolites of relevance to neural metabolism and metal ions other than calcium.

VOLTAGE IMAGING ANALYSIS OF SINGLE NEURON MEMBRANE DYNAMICS DURING BEHAVIOR

WORKSHOP 01 - VOLTAGE IMAGING AND BEYOND, NEXT-GENERATION MOLECULAR AND OPTICAL TOOLS FOR HIGH-SPEED BRAIN IMAGING - HE TIAN, ERIC SCHREITER, ROBERT CAMPBELL, XUE HAN, STéPHANE DIEUDONNE

Xue Han
Boston University, Biomedical Engineering, Boston, United States of America

Recent advances in genetically encoded voltage indicators have enabled the direct measurement of transmembrane voltage changes from individual neurons in the mammalian brain. In this talk, I will present a newly developed genetically encoded voltage indicator SomArchon, which faithfully translates cellular membrane potential dynamics into fluorescence intensity fluctuations. I will describe our recent effort in performing large scale voltage imaging from tens of individual neurons in the brains of behaving mice, and ultrafast ten kilohertz imaging of individual hippocampal neurons. Finally, I will highlight the use of membrane voltage imaging in understanding the relationship of single cell dynamics and circuit states during behavior.

Technologies to record membrane potential *in vivo* in defined neuronal populations with high fidelity will be essential to understand how information is represented, processed, and propagated in the brain. Genetically encoded voltage indicators (GEVIs) are especially promising as they can be expressed in defined cell types and are compatible with long-term chronic imaging *in vivo*. However, optical recording of cellular voltage *in vivo* is constrained by the speed and sensitivity inherent in current indicators and imaging modalities. *In vivo* 2P excitation of membrane proteins has been limited by three main factors: the low number of membrane proteins within a 2P focal volume, the low frame rate of standard 2P imaging and the possible imaging artefacts linked to brain motion in awake behaving mice. To address these three issues, we have developed light patterning strategies based on the acousto-optic technology. These strategies combine fast scanning (resonant rate), fast random-access (100 kHz- 1 MHz), holographic shaping of the focal volume and beam multiplexing. We demonstrate 10 kHz random-access voltage recordings from several neurons in awake behaving mice. Using ASAP3 and JEDI-2P, newly developed fast GEVIs, we report single spike detection with sub-millisecond precision and subthreshold membrane potential recordings with cellular resolution deep in the cortex and in the hippocampus of awake mice. Finally, we present new developments for 3D imaging within a 500x500x500 µm volume at 500 kHz sampling speed.

HIGH RESOLUTION DEEP BRAIN IMAGING USING ADAPTIVE OPTICS THREE-PHOTON MICROSCOPY

WORKSHOP 02 - MULTISCALE OPTICAL TECHNOLOGIES FOR DEEP AND LARGE-VOLUME BRAIN IMAGING - ROBERT PREVEDEL, ELIZABETH HILLMAN, ALIPASHA VAZIRI, ANGUS SILVER, BENJAMIN JUDKEWITZ

Robert Prevedel
European Molecular Biology Laboratory, Cell Biology And Biophysics, Heidelberg, Germany

Multiphoton microscopy has become a powerful tool to visualize the morphology and function of neural cells and circuits in the intact mammalian brain. Yet, tissue scattering, optical aberrations, and motion artifacts degrade the imaging performance at depth. In my talk, I will describe our efforts to overcome these limitations with the aim of advancing deep-tissue imaging in terms of imaging depth and spatial resolution. In particular, I will describe a recently developed minimally invasive intravital imaging methodology based on three-photon excitation, indirect adaptive optics (AO), and active electrocardiogram gating. Here we developed a modal-based, sensorless AO approach which we show to be robust to low signal-to-noise conditions as often encountered in deep in-vivo mouse brain imaging and that is sufficiently fast to be used on samples with slowly varying signal levels, including Ca^{2+} signals in astrocytes. We also found that our approach permits AO correction over large axial fields of view, i.e. AO enhancements in regions far away from the site of AO measurements and optimization. With this technique, we demonstrate near-diffraction-limited imaging of deep cortical spines and (sub)cortical dendrites up to a depth of 1.4 mm in the mouse CA1 hippocampus. In addition, we show applications to deep-layer calcium imaging of astrocytes, including fibrous astrocytes that reside in the highly scattering corpus callosum. Towards the end of my talk, I will discuss complementary strategies that in the future might allow to further push the performance of optical microscopy for recording neural structure and function in-vivo.

LIGHT SHEET MICROSCOPY FOR HIGH-SPEED VOLUMETRIC FUNCTIONAL IMAGING IN THE LIVING BRAIN

WORKSHOP 02 - MULTISCALE OPTICAL TECHNOLOGIES FOR DEEP AND LARGE-VOLUME BRAIN IMAGING - ROBERT PREVEDEL, ELIZABETH HILLMAN, ALIPASHA VAZIRI, ANGUS SILVER, BENJAMIN JUDKEWITZ

Elizabeth Hillman
Zuckerman Mind Brain Behavior Institute, Dept Of Biomedical Engineering, New York, United States of America

Although point-scanning microscopy can achieve high-resolution imaging deep into the living brain, 3D imaging speeds are fundamentally limited by low per-pixel integration times. Light-sheet microscopy represents a highly efficient form of spatial multiplexing that can overcome these speed limitations, enabling fast, high signal to noise, optically sectioned imaging with minimal photodamage. However, conventional orthogonal light-sheet geometries are unsuitable for high-speed 3D imaging in complex intact samples such as the in-vivo rodent brain. Our single-objective swept confocally-aligned planar excitation (SCAPE) microscopy approach leverages the benefits of light sheet microscopy in a simple form factor that can achieve imaging at between 10-100 volumes per second through a stationary objective lens in a diverse range of living, intact samples. This talk will demonstrate a range of different SCAPE configurations including 2P-SCAPE which uses two-photon light-sheet excitation to capture calcium activity in the living mouse brain to over 400 microns deep at 20 volumes per second with near isotropic 3D sampling over a continuous 300 micron depth range. The unique high-resolution 3D spatiotemporal analysis enabled by this kind of 3D data will also be demonstrated. Meso-scale SCAPE, designed to capture fields-of-view up to 4 mm across will also be demonstrated along with other novel configurations developed for deep brain imaging, as well as pan-neuronal imaging in freely moving C. elegans worms, and brain-wide imaging in awake, behaving Drosophila. This talk will showcase the unqiue and surprising advantages of light-sheet illumination over point-scanning microscopy methods for high-speed 3D functional brain imaging across species.

HIGH-SPEED CORTEX-WIDE BRAIN IMAGING WITH MULTIPLEXED MULTI-PHOTON MICROSCOPY

WORKSHOP 02 - MULTISCALE OPTICAL TECHNOLOGIES FOR DEEP AND LARGE-VOLUME BRAIN IMAGING - ROBERT PREVEDEL, ELIZABETH HILLMAN, ALIPASHA VAZIRI, ANGUS SILVER, BENJAMIN JUDKEWITZ

Alipasha Vaziri
Rockefeller University, Laboratory Of Neurotechnology And Biophysics, New York, United States of America

Understanding how sensory information is represented, processed and leads to generation of complex behavior from the activity of neurons is the major goal of systems neuroscience. However, the ability to detect and manipulate such large-scale functional circuits has been hampered by the lack of appropriate tools and methods that allow parallel and spatiotemporally specific manipulation of neuronal population activity while capturing the dynamic activity of the entire network at high spatial and temporal resolutions. Two-photon microscopy has enabled high-resolution imaging of neuroactivity at depth within scattering brain tissue. However, its various realizations have not overcome the tradeoffs between speed and spatiotemporal sampling that would be necessary to enable mesoscale volumetric recording of neuroactivity at cellular resolution and speed compatible with resolving calcium transients. Light beads microscopy (LBM) is a scalable and spatiotemporally optimal acquisition approach limited only by fluorescence lifetime. In LBM a set of axially separated and temporally distinct foci record the entire axial imaging range near-simultaneously, enabling volumetric recording at 1.41×10^8 voxels per second. Using LBM, we demonstrate mesoscopic and volumetric imaging at multiple scales in the mouse cortex, including cellular-resolution recordings within ~3 × 5 × 0.5 mm volumes containing >200,000 neurons at ~5 Hz and recordings of populations of ~1 million neurons within ~5.4 × 6 × 0.5 mm volumes at ~2 Hz, as well as higher speed (9.6 Hz) subcellular-resolution volumetric recordings. LBM provides an opportunity for discovering the neurocomputations underlying cortex-wide encoding and processing of information in the mammalian brain.

Determining how information is represented and transformed in microcircuits is essential for understanding brain function. However, the low density of some cell types, plus their 3D morphological complexity, make them challenging to investigate with conventional two-photon (2P) microscopy. Brain movement in behaving animals also complicates measurements from fine calibre structures like dendrites and axons. To overcome these limitations, we have developed a non-linear acousto-optic lens (nAOL) 2P microscope, which enables ultra-high speed remote focusing and line scanning in any orientation in X,Y, and Z. Inertia-free random-access scanning enables selective imaging of sparsely distributed regions of interest (ROI), such as cell bodies or dendritic trees within the 400x400x400µm volume. Combining 3D scanning with closed-loop FPGA-based processing has enabled real-time tracking and correction for tissue movement in behaving animals. We will present our latest nAOL microscope developments and illustrate its utility for multiscale imaging by showing movement stabilised calcium imaging of the 3D dendritic trees of layer II/III and V pyramidal cells in awake behaving mice. By combining this *Arboreal* scanning with selective imaging of multiple ROIs, we demonstrate multiscale recordings from spines, large fractions of the dendritic tree, and groups of neurons from the surrounding population, simultaneously.

WHOLE BRAIN IMAGING IN THE SMALLEST VERTEBRATE BRAIN

WORKSHOP 02 - MULTISCALE OPTICAL TECHNOLOGIES FOR DEEP AND LARGE-VOLUME BRAIN IMAGING - ROBERT PREVEDEL, ELIZABETH HILLMAN, ALIPASHA VAZIRI, ANGUS SILVER, BENJAMIN JUDKEWITZ

Benjamin Judkewitz
Charité and Humboldt University Berlin, Einstein Center For Neuroscience, Berlin, Germany

Understanding how distributed neuronal circuits integrate sensory information and generate behavior is a central goal of neuroscience. However, it has been difficult to study neuronal networks at single-cell resolution across the entire adult brain in vertebrates because of their size and opacity. We addressed this challenge by introducing the fish Danionella cerebrum (formerly D. translucida) as a model organism. This teleost remains small and transparent even in adulthood, when neural circuits and behavior have matured. Despite having the smallest known adult vertebrate brain, Danionella displays a rich set of behaviors, including courtship, shoaling, schooling and acoustic communication. In my talk I will present our latest work on oblique plane miscropscopy for large field-of-view whole-brain volumetric imaging in Danionella.

THE ROLE OF FUNCTIONAL CONNECTIVITY IN THE PROPAGATION OF LESIONS IN ALZHEIMER'S DISEASE

WORKSHOP 03 - NOVEL APPROACHES IN TRANSPECIES WHOLE-BRAIN NETWORK ANALYSIS - ROBIN DE FLORèS, CHRISTOPHE BERNARD, CHRISTINA GRIMM, LAURA HARSAN, MARINA CéLESTINE, DANIEL GUTIERREZ

Robin De Florès, Gaël Chételat
INSERM, U1237, Caen, France

From a neuropathologic point of view, Alzheimer's Disease (AD) is defined by the presence of neurofibrillary tangles (NFTs) due to hyperphosphorylated tau peptides and extracellular deposits of amyloid β (Aβ). Histopathological observations have consistently reported that these pathologies spread in a stereotypical manner. Nearly 30 years ago, Braak and Braak proposed a hierarchical scheme for tau propagation, where the pathology is first found in the medial temporal lobe before spreading to limbic regions and ultimately to the neocortex. Interestingly, the most sensitive regions to the pathology are strongly interconnected, which has led to the hypothesis that NFTs spread directly from cell to cell through anatomical connections. Technical progresses in neuroimaging methods reinforced this theory decades later, with multimodal studies showing a similar topography between neurodegeneration patterns, as measured using structural MRI or FDG-PET, and specific networks highlighted using resting-state fMRI. Then, the recent development of PET tracers targeting AD molecular alterations (ie NFTs and Aβ) has furthered our understanding of the role of functional connectivity in the propagation of lesions in the course of the disease. For example, studies showed that tau pathology is more strongly and specifically associated to brain networks than Aβ. In addition, tau spreading is not specific to a single network and seems to be partly promoted by the presence of Aβ, although Aβ-independent spreading processes have also been described. Overall, the recent multimodal imaging studies that will be discussed in our presentation play a pivotal role in our understanding of the biological mechanisms underlying AD.

CONTROLLING BRAIN DYNAMICS: FROM WHOLE BRAIN MODELLING TO EXPERIMENTAL VALIDATION IN INDIVIDUALS

WORKSHOP 03 - NOVEL APPROACHES IN TRANSPECIES WHOLE-BRAIN NETWORK ANALYSIS - ROBIN DE FLORèS, CHRISTOPHE BERNARD, CHRISTINA GRIMM, LAURA HARSAN, MARINA CéLESTINE, DANIEL GUTIERREZ

Christophe Bernard
Institut de Neurosciences des Systèmes, Umr Inserm 1106, Aix-marseille Université, Marseille, France

Whole-brain modeling offers the possibility to explore mechanisms in silico and provide predictions that can be tested experimentally. As each brain is unique, a personalized approach is necessary. The structural connectome (who is connected to who), which is unique to individuals, enables the construction of a personalized brain avatar. The Virtual Brain (TVB) platform uses individual brain avatars from humans and mice, and generative models to analyze whole-brain dynamics. I will show that individual connectomes from mice contain enough information for a personalized approach of whole-brain dynamics, and thus personalized medicine. I will show how it is possible to control brain dynamics via specific interventions, such as lesions and stimulation, in silico, and verify these predictions experimentally. I will show a concrete application of this approach in patients with drug-resistant epilepsy and who are candidates for neurosurgery.

[1]EPFL Lausanne, Institute Of Bioengineering, Lausanne, Switzerland, [2]ETH Zurich, Department Of Health Sciences And Technology, Zurich, Switzerland, [3]University of Sydney, Complex Systems Research Group, Sydney, Australia, [4]ETH Zurich, Department Of Information Technology And Electrical Engineering, Zurich, Switzerland

The Locus Coeruleus (LC) is a brain stem nucleus that provides norepinephrine (NE) to most of the forebrain and contributes to numerous brain functions. Collective behavioural and electrophysiological studies have suggested that the LC/NE system exerts its influence via different neuronal firing modes, which reflect on the amount of terminal NE release. In our previous work, we found that chemogenetic excitation of LC in mice – which mimics strong and sustained LC activation – leads to the recruitment of brain networks like those reported after stressful stimuli in humans. However, the role of the LC/NE system is not limited to stress, and distinct patterns of LC activity can have specific effects on behaviour. In this work, we implemented unilateral optogenetic stimulation of LC noradrenergic neurons at physiologically relevant tonic and burst firing patterns in anaesthetised mice and simultaneously recorded BOLD-fMRI. We show that LC activation evokes changes in whole-brain activity that are specific to both its firing frequency and firing pattern. Furthermore, we demonstrate macroscopic network and energy landscape reconfigurations highly dependent on LC firing frequency and firing pattern by tracking whole-brain BOLD signal fluctuations. Together these observations provide insight into systems-level differences between tonic and burst firing of LC and their impact on brain activity and neural network changes. This project lays the foundation for studying how the LC/NE system modulates whole-brain dynamics in health and disease using fMRI.

Introduction: Maladaptive changes in specific neuromodulatory systems and neural circuits can lead to manifestation of several prominent brain disorders, including anxiety, depression or other pathologies involving cognitive/memory impairments. Resting State Networks mapping and brain diffusion tractography in rodent models are increasingly used to capture such circuitry based underpinnings of pathological traits. **Aims and Methods:** We comparatively present findings from longitudinal mapping of functional and structural brain pathways in rodent models of mood disorders. We use the neuromodulatory approaches to create the depression phenotype in mice, via repetitive optogenetic activation of the pyramidal anterior cingulate cortex (ACC) neurons expressing Channel rhodopsin 2 (ChR). Upon the establishment of the depression phenotype we further use resting state functional MRI (rsfMRI at 7T) as non-invasive read-out of the effects at the level of functional brain connectivity. Seed based analysis and graph theory approaches are used to identify the functional circuitry signatures underlying depression phenotype. Dynamic resting-state functional connectivity (DFC) analyses using a sliding-window method complement the analytic approach. Additionally, we perform opto-fMRI for mapping the dynamics of brain responses upon optogenetic stimulation. **Results and conclusion:** Four consecutive sessions of optogenetic ACC stimulation induce strong depression phenotype and brain-wide modifications of the functional brain networks. Particularly, altered patterns of connectivity between key nodes of the mesocorticolimbc circuitry are observed, suggesting altered cognitive processing of motivation, aversion and reward. Additionally, our data indicate a major impact of optogenetic stimulation on the default mode network (DMN) pattern and on its cross-talk with the rest of the brain.

[1]Molecular imaging research center, CEA, Paris-saclay University, Laboratory Of Neurodegenerative Disease, Cnrs, Umr9199, Fontenay-aux-roses, France, [2]Molecular imaging research center, CEA, Laboratory Of Neurodegenerative Disease, Cnrs, Umr9199, Fontenay-aux-roses, France

Aims Resting-state functional magnetic resonance imaging (rs-fMRI) provides non-invasive *in vivo* exploration of large-scale brain networks. Yet, whole-brain fMRI imaging in rodents suffers from non-linear geometric and intensity distortions caused by static magnetic field inhomogeneity that worsen at higher field strengths. In the last decade, novel tools have emerged to analyze animal fMRI data including to correct preprocessing, but current software remain less powerful than the available tools that process human brain data. **Methods** We present here an adaptive protocol that perform data preprocessing using flexible and efficient pipelines encompassing in the python library Sammba-MRI. Then, to unveil brain network signatures, we investigated spatial brain signal decomposition using multi-subject dictionary learning. The method was used to investigate Alzheimer's disease (AD) pathology in rodents. Six-month-old APPswe/PS1dE9 mice (n=10) inoculated with AD related amyloid-β (Aβ) seeds were scanned on an 11.7T spectrometer. These mice were compared to their age-matched littermates inoculated with PBS. **Results** First, decomposition of brain signal into 25 components revealed nine bilateral cortical functional components that constitute networks involved in AD. We revealed abnormal brain connectivity through impairment of the default mode and the hippocampal-memory networks in pathological brains. Second, through seed-based analysis and atlas-based functional connectivity analysis, we highlighted functional connectivity disruption of the hippocampus (inoculum site) with other regions. **Conclusions** Our protocol allowed to register rs-fMRI data from numerous subjects and to analyze data using several complementary tools: from network analysis to region-to-region analysis. We were able to highlight functional connectivity differences between animals in pathological condition.

EVOLUTIONARILY CONSERVED FMRI NETWORK DYNAMIC PRINCIPLES IN THE MOUSE, MACAQUE, AND HUMAN BRAIN

WORKSHOP 03 - NOVEL APPROACHES IN TRANSPECIES WHOLE-BRAIN NETWORK ANALYSIS - ROBIN DE FLORèS, CHRISTOPHE BERNARD, CHRISTINA GRIMM, LAURA HARSAN, MARINA CéLESTINE, DANIEL GUTIERREZ

Daniel Gutierrez-Barragan[1], Stefano Panzeri[1,2], Ting Xu[3], Alessandro Gozzi[1]
[1]Italian Institute of Technology (IIT) - Center for Neuroscience and Cognitive Systems (CNCS), Functional Neuroimaging Laboratory, Rovereto, Italy, [2]University Medical Center Hamburg-Eppendorf (UKE), Department Of Neural Information Processing, Center For Molecular Neurobiology (zmnh), Hamburg, Germany, [3]Child Mind Institute, Center For The Developing Brain, New York, United States of America

Networks of synchronized brain activity have been robustly and reproducibly mapped in humans, primates and rodents using resting state fMRI (rsfMRI). Recent research has revealed that fMRI network activity dynamically reconfigures over the time scale of seconds into recurring and reproducible brain states. It is however unclear if the dynamic rules that govern fMRI network activity are species invariant and as such evolutionarily conserved, or if they follow species-specific principles. In my talk, I will illustrate recent research on how rsfMRI network topography and dynamics in the mammalian brain are governed by recurrent transitions between a limited set of fluctuating BOLD Co-Activation Patterns (CAPs), which can be simply obtained by clustering fMRI frames given their spatial similarity. I will explain the rich spatio-temporal features of CAPs and how to compute them. I will next show how this approach is sensitive to disease processes, neuromodulatory input and arousal states, critically shaping the ensuing spatio-temporal patterns of rsfMRI networks activity. I will finally demonstrate how key topographic and dynamic characteristics of CAPs are evolutionarily conserved in mouse, macaque, and human data, providing a novel interpretational framework to comparatively investigate whole-brain dynamics between species.

PERTURBATION OF INHIBITORY ACTIVITY INTERFERES WITH MEMORY REACTIVATION AND PREVENTS LEARNING IN VISUAL ASSOCIATION CORTEX

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Kristian Kinden Lensjø[1], Ingeborg Nymoen[1], Frederik Rogge[1], Arthur Sugden[2], Inga Shurnayte[2], Sverre Grødem[1], Torkel Hafting[3], Mark Andermann[2], Marianne Fyhn[1]

Consolidation of salient experiences to form memories rely on precise coupling of high-frequency neural network events between hippocampus and neocortex. Within these events, reactivation of subpopulations of neurons is believed to strengthen connections within and between networks. We have previously shown that reactivation occurs in visual association cortex during learning of a visual association task. Moreover, recent work suggests a role for parvalbumin-expressing (PV) inhibitory interneurons in consolidation by synchronizing hippocampal and cortical activity. We therefore hypothesize that PV interneurons ensure the precise timing between hippocampus and cortex to drive successful reactivations necessary for learning. To investigate this we trained mice in a visual association task, and silenced PV interneurons in visual association cortex after training by chemogenetics on alternating days. In ongoing experiments, we perform two-photon imaging of cell ensembles in visual association cortex, during and after daily training. Activity is estimated by RiboL1-jGCaMP8s fluorescence, and PV+ cells identified (and inhibited) by expressing DIO-DREADD-mScarlet, or DIO-Ruby in control mice. In a separate group we perform simultaneous electrophysiological recordings in visual association cortex and hippocampus area CA1 after training. Our preliminary results indicate that local silencing of PV interneurons strongly attenuates memory consolidation. Notably, the animals' performance improved following training days with saline injections, and reverted to chance levels following training days with PV silencing. Early imaging results suggest that reactivations are present after chemogenetic silencing, but less structured compared to controls. Together our preliminary data indicate that PV silencing during consolidation prevents learning, possibly by interfering with memory reactivations.

THE ANATOMICAL AND FUNCTIONAL COMPLEXITY OF MEDIAL THALAMUS-PREFRONTAL CORTEX CIRCUIT

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Aletta Magyar[1,2], Sándor Borbély[3,4], Judit Berczik[1,5], Kinga Kocsis[2,6], Ofer Yizhar[7], Ferenc Mátyás[8,9,10]

Of Anatomy And Histology, Budapest, Hungary, [10]Research Centre for Natural Sciences, Cognitive Neuroscience And Psychology, Budapest, Hungary

The medial thalamic regions (MT) play important role in regulation of cognitive processes through the prefrontal cortex (PFC). Previous data suggest a functional dichotomy in the MT-PFC circuit formed by the calretinin (CR+)-expressing and non-expressing (CR-) thalamic cells; however, the exact cellular and network features as well as the effector mechanism(s) of these pathways are poorly understood. Here, by integrating in vivo acute and chronic electrophysiological recordings, anatomical and optogenetic approaches in mice we demonstrate that the CR+ and CR- MT populations have qualitatively and quantitatively distinct cortical and subcortical input/output organization and possess diverse cortical functions. In general, CR+ MT (paraventricular thalamic) neurons have global efferent connections, drive persistent cortical activation and the majority of them show arousal-predicting firing pattern. In contrast, CR- MT (mediodorsal thalamic) cells target much fewer brain regions, provide focal excitations and their activity pattern only follow the behavioral arousal. Within the PFC, the CR+ and CR- MT cells activate qualitatively and quantitatively different PFC networks with laminar and subregional-specificity In addition, the proportions of the CR+ and CR- MT activated principal cells and interneuron are different in the prefrontal cortex. Finally, we also found potential indirect interaction between the CR+ and CR- systems, via the thalamic reticular nucleus and the deep-layers of PFC. These findings indicate that, although the CR+ and CR- MT-PFC networks are anatomically and functionally different, they form sequentially activated ‘inter-loop’ system. Building on each other, they can collectively mediate complex, arousal-dependent cognitive functions.

Associative and plastic thalamic signaling to the lateral amygdala controls fear behavior.
Decades of research support the idea that associations between a conditioned stimulus (CS) and an unconditioned stimulus (US) are encoded in the lateral amygdala (LA) during fear learning. However, direct proof for the sources of CS and US information is lacking. Definitive evidence of the LA as the primary site for cue association is also missing. Here, we show that calretinin (Calr)-expressing neurons of the lateral thalamus (CalrLT neurons) convey the association of fast CS (tone) and US (foot shock) signals upstream from the LA in mice. CalrLT input shapes a short-latency sensory-evoked activation pattern of the amygdala via both feedforward excitation and inhibition. Optogenetic silencing of CalrLT input to the LA prevents auditory fear conditioning. Notably, fear conditioning drives plasticity in CalrLT neurons, which is required for appropriate cue and contextual fear memory retrieval. Collectively, our results demonstrate that CalrLT neurons provide integrated CS-US representations to the LA that support the formation of aversive memories.

A highly collateralized thalamic cell type with arousal-predicting activity serves as a key hub for graded state transitions in the forebrain.
Sleep cycles consist of rapid alterations between arousal states, including transient perturbation of sleep rhythms, microarousals, and full-blown awake states. Here we demonstrate that the calretinin (CR)-containing neurons in the dorsal

medial thalamus (DMT) constitute a key diencephalic node that mediates distinct levels of forebrain arousal. Cell-type-specific activation of DMT/CR cells elicited active locomotion lasting for minutes, stereotyped microarousals, or transient disruption of sleep rhythms, depending on the parameters of the stimulation. State transitions could be induced in both slow-wave and rapid eye-movement sleep. The DMT/CR cells displayed elevated activity before arousal, received selective subcortical inputs, and innervated several forebrain sites via highly branched axons. Together, these features enable DMT/CR cells to summate subcortical arousal information and effectively transfer it as a rapid, synchronous signal to several forebrain regions to modulate the level of arousal.

SYSTEMATIC VARIATION OF SYNAPTIC PLASTICITY MARKERS ACROSS AREAS OF THE TEMPORAL CORTEX IN HUMANS

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Alicia Uceda Heras, Ariadna Sancha Velasco, Carmen Cavada, Miguel Ángel García-Cabezas
Universidad Autónoma de Madrid, Department Of Anatomy, Histology And Neuroscience, Madrid, Spain

The expression of synaptic plasticity markers varies systematically across cortical areas in primates, being higher in limbic areas, of poor laminar elaboration, and lower in eulaminate areas, with six-well developed layers (Eur J Neurosci 2017; 46: 2392-2405). In the temporal cortex, perirhinal and parahippocampal limbic areas are more vulnerable to epilepsy and Alzheimer's disease, suggesting that synaptic plasticity of cortical areas and selective vulnerability to neurological disorders are linked. In this context, we studied the expression and distribution of markers related to synaptic plasticity across the temporal cortex of neurotypical humans to identify areas with higher synaptic plasticity. Our goal is to stablish baseline distributions of plasticity markers in temporal areas for future comparison with pathological brains. We quantified the intracortical content of myelin and the density of perineuronal nets because both markers are strong inhibitors of synaptic plasticity. We also quantified the expression of GFAP, because it labels activated astrocytes and provides an indirect measurement of metabolic activity. Our data shows increased myelin and perineuronal net density in eulaminate areas compared to limbic areas. The content of myelin also increased across eulaminate areas of progressively better laminar elaboration. In contrast, the expression of GFAP was higher in limbic areas and lower in eulaminate areas. These findings suggest that limbic areas of the human temporal cortex are more plastic and have higher metabolic activity than eulaminate temporal areas. Higher synaptic plasticity of limbic temporal areas may be related to selective vulnerability to neurological disorders showed in perirhinal and parahippocampal areas.

CONDITIONAL DELETION OF GPRASP2 IN PV-POSITIVE NEURONS DRIVES HIPPOCAMPAL CIRCUIT ALTERATIONS AND COGNITIVE DYSFUNCTION

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Mariana Laranjo
University of Coimbra, Center For Neuroscience And Cell Biology, Coimbra, Portugal

While no single gene accounts for more than 1% of cases for diagnosed autism spectrum disorder, many neurodevelopmental disorders are connected to functional alterations in synaptic function. We previously showed that global deletion of Gprasp2, a regulator of metabotropic glutamate receptors, leads to cognitive and synaptic communication dysfunction. We found that Gprasp2 is enriched in parvalbumin (PV)-positive inhibitory neurons using in situ mRNA hybridization and single-cell RNA sequencing. Considering the role of PV neurons in brain disorders, we aim to study the consequences of specific loss of Gprasp2 in parvalbumin (PV) positive inhibitory neurons, and if loss of Gprasp2 only in PV-positive neurons is sufficient to drive cognitive and behavioural alterations. To achieve this, we generated a new mouse line via a triple cross of (i) ROSA26 loxP-STOP-loxP-tdTomato- mice with a (ii) PV-Cre driver line and (iii) our conditional Gprasp2 mice, in which Gprasp2 coding exon is flanked with loxP sites. Behavioural assessment and electrophysiological recordings showed that Gprasp2 deletion in PV inhibitory neurons was sufficient to disrupt performance in tasks associated with learning and memory and to alterations in inhibitory currents in the hippocampus of adult mice. These results suggest a functional role for Gprasp2 in PV inhibitory neurons and highlight the relevance of this cell type in the appearance of discrete phenotypes associated with neurodevelopmental disorders.

Abnormal mGluR-mediated synaptic plasticity and autism-like behaviours in Gprasp2 mutant mice.
Autism spectrum disorder (ASD) is characterized by dysfunction in social interactions, stereotypical behaviours and high co-morbidity with intellectual disability. A variety of syndromic and non-syndromic neurodevelopmental disorders have been connected to alterations in metabotropic glutamate receptor (mGluR) signalling. These receptors contribute to synaptic plasticity, spine maturation and circuit development. Here, we investigate the physiological role of Gprasp2, a gene linked to neurodevelopmental disabilities and involved in the postendocytic sorting of G-protein-coupled receptors. We show that Gprasp2 deletion leads to ASD-like behaviour in mice and alterations in synaptic communication. Manipulating the levels of Gprasp2 bidirectionally modulates the surface availability of mGluR and produces alterations in dendritic complexity, spine density and synaptic maturation. Loss of Gprasp2 leads to enhanced hippocampal long-term depression, consistent with facilitated mGluR-dependent activation. These findings demonstrate a role for Gprasp2 in glutamatergic synapses and suggest a possible mechanism by which this gene is linked to neurodevelopmental diseases.

A biocompatible redox MRI probe based on a Mn(ii)/Mn(iii) porphyrin.
For the development of redox responsive MRI probes based on the MnIII/MnII couple, stable complexation of both reduced and oxidized forms of the metal ion and appropriate tuning of the redox potential in the biologically relevant range are key elements. The water soluble fluorinated Mn-porphyrin derivative Mn-3 satisfies both requirements. In aqueous solutions, it can reversibly switch between MnIII/MnII oxidation states. In the presence of ascorbic acid or β-mercaptoethanol, the MnIII form undergoes reduction, which is slowly but fully reversed in the presence of air oxygen. A UV-Vis kinetic study of MnIII/MnII reduction under oxygen-free conditions yielded second-order rate constants, k2, of 46.1 M-1 s-1 and 13.8 M-1 s-1 for the reaction with ascorbic acid and β-mercaptoethanol, respectively. This could correspond, in the absence of oxygen, to a half-life of a few minutes in blood plasma and a few seconds in circulating immune cells where ascorbic acid reaches 20-40 μM and a few mM concentrations, respectively. In contrast to expectations based on the redox potential, reduction with glutathione or cysteine does not occur. It is prevented by the coordination of the glutathione carboxylate group(s) to MnIII in

the axial position, as was evidenced by NMR data. Therefore, MnIII-3 acts as an ascorbate specific turn-on MRI probe, which in turn can be re-oxidized by oxygen. The relaxivity increase from the oxidized to the reduced form is considerably improved at medium frequencies (up to 80 MHz) with respect to the previously studied Mn-TPPS4 analogues; at 20 MHz, it amounts to 150%. No in vitro cytotoxicity is detectable for Mn-3 in the typical MRI concentration range. Finally, 19F NMR resonances of MnIII-3 are relatively sharp which could open further opportunities to exploit such complexes as paramagnetic 19F NMR probes.

NEUROMODULATORY LOGIC OF AMYGDALA CIRCUITS

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Nikolaos Karalis, Andreas Lüthi
Friedrich Miescher Institute for Biomedical Research, Neurobiology, Basel, Switzerland

Emotional learning and behavior are associated with brain-wide changes in the activity of neuronal circuits. Such global shifts are believed to be implemented by the changes in the neuromodulatory tone. Neuromodulators originate from a few neurons and are released widely throughout the brain to alter the function of target neural circuits. The amygdala plays an essential role in the processing of emotional stimuli, and salience and synaptic alterations in this region are critical for learning and emotional processing. The amygdala is innervated by every major neuromodulator, yet we know little about the dynamics of neuromodulator release under physiological conditions and how neuromodulation regulates amygdala circuit activity during different behavioral states and learning. Here, we characterized the neuromodulatory inputs to the amygdala during reward and aversion. Using novel sensors that report the dynamics of neuromodulator release, paired with multi-site, multi-color fiber photometry, we simultaneously measured the activity of all major neuromodulators in the amygdala. Using this data, we characterized the release patterns during distinct behaviors and identified the interaction between different neuromodulators. Further, using simultaneous optical and electrophysiological recordings from the amygdala, we have identified distinct patterns of neuronal activity that are associated with differential neuromodulatory input during distinct behavioral states. In summary, using this novel approach and multi-modal recordings, we are able to jointly characterize the activity of these two core systems and to generate predictions about the causal influence of simultaneous combinatorial neuromodulation on the activity of downstream circuits and the resulting changes in the behavior.

A hallmark of the anterior cingulate cortex (ACC) is its functional heterogeneity. Functional and imaging studies revealed its importance in the encoding of anxiety-related and social stimuli, but it is unknown how microcircuits within the ACC encode these distinct stimuli. One type of inhibitory interneuron, which is positive for vasoactive intestinal peptide (VIP), is known to modulate the activity of pyramidal cells in local microcircuits, but it is unknown whether VIP cells in the ACC (VIP^{ACC}) are engaged by particular contexts or stimuli. Additionally, recent studies demonstrated that neuronal representations in other cortical areas can change over time at the level of the individual neuron. However, it is not known whether stimulus representations in the ACC remain stable over time. Using in vivo Ca^{2+} imaging and miniscopes in freely behaving mice to monitor neuronal activity with cellular resolution, we identified individual VIP^{ACC} that preferentially activated to distinct stimuli across diverse tasks. Importantly, although the population-level activity of the VIP^{ACC} remained stable across trials, the stimulus-selectivity of individual interneurons changed rapidly. These findings demonstrate marked functional heterogeneity and instability within interneuron populations in the ACC. This work contributes to our understanding of how the cortex encodes information across diverse contexts and provides insight into the complexity of neural processes involved in anxiety and social behavior.

REM AND NON-REM SLEEP-DEPENDENT NEURAL DYNAMICS IN THE HIPPOCAMPUS-AMYGDALA NETWORK

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Billel Khouader[1,2], Gabrielle Girardeau[2]
[1]Sorbonne Université, Ed3c, Paris, France, [2]Inserm, Institut Du Fer à Moulin, Paris, France

Sleep is a physiological state of reduced vigilance and alertness known to be important for brain homeostasis, memory consolidation, and emotional regulation. During sleep, the brain cycle through two main stages: Non-REM sleep (also called slow-wave sleep) and REM sleep. The neuronal dynamics of REM and Non-REM sleep have been extensively studied, notably in the hippocampus and neocortex, in link with homeostasis and plastic processes related to memory consolidation. The amygdala is a critical brain region for the processing of emotions. However, the sleep dynamics of the amygdala are comparatively understudied, despite a hypothesized role for both REM and Non-REM sleep in emotional memory consolidation. Here, using large-scale recording of LFPs and multiple single-unit activity in freely moving rats, we extensively describe the dynamics of neuronal firing in the basolateral amygdala (BLA) locally and in link with hippocampal sleep rhythms. At transitions from Non-REM to REM sleep, we observe an increase in the activity of BLA interneurons and principal cells. This heightened activity during REM sleep remains stable while firing rates during NREM across extended sleep epochs decrease. Hippocampal theta and local (BLA) theta and gamma oscillations during REM-sleep influence spiking activity in the amygdala. These unique firing patterns in the BLA during REM and Non-REM sleep might underlie the specific roles of these two sleep stages in homeostasis, emotional regulation, and memory.

BRIDGING THE GAP BETWEEN BEHAVIORAL- AND NETWORK-LEVEL PATTERN SEPARATION IN THE DENTATE GYRUS.

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Cecilia Kramar[1], Alexandra Keinath[1], Mohammad Yaghoubi[1], Lisa Saksida[2], Tim Bussey[2], Mark Brandon[1]
[1]Douglas Hospital Research Centre, McGill University, Department Of Psychiatry, Verdun, Canada, [2]Western University, Robarts Research Institute, Schulich School Of Medicine And Dentistry,, London, Canada

The large number of granule cells and presence of adult born neurons (ABNs) in the dentate gyrus (DG) have led to the hypothesis that this region is especially sensitive to small changes in input information, making it particularly important when encoding highly similar stimuli, a processed named 'Pattern Separation' (PS). While it is known that ABNs are required for spatial pattern separation at the behavioral level, the contribution of ABNs to network-level computations throughout the hippocampus remains less clear. To address this directly, we have obtained large population recordings from CA1 and CA3 regions of the hippocampus, as well from mature Granule Cells (mGCs) of the DG, before and after a gene-mediated ablation of ABNs as animals perform a spatial PS task. Specifically, we used the UCLA miniscope to obtain these recordings while animals performed on the Spontaneous Location Recognition task (SLR). Here, we report here that ABNs ablation impairs an animals' ability to perform on the SLR-PS task. Preliminary c-fos immunofluorescence experiments indicate an increase in neuronal activation in regions CA3 and CA1 after exposure to a version of the task that requires PS, compared to non-PS versions. We are now analyzing calcium imaging data to identify precisely how ABNs contribute to mGC-DG, CA3 and CA1 population codes that facilitate successful performance on the SLR-PS task.

AAV DELIVERY OF SHRNA AGAINST IRS1 IN GABAERGIC NEURONS IN RAT HIPPOCAMPUS ALTERS SYNAPTIC PLASTICITY AND IMPAIRS SPATIAL MEMORY IN FEMALES AND MALE RATS

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Sandra Sánchez-Sarasúa[1], Alberto Ribes-Navarro[2], Maria Teresa Beltrán-Bretones[3], Maria Meseguer-Beltrán[3], Ana María Sánchez-Pérez[3]
[1]University of Bordeaux, Institut Des Maladies Neurodégénératives - Cnrs Umr 5293, Bordeaux, France, [2]Instituto de Acuicultura de Torre de la Sal, Iats-csic, Castellón, Spain, [3]University Jaume I, Predepartmental Medicine Unit, Castellón de la Plana, Spain

Brain insulin resistance is a major factor leading to impaired cognitive function. Many studies have revealed how pro-inflammatory cytokines lead to insulin resistance by inhibiting insulin receptor substrate 1 (IRS1) function. Thus, dysfunction of insulin signaling is concomitant with inflammatory biomarkers. However, the effect of IRS1 impaired function in otherwise healthy brain has not been dissected out. Our aim is to study the specific role of IRS1 in the hippocampus, in absence of comorbidities. shRNA against rat and human IRS1 was designed and tested in cultured HEK cells to evaluate mRNA levels and specificity. Best candidate sequence was encapsulated in an AAV vector (strain DJ8). AAV-CMV-shIRS1-EGFP and control AAV-CMV-EGFP were inoculated into dorsal hippocampus of female and male Wistar rats. One month later, animals undertook behavioral paradigms evaluating memory and anxiety. Our results suggest that females displayed increased susceptibility to AAV-shIRS1 in the novel object recognition paradigm; whereas both females and males showed impaired performance in the T-maze when infected with AAV-shIRS1. We observed specific fluorescence within the hilus, in parvalbumin and somatostatin neurons. EGFP fibers were found in fornix, mammillary bodies and medial septum indicating that hippocampal efferent had been efficiently targeted by AAV DJ8 infection. We observed that AAV-shIRS1 alters spine maturation in hilar hippocampal neurons and reduced significantly synaptophysin puncta in hippocampal-septal projections compared to controls. These results support that small alterations in the insulin/IGF1 pathway in specific hippocampal circuitries can underlie modifications in synaptic plasticity and affect behavior, in the absence of inflammatory conditions.

FROM SYNAPSES TO BEHAVIOR: THE IMPACT OF DNA METHYLTRANSFERASE 1 (DNMT1) IN PARVALBUMINERGIC, MURINE INTERNEURONS

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Jenice Linde[1,2], Daniel Pensold[1], Julia Reichard[1,2], Georg Pitschelatow[1,2], Can Yildiz[1,2], Geraldine Zimmer-Bensch[1,2]
[1]RWTH Aachen University, Biology 2 - Functional Epigenetics In The Animal Model, Aachen, Germany, [2]RTG2416 MultiSenses -MultiScales, Biology Ii, Aachen, Germany

The mammalian cerebral cortex, the seat of higher cognitive function, is characterized by a sensitive balance between excitation and inhibition. This balance resembles a key element of the cortex´ function, enabling proper information processing. Although interneurons constitute, in comparison, a minority, their function sets the tone. The input of interneurons is crucial to synchronize surrounding neuronal activity and thus modulate circuit activity. A shift of interneuron abundance and/or function in any direction does usually have severe consequences for the whole organism. For example, this shift can result in neurodevelopmental or neuropsychiatric diseases, such as schizophrenia and autism. Next to genetic causes, environmental stimuli, often in specific phases of brain development, have a great impact on disease onset and severity. Thus, epigenetic mechanisms of transcriptional control were recently moved into the focus of research. Especially, the epigenetic regulation of interneuron development and function represents a disease-relevant topic of interest. Here, we investigated the role of the DNA methyltransferase 1 (DNMT1) in parvalbuminergic (PV) interneurons at different scales. On the cellular level, we found that DNMT1-dependent DNA methylations influence clathrin-mediated endocytosis. Moreover, we show that this change in endocytosis upregulates synaptic vesicle replenishment and GABAergic transmission. At first glance, these results suggest increased inhibition levels of DNMT1-deficient PV-interneurons. To further investigate the functional impacts of the DNMT1-knockout in PV-Cre mice at a behavioral level, we examined their convulsion susceptibility during repeated administrations of pentylenetetrazole as well as their visuo-spatial learning capabilities during navigation in a Morris Water Maze.

DNA Methyltransferase 1 (DNMT1) Shapes Neuronal Activity of Human iPSC-Derived Glutamatergic Cortical Neurons.
Epigenetic mechanisms are emerging key players for the regulation of brain function, synaptic activity, and the formation of neuronal engrams in health and disease. As one important epigenetic mechanism of transcriptional control, DNA methylation was reported to distinctively modulate synaptic activity in excitatory and inhibitory cortical neurons in mice. Since DNA methylation signatures are responsive to neuronal activity, DNA methylation seems to contribute to the neuron's capacity to adapt to and integrate changing activity patterns, being crucial for the plasticity and functionality of neuronal circuits. Since most studies addressing the role of DNA methylation in the regulation of synaptic function were conducted in mice or murine neurons, we here asked whether this functional implication applies to human neurons as well. To this end, we performed calcium imaging in human induced pluripotent stem cell (iPSC)-derived excitatory cortical neurons forming synaptic contacts and neuronal networks in vitro. Treatment with siRNA that diminishs the expression of the DNA (cytosine-5)-methyltransferase 1 (DNMT1) was conducted to investigate the functional relevance of DNMT1 as one of the main enzymes executing DNA methylations in the context of neuronal activity modulation. We observed a lowered proportion of actively firing neurons upon -knockdown in these iPSC-derived excitatory neurons, pointing to a correlation of DNMT1-activity and synaptic transmission. Thus, our experiments suggest that DNMT1 decreases synaptic activity of human glutamatergic neurons and underline the relevance of epigenetic regulation of synaptic function also in human excitatory neurons.

The Expression of the Cancer-Associated lncRNA Is Modulated by EphrinA5-Induced Signaling.
The Eph receptor tyrosine kinases and their respective ephrin-ligands are an important family of membrane receptors, being involved in developmental processes such as proliferation, migration, and in the formation of brain cancer such as glioma. Intracellular signaling pathways, which are activated by Eph receptor signaling, are well characterized. In contrast, it is

unknown so far whether ephrins modulate the expression of lncRNAs, which would enable the transduction of environmental stimuli into our genome through a great gene regulatory spectrum. Applying a combination of functional in vitro assays, RNA sequencing, and qPCR analysis, we found that the proliferation and migration promoting stimulation of mouse cerebellar granule cells (CB) with ephrinA5 diminishes the expression of the cancer-related lncRNA In a human medulloblastoma cell line (DAOY) ephrinA5 stimulation similarly reduced expression. Computational analysis identified triple-helix-mediated DNA-binding sites of in promoters of genes found up-regulated upon ephrinA5 stimulation and known to be involved in tumorigenic processes. Our findings propose a crucial role of downstream of ephrinA5-induced signaling in regulating gene transcription in the nucleus. These findings could be potentially relevant for the regulation of tumorigenic processes in the context of glioma.

DNA Methylation-Dependent Dysregulation of GABAergic Interneuron Functionality in Neuropsychiatric Diseases.
Neuropsychiatric diseases, such as mood disorders, schizophrenia, and autism, represent multifactorial disorders, differing in causes, disease onset, severity, and symptoms. A common feature of numerous neuropsychiatric conditions are defects in the cortical inhibitory GABAergic system. The balance of excitation and inhibition is fundamental for proper and efficient information processing in the cerebral cortex. Thus, altered inhibition is suggested to account for pathological symptoms like cognitive impairments and dysfunctional multisensory integration. While it became apparent that most of these diseases have a clear genetic component, environmental influences emerged as an impact of disease manifestation, onset, and severity. Epigenetic mechanisms of transcriptional control, such as DNA methylation, are known to be responsive to external stimuli, and are suspected to be implicated in the functional impairments of GABAergic interneurons, and hence, the pathophysiology of neuropsychiatric diseases. Here, we provide an overview about the multifaceted functional implications of DNA methylation and DNA methyltransferases in cortical interneuron development and function in health and disease. Apart from the regulation of gamma-aminobutyric acid-related genes and genes relevant for interneuron development, we discuss the role of DNA methylation-dependent regulation of synaptic transmission by the modulation of endocytosis-related genes as potential pathophysiological mechanisms underlying neuropsychiatric conditions. Deciphering the hierarchy and mechanisms of changes in epigenetic signatures is crucial to develop effective strategies for treatment and prevention.

DNA Methyltransferase 1 (DNMT1) Acts on Neurodegeneration by Modulating Proteostasis-Relevant Intracellular Processes.
The limited regenerative capacity of neurons requires a tightly orchestrated cell death and survival regulation in the context of longevity, as well as age-associated and neurodegenerative diseases. Subordinate to genetic networks, epigenetic mechanisms, such as DNA methylation and histone modifications, are involved in the regulation of neuronal functionality and emerge as key contributors to the pathophysiology of neurodegenerative diseases. DNA methylation, a dynamic and reversible process, is executed by DNA methyltransferases (DNMTs). DNMT1 was previously shown to act on neuronal survival in the aged brain, whereby a DNMT1-dependent modulation of processes relevant for protein degradation was proposed as an underlying mechanism. Properly operating proteostasis networks are a mandatory prerequisite for the functionality and long-term survival of neurons. Malfunctioning proteostasis is found, inter alia, in neurodegenerative contexts. Here, we investigated whether DNMT1 affects critical aspects of the proteostasis network by a combination of expression studies, live cell imaging, and protein biochemical analyses. We found that DNMT1 negatively impacts retrograde trafficking and autophagy, with both being involved in the clearance of aggregation-prone proteins by the aggresome-autophagy pathway. In line with this, we found that the transport of GFP-labeled mutant huntingtin (HTT) to perinuclear regions, proposed to be cytoprotective, also depends on DNMT1. Depletion of accelerated perinuclear HTT aggregation and improved the survival of cells transfected with mutant HTT. This suggests that mutant HTT-induced cytotoxicity is at least in part mediated by DNMT1-dependent modulation of degradative pathways.

DNA Methyltransferase 1 (DNMT1) Function Is Implicated in the Age-Related Loss of Cortical Interneurons.
Increased life expectancy in modern society comes at the cost of age-associated disabilities and diseases. Aged brains not only show reduced excitability and plasticity, but also a decline in inhibition. Age-associated defects in inhibitory circuits likely contribute to cognitive decline and age-related disorders. Molecular mechanisms that exert epigenetic control of gene expression contribute to age-associated neuronal impairments. Both DNA methylation, mediated by DNA methyltransferases (DNMTs), and histone modifications maintain neuronal function throughout lifespan. Here we provide evidence that DNMT1 function is implicated in the age-related loss of cortical inhibitory interneurons. deletion in parvalbumin-positive interneurons attenuates their age-related decline in the cerebral cortex. Moreover, conditional -deficient mice show improved somatomotor

performance and reduced aging-associated transcriptional changes. A decline in the proteostasis network, responsible for the proper degradation and removal of defective proteins, is implicated in age- and disease-related neurodegeneration. Our data suggest that DNMT1 acts indirectly on interneuron survival in aged mice by modulating the proteostasis network during life-time.

Phylogenetic and morphological influence on habitat choice in moisture-harvesting horned lizards (spp.).
In previous studies, the superhydrophilic skin of moisture-harvesting lizards has been linked to the morphological traits of the lizards' integument, that is, the occurrence of honeycomb-shaped microstructures. Interestingly, these structures can also cover the skin of lizards inhabiting wet habitats. We therefore tested the influence of the microstructures' main features on the habitat choice and wettability in the genus . The genus comprises moisture-harvesting species as well as nonspecialists. Lizards of this genus inhabit large areas of North America with diverse climatic conditions. Remarkably, the differences in the manifestation of microstructures are just as versatile as their surroundings. The phylogeny of the lizards as well as the depth of their ventral microstructures, though independent of each other, correlated with the precipitation in their respective habitat. All other morphological traits, as well as the skin's wettability itself, could not predict the habitat of species. Hence, it is unlikely that the microstructure influences the wettability, at least directly. Hence, we presume an indirect influence for the following reasons: (a) As the ventral side cannot get wet by rain, but the belly could easily interact with a wet surface, the microstructure might facilitate water absorption from wet soil following precipitation. (b) We found the number of dorsal microstructures to be linked to the occurrence of silt in the habitat. In our study, we observed scales being heavily contaminated, most likely with a mixture of dead skin (after shedding) and silt. As many lizards burrow themselves or even shovel sand onto their backs, deploying the substrate might be a mechanism to increase the skin's wettability.

NEUROPEPTIDERGIC MODULATION OF CORTICAL CIRCUITS FOR FEAR MEMORY

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Sarah Melzer, Elena Newmark, Eleonora Quiroli, Beatrice Righetti, Bernardo Sabatini
Howard Hughes Medical Institute - Harvard Medical School, Department Of Neurobiology, Howard Hughes Medical Institute, Boston, United States of America

Neuropeptides throughout the mammalian brain are diverse regulators of circuit excitability and plasticity. All major cell types in the cortex are marked by differential expression of neuropeptide receptors, suggesting highly diverse context- and experience-dependent peptidergic modulation of cortical processing. Our aim is to identify neuropeptides in the cortex that modulate the acquisition and retrieval of fear memories in mice. We found that the bombesin-like neuropeptide gastrin-releasing peptide (GRP) serves as an important regulator of cortical VIP cells. Using in vivo imaging approaches, CRISPR/Cas9-mediated knockout of the GRP receptor and a combination of anterograde and retrograde tracing techniques, we aimed at gaining a detailed understanding of the peptidergic signaling mechanisms and behavioral functions. Our data establish GRP as a regulator of cortical disinhibitory microcircuits that are involved in the modulation of auditory fear memories. We identified several downstream signaling pathways that are putative mediators of this behavioral effect.

The axon initial segment (AIS) is the site of action potential initiation and plays a crucial role in the generation of neuronal activity and the maintenance of network function during sensory processing and learning. Previous studies identified the AIS as a site of homeostatic plasticity. However, whether and how structural AIS plasticity occurs *in vivo* and its potential link to learning remains unknown. Here we established a gradient refractive index (GRIN) lens based two-photon imaging approach to monitor the structure and dynamics of the AIS in the medial prefrontal cortex (mPFC)-amygdala network of mice expressing an intrinsic AIS live-stain. We visualized and tracked AIS structure in the infralimbic subdivision of mPFC across a four-day fear conditioning and extinction paradigm and identified population level changes in AIS length with increasing levels of fear extinction. Importantly, AIS length remained stable during consecutive baseline sessions outside of the learning paradigm. Our results demonstrate that AIS length is dynamic during associative learning *in vivo* and might mediate experience-dependent changes in neuronal excitability and output upon learning.

Dynamics of a neuronal pacemaker in the weakly electric fish Apteronotus.
The precise timing of neuronal activity is critical for normal brain function. In weakly electric fish, the medullary pacemaker network (PN) sets the timing for an oscillating electric organ discharge (EOD) used for electric sensing. This network is the most precise biological oscillator known, with sub-microsecond variation in oscillator period. The PN consists of two principle sets of neurons, pacemaker and relay cells, that are connected by gap junctions and normally fire in synchrony, one-to-one with each EOD cycle. However, the degree of gap junctional connectivity between these cells appears insufficient to provide the population averaging required for the observed temporal precision of the EOD. This has led to the hypothesis that individual cells themselves fire with high precision, but little is known about the oscillatory dynamics of these pacemaker cells. As a first step towards testing this hypothesis, we have developed a biophysical model of a pacemaker neuron action potential based on experimental recordings. We validated the model by comparing the changes in oscillatory dynamics produced by different experimental manipulations. Our results suggest that this relatively simple model can capture a large range of channel dynamics exhibited by pacemaker cells, and will thus provide a basis for future work on network synchrony and precision.

Single cell plasticity and population coding stability in auditory thalamus upon associative learning.
Cortical and limbic brain areas are regarded as centres for learning. However, how thalamic sensory relays participate in plasticity upon associative learning, yet support stable long-term sensory coding remains unknown. Using a miniature microscope imaging approach, we monitor the activity of populations of auditory thalamus (medial geniculate body) neurons in freely moving mice upon fear conditioning. We find that single cells exhibit mixed selectivity and heterogeneous plasticity patterns to auditory and aversive stimuli upon learning, which is conserved in amygdala-projecting medial geniculate body neurons. Activity in auditory thalamus to amygdala-projecting neurons stabilizes single cell plasticity in the total medial geniculate body population and is necessary for fear memory consolidation. In contrast to individual cells, population level encoding of auditory stimuli remained stable across days. Our data identifies auditory thalamus as a site for complex neuronal plasticity in fear learning upstream of the amygdala that is in an ideal position to drive plasticity in cortical and limbic brain areas. These findings suggest that medial geniculate body's role goes beyond a sole relay function by balancing experience-dependent, diverse single cell plasticity with consistent ensemble level representations of the sensory

environment to support stable auditory perception with minimal affective bias.

Neuropeptide Y(NPY) Y1 receptor (Y1R) and galanin (GAL) receptor 2 (GALR2) interact in brain regions responsible for learning and memory processes, emphasizing the hippocampus. The current study assesses the sustained memory performance and antidepressive-like effects induced by GALR2 and NPYY1R agonists intranasal coadministration and their neurochemical hippocampal correlates. Object-in-place task and forced swimming test were conducted together with in situ proximity ligation assay (PLA) to manifest the formation of GALR2/Y1R heteroreceptor complexes. We evaluated cell proliferation through a 5-Bromo-2'-deoxyuridine (BrdU) expression study within the hippocampus. The GalR2 agonist M1145 was demonstrated to act with the Y1R agonist to improve memory retrieval and antidepressive-like actions at 24 hours in both tasks, enhancing the cell proliferation in the DG of the hippocampus through BrdU expression and the GALR2/Y1R heteroreceptor complexes upon agonist coactivation. Our results may provide the basis for developing heterobivalent agonist pharmacophores targeting GALR2-Y1R heterocomplexes. It involves especially the neuronal precursor cells of the dentate gyrus in the hippocampus for the novel treatment of Alzheimer's disease or depression. The work was supported by the UMA18-FEDERJA-100 and Proyecto Jovenes Investigadores (B1-2019_04) and Proyecto Puente (B4-2021) UMA , Spain to MN. Special mention to Grupo Vithas.

Galanin and neuropeptide Y interactions elicit antidepressant activity linked to neuronal precursor cells of the dentate gyrus in the ventral hippocampus.
A need for new antidepressants is necessary since traditional antidepressants have several flaws. Neuropeptide Y(NPY) Y1 receptor (NPYY1R) and galanin (GAL) receptor 2 (GALR2) interact in several regions of the limbic system, including the hippocampus. The current study assesses the antidepressant effects induced by GALR2 and NPYY1R coactivation, together with the evaluation of cell proliferation through 5-Bromo-2'-deoxyuridine expression within the dentate gyrus of the ventral hippocampus (vDG). We employed in situ proximity ligation assay to manifest GALR2/NPYY1R heteroreceptor complexes. Additionally, the expression pattern of GALR2 and the activation of the extracellular-regulated kinases (ERK) pathway after GALR2 and NPYY1R costimulation in cell cultures were examined. GALR2 and NPYY1R coactivation resulted in sustained antidepressant behaviors in the FST after 24 h, linked to increased cell proliferation in the vDG. Moreover, an increased density of GALR2/NPYY1R heteroreceptor complexes was observed in vDG, on doublecortin-expressing neuroblasts. Recruitment of the GALR2 expression to the plasma membrane was observed upon the coactivation of GALR2 and NPYY1R in cell cultures, presumably associated to the enhanced effects on the activation of ERK pathway. GALR2 may promote the GALR2/NPYY1R heteroreceptor complexes formation in the ventral hippocampus. It may induce a transformation of cell proliferation toward a neuronal lineage by enhancement of ERK pathway. Thus, it may give the mechanism for the antidepressant behavior observed. These results may provide the basis for the development of heterobivalent agonist pharmacophores, targeting GALR2/NPYY1R heteromers, especially in the neuronal precursor cells of the dentate gyrus in the ventral hippocampus for the novel treatment of depression.

Existence of FGFR1-5-HT1AR heteroreceptor complexes in hippocampal astrocytes. Putative link to 5-HT and FGF2 modulation of hippocampal gamma oscillations.

The majority of the fibroblast growth factor receptor 1-serotonin 1 A receptor (FGFR1-5-HT1AR) heterocomplexes in the hippocampus appeared to be located mainly in the neuronal networks and a relevant target for antidepressant drugs. Through a neurochemical and electrophysiological analysis it was therefore tested in the current study if astrocytic FGFR1-5-HT1AR heterocomplexes also exist in hippocampus. They may modulate the structure and function of astroglia in the hippocampus leading to possible changes in the gamma oscillations. Localization of hippocampal FGFR1-5-HT1AR heterocomplexes in astrocytes was found using in situ proximity ligation assay combined with immunohistochemistry using glial fibrillary acidic protein (GFAP) immunoreactivity as a marker for astroglia. Acute i.c.v. treatment with 8-OH-DPAT alone or together with basic fibroblast growth factor (FGF2) significantly increased FGFR1-5-HT1AR heterocomplexes in the GFAP positive cells, especially in the polymorphic layer of the dentate gyrus (PoDG) but also in the CA3 area upon combined treatment. No other hippocampal regions were studied. Also, structural plasticity changes were observed in the astrocytes, especially in the PoDG region, upon these pharmacological treatments. They may also be of relevance for enhancing the astroglial volume transmission with increased modulation of the neuronal networks in the regions studied. The effects of combined FGF2 and 5-HT agonist treatments on gamma oscillations point to a significant antagonistic interaction in astroglial FGFR1-5-HT1AR heterocomplexes that may contribute to counteraction of the 5-HT1AR-mediated decrease of gamma oscillations. This article is part of the special issue entitled 'Serotonin Research: Crossing Scales and Boundaries'.

Galanin receptor 2-neuropeptide Y Y1 receptor interactions in the amygdala lead to increased anxiolytic actions.
Galanin (GAL) and neuropeptide Y (NPY) are neuropeptides involved in behaviors associated with anxiety. Both neuropeptides interact in several central functions. However, the potential behavioral and cellular interactions between them in anxiety are unknown. GAL was found to act through GAL receptor 2 (GALR2) to enhance NPYY1 receptor (NPYY1R)-mediated anxiolytic behaviors in rats. Using receptor autoradiography, c-Fos expression and in situ proximity ligation assay, the medial paracapsular intercalated nuclei of the amygdala were determined to be a key area in the interaction probably involving the formation of GALR2/NPYY1R heteroreceptor complexes. In cell cultures costimulation of GALR2 and NPYY1R induced changes in the functions of these receptors. The changes involved a potentiation of the decrease in the phosphorylation of CREB induced by NPYY1R and a delay in the internalization of NPYY1R. These results indicate that GALR2/NPYY1R interactions can provide a novel integrative amygdaloid mechanism in anxiety.

Galanin receptor 2-neuropeptide Y Y1 receptor interactions in the dentate gyrus are related with antidepressant-like effects.
Galanin (GAL) and the NPYY1 agonist play a role in mood regulation and both neuropeptides interact in several central functions. The present study examined the interaction between Galanin receptor 2 (GALR2) and Neuropeptide Y Y1 receptor (NPYY1R) in the dentate gyrus (DG) of the Hippocampus in relation to depression-like behavior. Using receptor autoradiography, in situ hybridization and in situ proximity ligation assay an interaction between GALR and NPYY1R was demonstrated in the DG probably involving the formation of GALR2-NPYY1R heteroreceptor complexes. These complexes were specifically observed in the polymorphic and subgranular subregions of the DG, where both receptors were found to colocalize. Moreover, this GALR2/NPYY1R interaction was linked to an enhancement of the antidepressive-like behavior mediated by NPYY1R in the forced swimming test. Specific cells populations within DG subregions may be involved in this behavioral effect since the coactivation of GALR2 and NPYY1R enhances the NPYY1R-mediated reduction in the number of c-Fos immunoreactive nuclei in the polymorphic region. These results indicate that GALR2/NPYY1R interactions can provide a novel integrative mechanism in DG in depression-related behavior and may give the basis for the development of drugs targeting GALR2/NPYY1R heteroreceptor complexes in the DG of the hippocampus for the treatment of depression.

Galanin (1-15) enhances the antidepressant effects of the 5-HT1A receptor agonist 8-OH-DPAT: involvement of the raphe-

hippocampal 5-HT neuron system.
Galanin N-terminal fragment (1-15) [GAL(1-15)] is associated with depression-related and anxiogenic-like effects in rats. In this study, we analyzed the ability of GAL(1-15) to modulate 5-HT1A receptors (5-HT1AR), a key receptor in depression. GAL(1-15) enhanced the antidepressant effects induced by the 5-HT1AR agonist 8-OH-DPAT in the forced swimming test. These effects were stronger than the ones induced by Galanin (GAL). This action involved interactions at receptor level since GAL(1-15) affected the binding characteristics and the mRNA levels of 5-HT1AR in the dorsal hippocampus and dorsal raphe. The involvement of the GALR2 was demonstrated with the GALR2 antagonist M871. Proximity ligation assay experiments indicated that 5-HT1AR are in close proximity with GALR1 and GALR2 in both regions and in raphe RN33B cells. The current results indicate that GAL(1-15) enhances the antidepressant effects induced by 8-OH-DPAT acting on 5-HT1AR operating as postjunctional or as autoreceptors. These results may give the basis for the development of drugs targeting potential GALR1-GALR2-5-HT1AR heteroreceptor complexes linked to the raphe-hippocampal 5-HT neurons for the treatment of depression.

Evidence for the existence of A2AR-TrkB heteroreceptor complexes in the dorsal hippocampus of the rat brain: Potential implications of A2AR and TrkB interplay upon ageing.
Adenosine A2A receptors (A2AR) are crucial in facilitating the BDNF action on synaptic transmission in the rat hippocampus primarily upon ageing. Furthermore, it has been suggested that A2AR-Tropomyosin related kinase B receptor (TrkB) crosstalk has a pivotal role in adenosine A2AR-mediated modulation of the BDNF action on hippocampal plasticity. Considering the impact of the above receptors interplay on what concerns BDNF-induced enhancement of synaptic transmission, gaining a better insight into the mechanisms behind this powerful crosstalk becomes of primary interest. Using in situ proximity ligation assay (PLA), the existence of a direct physical interaction between adenosine A2AR and TrkB is demonstrated. The A2AR-TrkB heteroreceptor complexes show a heterogeneous distribution within the rat dorsal hippocampus. High densities of the heteroreceptor complexes were observed in the pyramidal cell layers of CA1-CA3 regions and in the polymorphic layer of the dentate gyrus (DG). The stratum radiatum of the CA1-3 regions showed positive PLA signal in contrast to the oriens region. The molecular and granular layers of the DG also lacked significant densities of PLA positive heteroreceptor complexes, but subgranular zone showed some PLA positive cells. Their allosteric receptor-receptor interactions may significantly modulate BDNF signaling impacting on hippocampal plasticity which is impaired upon ageing.

Acute Cocaine Enhances Dopamine DR Recognition and Signaling and Counteracts DR Internalization in Sigma1R-DR Heteroreceptor Complexes.
The current study was performed to establish the actions of nanomolar concentrations of cocaine, not blocking the dopamine transporter, on dopamine D2 receptor (DR)-sigma 1 receptor (δ1R) heteroreceptor complexes and the DR protomer recognition, signaling and internalization in cellular models. We report the existence of DR-δ1R heteroreceptor complexes in subcortical limbic areas as well as the dorsal striatum, with different distribution patterns using the in situ proximity ligation assay. Also, through BRET, these heteromers were demonstrated in HEK293 cells. Furthermore, saturation binding assay demonstrated that in membrane preparations of HEK293 cells coexpressing DR and δ1R, cocaine (1 nM) significantly increased the DR B values over cells singly expressing DR. CREB reporter luc-gene assay indicated that coexpressed δ1R significantly reduced the potency of the DR-like agonist quinpirole to inhibit via DR activation the forskolin induced increase of the CREB signal. In contrast, the addition of 100 nM cocaine was found to markedly increase the quinpirole potency to inhibit the forskolin-induced increase of the CREB signal in the DR-δ1R cells. These events were associated with a marked reduction of cocaine-induced internalization of DR protomers in DR-δ1R heteromer-containing cells vs DR singly expressing cells as studied by means of confocal analysis of DR-δ1R trafficking and internalization. Overall, the formation of DR-δ1R heteromers enhanced the ability of cocaine to increase the DR protomer function associated with a marked reduction of its internalization. The existence of DR-δ1R heteromers opens up a new understanding of the acute actions of cocaine.

Galanin receptor/Neuropeptide Y receptor interactions in the dorsal raphe nucleus of the rat.
The aim of this study was to evaluate by quantitative receptor autoradiography the interactions between Neuropeptide Y Y1 (NPY Y1) and Galanin (GAL) receptors in the dorsal raphe nucleus (DRN) where both GAL receptors and NPY Y1 receptors exist. The ability of the GAL receptor antagonist M35 to block the GAL action was also evaluated. Double immunocytochemical staining of 5-hydroxytryptmine and c-Fos and stereology techniques were used to study the specific cell activation in the DRN after the intracerebroventricular coinjections of GAL and the NPY Y1/Y5 agonist [(125)I] Leu(31),Pro(34)PYY. GAL (0.3 nM) decreases [(125)I] Leu(31),Pro(34)PYY binding in the DRN by 48% ($p < 0.01$) as shown by quantitative receptor autoradiography. This effect was reversed with the GAL receptor antagonist M35. Intracerebroventricular coinjections of NPY Y1/Y5 agonist and GAL reduced the c-Fos expression in the serotoninergic cells induced by the NPY Y1/Y5 agonist in DRN. These results indicate the existence of antagonistic interactions between GAL receptors and NPY Y1 receptors in the DRN that may be of relevance in mood disorders.

Associative learning links predictive sensory stimuli from the environment with their outcomes. The accuracy of this learning will depend on reliable integration of sensory inputs that result in behavioural adaptations to ensure an animal's survival. Several cortical and limbic brain areas have been identified as sites for associative learning. However, the role of thalamic structures that relay sensory information is largely unknown. The medial geniculate body (MGB), or auditory thalamus, is a site of convergence for auditory as well as somatosensory information and is crucial for associative learning (e.g. in fear conditioning). It receives feedforward sensory as well as neuromodulatory inputs. One prominent neuromodulatory cholinergic input to MGB originates in the pedunculopontine tegmental nucleus (PPT). However, the role of brainstem cholinergic inputs to MGB during associative learning remains elusive. Here, we use a combination of deep brain calcium imaging techniques such as fibre photometry and miniaturized microscopes combined with optogenetics to unravel the functional role of cholinergic projections in MGB during associative fear learning in freely moving mice. We found that optogenetic manipulation of cholinergic PPT inputs in MGB during fear acquisition affects learning. Furthermore, we show that cholinergic projections from the brainstem modulate sensory responses of MGB neurons during fear conditioning. This study identifies the role of brainstem cholinergic inputs in multimodal sensory integration during fear conditioning in MGB, which broadens our view on how neuromodulators contribute to associative learning in thalamic areas.

To be able to remember past experiences, we need to use two types of memory: one that will allow the “reconstruction” of the memory from sometimes partial information (pattern completion), one that will allow the discrimination of one memory from a very similar one (pattern separation). Pattern separation (PS) and pattern completion (PC) rely on a key brain structure of episodic memory, the hippocampus. Mechanistically, PS and PC are supported by a hippocampal circuit: the dentate gyrus (DG) and the CA3. Using a conditional knockout, we previously showed that the core Planar Cell Polarity (PCP) protein Vangl2 participate in these processes (Robert et al., 2020). We showed that a specific postnatal deletion of Vangl2 in the DG, impairs the PC and improves the PS processes. In order to bypass the need for Vangl2 deletion and modulate PCP signalling with spatio-temporal resolution, our team developed a molecular construct in order to block PCP signalling, without affecting Vangl2 levels. We injected the virus in the hippocampus of adult animal before testing the mice in PS and PC protocols. For this, we used an innovating and non-aversive technology, called the touchscreen chamber. Our preliminary results show an improvement in the discrimination memory test in the mice model for PCP disruption, supporting our team’s previous results.
Key-words: Hippocampus, PCP, behaviour, touchscreen, pattern separation/completion, DG/CA3 circuit

DISSOCIATING OBJECT VERSUS SPATIAL PATTERN SEPARATION: FROM BEHAVIOR TO NEURONAL CIRCUIT

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Marie Oulé[1], Mark Brandon[2]
[1]Douglas Hospital Research Center - McGill University, Psychiatry, Montreal, Canada, [2]Douglas Hospital Research Center, McGill University, Psychiatry, Montréal, Canada

Convergent behavioral, physiological, and anatomical observations have led to the hypothesis that the dentate gyrus (DG) of the hippocampus is especially sensitive to small changes in input, making it particularly important when encoding highly similar stimuli, a process named ‘pattern separation’. The entorhinal cortex (EC) is the main source of cortical inputs to the DG: while its medial segment (MEC) preferentially forwards spatial information, its lateral part (LEC) rather sends object-related information. Reelin-positive cells, located in the layer II EC, send direct projections onto granule cell dendrites, DG’s largest excitatory population. Nevertheless, how the EC-DG circuit defined by these two cell types participates to object and spatial pattern separation remains largely elusive. To address this question, we use comparable behavioral paradigms to assess object and spatial pattern separation in mice combined with immunohistological detection of cfos protein, a proxy of neuronal activation. Preliminary results show greater activation of the DG when spatial - but not object - pattern separation is required. On the other hand, object pattern separation seems to activate layer II cells in the LEC. Thanks to selective viral delivery of inhibitory DREADD receptors in sim1-cre mice – a mouse line that specifically allows manipulating reelin cells in the EC – we will further seek to determine whether inhibition of MEC or LEC reelin-positive neurons is associated with a deficit in spatial (MEC-DG) and object (LEC-DG) pattern separation.

COGNITIVE DEFICITS IN MOUSE MODEL OF FRAGILE X SYNDROME REFLECT SPECIFIC MEMORY ENSEMBLE RECRUITMENT FAILURE ALONG THE VENTRAL HIPPOCAMPUS-PRELIMBIC CORTEX AXIS

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Komal Bhandari, Pico Caroni
Friedrich Miescher Institute of Biomedical Research, Neuroscience, Basel, Switzerland

Fragile X Syndrome (FXS) is the most common form of intellectual disability and a leading monogenic cause of autism spectrum disorder (ASD). The protein whose expression is lost in FXS (FMRP) is expressed ubiquitously in the brain, where it has important roles for synaptic function and plasticity. Whether the defects in FXS, and their potential therapeutic alleviation, reflect ubiquitous loss of function or deficits specific to particular brain circuits has remained unclear. Here we show using brain area specific conditional knockout of FMRP (cKO) in principal neurons, that area-specific loss in adult wildtype (WT) mice behaviorally mimics acute silencing of the same area. However, in Fmr1(y/-) mice despite the ubiquitous absence of FMRP, behavioral and immediate early gene (IEG) expression analyses, revealed that cognitive functions of most brain areas were unaffected by the absence of FMRP, with the exception of ventral Hippocampus (vH) and Prelimbic cortex (PreL). Using conditional restoration of FMRP in Fmr1(y/-), we found that the specific behavioral deficits of Fmr1(y/-) mice can entirely be accounted for by absence of FMRP in a vH-PreL axis. Mechanistic investigations revealed that despite of apparently normal re-expression of cFos at recall in vH neurons of Fmr1(y/-) mice, vH cFos+ ensemble recruitment was insufficient for cognitive function.

Parvalbumin Interneuron Plasticity for Consolidation of Reinforced Learning.
Parvalbumin (PV) basket cells are widespread local interneurons that inhibit principal neurons and each other through perisomatic boutons. They enhance network function and regulate local ensemble activities, particularly in the γ range. Organized network activity is critically important for long-term memory consolidation during a late time window 11-15 h after acquisition. Here, we discuss the role of learning-related plasticity in PV neurons for long-term memory consolidation. The plasticity can lead to enhanced (high-PV) or reduced (low-PV) expression of PV/GAD67. High-PV plasticity is induced upon definite reinforced learning in early-born PV basket cells, whereas low-PV plasticity is induced upon provisional reinforced learning in late-born PV basket cells. The plasticity is first detectable 6 h after acquisition, at the end of a time window for memory specification through experience, and is critically important 11-15 h after acquisition for enhanced network activity and long-term memory consolidation. High- and low-PV plasticity appear to regulate activity in distinct local networks of principal neurons and PV basket cells. These findings suggest how flexibility and stability in learning and memory might be implemented through parallel circuits and networks.

Memory consolidation at systems level refers to the process by which a recently encoded memory trace is transformed into a persistent one. This process requires a hippocampo-cortical dialog. The midline thalamic nuclei, the reuniens and rhomboid (ReRh), and their bidirectional connections with the hippocampus and medial prefrontal cortex holds a key position to regulate these cortico-hippocampal interactions. We previously demonstrated their role in contextuel memory persistence, after permanent fiber-sparing ReRh lesion (Quet et al., 2020). We have also shown that the ReRh nuclei are not required for retrieval process of such memory. Based on the idea that interactions crucial for systemic memory consolidation might also be engaged during information encoding, we asked if the ReRh nuclei are necessary for encoding contextual information. We used a chemogenetic ReRh inhibition (DREADD) performed before encoding a context in a fear-conditioning memory task. We found that pre-encoding ReRh inactivation had no impact on contextual fear conditioning, although DREADD silencing altered a strategy-shifting task sensitive to the disruption of ReRh function. The data suggest that ReRh nuclei do not play a crucial role in processing contextual information, what challenges recent data pointing to their possible contribution to contextual encoding.

COMMUNICATION BETWEEN THE NUCLEUS INCERTUS AND THE MEDIAL SEPTUM AND THE ENTORHINAL CORTEX

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Isis Gil-Miravet, Mónica Navarro Sánchez, Aroa Mañas-Ojeda, Clara García-Mompó, Francisco Olucha-Bordonau
Universitat Jaume I, Unitat Predepartamental De Medicina, Castelló de la Plana, Spain

The nucleus incertus (NI) in the pontine tegmentum contains the largest population of neurons that produce and release the neuropeptide Relaxin3. The NI is involved in different cognitive processes such as memory and learning, mediated by the medial septum, hippocampus, and entorhinal cortex. A portion of these connections are mediated by Relaxin3 and its receptor RXFP3. This work aims to analyse is collateralization of the projections from the NI to the medial septum and/or the medial entorhinal cortex. Combinations of the retrograde tracers FluoroGold (FG) and cholera toxin subunit B (CTB) injected in the medial septum (MS) or medial entorhinal cortex (MEnt) and lateral entorhinal cortex (LEnt) with immunofluorescence to relaxin3. After surgeries, the number of Relaxin3 positive neurons projecting from the NI to each of these nuclei was recorded. Retrograde tracer injections placed in the medial and lateral entorhinal cortex produced prominent retrograde labelling in the ipsilateral NI and some labelling in the contralateral NI. Moreover, the projections from the NI to the MS were twice as numerous as to the entorhinal. Most of NI neurons projects independently to the medial septum or entorhinal cortex. In addition, we observed that approximately a 21% of the NI-MS, 28% of NI-MEnt and 37% of NI-LEnt projections were Relaxin3 positive. These results show the importance of the Relaxin3-NI projections over the medial septum and entorhinal cortex.

Involvement of the and Relaxin-3/RXFP3 Signaling System in Explicit and Implicit Memory.
Telencephalic cognitive and emotional circuits/functions are strongly modulated by subcortical inputs. The main focus of past research on the nature of this modulation has been on the widespread monoamine projections to the telencephalon. However, the (NI) of the pontine tegmentum provides a strong GABAergic and peptidergic innervation of the hippocampus, basal forebrain, amygdala, prefrontal cortex, and related regions; and represents a parallel source of ascending modulation of cognitive and emotional domains. NI GABAergic neurons express multiple peptides, including neuromedin-B, cholecystokinin, and relaxin-3, and receptors for stress and arousal transmitters, including corticotrophin-releasing factor and orexins/hypocretins. A functional relationship exists between NI neurons and their associated peptides, relaxin-3 and neuromedin-B, and hippocampal theta rhythm, which in turn, has a key role in the acquisition and extinction of declarative and emotional memories. Furthermore, RXFP3, the cognate receptor for relaxin-3, is a G protein-coupled receptor, and its activation inhibits the cellular accumulation of cAMP and induces phosphorylation of ERK, processes associated with memory formation in the hippocampus and amygdala. Therefore, this review summarizes the role of NI transmitter systems in relaying stress- and arousal-related signals to the higher neural circuits and processes associated with memory formation and retrieval.

Mammals show remarkable flexibility of behaviors, and have the ability to abstract specific rules and learning sets into generalized low dimensional structures that can be applied in new conditions. Recent work suggests that this generalization could take place in parahippocampal regions, in particular in the entorhinal cortex (EC). Here, the medial part (MEC) seems to extract the structure of state space irrespective of modality (e.g. spatial or sound). The lateral part (LEC) receives input about complex features of objects and multimodal sensory information from association cortices, including the postrhinal cortex (POR). This puts the EC in a unique position to function as an integration center for higher order representations. To investigate the role of the entorhinal cortex in abstracting and generalizing task content, we have established a set of simple association tasks for mice that enable both rule switching and change of sensory modality. We train mice in these tasks over multiple sessions and record large neuronal populations in the EC during and after training using two-photon imaging. To this end, we utilize custom right-angle prism assemblies that cover either the MEC, or POR and LEC. We hypothesize that both MEC and LEC will display learning-induced changes in the low dimensional neural representations over time, with consistent structures that are used and transferred across different tasks. Our preliminary data from mice trained in a visual association task indicate that neurons in both regions develop representations of task structure with training.

NEURAL ENSEMBLE DYNAMICS OF AUDITORY THALAMUS UPON SENSORY LEARNING

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Masashi Hasegawa[1,2], Ziyan Huang[2], Jan Gründemann[1,2]
[1]Universität Basel, Department Of Biomedicine, Basel, Switzerland, [2]Deutsches Zentrum für Neurodegenerative Erkrankungen (DZNE), Neural Circuit Computations, Bonn, Germany

Sensory cortices receive and process feedforward uni- and multisensory information from the thalamus to guide perception and behaviours. However, so far, the neural coding strategies of sensory thalamic nuclei that precede cortex remain poorly understood on both, the single cell as well as the population level. Here, we established a gradient refractive index (GRIN) lens-based in vivo two-photon calcium imaging approach to monitor the activity of large populations of individual neurons in auditory thalamus (medial geniculate body, MGB) in awake mice during a sensory learning paradigm. Using a go/no-go task where the animals associated auditory or visual stimuli with a reward, we followed the same cells across weeks and identified distinct ensembles of MGB neurons that differentially encode the reward-contingency of the sensory stimuli as well as task-features. We found distinct classes of auditory thalamus neurons that exhibit plasticity to the go or no-go stimuli, both dependent or independent of the sensory modality. Additionally, we found a class of neurons that predicts the stimulus outcome by ramping their activity during the go stimulus and exhibit persistent calcium responses during the delay period preceding the reward, which may maintain the stimulus information and instruct the reward-related action. Our findings support the view that sensory thalamic nuclei are more than a mere sensory relay and contribute actively to the systemwide computation of cognitive processes in a bottom-up fashion.

A volumetric analysis of the brain and hippocampus of rats rendered perinatal hypothyroid.
The thyroid hormone is essential for the proper development of the central nervous system (CNS). Hormone deficiency during CNS development causes neurological abnormalities in the brain. The hippocampus is one of the brain regions vulnerable to hormone deficiency, and the volume of dentate gyrus (DG) and cornu ammonis (CA) are reduced by transient hypothyroidism during CNS development. However, it remains unclear whether transient hypothyroidism specifically reduces the whole hippocampal volume. In the present study, we used magnetic resonance imaging (MRI) to examine the effects of perinatal hypothyroidism on the ratio of hippocampal volume to brain volume as well as brain and hippocampal volumes overall. Perinatal hypothyroidism was induced by adding the anti-thyroid drug, methimazole, to the drinking water of pregnant dams from gestational day 15 to postnatal day 21. The MRI experiment was conducted when the rats were between 7 and 11 months old. The results showed reductions of the hippocampal and brain volume of the treated group. However, the ratio of hippocampal volume to brain volume was comparable between the control and treated groups. These results indicate that perinatal hypothyroidism minimizes the brain as a whole, but does not minimize the hippocampus in particular.

Developmental hypothyroidism disrupts visual signal detection performance in rats.
Thyroid hormones (THs) are essential for proper brain development in mammals. TH insufficiency during early development causes structural and functional abnormalities in brain leading to cognitive dysfunction. The specific effects of developmental hypothyroidism on attention have not been well characterized in animal models. The present study was conducted to characterize the effects of developmental hypothyroidism on attention in rats, and tested the hypothesis that the hypothyroidism has adverse impacts on attention by means of a visual signal detection task. Pregnant rats were exposed to the anti-thyroid drug, methimazole (0.02% w/v) via drinking water from gestational day 15 through postnatal day (PND) 21 to induce maternal and neonatal hypothyroidism. Male offspring served as subjects for the task started on PND 90. A light stimulus (500 ms, 250 ms or 50 ms) was presented in signal trials and not in blank trials. The offspring were required to discriminate these signal events, and subsequently press the correct lever. The correct response for signal and non-signal events was considered as hit and correct rejection, respectively. The hypothyroid offspring exhibited a decreased hit response for short signals (250 ms and 50 ms) which requires the higher attentional demand. The total number of lever

responses during inter-trial interval (ITI) was also increased in the hypothyroid group. The number of lever responses was negatively correlated with a hit response at 50 ms, not at 250 ms. These results suggest that developmental hypothyroidism disrupts signal detection performance via impairment of visual attention and the altered lever response behavior.

Thermoregulatory deficits in adult Long Evans rat exposed perinatally to the antithyroidal drug, propylthiouracil.
Developmental exposure to endocrine disrupting drugs and environmental toxicants has been shown to alter a variety of physiological processes in mature offspring. Body (core) temperature (T(c)) is a tightly regulated homeostatic system but is susceptible to disruptors of the hypothalamic pituitary thyroid (HPT) axis. We hypothesized that thermoregulation would be disrupted in adult offspring exposed perinatally to an HPT disruptor. Propylythiouracil (PTU) was used as a prototypical compound because of its well known antithyroidal properties. PTU was added to the drinking water of pregnant rats in concentrations of 0, 1, 2, 3, and 10 ppm from gestational day (GD) 6 through postnatal day (PND) 21. Adult male offspring were implanted with radiotransmitters to monitor Tc and motor activity (MA) and were observed undisturbed at an ambient temperature of 22 °C for 12 consecutive days. Data were averaged into a single 24 hour period to minimize impact of ultradian changes in T(c) and MA. All treatment groups showed a distinct circadian temperature rhythm. Rats exposed to 10 ppm PTU exhibited a marked deviation in their regulated T(c) with a reduction of approximately 0.4 °C below that of controls throughout the daytime period and a smaller reduction at night. Rats exposed to 1 or 2 ppm also had smaller but significant reductions in T(c). MA was unaffected by PTU. Overall, developmental exposure to moderate doses of an antithyroidal drug led to an apparent permanent reduction in T(c) of adult offspring that was independent of changes in MA.

Sleep-Stage-Specific Regulation of Cortical Excitation and Inhibition.
Sleep is characterized by unique patterns of cortical activity alternating between the stages of slow-wave sleep (SWS) and rapid-eye movement (REM) sleep. How these patterns relate to the balanced activity of excitatory pyramidal cells and inhibitory interneurons in cortical circuits is unknown. We investigated cortical network activity during wakefulness, SWS, and REM sleep globally and locally using in vivo calcium imaging in mice. Wide-field imaging revealed a reduction in pyramidal cell activity during SWS compared with wakefulness and, unexpectedly, a further profound reduction in activity during REM sleep. Two-photon imaging on local circuits showed that this suppression of activity during REM sleep was accompanied by activation of parvalbumin (PV)+ interneurons, but not of somatostatin (SOM)+ interneurons. PV+ interneurons most active during wakefulness were also most active during REM sleep. Our results reveal a sleep-stage-specific regulation of the cortical excitation/inhibition balance, with PV+ interneurons conveying maximum inhibition during REM sleep, which might help shape memories in these networks.

Selective Suppression of Local Circuits during Movement Preparation in the Mouse Motor Cortex.
Prepared movements are more efficient than those that are not prepared for. Although changes in cortical activity have been observed prior to a forthcoming action, the circuits involved in motor preparation remain unclear. Here, we use in vivo two-photon calcium imaging to uncover changes in the motor cortex during variable waiting periods prior to a forepaw reaching task in mice. Consistent with previous reports, we observed a subset of neurons with increased activity during the waiting period; however, these neurons did not account for the degree of preparation as defined by reaction time (RT). Instead, the suppression of activity of distinct neurons in the same cortical area better accounts for RT. This suppression of neural activity resulted in a distinct and reproducible pattern when mice were well prepared. Thus, the selective suppression of network activity in the motor cortex may be a key feature of prepared movements.

Streamlined sensory motor communication through cortical reciprocal connectivity in a visually guided eye movement task.
Cortical computation is distributed across multiple areas of the cortex by networks of reciprocal connectivity. However, how such connectivity contributes to the communication between the connected areas is not clear. In this study, we examine the communication between sensory and motor cortices. We develop an eye movement task in mice and combine it with optogenetic suppression and two-photon calcium imaging techniques. We identify a small region in the secondary motor cortex (MO) that controls eye movements and reciprocally connects with a rostrolateral part of the higher visual areas (V). These two regions encode both motor signals and visual information; however, the information flow between the regions depends on the direction of the connectivity: motor information is conveyed preferentially from the MO to the V, and sensory information is transferred primarily in the opposite direction. We propose that reciprocal connectivity streamlines information

flow, enhancing the computational capacity of a distributed network.

Single cell plasticity and population coding stability in auditory thalamus upon associative learning.
Cortical and limbic brain areas are regarded as centres for learning. However, how thalamic sensory relays participate in plasticity upon associative learning, yet support stable long-term sensory coding remains unknown. Using a miniature microscope imaging approach, we monitor the activity of populations of auditory thalamus (medial geniculate body) neurons in freely moving mice upon fear conditioning. We find that single cells exhibit mixed selectivity and heterogeneous plasticity patterns to auditory and aversive stimuli upon learning, which is conserved in amygdala-projecting medial geniculate body neurons. Activity in auditory thalamus to amygdala-projecting neurons stabilizes single cell plasticity in the total medial geniculate body population and is necessary for fear memory consolidation. In contrast to individual cells, population level encoding of auditory stimuli remained stable across days. Our data identifies auditory thalamus as a site for complex neuronal plasticity in fear learning upstream of the amygdala that is in an ideal position to drive plasticity in cortical and limbic brain areas. These findings suggest that medial geniculate body's role goes beyond a sole relay function by balancing experience-dependent, diverse single cell plasticity with consistent ensemble level representations of the sensory environment to support stable auditory perception with minimal affective bias.

PLASTICITY OF AMYGDALA INTERNEURONS IN ASSOCIATIVE LEARNING

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Jessica Capece Marsico[1], Natalia Favila[1], Yael Bitterman[2], Jan Gründemann[3,4], Andreas Lüthi[2], Sabine Krabbe[1]
[1]DZNE, Functional Diversity Of Neural Circuits, Bonn, Germany, [2]Friedrich Miescher Institute for Biomedical Research, Neurobiology, Basel, Switzerland, [3]DZNE, Neural Circuit Computations, Bonn, Germany, [4]Universität Basel, Department Of Biomedicine, Basel, Switzerland

The basolateral amygdala (BLA) is a cortex-like structure known to be involved in simple forms of emotional learning such as fear conditioning. It is the main entry site for sensory information to the amygdala complex, and local plasticity in the BLA is crucial for associative memory formation. Plastic changes of glutamatergic projection neurons (PNs) induced during learning have been well characterized, while little is known about the contribution of GABAergic interneurons. Although inhibitory interneurons only constitute about 20% of the neuronal population in the BLA, they tightly control PN activity and plasticity. Nonetheless, the behavioral relevance of different interneuron subtypes and their plasticity upon learning remain largely unexplored. Thus, the present study aimed to assess how the activity of local interneurons in the BLA is modulated across fear conditioning and extinction. To address this, we performed deep-brain calcium imaging with miniature microscopes in freely behaving mice during an associative fear learning paradigm. We selectively targeted discrete interneuron subtypes by injecting a cre-dependent GCaMP6 into the BLA of VIP-Cre, SST-Cre, or PV-Cre mice, followed by an implantation of a gradient-index (GRIN) lens. Following the same neuronal populations across days, we found that interneuron subtypes show diverse activity patterns during the conditioning paradigm, with distinct plastic responses upon fear and extinction learning. Overall, our results suggest that BLA inhibitory interneuron plasticity can contribute to the acquisition and expression of associative fear memories.

NEURAL CORRELATES AND MODULATION OF THREAT PREDICTION IN AUDITORY THALAMUS UPON ASSOCIATE FEAR LEARNING.

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

James Alexander Taylor[1], Joana Amorim Freire[1], Masashi Hasegawa[1,2], Benay Baskurt[2], Jan Gründemann[1,2]
[1]University of Basel, Department Of Biomedicine, Basel, Switzerland, [2]Deutsches Zentrum für Neurodegenerative Erkrankungen (DZNE), Neural Circuit Computations, Bonn, Germany

The medial geniculate body (MGB) is the thalamus' key hub for auditory transmission and processing. Besides feedforward relay of sensory information, it has been shown that MGB neurons exhibit response plasticity to reward- or threat-predicting conditioned tones (CS+) across learning. Here, we use a miniature microscope-based deep brain imaging approach in freely moving mice to track the dynamics of foot shock (US) predicting CS+ tone responses upon auditory fear conditioning. We identified a subtype of CS+ responsive neurons, which exhibit ramping calcium response throughout the shock-predicting 30 second CS+ period. These CS+ ramp-up cells were not present during habituation and their proportion increased with consecutive CS+ - US pairings during conditioning. Vice versa, the proportion of ramp-up cells decreased with advancing reduction of the animals' CS+-driven freezing response during extinction sessions following fear conditioning. Furthermore, the magnitude of the calcium signal of ramp-up cells was correlated with the vigor of the US-driven escape behavior of the animal suggesting that ramp-up cells are predictive of the unconditioned behavioral response. Finally, we found that optogenetic manipulation of brainstem-originating cholinergic inputs to MGB leads to a reduction in the proportion of ramp-up cells, suggesting that the response plasticity of ramp-up cells is controlled by acetylcholine. Overall, this study identified a subtype of MGB neurons that are predictive of the behavioral response to an upcoming threat and may play a key role in associative fear learning.

POPULATION LEVEL CODING OF SENSORY REPRESENTATIONS AND TASK FEATURES IN AUDITORY THALAMUS

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Ziyan Huang[1], Masashi Hasegawa[1,2], Jan Gründemann[1,2]
[1]Deutsches Zentrum für Neurodegenerative Erkrankungen (DZNE), Neural Circuit Computations, Bonn, Germany, [2]Universität Basel, Department Of Biomedicine, Basel, Switzerland

Primary sensory areas are crucial for the computations of sensory representations, learning and cognition, while the role of their bottom-up inputs from thalamic areas remains less well understood. Here, we use a gradient refractive index (GRIN) lens-based in vivo two-photon calcium imaging approach to monitor the activity of large populations of individual neurons in auditory thalamus (medial geniculate body, MGB) in awake mice longitudinally during a sensory mapping and go/no-go learning paradigm. Using a cluster analysis approach, we found that pure tone frequency tuning of groups of MGB neurons is plastic across learning. During learning, we found an increase in trial-by-trial population vector correlations during the pre-reward delay period following the go-stimulus in expert animals, while correlations of the sensory period remained unchanged. This indicates that auditory thalamus encodes task-outcomes during a preparatory period by more consistent population-level representations further supporting thalamus' role in learning upon complex behaviours.

[1]University of Zürich, Institute of Anatomy, Division Of Functional Neuroanatomy, Zurich, Switzerland, [2]University of Zürich, Institute of Anatomy, Division of Functional Neuroanatomy, Eth Zürich, Department Of Health Sciences And Technology, Zürich, Switzerland, [3]Natural History Museum, Natural History Museum, St.Gallen, Switzerland, [4]Pasteur Institute of Novi Sad, Department Of Microbiology, Novi Sad, Serbia

A reflected blade (RB) of CA3 is present in many species, including humans, but not in laboratory rats or mice. Distinguishing the RB from typical CA3, RB neuron may extend their dendrites into the dentate molecular layer or may not receive entorhinal inputs in some species. Direct evidence for RB function is absent, but, extrapolating from rodent CA3c, they are more likely to function with dentate neurons in pattern separation rather than with CA3 in pattern completion. We have shown before that the size of CA3 and hilar cell populations (including RB neurons) differentiate between taxonomic groups. In this study, we investigated three issues related to the RB in nine species in which RB cells and hilar polymorphic cells could be reliably distinguished: rock mouse, guinea pig, rabbit, hare, jackal, sheep, wild boar, roe deer and red deer. (1) we describe the histoarchitecture of the RB, and (2) the distribution of the Ca-binding proteins. (3) We answer how the assignment of the RB neuron population to CA3 or hilus impacts on taxonomic assessment. Our results show that (1) there are prominent RB septotemporal differences, (2) calretinin does not reliably distinguish between RB and hilar polymorphic cells, but, in some species between CA3 and the RB and (3) that the pooling RB and hilus results in a strong species differentiation, while assigning the RB to CA3 leads to clustering of all species that include humans.

DENTATE GYRUS OF THE VENTRAL HIPPOCAMPUS UNDER CONTROL OF BRAINSTEM NUCLEUS INCERTUS - ELECTROPHYSIOLOGICAL, ANATOMICAL AND NEUROCHEMICAL STUDIES IN RAT

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Aleksandra Trenk[1], Kinga Przybylska[1], Anna Gugula[1], Sylwia Drabik[1], Magdalena Walczak[1], Angelika Kaleta[1], Akhter Hossain[2], Andrew Gundlach[2], Anna Blasiak[1]
[1]Institute of Zoology and Biomedical Research, Jagiellonian University, Department Of Neurophysiology And Chronobiology, Krakow, Poland, [2]The University of Melbourne, The Florey Institute Of Neuroscience And Mental Health, Parkville, Australia

The ventral hippocampus (vHPC), a key region involved in processing emotional information, is heavily innervated by the brainstem *nucleus incertus* (NI). NI neurons are the main source of the neuropeptide relaxin-3 (RLN3) and activation of the relaxin-3 receptor, RXFP3, in vHPC promotes anxiety and social avoidance. However, little is known about the neuronal mechanisms underlying NI-vHPC interactions. Therefore, the aims of these studies were to map the distribution of NI originating fibres within vHPC, define the neurochemical nature of vHPC cells expressing RXFP3 mRNA, and verify the influence of the RXFP3 agonist, A2, on vHPC neuronal activity. Viral-based, neural tract-tracing revealed a high density of NI-originating fibres within the polymorph layer of the dentate gyrus (DG) with the majority RLN3-positive. Using fluorescent multiplex *in situ* hybridization we demonstrated that a majority of vGAT1 mRNA-positive cells in vHPC GC express RXFP3-mRNA. Finally, using *ex vivo* multielectrode array recordings we demonstrated that specific RXFP3 activation (A2, 1 µM), exerted both inhibitory and excitatory effects on vHPC network activity, and that D2-receptor agonist sensitive, vHPC mossy cells are both directly and indirectly sensitive to A2. These findings indicate that NI influences information processing in the vHPC by modulation of DG neuronal activity, and this (mostly inhibitory) influence may underlie the observed increase in anxiety behaviour and social avoidance upon chronic RXFP3 activation in vHPC. Further studies are needed to verify the influence of NI/RLN3 signalling in vHPC on specific DG cell types, and its possible impact on DG-dependent pattern separation. Funding: UMO-2018/30/E/NZ4/00687.

Bidirectional Communication between the Pontine Nucleus Incertus and the Medial Septum Is Carried Out by Electrophysiologically-Distinct Neuronal Populations.
Theta oscillations are key brain rhythm involved in memory formation, sensorimotor integration, and control of locomotion and behavioral states. Generation and spatiotemporal synchronization of theta oscillations rely on interactions between brain nuclei forming a large neural network, which includes pontine nucleus incertus (NI). Here we identified distinct populations of NI neurons, based on the relationship of their firing to hippocampal waves, with a special focus on theta oscillations, and the direction and type of interaction with the medial septum (MS) in male, urethane-anesthetized rats. By recording NI neuronal firing and hippocampal LFP, we described NI neurons that fire action potentials in a theta phase-independent or theta phase-locked and delta wave-independent or delta wave-locked manner. Among hippocampal activity-independent NI neurons, irregular, slow-firing, and regular, fast-firing cells were observed, while hippocampal oscillation-/wave-locked NI neurons were of a bursting or nonbursting type. By projection-specific optotagging, we revealed that only fast-firing theta phase-independent NI neurons innervate the MS, rarely receiving feedback information. In contrast, the majority of theta-bursting NI neurons were inhibited by MS stimulation, and this effect was mediated by direct GABAergic input. Described NI neuronal populations differ in reciprocal connections with the septohippocampal system, plausibly forming separate neuronal loops. Our results suggest that theta phase-independent NI neurons participate in theta rhythm generation through direct innervation of the MS, while theta-bursting NI neurons further transmit the rhythmic signal received from the MS to stabilize and/or strengthen rhythmic activity in other structures. The generation and spatiotemporal synchronization of theta oscillations rely on interactions between nuclei forming a large neural network, part of which is the pontine nucleus incertus (NI). Here we describe that within NI there are populations of neurons that can be distinguished based on the relationship of their firing to hippocampal theta oscillations and delta waves. We show that these neuronal populations largely do not have reciprocal connections with the septohippocampal system, but form separate neuronal loops. Our results suggest that medial septum (MS)-projecting, fast-firing, theta phase-independent NI neurons may participate in theta rhythm generation through direct

innervation of the MS, while theta-bursting NI neurons may further transmit the rhythmic signal received from the MS to other structures.

Several behavioral traits relevant for alcoholism are controlled by γ2 subunit containing GABA receptors on dopamine neurons in mice.
The risk factors for developing alcohol addiction include impulsivity, high sensitivity to the rewarding action of ethanol, and low sensitivity to its sedative and intoxicating effects. Genetic variation in GABA receptor subunits, including the γ2 subunit (Gabrg2), affects the risk for developing alcoholism. Alcohol directly potentiates GABA receptors and activates the mesolimbic dopamine system. Here, we deleted Gabrg2 selectively in dopamine cells of adult mice. The deletion resulted in elevated firing of dopamine neurons and made them less sensitive to drugs acting at GABA receptors. At the behavioral level, the deletion increased exploratory behavior and augmented both correct and incorrect responding in the go/no-go task, a test often used to assay the response inhibition component of impulsivity. In addition, conditioned place preference to alcohol, but not to cocaine or morphine, was increased. Ethanol-induced locomotor activation was enhanced in the mice lacking Gabrg2 on dopaminergic cells, whereas the sedative effect of alcohol was reduced. Finally, the alcohol drinking, but not the alcohol preference, at a high concentration was increased in the mutant mice. In summary, deletion of Gabrg2 on dopamine cells induced several behavioral traits associated with high risk of developing alcoholism. The findings suggest that mice lacking Gabrg2 on dopaminergic cells could be used as models for individuals at high risk for developing alcoholism and that GABA receptors on dopamine cells are protective against the development of excessive alcohol drinking.

Imipramine ameliorates early life stress-induced alterations in synaptic plasticity in the rat lateral amygdala.
Long-term potentiation (LTP) and long-term depression (LTD) are two opposite forms of synaptic plasticity at the cortical and thalamic inputs to the lateral amygdala (LA). It has been demonstrated that maternal separation (MS) of rat pups results in alterations in the potential for both pathways to undergo LTP and LTD in adolescence. Imipramine, a prototypic tricyclic antidepressant, has been shown to counteract some detrimental effects of MS on rat behavior, however it is not known whether MS-induced alterations in the potential for bidirectional synaptic plasticity in the LA could be reversed by imipramine treatment. To this end, rat pups were subjected to MS (3h/day) on postnatal days (PNDs) 1-21. On each of PNDs 29-42, male rats previously subjected to MS were injected subcutaneously with imipramine (10mg/kg). Field potentials were recorded ex vivo from slices containing the LA and saturating levels of LTP and LTD were induced. At the thalamic input to the LA, both the maximum LTP and the maximum LTD were reduced in rats subjected to MS when compared to control animals, confirming earlier results. However, these effects were no longer present in rats subjected to MS and later treated with imipramine. At the cortical input in slices prepared from MS-subjected rats, an impairment of the maximum LTP and an enhancement of the maximum LTD were observed. At the cortical input in rats subjected to MS and receiving imipramine treatment, the level of LTD was comparable to control but imipramine did not restore the potential for LTP at this input. These results demonstrate that imipramine fully reverses the effects of MS in the thalamo-amygdalar pathway, however, in the cortico-amygdalar pathway the reversal of the effects of MS by imipramine is partial.

Transition from the juvenile to the adult brain coincides with maturation of parvalbumin expressing (PV+) inhibitory neurons, and assembly of perineuronal nets (PNNs).The PNNs are specialized extracellular matrix structures that reduce neural plasticity. Aggrecan is a major component of PNNs, and adult knock-out of aggrecan reactivates juvenile plasticity, but the mechanisms by which aggrecan regulates PV+ neurons and network function are not understood. To this end, we have generated a PV+ specific germline aggrecan knock-out (AcanKO), by crossing the PV-Cre mice strain with Acan-flex mice. In a separate group of adult Acan-flex mice, we systemically inject a viral vector that expresses Cre under control of a PV enhancer. We show that without expression of aggrecan, PNNs do not assemble. In behavioral testing, AcanKO mice showed lower levels of anxiety-like behavior compared to controls, in both standardized anxiety tests and the Morris water maze. Notably, electrophysiological properties of PV+ interneurons in visual cortex (V1) of adult AcanKO mice were similar to controls *in vitro*, and neither spontaneous nor visually evoked network activity in V1 revealed significant differences between AcanKOs and controls *in vivo*. In ongoing work, we are testing expression levels of PNN components in adult AcanKO mice. In summary, our data shows that PV+ neurons produce aggrecan that is necessary for correct formation of PNNs during the transition from juvenile to adult. Germline knock-out of aggrecan led to minor phenotypic effects compared to adult knock-out, suggesting compensatory mechanisms. The nature of these mechanisms will be the focus of future work.

Behavior-related neural dynamics in the frontal cortex is an emergent property of network connectivity. The network structure at the level of individual neurons, and its relationship to neural coding are largely unknown. Here we developed an optical method for *rapid* (500k pairwise connections / 30 minutes) mapping of effective connectivity *in vivo*. This method is based on 2-photon optogenetic stimulation of individual excitatory neurons and simultaneous 2-photon volumetric calcium imaging of evoked responses in non-stimulated neurons ('effective connection'). We applied this method in anterior lateral motor cortex (ALM) in a novel behavioral task in which untrained mice performed multidirectional tongue-reaching for water rewards presented at multiple (up to 16) locations on a grid in front of the mouse face. A majority of ALM neurons were modulated by task variables with a subset of neurons (~25%) exhibited strong tuning to the reward location. Specifically, some neurons showed tuning to direction of the reward location with respect to the mouse face, whereas other neurons were selective for particular reward locations. We then mapped effective connectivity between 10,000,000 pairs of layer 2/3 neurons imaged in this task. Nearby neurons were more strongly connected and shared directional selectivity, revealing a fine-scale columnar architecture. By analyzing connectivity patterns with methods borrowed from network science, we discovered neurons that function as network hubs. Hub neurons had an unexpectedly high number of connections, weak directional tuning, and strong influence on neighboring neurons – suggesting that they may act as local conductors of the neural orchestra.

ADAPTIVE CHANGES IN MEMORY-RELATED BRAIN REGIONS UPON CHRONIC CIRCADIAN MANIPULATION

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Inês Marques-Morgado[1], Marcelo Dias[1], Joana Coelho[1], Joana Ribeiro[1], Miguel Remondes[1], Neil Dawson[2], Luisa Lopes[1]
[1]Instituto de Medicina Molecular João Lobo Antunes, Fml, Lisboa, Portugal, [2]Faculty of Health and Medicine, Lancaster University, Lancaster, UK., Division Of Biomedical And Life Sciences, Lancaster, United Kingdom

There are important circadian rest-activity pattern changes in aging and preclinical Alzheimer's Disease (Musiek et al, Jama Neurology. 2018). Despite these observations, little is known on the manner circadian timing modulates hippocampal-based learning and memory. Whole-brain functional connectivity was modelled by combining ^{14}C-2- deoxyglucose functional brain imaging with Partial Least Squares Regression (as in Dawson et al, Neuropsychopharmacol. 2014) on male Sprague-Dawley rats; either under a normal circadian cycle or after a chronic circadian alteration (Craig et al, Brain Res. Bull. 2008). The anatomical connectivity between SCN and memory-related regions was traced by injecting transsynaptic anterograde [rVSV-(VSV-G)-Venus] and retrograde [rVSV-(RABV-G)-eGFP] viral tracers in the rat SC N and HIPP, using our optimized surgical procedure (Marcelo, Marques-Morgado et al, (2021) ENEURO.0146-21.2021) We found alterations in the metabolic activity of SCN and the HIPP, Medial Entorhinal Cortex, Perirhinal Cortex and Dorsal Raphé. A total of 127 functional interactions were impacted by the circadian shift, with a strong remodelling of the connections between cognitive regions, suggesting theta oscillations as a mechanism for the interaction between circadian rhythms and cognition. Moreover, trans-synaptic antero- and retrograde tracing found anatomical projections between the SCN and the HIPP with a relay in the Septum, that may act as a hub of circadian information onto the hippocampal system. We describe a functional network between circadian clock components and memory-encoding regions, pointing new targets to explore the physiological role of circadian rhythms in memory. OLFACTORY CODING IN HIPPOCAMPAL AREA CA2

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Sami Hassan
Zuckerman Institute | Columbia University, Department Of Neuroscience, New York, United States of America

Although the hippocampus is crucial for social memory, how social sensory information is incorporated with contextual information to form episodic social memories remains unknown. Here we investigate the mechanisms for social sensory information processing by performing high-resolution calcium imaging from hippocampal neurons in awake head-fixed mice exposed to social and non-social odors. We focus on the CA2 region because of its importance for social memory. We describe for the first time how novel social odors from single conspecifics rapidly evoke unique representations in a subpopulation of CA2 pyramidal cells upon repeated odor exposure. The representations are refined during associative social-odor-reward learning, and CA2 activity is important for this learning. Finally, we find that CA2 firing in response to sets of odors from different categories (i.e, mouse urine, monomolecular odors, or human urine sampoes) enables generalization of representations along categories of social versus non-social odors. Thus, our study provides the first evidence that hippocampus encodes and distinguishes complex social odors and their reward associations, providing a likely substrate for CA2's crucial function in social memory.

ORGANISATION OF INPUTS FROM THE BASO-AMYGDALA TO THE MEDIAL AND LATERAL ENTORHINAL CORTEX

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Christina Brown, Matthew Nolan
University of Edinburgh, Centre For Discovery Brain Sciences, Edinburgh, United Kingdom

The baso-amygdala complex (BA) contains highly inter-connected nuclei involved in emotional, contextual and reward learning. It has been proposed that the BA to medial entorhinal cortex (MEC) pathway modulates the consolidation of spatial and contextual information, yet the cell types that the BA innervates within the medial or lateral entorhinal cortex (LEC) have yet to be established. To localise BA inputs to the entorhinal cortex, we injected AAVs expressing mCherry or anterograde dextrans tracers into sub-regions of the BA of C57Bl/6 mice. To trace the origin of BA inputs, we injected retrograde AAVs expressing mCherry or GFP into the EC, or applied a combinatorial approach targeting a retro-AAV expressing Cre to the LEC and a Cre-dependent reporter AAV to the BA. We identified entorhinal cortex neurons that receive BA inputs by injecting AAVs expressing channelrhodopsin-2 into the BA and made patch-clamp recordings from entorhinal cortex neurons in ex-vivo brain slices and activated axons using blue light. We found that BA axons project to all layers of the LEC but are restricted to layer 1 and 5a of the MEC. Separate populations of cells in the BA project to different sublayers of the MEC and LEC. Optogenetic activation of BA axons generated glutamatergic excitatory responses in cells in layer 2, 3 and 5a of the MEC and LEC. The majority of cells that received BA input project to the hippocampus, suggesting distinct emotional signals may be passed onto brain areas involved in episodic and contextual memories.

Deep entorhinal cortex: from circuit organization to spatial cognition and memory.
The deep layers of the entorhinal cortex are important for spatial cognition, as well as memory storage, consolidation and retrieval. A long-standing hypothesis is that deep-layer neurons relay spatial and memory-related signals between the hippocampus and telencephalon. We review the implications of recent circuit-level analyses that suggest more complex roles. The organization of deep entorhinal layers is consistent with multi-stage processing by specialized cell populations; in this framework, hippocampal, neocortical, and subcortical inputs are integrated to generate representations for use by targets in the telencephalon and for feedback to the superficial entorhinal cortex and hippocampus. Addressing individual sublayers of the deep entorhinal cortex in future experiments and models will be important for establishing systems-level mechanisms for spatial cognition and episodic memory.

Origin and neurochemical properties of bulbospinal neurons projecting to the rat lumbar spinal cord via the medial longitudinal fasciculus and caudal ventrolateral medulla.
Bulbospinal systems (BS) originate from various regions of the brainstem and influence spinal neurons by classical synaptic and modulatory mechanisms. Our aim was to determine the brainstem locations of cells of origin of BS pathways passing through the medial longitudinal fasciculus (MLF) and the caudal ventrolateral medulla (CVLM). We also examined the transmitter content of spinal terminations of the CVLM pathway. Six adult rats received Fluorogold (FG) injections to the right intermediate gray matter of the lumbar cord (L1-L2) and the b-subunit of cholera toxin (CTb) was injected either into the MLF or the right CVLM (3 animals each). Double-labeled cells were identified within brainstem structures with confocal microscopy and mapped onto brainstem diagrams. An additional 3 rats were injected with CTb in the CVLM to label axon terminals in the lumbar spinal cord. Double-labeled cells projecting via the MLF or CVLM were found principally in reticular regions of the medulla and pons but small numbers of cells were also located within the midbrain. CVLM projections to the lumbar cord were almost exclusively ipsilateral and concentrated within the intermediate gray matter. Most (62%) of terminals were immunoreactive for the vesicular glutamate transporter 2 while 23% contained the vesicular GABA transporter. The inhibitory subpopulation was glycinergic, GABAergic or contained both transmitters. The proportions of excitatory and inhibitory axons projecting via the CVLM to the lumbar cord are similar to those projecting via the MLF. Unlike the MLF pathway, CVLM projections are predominantly ipsilateral and concentrated within intermediate gray but do not extend into motor nuclei or

laminia VIII. Terminations of the CVLM pathway are located in a region of the gray matter that is rich in premotor interneurons; thus its primary function may be to coordinate activity of premotor networks.

PRENATAL EXPOSURE TO DEXAMETHASONE IMPAIRS LEARNING AND MEMORY IN A SEX-DEPENDENT MANNER

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Mai Abul, Abdeslam Mouihate, Maie Al-Bader
Kuwait University, Physiology, Kuwait, Kuwait

Background: The synthetic glucocorticoid (sGC) dexamethasone (DEX) is prescribed to pregnant women at risk of preterm delivery or who are bearing fetuses at risk of developing congenital adrenal hyperplasia. However, prenatal activation of glucocorticoid receptors results in long-lasting deleterious effects on cognitive functions during adulthood. **Aim:** Assess prenatal DEX effects on learning, memory and synaptic proteins expression in the prefrontal cortex (PFC) and dorsal hippocampus (D-HPC). **Methods:** Pregnant rats received daily intra-peritoneal injections of either DEX (0.2 mg/kg) or saline from gestation day (GD)14 until GD21. Protein expression of the pre- (synaptophysin: SynP) and post-synaptic proteins (post synaptic density 95:PSD95) in the PFC & D-HPC of adult male & female offspring were explored using western blot. Adult offspring were subjected to spatial Morris water maze (MWM) and novel object recognition memory (NOR) tests. **Results:** Prenatal exposure to DEX was associated with reduced expression of SynP and PSD95 proteins in the D-HPC and the PFC of adult female but not male rat offspring. Prenatal DEX was associated with a significant decrease in the time spent in the target quadrant and significant increase in the latency to enter the target quadrant in the MWM in females but not males' adult offspring. Maternal exposure to sGC led to reduced time in exploring and roaming around the novel object in the NOR test in both female and male adult offspring. **Conclusion:** Prenatal DEX-induced decrease in synaptic proteins expression is associated with memory impairment in a sex-dependent manner.

KETAMINE REGULATES HOMEOSTATIC FIRING RATE SET POINT IN HIPPOCAMPAL CIRCUITS

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Leore Heim, Antonella Ruggiero, Inna Slutsky
Tel Aviv University, Department Of Physiology And Pharmacology, Tel Aviv, Israel

N-methyl-D-aspartate receptors (NMDARs) function as key regulators of synaptic plasticity and thus are one of the few well-known mechanisms of learning and memory. In parallel, NMDAR antagonists present antidepressant effects that are remarkably fast-acting and long-lasting. Still, the effects of NMDAR antagonists on spiking activity at the network level remain elusive. Long-term recordings of hippocampal cultures using multi electrode arrays revealed that chronic application of structurally distinct NMDAR blockers stably (> 24hr) suppressed mean firing rate (MFR) while preserving homeostatic responses to activity perturbations. In the presence of the NMDAR antagonist ketamine, knocking out eukaryotic elongation factor 2 kinase (eEF2K) or chelating brain derived neurotrophic factor (BDNF) restored MFR set point to its baseline, pre-ketamine levels. This renormalization of MFR occurred in the absence of synaptic scaling at excitatory synapses and solely by intrinsic plasticity. *In vivo,* mice implanted with tetrodes and a cannula directed towards CA1 *stratum pyramidale* showed a stable (> 6hr) reduction in MFR of both putative pyramidal cells and interneurons following local administration of ketamine. Notably, LFP oscillations, state-dependent modulation of MFRs, and neuronal firing patterns (e.g. burstiness) were not affected by ketamine. These local and long-term effects of ketamine imply that NMDAR regulate firing rate set points via the eEF2K-BDNF pathway. Further, ketamine selectively reduces MFR in the hippocampus while preserving other temporal features of neuronal activity that are fundamental to cognitive processing. Taken together, our data can help bridge the gap between the synaptic effects of NMDAR and the clinical features of rapid antidepressants.

Measuring synaptic transmission and plasticity with fEPSP recordings in behaving mice.
Spontaneous spiking activity depends on intrinsic excitability and synaptic input. Historically, synaptic activity has been mostly studied . Here, we describe a versatile and robust protocol to record field excitatory postsynaptic potentials (fEPSPs) in behaving rodents. The protocol allows estimating the input-output relationship of a specific pathway, short-term and long-term plasticity, and their modulation by pharmacological or pharmacogenetic interventions and behavioral states. However, experimenters must be aware of the protocol's specificity and interpret results with care. For complete details on the use and execution of this profile, please refer to Styr et al. (2019).

Disrupted neural correlates of anesthesia and sleep reveal early circuit dysfunctions in Alzheimer models.
Dysregulated homeostasis of neural activity has been hypothesized to drive Alzheimer's disease (AD) pathogenesis. AD begins with a decades-long presymptomatic phase, but whether homeostatic mechanisms already begin failing during this silent phase is unknown. We show that before the onset of memory decline and sleep disturbances, familial AD (fAD) model mice display no deficits in CA1 mean firing rate (MFR) during active wakefulness. However, homeostatic down-regulation of CA1 MFR is disrupted during non-rapid eye movement (NREM) sleep and general anesthesia in fAD mouse models. The resultant hyperexcitability is attenuated by the mitochondrial dihydroorotate dehydrogenase (DHODH) enzyme inhibitor, which tunes MFR toward lower set-point values. Ex vivo fAD mutations impair downward MFR homeostasis, resulting in pathological MFR set points in response to anesthetic drug and inhibition blockade. Thus, firing rate dyshomeostasis of hippocampal circuits is masked during active wakefulness but surfaces during low-arousal brain states, representing an early failure of the silent disease stage.

Mitochondrial Regulation of the Hippocampal Firing Rate Set Point and Seizure Susceptibility.

Maintaining average activity within a set-point range constitutes a fundamental property of central neural circuits. However, whether and how activity set points are regulated remains unknown. Integrating genome-scale metabolic modeling and experimental study of neuronal homeostasis, we identified mitochondrial dihydroorotate dehydrogenase (DHODH) as a regulator of activity set points in hippocampal networks. The DHODH inhibitor teriflunomide stably suppressed mean firing rates via synaptic and intrinsic excitability mechanisms by modulating mitochondrial Ca buffering and spare respiratory capacity. Bi-directional activity perturbations under DHODH blockade triggered firing rate compensation, while stabilizing firing to the lower level, indicating a change in the firing rate set point. In vivo, teriflunomide decreased CA3-CA1 synaptic transmission and CA1 mean firing rate and attenuated susceptibility to seizures, even in the intractable Dravet syndrome epilepsy model. Our results uncover mitochondria as a key regulator of activity set points, demonstrate the differential regulation of set points and compensatory mechanisms, and propose a new strategy to treat epilepsy.

The Invisibility of Mild Traumatic Brain Injury: Impaired Cognitive Performance as a Silent Symptom.
The present study was designed to tackle two notorious features of mild traumatic brain injury (mTBI)-heterogeneity and invisibility-by characterizing the full scope of mTBI symptoms. Mice were exposed to brain injuries of different intensities utilizing a weight-drop model (10, 30, 50, and 70 g) and subsequently subjected to a comprehensive battery of behavioral tests at different time points and immunohistochemical examination of cortical slices. Whereas the physiological, neurological, emotional, and motor function of mTBI mice (i.e., their well-being) remained largely intact, cognitive deficits were identified by the y-maze and novel object recognition. Results from these two cognitive tests were combined and a dose-response relationship was established between injury intensity and cognitive impairment, ranging from an 85% decline after a 70-g impact ($p < 0.001$) to a 20% decline after a 10-g impact (essentially no effect). In addition, higher intensities of injury were accompanied by decreased expression of axonal and synaptic markers. Thus, our mTBI mice showed a clear discrepancy between performance (poor cognitive function) and appearance (healthy demeanor). This is of major concern given that diagnosis of mTBI is established on the presence of clinical symptoms and emphasizes the need for an alternative diagnostic modality.

Thioredoxin-Mimetic-Peptides Protect Cognitive Function after Mild Traumatic Brain Injury (mTBI).
Mild traumatic brain injury (mTBI) is recognized as a common injury among children, sportsmen, and elderly population. mTBI lacks visible objective structural brain damage but patients frequently suffer from long-lasting cognitive, behavioral and emotional difficulties associated with biochemical and cellular changes. Currently there is no effective treatment for patients with mTBI. The thioredoxin reductase/thioredoxin pathway (TrxR/Trx1) has both anti-inflammatory and anti-oxidative properties. If the system is compromised, Trx1 remains oxidized and triggers cell death via an ASK1-Trx1 signal transduction mechanism. We previously showed tri and tetra peptides which were derived from the canonical -CxxC- motif of the Trx1-active site, called thioredoxin mimetic (TXM) peptides, reversed inflammatory and oxidative stress damage mimicking Trx1 activity. Here, TXM-peptides were examined for protecting cognitive function following weight drop closed-head injury in a mouse model of mTBI. TXM-CB3 (AcCys-Pro-CysNH2), TXM-CB13 (DY-70; AcCys-Met-Lys-CysNH2) or AD4 (ACysNH2) were administered at 50 mg/kg, 60 min after injury and cognitive performance was monitored by the novel-object-recognition and Y-maze tests. Behavioral deficits subsequent to mTBI injury were reversed by a single dose of TXM-CB3, TXM-CB13 and, to a lesser extent, by AD4. TXM-CB13 similar to TXM-CB3 and AD4 reversed oxidative stress-induced phosphorylation of mitogen-activated kinases, p38MAPK and c-Jun N-terminal kinase, (JNK) in human neuronal SH-SY5Y cells. We conclude that significantly improved cognitive behavior post mTBI by the TXM-peptides could result from anti-apoptotic, and/or anti-inflammatory activities. Future preclinical studies are required to establish the TXM-peptides as potential therapeutic drugs for brain injuries.

Enriched environment improves the cognitive effects from traumatic brain injury in mice.
To date, there is yet no established effective treatment (medication or cognitive intervention) for post-traumatic brain injury (TBI) patients with chronic sequelae. Enriched environment (EE) has been recognized of importance in brain regulation, behaviour and physiology. Rodents reared in, or pre-exposed to EE, recovered better from brain insults. Using the concussive head trauma model of minimal TBI in mice, we evaluated the effect of transition to EE following a weight-drop (30g or 50g) induced mTBI on behavioural and cognitive parameters in mice in the Novel Object Recognition task, the Y- and the Elevated Plus mazes. In all assays, both mTBI groups (30g, 50g) housed in normal conditions were equally and significantly impaired 6 weeks post injury in comparison with the no-mTBI ($p<0.001$ and $p<0.03$, respectively) and the

mTBI+EE groups ($p<0.001$ for the 30g, and $p<0.017$ for the 50g). No differences were found between the control and the EE mice. Two separate finding emerge: (1) the significantly positive effects of the placement in EE following mTBI, on the rehabilitative process of the tested behaviours in the affected mice; (2) the lack of difference between the groups of mice affected by 30g or by 50g. Further studies are needed in order to characterize the exact pathways involved in the positive effects of the EE on mice recovery from mTBI. Possible clinical implications indicate the importance of adapting correlates of EE to humans, i.e., prolonged and intensive physical activity - possibly combined with juggling training and intensive cognitive stimulation.

Adapting to changing associations between environmental cues and rewards is necessary for survival. Medial prefrontal cortex (mPFC) neurons mediate these associations and show altered signal processing in response to learning. However, the processes underlying these alterations remain to be elucidated. The protein Arc is expressed in highly stimulated neuronal ensembles following associative learning and is well a recognized marker for persistent plasticity. Yet, how Arc-expressing ensembles acquire dynamic attributes during associative learning is unclear. **Aim:** Thus, our goal is to characterize the dynamics of mPFC Arc-expressing ensembles during associative learning. **Methods:** To this aim, we performed longitudinal in vivo 2-photon imaging of the mPFC in mice as they performed a cue-reward associative learning task. Imaged mice were injected with viral constructs coding for both the calcium indicator XCaMP-G and a red fluorophore driven by the active ensemble-marking E-SARE promoter. This method allowed us to track the temporal and spatial dynamics of mPFC Arc-expressing ensembles and their activity patterns during learning epochs. **Results:** We observed that Arc-expressing ensembles demonstrated increased neuronal activity to task-related cues compared to surrounding control neurons. However, ensembles identified in early learning did not show increased signaling in subsequent sessions. Instead, early learning Arc- expressing ensembles demonstrated reduced neuronal activity during reward-seeking behavior in later sessions. **Conclusion:** This suggests a two-way dynamic interaction between neuronal activity and Arc expression during associative learning. We hypothesize that Arc may be involved in regulating persistence of mPFC circuit strength to enable future flexible behaviors.

SOCIAL AND SPATIAL CODES IN HIPPOCAMPUS CA2 AND ENTORHINAL CORTEX

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Sarah Thon[1], Ane Charlotte Christensen[1], Maria Fjeldstad[2], Vemund Schøyen[3], Elise Olsen[1], Mikkel Lepperød[4], Marianne Fyhn[3], Torkel Hafting[1]
[1]University of Oslo, Institute Of Basic Medical Sciences, Oslo, Norway, [2]University of Oslo, Department Of Informatics, Oslo, Norway, [3]University of Oslo, Department Of Biosciences, Oslo, Norway, [4]University of Oslo, Department Of Physics, Oslo, Norway

The hippocampal formation and parahippocampal regions are important for formation, consolidation and retrieval of episodic memories. While the spatial aspect of episodic memories has been studied in great detail, it remains elusive how social information is encoded in the brain. Emerging evidence suggests that the hippocampus region CA2 plays an essential role for social recognition memories, and silencing of neuronal activity in this area impairs social recognition. In contrast to the place cells in hippocampus CA1 and CA3, which show precise location-specific activity, place cells in CA2 change their activity over time and in response to novel objects and conspecifics. Entorhinal cortex is directly connected to CA2, but the contribution to social memories by this route is largely unknown. Here, we recorded from CA2 and entorhinal cortex from rats in a social recognition task to determine the social and spatial coding in the two regions. Social recognition can be defined as the ability to recognize and memorize familiar conspecifics. We measured this as a decrease in time that a rat spends around a previous littermate compared to a novel conspecific in a social recognition task, which was then followed by a similar task with object exploration. Preliminary data analysis confirms that grid cells from entorhinal cortex show a stable spatial code during the recordings, while the CA2 cells contains a more diverse code.

PROBING SUBTHRESHOLD DYNAMICS OF HIPPOCAMPAL NEURONS BY PULSED OPTOGENETICS

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Manuel Valero García, György Buzsáki
New York University, Neuroscience And Physiology, New York, United States of America

A basic transformation process in the brain is the conversion of a neuron's excitatory and inhibitory inputs to spikes. Experimentally examining the transformation process requires access to subthreshold membrane dynamics. To date, only intracellular recordings meet this requirement. Here we probed the subthreshold dynamics using optogenetic depolarizing pulses in hippocampal neuronal assemblies in freely moving mice. Using chronically implanted µLED probes (4 shanks with 3 µLED on each shank), we recorded and probed large numbers of neurons simultaneously in freely moving CamKIIα-Cre::Ai32 mice. Light-sensitive neurons responded to one or more µLEDs and the spike numbers were used as a proxy for estimating relative changes of the membrane potential dynamics. Excitability decreased during sharp-wave ripples coupled with increased inhibitory tone. In contrast to this "negative gain," optogenetic probing showed increased within-field excitability in place cells by weakening and unmasked stable place fields in initially non–place cells. Neuronal assemblies active during sharp-wave ripples in the home cage predicted spatial overlap and sequences of place fields of both place cells and unmasked preexisting place fields of non–place cells during track running. We have developed a method for studying subthreshold dynamics of individual cells in chronic recordings using novel high-resolution optical stimulation as a proxy for the membrane polarization. Indirect probing of subthreshold dynamics in neuronal populations permits the disclosing of preexisting assemblies and modes of neuronal operations.

Probing subthreshold dynamics of hippocampal neurons by pulsed optogenetics.
Understanding how excitatory (E) and inhibitory (I) inputs are integrated by neurons requires monitoring their subthreshold behavior. We probed the subthreshold dynamics using optogenetic depolarizing pulses in hippocampal neuronal assemblies in freely moving mice. Excitability decreased during sharp-wave ripples coupled with increased I. In contrast to this "negative gain," optogenetic probing showed increased within-field excitability in place cells by weakening I and unmasked stable place fields in initially non-place cells. Neuronal assemblies active during sharp-wave ripples in the home cage predicted spatial overlap and sequences of place fields of both place cells and unmasked preexisting place fields of non-place cells during track running. Thus, indirect probing of subthreshold dynamics in neuronal populations permits the disclosing of preexisting assemblies and modes of neuronal operations.

Sleep down state-active ID2/Nkx2.1 interneurons in the neocortex.
Pyramidal cells and GABAergic interneurons fire together in balanced cortical networks. In contrast to this general rule, we describe a distinct neuron type in mice and rats whose spiking activity is anti-correlated with all principal cells and interneurons in all brain states but, most prevalently, during the down state of non-REM (NREM) sleep. We identify these down state-active (DSA) neurons as deep-layer neocortical neurogliaform cells that express ID2 and Nkx2.1 and are weakly immunoreactive to neuronal nitric oxide synthase. DSA neurons are weakly excited by deep-layer pyramidal cells and strongly inhibited by several other GABAergic cell types. Spiking of DSA neurons modified the sequential firing order of other neurons at down-up transitions. Optogenetic activation of ID2Nkx2.1 interneurons in the posterior parietal cortex during NREM sleep, but not during waking, interfered with consolidation of cue discrimination memory. Despite their sparsity, DSA neurons perform critical physiological functions.

The hippocampus in depth: a sublayer-specific perspective of entorhinal-hippocampal function.
Understanding how the brain represents events is a fundamental question in neuroscience. The entorhinal-hippocampal system is central to such representations, which are severely compromised in some neurological diseases. In spite of much

progress, a comprehensive, integrated view of spatial, temporal and other aspects of episodic representation remains elusive. Here, we review recent data on the role of cell-type specific entorhinal inputs which excite deep and superficial CA1 pyramidal cells by direct and indirect pathways. We discuss how an entorhinal dialogue with deep-superficial CA1 cells can multiplex neuronal activity along theta phases and how their reactivation may be segregated during sharp-wave ripples. Thus, deep and superficial CA1 sublayers provide substrate for general hippocampal function.

Mechanisms for Selective Single-Cell Reactivation during Offline Sharp-Wave Ripples and Their Distortion by Fast Ripples.
Memory traces are reactivated selectively during sharp-wave ripples. The mechanisms of selective reactivation, and how degraded reactivation affects memory, are poorly understood. We evaluated hippocampal single-cell activity during physiological and pathological sharp-wave ripples using juxtacellular and intracellular recordings in normal and epileptic rats with different memory abilities. CA1 pyramidal cells participate selectively during physiological events but fired together during epileptic fast ripples. We found that firing selectivity was dominated by an event- and cell-specific synaptic drive, modulated in single cells by changes in the excitatory/inhibitory ratio measured intracellularly. This mechanism collapses during pathological fast ripples to exacerbate and randomize neuronal firing. Acute administration of a use- and cell-type-dependent sodium channel blocker reduced neuronal collapse and randomness and improved recall in epileptic rats. We propose that cell-specific synaptic inputs govern firing selectivity of CA1 pyramidal cells during sharp-wave ripples.

Determinants of different deep and superficial CA1 pyramidal cell dynamics during sharp-wave ripples.
Sharp-wave ripples represent a prominent synchronous activity pattern in the mammalian hippocampus during sleep and immobility. GABAergic interneuronal types are silenced or fire during these events, but the mechanism of pyramidal cell (PC) participation remains elusive. We found opposite membrane polarization of deep (closer to stratum oriens) and superficial (closer to stratum radiatum) rat CA1 PCs during sharp-wave ripples. Using sharp and multi-site recordings in combination with neurochemical profiling, we observed a predominant inhibitory drive of deep calbindin (CB)-immunonegative PCs that contrasts with a prominent depolarization of superficial CB-immunopositive PCs. Biased contribution of perisomatic GABAergic inputs, together with suppression of CA2 PCs, may explain the selection of CA1 PCs during sharp-wave ripples. A deep-superficial gradient interacted with behavioral and spatial effects to determine cell participation during sleep and awake sharp-wave ripples in freely moving rats. Thus, the firing dynamics of hippocampal PCs are exquisitely controlled at subcellular and microcircuit levels in a cell type-selective manner.

Extrinsic control and intrinsic computation in the hippocampal CA1 circuit.
In understanding circuit operations, a key problem is the extent to which neuronal spiking reflects local computation or responses to upstream inputs. We addressed this issue in the hippocampus by performing combined optogenetic and pharmacogenetic local and upstream inactivation. Silencing the medial entorhinal cortex (mEC) largely abolished extracellular theta and gamma currents in CA1 while only moderately affecting firing rates. In contrast, CA3 and local CA1 silencing strongly decreased firing of CA1 neurons without affecting theta currents. Each perturbation reconfigured the CA1 spatial map. However, the ability of the CA1 circuit to support place field activity persisted, maintaining the same fraction of spatially tuned place fields and reliable assembly expression as in the intact mouse. Thus, the CA1 network can induce and maintain coordinated cell assemblies with minimal reliance on its inputs, but these inputs can effectively reconfigure and assist in maintaining stability of the CA1 map.

GABAergic signaling to astrocytes in the prefrontal cortex sustains goal-directed behaviors.
GABA interneurons play a critical role in higher brain functions. Astrocytic glial cells interact with synapses throughout the whole brain and are recognized as regulatory elements of excitatory synaptic transmission. However, it is largely unknown how GABAergic interneurons and astrocytes interact and contribute to stable performance of complex behaviors. Here, we found that genetic ablation of GABA receptors in medial prefrontal cortex astrocytes altered low-gamma oscillations and firing properties of cortical neurons, which affected goal-directed behaviors. Remarkably, working memory deficits were restored by optogenetic stimulation of astrocytes with melanopsin. Furthermore, melanopsin-activated astrocytes in wild-type mice enhanced the firing rate of cortical neurons and gamma oscillations, as well as improved cognition. Therefore, our work identifies astrocytes as a hub for controlling inhibition in cortical circuits, providing a novel pathway for the behaviorally

relevant midrange time-scale regulation of cortical information processing and consistent goal-directed behaviors.

Multimodal determinants of phase-locked dynamics across deep-superficial hippocampal sublayers during theta oscillations.
Theta oscillations play a major role in temporarily defining the hippocampal rate code by translating behavioral sequences into neuronal representations. However, mechanisms constraining phase timing and cell-type-specific phase preference are unknown. Here, we employ computational models tuned with evolutionary algorithms to evaluate phase preference of individual CA1 pyramidal cells recorded in mice and rats not engaged in any particular memory task. We applied unbiased and hypothesis-free approaches to identify effects of intrinsic and synaptic factors, as well as cell morphology, in determining phase preference. We found that perisomatic inhibition delivered by complementary populations of basket cells interacts with input pathways to shape phase-locked specificity of deep and superficial pyramidal cells. Somatodendritic integration of fluctuating glutamatergic inputs defined cycle-by-cycle by unsupervised methods demonstrated that firing selection is tuneable across sublayers. Our data identify different mechanisms of phase-locking selectivity that are instrumental for flexible dynamical representations of theta sequences.

Head-mounted approaches for targeting single-cells in freely moving animals.
Neural network processing is usually studied using the spike times of many extracellularly recorded neurons. Elucidating the cellular-synaptic mechanisms underlying these firing patterns requires identifying and controlling single cells and assessing their inputs. Single cell glass electrode techniques (intracellular, patch and juxtacellular) are well suited to filling this gap, in terms of physiology, cell identity and behavior. However, they are typically limited to in vitro and immobilized in vivo experiments, primarily due to the necessity for mechanical stability and steep learning curves. Several approaches have been recently developed to extend these technologies to freely moving animals. Here we summarize the advantages and results for different methods of single neuron glass recordings in vivo. We further review three approaches used to date for single cell recording in freely moving animals: static anchor systems, manual mechanic drives and motorized drives. Finally, we highlight new technologies capable of expanding the utility of single neuron recording in freely moving animals.

Mechanisms and plasticity of chemogenically induced interneuronal suppression of principal cells.
How do firing patterns in a cortical circuit change when inhibitory neurons are excited? We virally expressed an excitatory designer receptor exclusively activated by a designer drug (Gq-DREADD) in all inhibitory interneuron types of the CA1 region of the hippocampus in the rat. While clozapine N-oxide (CNO) activation of interneurons suppressed firing of pyramidal cells, unexpectedly the majority of interneurons also decreased their activity. CNO-induced inhibition decreased over repeated sessions, which we attribute to long-term synaptic plasticity between interneurons and pyramidal cells. Individual interneurons did not display sustained firing but instead transiently enhanced their activity, interleaved with suppression of others. The power of the local fields in the theta band was unaffected, while power at higher frequencies was attenuated, likely reflecting reduced pyramidal neuron spiking. The incidence of sharp wave ripples decreased but the surviving ripples were associated with stronger population firing compared with the control condition. These findings demonstrate that DREADD activation of interneurons brings about both short-term and long-term circuit reorganization, which should be taken into account in the interpretation of chemogenic effects on behavior.

Background: In mice, adult hippocampal neurogenesis is elevated by interventions that improve affect and cognition. Here, we test whether chronic treatment with a novel neurogenic compound, RO6871135, can alter behaviors relevant to cognitive, anxiety, mood, and trauma-related disorders. We also test which behavioral effects are neurogenesis-dependent by ablating neurogenesis with irradiation. Methods: Aged and young adult c57BL/6J male mice were administered 7.5 mg/kg of RO6871135 compound daily for 21 days prior to behavioral testing. When applicable, X-irradiation was applied to bilateral hippocampi, prior to initiation of drug treatment. Mice were tested in a contextual fear discrimination task where they explored two similar contexts but received a foot shock in only one context. (*N* = 8-9 mice/group). Results: Aged mice showed a deficit in pattern separation compared to young adult mice. Compared to vehicle, treatment with RO6871135 improved the ability to distinguish between the similar contexts in both age groups of mice when task difficulty was appropriately tuned. RO6871135 did not alter initial contextual fear conditioning. Doublecortin staining in the dentate gyrus was increased after treatment with RO6871135 compared to vehicle as well. RO6871135 effects on context discrimination were blocked by X-irradiation. Conclusions: We demonstrated that RO6871135 improved performance of both aged and young adult mice in a contextual fear discrimination task, a measure of pattern separation. This effect was blocked by ablating neurogenesis in young mice. These findings support the further development of neurogenic compounds for novel therapeutics.

Meta-analysis of neuroimaging studies of the Wisconsin card-sorting task and component processes.
A quantitative meta-analysis using the activation likelihood estimation (ALE) method was used to investigate the brain basis of the Wisconsin Card-Sorting Task (WCST) and two hypothesized component processes, task switching and response suppression. All three meta-analyses revealed distributed frontoparietal activation patterns consistent with the status of the WCST as an attention-demanding executive task. The WCST was associated with extensive bilateral clusters of reliable cross-study activity in the lateral prefrontal cortex, anterior cingulate cortex, and inferior parietal lobule. Task switching revealed a similar, although less robust, frontoparietal pattern with additional clusters of activity in the opercular region of the ventral prefrontal cortex, bilaterally. Response-suppression tasks, represented by studies of the go/no-go paradigm, showed a large and highly right-lateralized region of activity in the right prefrontal cortex. The activation patterns are interpreted as reflecting a neural fractionation of the cognitive components that must be integrated during the performance of the WCST.

Genetic contributions to white matter architecture revealed by diffusion tensor imaging in Williams syndrome.
Little is known about genetic regulation of the development of white matter. This knowledge is critical in understanding the pathophysiology of neurodevelopmental syndromes associated with altered cognition as well as in elucidating the genetics of normal human cognition. The hemideletion of approximately 25 genes on chromosome 7q11.23 that causes Williams syndrome (WS) includes genes that regulate cytoskeletal dynamics in neurons, especially LIMK1 and CYLN2, and therefore offers the opportunity to investigate the role of these genes in the formation of white matter tracts. We used diffusion tensor imaging to demonstrate alteration in white matter fiber directionality, deviation in posterior fiber tract course, and reduced lateralization of fiber coherence in WS. These abnormalities are consistent with an alteration of the late stages of neuronal migration, define alterations of white matter structures underlying dissociable behavioral phenotypes in WS, and provide human in vivo information about genetic control of white matter tract formation.

Normal human aging and early-stage schizophrenia share common molecular profiles.
We examined genome-wide expression datasets from human prefrontal cortex of normal and schizophrenic individuals ranging from 19 to 81 years of age. We found that changes in gene expression that are correlated with aging in normal subjects differ dramatically from those observed with aging in schizophrenic subjects. Only 2.5% of genes were correlated with age in both groups. Surprisingly, we also found a significant overlap (29-34%) between those genes whose expression was correlated with aging in normal subjects and those significantly altered in subjects with early-stage schizophrenia (within 4 years of diagnosis). This suggests that schizophrenia onset anticipates the normal aging process, and further, that some symptoms of aging, i.e. dementia and psychosis, might be explained by these common molecular profiles.

Parametric approaches towards understanding the effects of the preferential D3 receptor agonist pramipexole on prepulse inhibition in rats.
The preferential dopamine D3 receptor agonist pramipexole (PRA) disrupts prepulse inhibition (PPI) of acoustic startle, an operational measure of sensorimotor gating, in rats. Drug effects on PPI are sensitive to numerous experimental variables; proceeding with in-depth analyses of drug effects without a clear understanding of these variables is inefficient. The present studies characterized the impact on PRA-induced PPI deficits by a range of experimental parameters. As shown previously, PRA reduced both PPI and startle magnitude beginning 5-15 min post-injection; PRA effects on PPI were statistically significant through 35 min post-injection, while those on startle magnitude were still significant 65 min post-injection. PRA-induced PPI deficits were evident under conditions that matched startle magnitude in vehicle and PRA conditions and were independent of PRA-induced changes in prepulse-elicited motor activity. Additionally, PRA-induced PPI deficits did not differ significantly between uni- vs. cross-modal stimuli or between male vs. female rats, with no robust effect of estrous phase in females. These findings demonstrate that PRA effects on PPI are observed across several different experimental conditions and are dissociable from changes in startle magnitude or prepulse-elicited responses. Recommendations are made regarding "optimal" experimental conditions for studying the neurobiology of PRA-induced changes in PPI in rats.

Heritable strain differences in sensitivity to the startle gating-disruptive effects of D2 but not D3 receptor stimulation.
Prepulse inhibition (PPI) of the startle reflex is an operational measure of sensorimotor gating that is deficient in several brain disorders and is disrupted in rats by dopamine (DA) agonists. Robust heritable strain differences are observed between Sprague-Dawley (SD) and Long-Evans (LE) strains in sensitivity to the PPI-disruptive effects of DA agonists associated with differential gene expression in the nucleus accumbens. Here, we compared the contribution of D2 versus D3 receptors with this heritable difference, using the D3-preferential agonist (pramipexole), the mixed D3/D2 agonist (quinpirole), the mixed D1/D2-like agonist (apomorphine), and the preferential D2 antagonist (L741,626). All DA agonists disrupted PPI in SD and LE rats. Greater sensitivity for this effect was evident with apomorphine and quinpirole in SD than LE rats, but not with pramipexole. The selective D2 antagonist L741,626 preferentially reversed apomorphine-induced PPI deficits at a dose that did not alter pramipexole-induced PPI deficits. We conclude that the heritable pattern of greater PPI 'disruptability' by DA agonists in SD versus LE rats reflects differences in D2 but not D3 receptor-associated mechanisms.

Stereochemical and neuroanatomical selectivity of pramipexole effects on sensorimotor gating in rats.
In rats, prepulse inhibition (PPI) of acoustic startle is disrupted by systemic administration of dopaminergic agonists, such as the dopamine D3 receptor (D3R)-preferential agonist pramipexole (PPX). PPX has D3R-active (S) and -inactive (R) stereoisomers. Here, we tested the neuroanatomical and stereochemical selectivity of PPX effects on PPI.
Brain Res, 2012; 1437

Disparate effects of pramipexole on locomotor activity and sensorimotor gating in Sprague-Dawley rats.
Prepulse inhibition (PPI) of acoustic startle and locomotor activity are both widely studied in the preclinical development of dopaminergic agents, including those acting at D3 dopamine receptors. In mice, the dopamine D3 receptor-preferential agonist pramipexole (PPX) alters locomotor activity in a biphasic manner at doses that have no effect on PPI. The present study examined the time-course of PPX effects on locomotion and PPI in rats. In adult male Sprague-Dawley rats, PPX (0, 0.1, 0.3, 1.0mg/kg) was injected prior to measurement of locomotor activity for 90 min in photobeam chambers. Based on disparate early vs. late effects of PPX on locomotion, the effects of PPX (0 vs. 0.3mg/kg) on PPI were tested 20 and 80 min after injection. All doses of PPX decreased locomotor activity for 30 min compared to vehicle, and the higher doses

stimulated hyperlocomotion later in the session; the late hyperlocomotion, but not the early hypolocomotion, was blocked by the D2-selective antagonist, L741626 (1.0mg/kg sc). In contrast to its locomotor effects, PPX caused a similar reduction in PPI at 20 and 80 min after administration. These findings suggest both a temporal and pharmacological dissociation between PPX effects on locomotor activity and PPI; these two behavioral measures contribute non-redundant information to the investigation of D3-related behavioral pharmacology.

The effects of pramipexole on prepulse inhibition and locomotor activity in C57BL/6J mice.
Pramipexole (PRA) is a preferential D3R agonist that, in rats and humans, modifies prepulse inhibition (PPI) of the acoustic startle reflex, an operational measure of sensorimotor gating. The ability to use similar PPI measures across species, and the relative ease of genetic manipulations in mice, suggests that molecular studies of the D3R regulation of sensorimotor gating might be best pursued in mice. Here, we evaluate the effects of PRA on PPI and locomotion in C57BL/6J mice, the background strain for many gene knockout mouse models. Male C57BL/6J mice were tested for PPI and locomotor activity after injection of PRA. No significant effects of PRA on PPI were observed at any dose (0.1-10.0 mg/kg), but a significant reduction in startle magnitude was observed after 10 mg/kg PRA. In contrast, the D1/2 agonist, apomorphine (5 mg/kg) significantly reduced PPI in these mice. At doses of PRA that did not alter startle magnitude (0.3, 1, 3 mg/kg), significant decreases in the amount of locomotor and investigatory behavior were observed. Distinct from findings in rats and humans, it seems that either: (i) PRA does not activate D3Rs in C57BL/6J mice, or (ii) D3R agonists are not sufficient to alter PPI in this mouse strain.

The effects of the dopamine D2 agonist sumanirole on prepulse inhibition in rats.
Dopamine agonists reduce prepulse inhibition (PPI) of startle in rats. While it is used to predict antipsychotic efficacy, the specific receptor subtypes mediating this effect of dopamine agonists remain unclear. We characterized the effects of sumanirole, a highly selective D2 agonist, on PPI in rats. Sumanirole decreased PPI at 60-120 ms prepulse intervals, and increased PPI at 10-20 ms intervals. PPI deficits were antagonized by low doses of the preferential D2 antagonist L741626, supporting a D2 mechanism of action. Sumanirole is a valuable tool for parsing the role of dopamine receptor subtypes in the regulation of PPI.

In hippocampal neuronal circuit, Pten/PI3K opposing expression is crucial for maintaining synaptic strength and plasticity. Pten mutation causes overactivation of mTOR through PI3K-AKT pathway. Active state of this intrinsic pathway promotes long-term synaptic plasticity underlying learning and memory. Pten loss in several brain structures during neurodevelopment at neonatal stage causes morphological changes that affects neuronal connectivity contributing to memory impairment and ASD, ataxia and seizures development. However, Pten function in adult neurons is not fully examined. We investigated whether Pten loss in adult glutaminergic neurons causes improved cognitive function in hippocampal-dependent spatial learning tasks. To knockout Pten gene in hippocampus, we used $Pten^{flox/flox}$ mouse model and AAV-CaMKII*α*-Cre vector (stereotactic injection).
Between 7th and 15th weeks post-AAV treatment, we conducted cognitive tests in the IntelliCage and recorded ultrasonic vocalizations (USV). Additionally, at 7th weeks, we checked neurons excitability from CA1 area and animals' phenotype: activity, anxiety, social memory and skills. Around 7 weeks' time-point, when mTOR hyperactivation occurs (IHC staining), and decreased Pten expression was observed (western blot), Pten KO mice achieved improved learning performance compared to controls in simple and advanced tests. Additionally, mutant mice showed hyperactivity and altered social novelty behavior but normal sociability skills, and normal USV suggesting that Pten KO have not developed ASD phenotype. Whole-cell patch-clamp recordings revealed altered excitability. At 15 weeks post mutation induction, there was no significant differences between groups in learning observed. However, we have detected altered USV and mTOR expression attenuation due to progressive neurodegeneration that occurred in hippocampal neurons.

STABLE PATTERNS OR DYNAMIC CHANGES: HOW DOES THE PREFRONTAL CORTEX COPE WITH CHANGING BEHAVIORAL DEMANDS?

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Johannes Hahn[1,2], Torfi Sigurdsson[3]
[1]Max Planck Institute for Brain Research, Imprs For Neural Circuits, Frankfurt, Germany, [2]Goethe University Frankfurt, Institute Of Neurophysiology, Frankfurt, Germany, [3]Goethe University Frankfurt, Institute Of Neurophysiology, Frankfurt am Main, Germany

The prefrontal cortex (PFC) plays an important role in cognitive processes such as working memory, but it is also involved in emotional and motivational processes such as anxiety and social interaction. Previous studies using electrophysiological recordings have shown that PFC neurons are modulated by different variables in one specific task, but it remains unclear how the same neurons respond during different tasks. Do PFC neurons show stable coding for similar events across tasks, or do they change their responses? Here we address this question by imaging the same PFC neurons in mice while they perform multiple tasks. We infused an adeno-associated virus to express the calcium indicator GCaMP6f under the CamKII-promoter into the medial PFC (mPFC) of C57BL/6N mice and implanted a GRIN lens to image the activity of mPFC neurons over multiple weeks. Animals were food restricted and imaged during five distinct behavioral tests: A T-maze spatial working memory task, elevated plus-maze exploration, social interaction, novel object recognition and discriminative auditory fear conditioning. We successfully imaged the same cells over multiple sessions and tasks. We used generalized linear models to identify the task variables that mPFC neurons coded for and compared this across multiple tasks. While many task variables were encoded by mPFC neurons, animals' position influenced cell activity most prominently across the different tasks. We also found stable representations of task variables across multiple sessions of the same task and currently investigate how the same neurons' responses are influenced by the changing demands of different tasks.

THE ROLE OF HIPPOCAMPAL CA1 IN RELATIONAL LEARNING IN MICE

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Svenja Nierwetberg[1], David Orme[2], Andrew Macaskill[1]
[1]University College London, Neuroscience, Physiology And Pharmacology, London, United Kingdom, [2]University College London, Ucl Queen Square Institute Of Neurology, London, United Kingdom

Learning relationships between cues in our environment enables us to recognise common underlying structures of events and is thought to form the basis of episodic memory. This type of learning - often called relational learning - requires retaining both the stimulus identity as well as its relation to other cues. Despite being essential for many of our everyday decisions, there is limited insight into how relational learning is achieved within the brain. One area implicated in relational learning is the hippocampus. Specifically, neurons in the CA1 area of the hippocampus have been shown to represent variables that are essential for constructing a relational structure of the environment, such as cue configurations, the value of such configurations and their order in space and time. To investigate the neural mechanisms of relational learning, we designed an odour sequence task for mice that requires subjects to learn about both the identity of an odour and its temporal position within a sequence. Importantly, the task design allows for manipulation of the temporal structure and value of cues separately. This allowed us to probe generalisation to novel cues in the same structure, and the ability to update the value associated with learnt relational structure. We found that mice quickly learnt this task and, in line with a key role for hippocampal circuitry, optogenetic inactivation of CA1 impaired task performance. In addition, we found that after initial learning, mice could adapt to manipulations of cue value and identity, suggesting flexible use of previously learnt relational structures.

COMPUTATIONAL STRATEGIES AND NEURAL CORRELATES OF PROBABILISTIC REVERSAL LEARNING IN MICE

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Karyna Mishchanchuk, Andrew Macaskill
University College London, Neuroscience, Physiology And Pharmacology, London, United Kingdom

When faced with a changing, uncertain environment it is necessary to infer its underlying structure to guide behaviour. This has often been formalised as a value updating problem – where actions are chosen based on the weighted average of past reward. Activity of midbrain dopamine neurons is commonly associated with the error in such value prediction, and is proposed to be crucial for learning and updating of values to inform decision making. However, it has become increasingly apparent that both humans and animals often use an alternative strategy – inferring hidden states to make predictions and guide behaviour. In this study we hypothesised that mice might also use hidden state strategies during decision making, and that this would be reflected in midbrain dopamine activity. To investigate this, we used a probabilistic reversal learning task in mice. In this paradigm, for optimal performance it is necessary to continuously integrate past trial outcomes to predict reward contingencies associated with different actions across reversals. Probing animals' behaviour with computational modelling, we found that it was consistently best fit by models that incorporated hidden states. Furthermore, by recording dopamine release in the nucleus accumbens during the task, we found phasic dopamine was most strongly predicted by error associated with hidden state inference strategies. Overall, we find that mouse behaviour and midbrain dopamine activity during probabilistic reversal learning is best described by a hidden state inference strategy. Ongoing work is investigating the sources of the state prediction that influence dopamine signalling during decision making.

Two opposing hippocampus to prefrontal cortex pathways for the control of approach and avoidance behaviour.
The decision to either approach or avoid a potentially threatening environment is thought to rely upon the coordinated activity of heterogeneous neural populations in the hippocampus and prefrontal cortex (PFC). However, how this circuitry is organized to flexibly promote both approach or avoidance at different times has remained elusive. Here, we show that the hippocampal projection to PFC is composed of two parallel circuits located in the superficial or deep pyramidal layers of the CA1/subiculum border. These circuits have unique upstream and downstream connectivity, and are differentially active during approach and avoidance behaviour. The superficial population is preferentially connected to widespread PFC inhibitory interneurons, and its activation promotes exploration; while the deep circuit is connected to PFC pyramidal neurons and fast spiking interneurons, and its activation promotes avoidance. Together this provides a mechanism for regulation of behaviour during approach avoidance conflict: through two specialized, parallel circuits that allow bidirectional hippocampal control of PFC.

Control of parallel hippocampal output pathways by amygdalar long-range inhibition.
Projections from the basal amygdala (BA) to the ventral hippocampus (vH) are proposed to provide information about the rewarding or threatening nature of learned associations to support appropriate goal-directed and anxiety-like behaviour. Such behaviour occurs via the differential activity of multiple, parallel populations of pyramidal neurons in vH that project to distinct downstream targets, but the nature of BA input and how it connects with these populations is unclear. Using channelrhodopsin-2-assisted circuit mapping in mice, we show that BA input to vH consists of both excitatory and inhibitory projections. Excitatory input specifically targets BA- and nucleus accumbens-projecting vH neurons and avoids prefrontal cortex-projecting vH neurons, while inhibitory input preferentially targets BA-projecting neurons. Through this specific connectivity, BA inhibitory projections gate place-value associations by controlling the activity of nucleus accumbens-projecting vH neurons. Our results define a parallel excitatory and inhibitory projection from BA to vH that can support goal-directed behaviour.

Irregular distribution of grid cell firing fields in rats exploring a 3D volumetric space.
We investigated how entorhinal grid cells encode volumetric space. On a horizontal surface, grid cells usually produce multiple, spatially focal, approximately circular firing fields that are evenly sized and spaced to form a regular, close-packed, hexagonal array. This spatial regularity has been suggested to underlie navigational computations. In three dimensions, theoretically the equivalent firing pattern would be a regular, hexagonal close packing of evenly sized spherical fields. In the present study, we report that, in rats foraging in a cubic lattice, grid cells maintained normal temporal firing characteristics and produced spatially stable firing fields. However, although most grid fields were ellipsoid, they were sparser, larger, more variably sized and irregularly arranged, even when only fields abutting the lower surface (equivalent to the floor) were considered. Thus, grid self-organization is shaped by the environment's structure and/or movement affordances, and grids may not need to be regular to support spatial computations.

Volumetric spatial behaviour in rats reveals the anisotropic organisation of navigation.
We investigated how access to the vertical dimension influences the natural exploratory and foraging behaviour of rats. Using high-accuracy three-dimensional tracking of position in two- and three-dimensional environments, we sought to determine (i) how rats navigated through the environments with respect to gravity, (ii) where rats chose to form their home bases in volumetric space, and (iii) how they navigated to and from these home bases. To evaluate how horizontal biases may affect these behaviours, we compared a 3D maze where animals preferred to move horizontally to a different 3D configuration where all axes were equally energetically costly to traverse. Additionally, we compared home base formation in two-dimensional arenas with and without walls to the three-dimensional climbing mazes. We report that many behaviours exhibited by rats in horizontal spaces naturally extend to fully volumetric ones, such as home base formation and foraging excursions. We also provide further evidence for the strong differentiation of the horizontal and vertical axes: rats showed a horizontal movement bias, they formed home bases mainly in the bottom layers of both mazes and they generally solved the vertical component of return trajectories before and faster than the horizontal component. We explain the bias towards horizontal movements in terms of energy conservation, while the locations of home bases are explained from an information gathering view as a method for correcting self-localisation.

The place-cell representation of volumetric space in rats.
Place cells are spatially modulated neurons found in the hippocampus that underlie spatial memory and navigation: how these neurons represent 3D space is crucial for a full understanding of spatial cognition. We wirelessly recorded place cells in rats as they explored a cubic lattice climbing frame which could be aligned or tilted with respect to gravity. Place cells represented the entire volume of the mazes: their activity tended to be aligned with the maze axes, and when it was more difficult for the animals to move vertically the cells represented space less accurately and less stably. These results demonstrate that even surface-dwelling animals represent 3D space and suggests there is a fundamental relationship between environment structure, gravity, movement and spatial memory.

NEUROPROTECTIVE POTENTIAL OF CHEBULINIC ACID IN STREPTOZOTOCIN-INDUCED DIABETES-ASSOCIATED COGNITIVE DECLINE: BEHAVIORAL AND BIOCHEMICAL EVIDENCES

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Rimpi Arora
ISF College of Pharmacy Moga India, Neuropharmacology, Moga, India

Previous studies demonstrated that streptozotocin (STZ) induced intracellular glucose following neurochemical and structural abnormalities are the leading causes of neuronal damage consequently learning and memory deficits. Chebulinic acid (ChA), a flavonoid isolated from Terminalia Chebula, has potent protective effects on peripheral and central streptozotocin (STZ)-induced diabetic and diabetic AD rats. Recently, the effects of ChA on learning and memory performances were monitored in many animal models of cognitive impairment. However, to date, no studies have investigated the ameliorative effects of ChA on diabetes associated with cognitive decline (DACD). In this study, we investigated the effects of ChA, using a STZ-treated rat model and explored its potential mechanism. Diabetic rats were treated with ChA (25, 50 and 100 mg/kg/i.p) for 14 days. The learning and memory function were evaluated by Morris water maze test. The oxidative stress markers malondialdehyde (MDA), nitrite (NO) and GSH (glutathione) and inflammatory cytokines (TNF-a, IL-1β, and IL-6) were measured in hippocampus. P38 MPAK was evaluated using Elisa. The results showed that ChA supplement in STZ administered rats amended learning and memory performances compared with the STZ group. Moreover, ChA complement GSH levels, reduced MDA and NO levels, and alleviated TNF-α, IL-1β, and IL-6 compared with the STZ group in the hippocampus. The post-treatment with ChA also significantly decreased p38 MAPK expression. Our results showed that ChA may be a promising satisfying agent for improving cognitive decline in DACD.

Embelin Attenuates Intracerebroventricular Streptozotocin-Induced Behavioral, Biochemical, and Neurochemical Abnormalities in Rats.
Embelin, the main active constituent of Embelia ribes, has been reported to possess various pharmacological actions, including anti-inflammatory, antioxidant, anticonvulsant, and neuroprotective. The present study was designed to investigate neuroprotective mechanisms and therapeutic potential of embelin against intracerebroventricular streptozotocin (ICV-STZ)-induced experimental sporadic dementia in rats. STZ was infused bilaterally at the dose of (3 mg/kg/1 µl/1 min) ICV on day first and third. Spatial and non-spatial memory was evaluated using Morris water maze and object recognition task in rats. Embelin (2.5, 5, and 10 mg/kg, i.p.) was administrated for 14 days from seventh day onwards after first ICV-STZ infusion in rats. On day 22, rats were sacrificed and hippocampal brain regions were used to identify biochemical, neurochemical, and neuroinflammatory alterations. STZ-infused rats showed significant learning and memory deficit which was associated with an increase in oxidative stress (lipid peroxidation and nitrite), compromised antioxidant defense (reduced glutathione), neurotransmitter alterations (AChE, dopamine, noradrenaline, 5-hydroxytryptamine, gama amino butyric acid, and glutamate), and elevation in neuroinflammatory cytokine (IL-1 β, IL-6, and TNF-α) levels. Embelin dose dependently attenuated STZ-induced cognitive deficit and biochemical alterations and restored hippocampal neurochemical levels. The observed protective effect might be attributed to the antioxidant and anti-inflammatory potential of embelin and its ability to restore hippocampal neurochemistry. Thus, the outcomes of the current study suggest therapeutic potential of embelin in cognitive disorders such as sporadic Alzheimer's disease (SAD).

FK506 attenuates intracerebroventricular streptozotocin-induced neurotoxicity in rats.

Upregulation in calcineurin (CaN) signaling has been implicated in various neurodegenerative disorders. In the present study, we have investigated the effect of FK506--a CaN inhibitor--on streptozotocin (STZ)-induced experimental dementia of the Alzheimer's type in rats. STZ was administered intracerebroventricularly to induce a cognitive deficit and oxidative stress. Nonimmunosuppressive doses (0.5 and 1 mg/kg postoperatively) of FK506 (tacrolimus) were administered for 21 day in STZ-treated rats. Cognitive functions were assessed using the Morris water maze and passive avoidance tasks. Malondialdehyde and nitrite glutathione levels, as well as acetylcholinesterase activity, were determined to evaluate oxidative stress and cholinergic functions. Lactate dehydrogenase levels were estimated and histological analysis of the dentate gyrus and the CA1 region of the hippocampus was carried out to identify degenerative changes. STZ produced significant deterioration of cognitive functions, oxidative stress, and degenerative changes in the cortical and hippocampal brain regions. FK506 dose-dependently attenuated STZ-induced cognitive deficits, oxidative stress, and degenerative changes in the cortex and hippocampus. These results suggest a potential role of CaN signaling in degenerative processes, and that inhibition of CaN may be useful in the treatment of neurodegenerative disorders such as Alzheimer's disease.

MOTIVATIONAL PERFORMANCE IN HUMANS AS A FUNCTION OF THE NEUROCHEMICAL COMPOSITION OF ANTERIOR INSULA AND DORSOMEDIAL PREFRONTAL CORTEX/DORSAL ANTERIOR CINGULATE CORTEX.

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Arthur Barakat[1], Nicolas Clairis[2], Carmen Sandi[1]

Aims: Motivation can be characterized as a series of cost–benefit valuations in which individuals weight the amount of effort expendable in return for a chosen reward. Previous work has revealed that several brain regions, such as the dorsomedial prefrontal cortex/dorsal anterior cingulate cortex (dmPFC/dACC) and the anterior insula (IA), are involved in different aspects of motivated behavior. However, little is known about the neurochemical underpinnings of individual differences in motivation, particularly in these brain regions. Methods: We apply proton magnetic resonance spectroscopy (^{1}H-MRS) at ultra-high field (7T), enabling distinction between glutamine (Gln) and glutamate (Glu), in two different brain regions: the dmPFC/dACC and AI. Specifically, we inquire whether levels of metabolites in each of these brain regions correlate with inter-individual motivational parameters. Using effort-based monetary incentivized tasks involving either physical and mental effort, we extract computational parameters from participants' behaviors allowing to relate brain metabolites to sensitivity to reward, effort, and fatigue. Given the relevant literature comparing win and loss aversion, we also examine participants' differences in loss versus gain sensitivity. Results: Our results reveal relationships between specific metabolites including Gln, γ-aminobutyric acid (GABA), Glu and their ratios with participants' motivational parameters mainly in the AI. Conclusion: Our findings provide insights implicating specific brain metabolites on computational components of motivated performance. This approach and findings can help to develop novel therapeutic strategies based on the targeting of brain metabolism to ameliorate deficits in motivated behavior.

REDUCTION OF ADULT NEUROGENESIS BY TEMOZOLOMIDE INHIBITS INTRINSIC PREFERENCE FOR EXPLORING COMPLEX OBJECTS IN MICE

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Sonia Melgar-Locatelli[1], M. Carmen Mañas-Padilla[1], Sara Gil-Rodríguez[1], Lucía Vicente[2], Ana M. Gálvez-Callejón[1], Celia Rodríguez-Pérez[3], Estela Castilla-Ortega[1]
[1]University of Malaga-IBIMA, Psychobiology And Methodology Of Behavioral Sciences, Malaga, Spain, [2]University of Deusto, Psychology And Education, Bilbao, Spain, [3]University of Granada, Nutrition And Food Science, Granada, Spain

Intrinsic exploratory bias is an innate tendency to prefer certain types of stimuli or environments over others. For example, mice would genuinely spent more time exploring perceptually complex objects (i.e. with edges and concavities) than simpler objects without irregularities. Intrinsic exploratory bias are relevant as they may be associated to cognitive, emotional and even personality-like traits. However, their neurobiological basis are scarcely investigated. Adult hippocampal neurogenesis (AHN) is a key neuroplastic phenomenon for the processing of spatial and contextual stimuli in rodents, being involved in novelty recognition, spatial navigation and spatial pattern separation tasks. Therefore, here we studied whether a pharmacological inhibition of AHN influences intrinsic motivation for exploring complex objects. Twenty male young adult C57BL/6J mice (~3 months old) received vehicle or the DNA alkylating agent temozolomide (TMZ) for four weeks. Bromodeoxyuridine (BrdU) was administered weekly, confirming a reduction of AHN-related markers by TMZ. After the pharmacological treatment, mice were tested for behavior. TMZ did not impair mice's health nor their general exploratory and anxiety-like responses. Unlike control mice, the TMZ-treated mice did not prefer exploring a complex (i.e. irregular) object over a simple (i.e. non-irregular) object of similar size presented at once. Nevertheless, they were able to discriminate a novel complex object from a familiar complex object. This suggest that the lack of intrinsic preference for complexity could be explained by motivational and not by cognitive variables. Future studies should investigate a new role of AHN in modulating exploratory bias. **Project PID2020-114374RB-I00 funded by MCIN/AEI/10.13039/501100011033/. University of Malaga.**

AIMS: Understanding brain operation demands linking basic behavioural traits to cell-type specific dynamics of different brain-wide subcircuits. This requires a system to classify the basic operational modes of neurons and circuits. Single-cell phenotyping of firing behaviour during ongoing oscillations in vivo has provided a large body of evidence on hippocampal function, but data are dispersed and diverse. METHODS: We mined literature to search for in vivo single-cell firing patterns and phase-locking values of multiple cell types from the hippocampal formation and entorhinal cortex during spontaneous oscillations. To complement missing and unresolved pieces of knowledge, we combined single-cell sharp and silicon probe recordings in adult rats and mice under urethane and in awake head-fixed conditions. RESULTS: We updated information on oscillatory dynamics of over 100 hippocampal neuronal types defined in Hippocampome.org. We integrated all current knowledge about the morphology, biophysics, genetic identity, connectivity, and firing patterns of a wealth of GABAergic and glutamatergic neurons to provide a comprehensive single-cell map of the hippocampal region. By exploiting this resource, we explored trends of firing dynamics across the hippocampal proximo-distal and deep-superficial axes. Finally, we show how using Hippocampome.org can provide knowledge-based classification of hippocampal cell types when coupled to genetically driven optotagging approaches. CONCLUSIONS: An online resource that is a part of Hippocampome.org has been created that integrates data about which cell activities occur during oscillations across experimentation modalities with single cell resolution.

An update to Hippocampome.org by integrating single-cell phenotypes with circuit function in vivo.
Understanding brain operation demands linking basic behavioral traits to cell-type specific dynamics of different brain-wide subcircuits. This requires a system to classify the basic operational modes of neurons and circuits. Single-cell phenotyping of firing behavior during ongoing oscillations in vivo has provided a large body of evidence on entorhinal-hippocampal function, but data are dispersed and diverse. Here, we mined literature to search for information regarding the phase-timing dynamics of over 100 hippocampal/entorhinal neuron types defined in Hippocampome.org. We identified missing and unresolved pieces of knowledge (e.g., the preferred theta phase for a specific neuron type) and complemented the dataset with our own new data. By confronting the effect of brain state and recording methods, we highlight the equivalences and differences across conditions and offer a number of novel observations. We show how a heuristic approach based on oscillatory features of morphologically identified neurons can aid in classifying extracellular recordings of single cells and discuss future opportunities and challenges towards integrating single-cell phenotypes with circuit function.

Development of Action Potential Waveform in Hippocampal CA1 Pyramidal Neurons.
CA1 pyramidal neurons undergo intense morphological and electrophysiological changes from the second to third postnatal weeks in rats throughout a critical period associated with the emergence of exploratory behavior. Using whole cell current-clamp recordings in vitro and neurochemical methods, we studied the development of the somatic action potential (AP) waveform and some of the underlying channels in this critical period. At the third postnatal week, APs showed a more

hyperpolarized threshold, higher duration and amplitude. Subthreshold depolarization broadened APs and depolarized their peak overshoots more pronouncedly in immature neurons (2 weeks old). These features were mimicked by pharmacologically blocking the fast-inactivating A-type potassium current (I) and matched well with the higher concentrations of K4.2 and K4.3 and the lower concentrations of BK and K1.2 channels detected by Western blotting. Repetitive stimulation with high frequency trains (50 Hz) reproduced AP broadening associated to inactivation of the A-type current in immature cells. Moreover, repetitive firing showed changes in AP amplitude consistent with the inactivation of both sodium and potassium subthreshold currents, which resulted in higher AP amplitudes in the more immature neurons. We propose that maturation of AP waveform and excitability in this critical developmental period could be related to the onset of exploratory behaviors.

Proximodistal Organization of the CA2 Hippocampal Area.
The proximodistal axis is considered a major organizational principle of the hippocampus. At the interface between the hippocampus and other brain structures, CA2 apparently breaks this rule. The region is involved in social, temporal, and contextual memory function, but mechanisms remain elusive. Here, we reveal cell-type heterogeneity and a characteristic expression gradient of the transcription factor Sox5 within CA2 in the rat. Using intracellular and extracellular recordings followed by neurochemical identification of single cells, we find marked proximodistal trends of synaptic activity, subthreshold membrane potentials, and phase-locked firing coupled to theta and gamma oscillations. Phase-shifting membrane potentials and opposite proximodistal correlations with theta sinks and sources at different layers support influences from different current generators. CA2 oscillatory activity and place coding of rats running in a linear maze reflect proximodistal state-dependent trends. We suggest that the structure and function of CA2 are distributed along the proximodistal hippocampal axis.

Loss of Cntnap2 Causes Axonal Excitability Deficits, Developmental Delay in Cortical Myelination, and Abnormal Stereotyped Motor Behavior.
Contactin-associated protein-like 2 (Caspr2) is found at the nodes of Ranvier and has been associated with physiological properties of white matter conductivity. Genetic variation in CNTNAP2, the gene encoding Caspr2, has been linked to several neurodevelopmental conditions, yet pathophysiological effects of CNTNAP2 mutations on axonal physiology and brain myelination are unknown. Here, we have investigated mouse mutants for Cntnap2 and found profound deficiencies in the clustering of Kv1-family potassium channels in the juxtaparanodes of brain myelinated axons. These deficits are associated with a change in the waveform of axonal action potentials and increases in postsynaptic excitatory responses. We also observed that the normal process of myelination is delayed in Cntnap2 mutant mice. This later phenotype is a likely modulator of the developmental expressivity of the stereotyped motor behaviors that characterize Cntnap2 mutant mice. Altogether, our results reveal a mechanism linked to white matter conductivity through which mutation of CNTNAP2 may affect neurodevelopmental outcomes.

Activity-Dependent Gating of Parvalbumin Interneuron Function by the Perineuronal Net Protein Brevican.
Activity-dependent neuronal plasticity is a fundamental mechanism through which the nervous system adapts to sensory experience. Several lines of evidence suggest that parvalbumin (PV+) interneurons are essential in this process, but the molecular mechanisms underlying the influence of experience on interneuron plasticity remain poorly understood. Perineuronal nets (PNNs) enwrapping PV+ cells are long-standing candidates for playing such a role, yet their precise contribution has remained elusive. We show that the PNN protein Brevican is a critical regulator of interneuron plasticity. We find that Brevican simultaneously controls cellular and synaptic forms of plasticity in PV+ cells by regulating the localization of potassium channels and AMPA receptors, respectively. By modulating Brevican levels, experience introduces precise molecular and cellular modifications in PV+ cells that are required for learning and memory. These findings uncover a molecular program through which a PNN protein facilitates appropriate behavioral responses to experience by dynamically gating PV+ interneuron function.

Role of low-voltage-activated calcium current and extracellular calcium in controlling the firing pattern of developing CA1 pyramidal neurons.
The firing pattern of individual neurons is an important element for information processing and storing. During the first weeks of development, there is a transitional period during which CA1 pyramidal neurons display burst-spiking behavior in contrast to the adult regular-firing pattern. Spike after-depolarizations (ADPs) constitute a major factor underlying burst-spiking behavior. Using current-clamp recordings, we studied ADP waveforms and firing patterns in CA1 pyramidal neurons of Wistar rats from 9 to 19 postnatal days (P9-19). The percentage of burst-spiking neurons increased up to P16, in correlation with the emergence of an active component in the ADP. The application of low-voltage-activated (LVA) calcium channel blockers such as nickel or mibefradil suppressed the generation of the active ADP component and burst-spiking behavior. In agreement with the development of the ADP waveform and burst-spiking behavior, voltage-clamp experiments in dissociated pyramidal neurons showed an increase in the LVA calcium current in P16-19 vs P9-12. Finally, we found that a reduction of extracellular calcium levels decreases the percentage of burst-spiking cells due to a reduction in the active component of the ADP. We conclude that a major contribution of LVA calcium channels to ADP determines the bursting capability of CA1 pyramidal neurons during a transitional postnatal period in contrast to adulthood.

Determinants of different deep and superficial CA1 pyramidal cell dynamics during sharp-wave ripples.
Sharp-wave ripples represent a prominent synchronous activity pattern in the mammalian hippocampus during sleep and immobility. GABAergic interneuronal types are silenced or fire during these events, but the mechanism of pyramidal cell (PC) participation remains elusive. We found opposite membrane polarization of deep (closer to stratum oriens) and superficial (closer to stratum radiatum) rat CA1 PCs during sharp-wave ripples. Using sharp and multi-site recordings in combination with neurochemical profiling, we observed a predominant inhibitory drive of deep calbindin (CB)-immunonegative PCs that contrasts with a prominent depolarization of superficial CB-immunopositive PCs. Biased contribution of perisomatic GABAergic inputs, together with suppression of CA2 PCs, may explain the selection of CA1 PCs during sharp-wave ripples. A deep-superficial gradient interacted with behavioral and spatial effects to determine cell participation during sleep and awake sharp-wave ripples in freely moving rats. Thus, the firing dynamics of hippocampal PCs are exquisitely controlled at subcellular and microcircuit levels in a cell type-selective manner.

A novel short-term plasticity of intrinsic excitability in the hippocampal CA1 pyramidal cells.
Changes in neuronal activity often trigger compensatory mechanisms aimed at regulating network activity homeostatically. Here we have identified and characterized a novel form of compensatory short-term plasticity of membrane excitability, which develops early after the eye-opening period in rats (P16-19 days) but not before that developmental stage (P9-12 days old). Holding the membrane potential of CA1 neurons right below the firing threshold from 15 s to several minutes induced a potentiation of the repolarizing phase of the action potentials that contributed to a decrease in the firing rate of CA1 pyramidal neurons in vitro. Furthermore, the mechanism for inducing this plasticity required the action of intracellular Ca(2+) entering through T-type Ca(2+) channels. This increase in Ca(2+) subsequently activated the Ca(2+) sensor K(+) channel interacting protein 3, which led to the increase of an A-type K(+) current. These results suggest that Ca(2+) modulation of somatic A-current represents a new form of homeostatic regulation that provides CA1 pyramidal neurons with the ability to preserve their firing abilities in response to membrane potential variations on a scale from tens of seconds to several minutes.

ROLE OF A HYPOTHALAMUS-HABENULA CIRCUIT IN ACUPUNCTURE INHIBITION OF COCAINE ADDICTION-LIKE BEHAVIORS

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Han Byeol Jang[1], Danbi Ahn[1], Cong Zhan[1], Hee Young Kim[2]
[1]Daegu hanny university, Department Of Physiology, College Of Korean Medicine, Daegu, Korea, Republic of, [2]Daegu Haany University, Department Of Physiology, College Of Korean Medicine, Daegu, Korea, Republic of

Abstract: Acupuncture has been used to treat drug addiction, although the underlying mechanism is largely unknown. The lateral habenula (LHb), the lateral hypothalamus (LH), and the mesolimbic dopamine (DA) system are not only reciprocally connected, but also involved in drug reward. We explored the role of the LH-LHb circuit in acupuncture inhibition of cocaine seeking-behavior. Acupuncture at HT7, but not LI5, attenuated locomotor activity and 50-kHz USVs and NAc DA release following cocaine injection. The acupuncture effects were ablated by electrolytic lesion or optogenetic inhibition of LHb. Optogenetic activation of LHb suppressed cocaine-enhanced 50 kHz USVs and locomotion. Acupuncture at HT7 reversed cocaine suppression of neuronal activity of LHb. Acupuncture at HT7 inhibited cocaine-primed reinstatement of drug-seeking behavior, which was blocked by chemogenetic inhibition of an LH-LHb circuit. These findings suggest that acupuncture requires LH-LHb pathways to attenuate cocaine-induced psychomotor responses and seeking behaviors. **Key words**: Acupuncture, cocaine, Lateral habenula, locomotor activity, ultrasonic vocalization (USVs), optogenetics Acknowledgment: This research was supported by the National Research Foundation of Korea (NRF) grant funded by the Korean government (MSIT) (Nos. 2018R1A5A2025272, 2019R1A2C1002555 and KMDF_PR_20200901_01179991006790).

THE EFFECTS OF THE JAGEUMJUNG AND ACUPUNCTURE ON METH'S REINFORCING EFFECTS THROUGH THE CENTRAL AMYGDALA

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Jin Gyeom Lee, Han Byeol Jang, Bong Hyo Lee
Daegu Haany University, College Of Korean Medicin, Daegu, Korea, Republic of

Methamphetamine(METH) is a representative widely abused drug, and acupuncture has been used to treat drug addiction. The present study was conducted to investigate the effects of acupuncture(SI5) and Jageumjung(JGJ) on METH's reinforcing effects through the central amygdala(CeA). The CeA plays a critical role in physiological and behavioral responses. JGJ is composed of six herbs and its effect on drug-enhanced treatment is unclear. And there are no studies examining the combined effects of the two treatments, JGJ and SI5. To measure the reinforcing effects of METH, locomotor activity, 50-kHz ultrasonic vocalization(USV), Fast-scan cyclic voltammetry(FSCV) and immunochemistry were used. JGJ, METH, and GABA receptor agonists($GABA_A$, $GABA_B$) were administered through oral, intravenous or intraperitoneal, and intracerebral administration, respectively, and then acupuncture was treated by manual stimulation. The results show that JGJ inhibits METH-induced increases in locomotor activity and USVs. Acupuncture had an inhibitory effect on METH, especially SI5 not HT7. And the group that treated JGJ and SI5 together showed more inhibitory effects than the group that treated JGJ and SI5, respectively. The GABA agonists significantly reversed the inhibition of the METH's effect by JGJ. However, FSCV unlikes the previous experiments. Taken together, our findings indicate that JGJ contributes to the effect of METH inhibition by the GABA receptor in CeA, and that the combination of SI5 and JGJ may be an effective strategy in reducing the reinforcing properties of METH. This research was supported by the National Research Foundation of Korea(NRF) grants funded by the Korea government(MSIT)(No.2018R1A5A2025272) and 2020R1A2C1103154.

ESTABLISHING AN ASSAY FOR INDIVIDUAL OLFACTORY LEARNING IN DROSOPHILA LARVAE

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Amina Dulac[1], Nicolo Ceffa[2], Kun Wang[2], Marta Zlatic[1]
[1]Cambridge University, Department Of Zoology, Cambridge, United Kingdom, [2]Laboratory of molecular biology, Neurobiology, Cambridge, United Kingdom

Inter-individual variation is present in every animal species and reflected in many behavioural aspects, one being the learning speed: while all animals can learn, the speed with which different individuals from the same species learn can vary widely. Very little is known about the circuit and molecular mechanisms underlying inter-individual differences. Investigating such questions requires both a deep understanding of the neural computations and circuit responsible for a chosen task and knowledge of anatomical and functional differences between those circuits in different individuals. Such level of precision remains out of reach for most model organisms, including rodents. However, for some invertebrate models such as the drosophila larva, the relative simplicity and small size of their brains coupled to the development of new high-resolution tools now allow to address these problematics. To assess individual behaviour, we have adapted an experimental set-up previously developed by the Gershow laboratory to be able to test a single drosophila larva in an olfactory associative paradigm. The animal is freely crawling in a Y-maze where it is given the choice between two different odours every time it reaches the 3-arms intersection. Choices are recorded before and after an odour-punishment paired training to assess learning. This fully automated system will allow the behavioural classification of individuals according to their learning speed. Structural and functional differences in the relevant neuronal circuits between the identified subgroups will then be assessed to characterize the neuronal basis of inter-individual variation.

DIFFERENTIAL VALUE AND OUTCOME PROCESSING BETWEEN DORSAL AND VENTRAL CA1 REGIONS OF THE HIPPOCAMPUS

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Jiyoung Hwang, Miru Yun, Min Jung
IBS/Korea Advanced Institute of Science and Technology (KAIST), Biological Sciences, Daejeon, Korea, Republic of

Despite tremendous progress, our understanding of the full spectrum of hippocampal functions is still incomplete. This is in large part because of our limited understanding of functional specialization along the longitudinal axis of the hippocampus. To tackle this matter, we examined how value- and outcome-related neural activity varies between the dorsal (dCA1) and ventral CA1 (vCA1) in mice performing probabilistic classical conditioning tasks. Inactivation of either structure disrupted value-dependent anticipatory licking, and value-coding neurons were found in both structures, indicating their involvement in value processing. However, we found several outstanding differences in value- and outcome-related neural activity between the dCA1 and vCA1. The dCA1 neuronal population increased activity monotonically as a function of value, while the vCA1 neuronal population was preferentially responsive to the highest-value sensory cue. Also, signals related to outcome-dependent value learning (value and outcome signals during the outcome period; signals related to the history of past cues and outcomes; and signals related to updated value) were stronger in the dCA1. vCA1 neurons instead showed rapid responses to punishment and strongly biased responses to negative prediction error. These findings suggest that the dCA1 faithfully represents values associated with sensory cues, while the vCA1 preferentially represents behaviorally relevant, salient features of experienced events.

NEURAL REPRESENTATIONS OF LEARNED CATEGORIES IN MOUSE PREFRONTAL CORTEX

POSTER SESSION 01 - SECTION: CIRCUITRY OF MEMORY AND LEARNING

Sandra Reinert, Mark Hübener, Tobias Bonhoeffer, Pieter Goltstein
Max Planck Institute for Biological Intelligence (in foundation), Synapses - Circuits - Plasticity, Martinsried, Germany

Grouping objects and experiences into categories is a fundamental skill for humans and many animals. Particularly, learning and recalling rules for categorization enables us to flexibly adapt to changes in context. Because the neuronal mechanisms underlying this process are not understood, we characterized representations of learned categories in mouse medial prefrontal cortex (mPFC) by chronically recording neuronal activity during visual categorization learning. In a head-fixed go/no-go task, mice were trained to categorize drifting gratings either based on orientation or spatial frequency. All mice successfully learned to group the stimuli into categories and generalized the learned rule to novel stimuli. Upon a rule-switch, mice quickly sorted the stimuli into new categories. Strikingly, the animals also generalized the new rule to stimuli they had previously only experienced under the old rule. Thus, mice can learn rules for categorization. Throughout this learning paradigm, we followed the activity of neurons in layer 2/3 of mPFC using two-photon calcium imaging. We found that a set of neurons acquired category-selective responses. After the rule-switch, category-selective neurons partly remapped and previously non-selective neurons became responsive to the new categories. By requiring mice to change their learned motor response from go/no-go to go-right/go-left, we aimed to disentangle task parameters, like behavioral choice and reward, from category selectivity. Hereby, we identified uniquely category-modulated neurons that represented the category identity of stimuli across tasks. Together, these results demonstrate that mouse mPFC forms representations of learned categories and flexibly encodes changes in rules.

DOPAMINE REWARD PREDICTION ERRORS REPORT BUT ARE NOT USED TO UPDATE CHOICE BEHAVIOUR IN STRUCTURED ENVIRONMENTS

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Marta Blanco-Pozo, Thomas Akam, Mark Walton
University of Oxford, Experimental Psychology, Oxford, United Kingdom

Aims Dopamine signals are thought to aid flexible behaviour by carrying reward prediction errors (RPEs), used as a teaching signal to update values and future behaviour. However, in real-world situations, environments contain structure, meaning changes have patterns or rules that can be learned, like the day-night cycle. In these situations, instead of continuously updating and changing values, *inferring* that the *state* of the world has changed can allow prior experiences to be reused when situations are reencountered, which can enable more efficient updating. In this study, we explored dopamine's involvement in such structured environments. Methods We i) trained mice to solve a sequential probabilistic decision task in which the reward state (i.e. the location of reward) could be inferred, ii) performed behavioural modelling, iii) recorded calcium activity in midbrain dopamine neuron cell bodies, and axons in ventral and dorsomedial striatum using GCaMP fibre photometry, together with dopamine concentrations using dLight, and iv) optogenetically stimulated and inhibited midbrain dopamine activity during the task. Results Choice behaviour and dopamine signals indicated mice learned the task structure. Dopamine was strongly influenced by the value of state and actions, consistent with RPE signalling, using value information that respected the task structure. Nonetheless, neither activating nor inhibiting dopamine at trial outcome affected subsequent choices, although both manipulations strongly modulated choices in separate task contexts. Conclusion During flexible behaviour in well-learned structured environments, **dopamine RPEs** are strongly influenced by **state value**, but this relationship is not reciprocal, and rewards have a **dopamine-independent influence on behaviour**.

Dissociable and Paradoxical Roles of Rat Medial and Lateral Orbitofrontal Cortex in Visual Serial Reversal Learning.
Much evidence suggests that reversal learning is mediated by cortico-striatal circuitries with the orbitofrontal cortex (OFC) playing a prominent role. The OFC is a functionally heterogeneous region, but potential differential roles of lateral (lOFC) and medial (mOFC) portions in visual reversal learning have yet to be determined. We investigated the effects of pharmacological inactivation of mOFC and lOFC on a deterministic serial visual reversal learning task for rats. For reference, we also targeted other areas previously implicated in reversal learning: prelimbic (PrL) and infralimbic (IL) prefrontal cortex, and basolateral amygdala (BLA). Inactivating mOFC and lOFC produced opposite effects; lOFC impairing, and mOFC improving, performance in the early, perseverative phase specifically. Additionally, mOFC inactivation enhanced negative feedback sensitivity, while lOFC inactivation diminished feedback sensitivity in general. mOFC and lOFC inactivation also affected novel visual discrimination learning differently; lOFC inactivation paradoxically improved learning, and mOFC inactivation had no effect. We also observed dissociable roles of the OFC and the IL/PrL. Whereas the OFC inactivation affected only perseveration, IL/PrL inactivation improved learning overall. BLA inactivation did not affect perseveration, but improved the late phase of reversal learning. These results support opponent roles of the rodent mOFC and lOFC in deterministic visual reversal learning.

Predictive and reactive reward signals conveyed by climbing fiber inputs to cerebellar Purkinje cells.
There is increasing evidence for a cerebellar contribution to cognitive processing, but the specific input pathways conveying this information remain unclear. We probed the role of climbing fiber inputs to Purkinje cells in generating and evaluating predictions about associations between motor actions, sensory stimuli and reward. We trained mice to perform a visuomotor integration task to receive a reward and interleaved cued and random rewards between task trials. Using two-photon calcium imaging and Neuropixels probe recordings of Purkinje cell activity, we show that climbing fibers signal reward expectation, delivery and omission. These signals map onto cerebellar microzones, with reward delivery activating some microzones and suppressing others, and with reward omission activating both reward-activated and reward-suppressed microzones.

Moreover, responses to predictable rewards are progressively suppressed during learning. Our findings elucidate a specific input pathway for cerebellar contributions to reward signaling and provide a mechanistic link between cerebellar activity and the creation and evaluation of predictions.

MULTIPLE STIMULUS-STIMULUS ASSOCIATIONS DURING MULTI-STEP REINFORCEMENT LEARNING IN HUMANS IN SPATIALLY STRUCTURED AND UNSTRUCTURED FRAMES

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Sabrine Hamroun[1], Mael Lebreton[2], Stefano Palminteri[3]
[1]Ecole Normale Supérieure, Departement Des Etudes Cognitives, Paris, France, [2]Paris School of Economics, Paris-jourdan Sciences Économiques, Paris, France, [3]École Normale Supérieure - PSL Research University, Département D'etudes Cognitives, Paris, France

Multi-step learning and decision-making paradigm are the most commonly used tools to investigate the trade-off between retrospective, model-free reinforcement learning that requires the representation of state-action-reward and prospective, model-based one that requires to explicitly represent the state transitions. In most paradigms, state transitions are provided by instructions, while reward values have to be learned on the fly. The goal of the present study was to investigate the mechanisms of learning in parallel action-state transitions and reward values and the impact of the spatial structure of the task on the learning. Therefore, we conducted laboratory (N=30) and online (N=200) experiments using new proposed designs of the two-step paradigm. After the learning phase, we administered additional tests to explicitly assess different stimulus-stimulus associations. The results revealed that subjects could retrieve the correct action-state transitions, despite behavior in the learning not showing signs of prospective valuation. We concluded the experiment using Raven's matrices and cognitive reflection tests. Scores in these tests correlated with spatially unstructured learning, spatially structured learning (marginally) and not at all with action-state transition learning, suggesting that fluid intelligence and cognitive control do not play a role in action-state transition learning, but in the deployment of structure learning at the service of decision-making. Finally these results are not affected by the task's spatial framing. Together our results indicate that the reward values and the action-state transitions are concomitantly learned, even if behavior does not provide signs of prospective valuation suggesting an intriguing dissociation between knowledge and performance in reinforcement learning.

TASK ELICITED CONTEXT-DEPENDENCY AND VALENCE BIAS IN VALUE ENCODING: AN ELUSIVE RELATIONSHIP WITH MENTAL HEALTH PROFILES

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Zoe Koopmans, Sophie Bavard, Stefano Palminteri
École Normale Supérieure - PSL, Laboratoire De Neurosciences Cognitives, Paris, France

Poor mental health has frequently been associated with decision-making that deviates from the norm. An integral step of decision-making is value encoding. We aim to explore a relationship between mental health profiles and value encoding, as elicited by features of two tasks; the Hiragana task (Frank et al. 2004) and the Agathodaimon task (Pessiglione et al. 2006). Both have been fundamental in providing firm support for a relationship between dopamine availability in the brain and valence induced bias in value encoding. Thereupon we conducted a focused literature survey on published data from either of the tasks. Informed about the limitations of the current literature, we developed refined research approaches to experimentally address our aim. For the ensuing dimensional approach to mental health, our participants answered a novel combination of standard mental health questionnaires. The analysis supports the emergence of three psychiatric dimensions, including a dimension describing substance abuse profiles. Our online behavioural task features a valanced learning phase and a knowledge transfer phase. The performance data suggests context-dependent value encoding and valence bias. Furthermore, our reinforcement learning model analysis supports interindividual differences in context-dependency and asymmetric learning. Nevertheless, there was no robust evidence for a relationship between behavioural features and mental health profiles. While behavioural features are thoroughly replicated, the interindividual reliability measures are poor. This suggests the behavioural traits this task elicits, and our model characterises, might lack temporal sturdiness. In conclusion, we present a difficulty in relating mental health profiles to a reinforcement learning characterisation of value encoding.

EMOTIONAL DYSREGULATION AND ALTERED REWARD PROCESSING IN SELF-HARM

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Emre Yavuz[1], Martina Di Simplicio[1], Rachel Rodrigues[1], Anne Lingford-Hughes[2]
[1]Imperial College London, Department Of Brain Sciences, London, United Kingdom, [2]Imperial College London, Division Of Psychiatry, Department Of Brain Sciences, London, United Kingdom

Background: Self-Harm (SH), being “any act of self-injury or poisoning carried out by someone irrespective of motivation”, increases suicide risk, necessitating intervention. People mostly SH to relieve negative affect (NA), with NA precipitating SH. SH participants show reward hypersensitivity. NA may trigger reward hypersensitivity, instigating SH, but whether this interaction exists remains unclear. Aim: Investigate whether SH participants process potentially rewarding SH stimuli differently to healthy controls (HCs) post-NA induction. Hypothesis: Post-NA induction, SH participants will have significantly shorter reaction latencies (RL) and greater reaction accuracies (RA) in the SH condition of the Incentive Delay task (IDT) than HCs. Methods: 16-25-year-old SH (n=35) and HC (n=20) participants recruited using social media completed the Trier Social Stress Test, to induce NA, then the IDT. In the latter, participants were cued to respond to a target as quickly as possible, seeing images of either SH acts, people socializing or money on responding (SH, social and monetary conditions respectively). Control conditions showed a neutral image on responding (SH-neutral, social-neutral, and monetary-neutral conditions respectively). Results: A main effect of condition on RA ($p < 0.05$) but not RL ($p > 0.05$), and no main group or group-by-condition interaction effect on either ($p > 0.05$) was found. Past-week SH frequency and RA positively correlated in social, social-neutral, and monetary conditions ($p < 0.05$). Conclusion: Reward processing non-significantly differed by group post-NA induction. However, past-week SH frequency significantly correlated with RA. Larger longitudinal studies investigating this interaction may help elucidate SH triggers and develop therapeutic strategies.

FEEDBACK-RELATED NEURAL ACTIVITY OBSERVED IN A DRUMMING TASK PREDICTS SUBSEQUENT TIMING PERFORMANCE

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Yan Yan, Laurence Hunt, Cameron Hassall
University of Oxford, Department Of Psychiatry, Oxford, United Kingdom

Aims: Recent studies showed that reward prediction error can bias interval timing, but the direction of impact remains inconclusive (Soares et al., 2016; Toren et al., 2020). Feedback-related negativity (FRN), an EEG signal around 250ms following negative feedback, may reflect a neural prediction error (Holroyd et al., 2011). This study utilises the FRN to test how performance feedback, as a special case of reward, biases subsequent timing. **Methods:** We recorded electroencephalogram (EEG) from 20 participants while they engaged in a drumming task with varying tempo. To evaluate the impact of the neural prediction error on timing, we derived a trial-by-trial proxy of FRN using regression-based EEG analysis, and used it to predict the timing adjustment in the next trial. We compared a series of hierarchical linear models, controlling for tempo, learning effect, drumming pattern, handedness, etc. **Results:** On the participant level, larger FRN was observed for slower tempos, and its amplitude did not differentiate between early and late feedback. This may imply that “early” and “late” feedback elicit a similar negative neural prediction error compared to “on time” feedback. On the trial level, larger trial-by-trial FRN (i.e., more negative residual EEG) predicted greater timing adjustment following late, but not early feedback. This result most likely supports the hypothesis that negative prediction errors temporarily slow down psychological timing.

Aim Value-based decision-making impairment in depression is a complex phenomenon: while some studies did find evidence of blunted reward learning and reward-related signals in the brain, others indicate no effect. Here we test whether such reward sensitivity deficits are dependent on the overall value of the decision problem. **Methods** We used a two-armed bandit task with two different contexts: one 'rich', one 'poor' where both options were associated with an overall positive, negative expected value, respectively. We tested patients (N=30) undergoing a major depressive episode and age, gender and socio-economically matched controls (N=26). To assess whether differences in learning performance were due to a decision or a value-update process, we analysed performance in a transfer phase, where options were extrapolated from their original learning context. **Results** Healthy subjects showed similar learning performance in the 'rich' and the 'poor' contexts, while patients showed reduced learning in the 'poor' context. Analysis of the transfer phase showed that the context-dependent deficit in patients generalized, thus suggesting that the effect of depression has to be traced to the outcome encoding. Computational model-based results showed that patients displayed higher learning rate for negative compared to positive outcomes (the opposite was true in healthy controls). **Conclusions** Our results illustrate that reinforcement learning performances in depression depend on the value of the context. We show that depressive patients have a specific trouble in contexts with an overall negative state value, which in our task is consistent with a negativity bias at the level of learning rates.

REDUCED ANHEDONIA FOLLOWING INTERNET-BASED COGNITIVE BEHAVIORAL THERAPY FOR DEPRESSION IS MEDIATED BY ENHANCED REWARD CIRCUIT ACTIVATION

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Shir Hanuka[1], Elizabeth Olson[2,3], Roee Admon[1,4], Christian Webb[2,5], William Killgore[6], Scott Rauch[2,3], Isabelle Rosso[2,3], Diego Pizzagalli[2,5]
[1]University of Haifa, School Of Psychological Sciences, Haifa, Israel, [2]McLean Hospital, Center For Depression, Anxiety And Stress Research, Belmont, United States of America, [3]Harvard Medical School, Boston, Department Of Psychiatry, Boston, United States of America, [4]University of Haifa, The Integrated Brain And Behavior Research Center (ibbrc), Haifa, Israel, [5]Harvard Medical School, Department Of Psychiatry, Boston, United States of America, [6]University of Arizona, Department Of Psychiatry, Tucson, United States of America

Background: Major depressive disorder (MDD) is a highly prevalent psychiatric condition, yet many patients do not receive adequate treatment. Novel and highly scalable interventions such as internet-based cognitive-behavioral-therapy (iCBT) may help to address this treatment gap. Anhedonia, a hallmark symptom of MDD that accounts for diminished interest and ability to experience pleasure, has been associated with reduced reactivity in a neural reward circuit that includes medial prefrontal and striatal brain regions. Whether iCBT can reduce anhedonia severity in MDD patients, and whether these therapeutic effects are accompanied by enhanced reward circuit reactivity has yet to be examined. Methods: Fifty-two MDD patients were randomly assigned to either 10-week iCBT (*n*=26) or monitored attention control (MAC, *n*=26) programs. All patients completed pre- and post-treatment assessments of anhedonia (Snaith–Hamilton Pleasure Scale; SHAPS) and reward circuit reactivity (monetary incentive delay; MID) task during functional magnetic resonance imaging (fMRI). Results: Both iCBT and MAC groups exhibited reduction in anhedonia severity post-treatment (P_{iCBT} = 0.001; P_{MAC} = 0.006). Nevertheless, only the iCBT group exhibited enhanced nucleus accumbens (Nacc) (*P* = 0.005) and subgenual anterior cingulate cortex (sgACC) activation (*P* = 0.009) and functional connectivity from pre- to post-treatment in response to reward feedback. Enhanced Nacc and sgACC activations were associated with reduced anhedonia severity following iCBT treatment (*P* = 0.01, *P* = 0.023), with enhanced Nacc activation also mediating the reduction in anhedonia severity post-treatment (*P* = 0.004). Conclusions: These findings suggest that increased reward circuit reactivity may contribute to reduction in anhedonia severity following iCBT treatment for depression.

THE COMPUTATIONAL RULES OF VALUE NORMALIZATION IN HUMAN REINFORCEMENT LEARNING

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Sophie Bavard[1,2], Stefano Palminteri[2,3]
[1]University of Hamburg, Faculty Of Psychology And Human Movement Science, Hamburg, Germany, [2]Ecole Normale Superieure, Laboratoire De Neurosciences Cognitives Et Computationnelles, Inserm U960, Département D'etudes Cognitives, Paris, France, [3]HSE, Institute For Cognitive Science, Moscow, Russian Federation

Context-dependent learning has been shown to lead to irrational choices in humans. This is specifically true when the options are extrapolated from their original learning context. In a previous study, we showed that this process was well captured by a dynamical range normalization model, inspired by the range-frequency theory and electrophysiological findings in monkeys. However, the previously used two-armed bandit task is ill-suited to precisely characterize the functional form of context-dependence as range normalization or divisive normalization. To fill this gap, we designed a new online-based learning task simultaneously manipulating the number of options per context (2-armed bandit versus 3-armed bandit) and the range magnitude of the options, by varying their expected values. We also included an explicit valuation phase where participants had to report their estimation of each option. Behavioral and computational analyses seriously challenge divisive normalization, but suggest that simple range normalization cannot account for all behavioral patterns. Together, these results shed new light on the mechanisms of context-dependent learning in humans.

FRONTAL MIDLINE THETA REFLECTS AN INTEGRATED COST/BENEFIT SIGNAL, BUT NOT DISCOUNTED NET VALUE

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Paula Lopez-Gamundi[1,2], Ernest Mas Herrero[1,2], Josep Marco Pallarés[1,2]
[1]University of Barcelona, Cognition, Development And Educational Psychology, Barcelona, Spain, [2]Bellvitge Biomedical Research Institute, Cognition And Brain Plasticity Unit, Hospitalet de Llobregat, Spain

Overcoming effort costs to obtain a reward is critical for successful goal-directed behavior. Dominate theories of effort-based decision-making posit that the ACC plays a critical role in valuing and integrating reward and effort signals. However, it remains unclear if the ACC tracks the subjective value of effort-based rewards or is simply implicated in cognitive control functions that subserve effort-based choice. In this study, we investigated the effect of effort costs and reward magnitude on ACC activity – putatively measured by frontal midline theta (FMT) – at both cue and feedback, and compared this pattern of activity to a well-established index of incentive salience, the P-300 component. 32 participants completed an EEG experiment with a novel task where they obtained low or high rewards by completing a cognitive task with different degrees of difficulty (low or high), but same reward probability rate. Findings indicate that FMT was significantly enhanced when evaluating high compared to low effort cues, but only when rewards were high. This signal was qualitatively different from the pattern of the P-300 component, which tracked reward magnitude during the cue evaluation phase and was enhanced for both high reward and high effort at feedback. These findings suggest that FMT activity does not reflect pure incentive value or a discounted net value signal, but instead an integrated cost/benefit signal that reflects the need to exert cognitive control to facilitate goal attainment.

The neural basis of effort valuation: A meta-analysis of functional magnetic resonance imaging studies.
Choosing how much effort to expend is critical for everyday decisions. While several neuroimaging studies have examined effort-based decision-making, results have been highly heterogeneous, leaving unclear which brain regions process effort-related costs and integrate them with rewards. We conducted two meta-analyses of functional magnetic resonance imaging data to examine consistent neural correlates of effort demands (23 studies, 15 maps, 549 participants) and net value (15 studies, 11 maps, 428 participants). The pre-supplementary motor area (pre-SMA) scaled positively with pure effort demand, whereas the ventromedial prefrontal cortex (vmPFC) showed the opposite effect. Moreover, regions that have been previously implicated in value integration in other cost domains, such as the vmPFC and ventral striatum, were consistently involved in signaling net value. The opposite response patterns of the pre-SMA and vmPFC imply that they are differentially involved in the representation of effort costs and value integration. These findings provide conclusive evidence that the vmPFC is a central node for net value computation and reveal potential brain targets to treat motivation-related disorders.

Using pharmacological manipulations to study the role of dopamine in human reward functioning: A review of studies in healthy adults.
Dopamine (DA) plays a key role in reward processing and is implicated in psychological disorders such as depression, substance use, and schizophrenia. The role of DA in reward processing is an area of highly active research. One approach to this question is drug challenge studies with drugs known to alter DA function. These studies provide good experimental control and can be performed in parallel in laboratory animals and humans. This review aimed to summarize results of studies using pharmacological manipulations of DA in healthy adults. 'Reward' is a complex process, so we separated 'phases' of reward, including anticipation, evaluation of cost and benefits of upcoming reward, execution of actions to obtain reward, pleasure in response to receiving a reward, and reward learning. Results indicated that i) DAergic drugs have different effects on different phases of reward; ii) the relationship between DA and reward functioning appears unlikely to be linear; iii) our ability to detect the effects of DAergic drugs varies depending on whether subjective, behavioral, imaging measures are used.

Dose-response effects of d-amphetamine on effort-based decision-making and reinforcement learning.
Effort-related decision-making and reward learning are both dopamine-dependent, but preclinical research suggests they depend on different dopamine signaling dynamics. Therefore, the same dose of a dopaminergic medication could have differential effects on effort for reward vs. reward learning. However, no study has tested how effort and reward learning respond to the same dopaminergic medication within subjects. The current study aimed to test the effect of therapeutic doses of d-amphetamine on effort for reward and reward learning in the same healthy volunteers. Participants (n = 30) completed the Effort Expenditure for Reward Task (EEfRT) measure of effort-related decision-making, and the Probabilistic Reward Task (PRT) measure of reward learning, under placebo and two doses of d-amphetamine (10 mg, and 20 mg). Secondarily, we examined whether the individual characteristics of baseline working memory and willingness to exert effort for reward moderated the effects of d-amphetamine. d-Amphetamine increased willingness to exert effort, particularly at low to intermediate expected values of reward. Computational modeling analyses suggested this was due to decreased effort discounting rather than probability discounting or decision consistency. Both baseline effort and working memory emerged as moderators of this effect, such that d-amphetamine increased effort more in individuals with lower working memory and lower baseline effort, also primarily at low to intermediate expected values of reward. In contrast, d-amphetamine had no significant effect on reward learning. These results have implications for treatment of neuropsychiatric disorders, which may be characterized by multiple underlying reward dysfunctions.

The cognitive effort expenditure for rewards task (C-EEfRT): A novel measure of willingness to expend cognitive effort.
Research in animals suggests that decisions about physical versus cognitive effort have distinct neural bases, but exploration of this question in humans is hampered by lack of parallel measures of physical and cognitive effort for rewards. We developed a novel measure of willingness to exert cognitive effort for rewards, the C-EEfRT, paralleling the validated physical effort expenditure for rewards task (EEfRT). To validate the C-EEfRT we: (a) tested whether EEfRT and C-EEfRT tasks were equivalently difficult; (b) tested whether decisions on the EEfRT and C-EEfRT were equivalently responsive to changes in reward; (c) examined relationships between the C-EEfRT and anhedonia, intelligence, and working memory. Last, we tested the relationship between willingness to exert physical and cognitive effort for rewards in humans. Sixty healthy adults completed the EEfRT, the C-EEfRT, an anhedonia self-report, an intelligence test, and a working memory task. Overall willingness to exert effort was higher on the C-EEfRT than the EEfRT, particularly when reward probability and amount were low. This was despite participants perceiving the cognitive task as more difficult, and having greater difficulty completing it. Differential effects of physical fatigue may have contributed. Anhedonia was not related to effort on either measure. Working memory, but not intelligence, was associated with cognitive effort. There was a moderate relationship between cognitive and physical effort. These findings suggest the importance of measuring cognitive effort as distinct from physical effort in humans. Future studies should consider calibrating task difficulty for each individual, and exploring cognitive effort in clinical populations. (PsycINFO Database Record

HIV Anxiety Reduction/Management Program (HAMRT): pilot randomized controlled trial.
Research has indicated that mental health disorders, particularly anxiety, predicts poorer antiretroviral medication adherence among persons living with HIV/AIDS (PLWHA). The present study tests a novel six-session Cognitive-Behavioral Therapy-based integrated treatment/management program for PLWHA with concurrent anxiety delivered in community health clinics Houston, Texas. Twenty-Seven PLWHA (= 48.5, SD = 8.9, 44.4% female) were recruited for a proof-of-concept study and randomized to either an active treatment condition, or a waitlist control condition of equal length. Participants were assessed pre-randomization, at the mid-treatment time point (after three sessions for the active participants and three weeks for the

control participants) and post-treatment (six sessions for active participants, six weeks for control participants). Data were examined used Bayesian multilevel models. Results indicated a reliable (99.87% posterior probability of a moderating effect) interaction between active and control groups for depressive symptoms and reliable (99.65% probability) interaction for anxiety symptoms. Results indicated an unreliable interaction for combined antiretroviral therapy adherence. These findings are discussed in terms of the feasibility and potential utility of administering an anxiety-reduction therapy program designed for PLWHA with HIV medication adherence difficulties.

Integrated cognitive behavioral therapy for comorbid cannabis use and anxiety disorders: A pilot randomized controlled trial.
Cannabis use disorder (CUD) is the most common illicit substance use disorder and individuals with CUD have high rates of comorbid anxiety disorders. Comorbidity between CUD and anxiety disorders is of public health relevance given that although motivation enhancement therapy (MET) combined with cognitive-behavioral therapy (CBT) is an efficacious intervention for CUD, outcomes are worse for patients with elevated anxiety. The current study tested the acceptability and efficacy of the integration of a transdiagnostic anxiety CBT (i.e., treatment of patients with any anxiety disorder) with MET-CBT (integrated cannabis and anxiety reduction treatment, or ICART) for CUD compared to MET-CBT alone. Treatment-seeking cannabis users (56.4% male, M = 23.2, 63.3% non-Hispanic White) with CUD and at least one comorbid anxiety disorder were randomly assigned to ICART (n = 27) or MET-CBT (n = 28). Patients in the ICART condition attended significantly more treatment sessions than those in the MET-CBT condition. Patients in the ICART condition were more likely to be abstinent post-treatment than those in MET-CBT. Further, treatment produced decreases in cannabis use and related problems. Notably, therapy type did not moderate the impact of treatment on frequency of use and related problems. Together, these data suggest that ICART may be at least as efficacious as a gold-standard psychosocial CUD treatment, MET-CBT, for a difficult-to-treat subpopulation of cannabis users.

Effects of an acute bout of physical exercise on reward functioning in healthy adults.
Exercise has been proposed as a treatment for several psychiatric disorders. Exercise may act in part through beneficial effects on reward functioning, as it alters neurotransmitter levels in reward-related circuits. However, there has been little investigation of the effect of exercise on reward functions in humans. We hypothesized an acute bout of exercise would increase motivation for and pleasurable responses to rewards in healthy humans. In addition, we examined possible moderators of exercise's effects, including demographics, fitness and previous exercise experience. Thirty-five participants completed exercise and sedentary control sessions in randomized, counterbalanced order on separate days. Immediately after each activity, participants completed measures of motivation for and pleasurable responses to rewards, consisting of willingness to exert effort for monetary rewards and subjective responses to emotional pictures. Exercise did not increase motivation or pleasurable responses on average. However, individuals who had been running for more years showed increases in motivation for rewards after exercise, while individuals with less years running showed decreases. Further, individuals with higher resting heart rate variability reported lower arousal in response to all emotional pictures after exercise, while individuals with low heart rate variability reported increased arousal in response to all emotional pictures after exercise. General fitness did not have similar moderating effects. In conclusion, acute exercise improved reward functioning only in individuals accustomed to that type of exercise. This suggests a possible conditioned effect of exercise on reward functioning. Previous experience with the exercise used should be examined as a possible moderator in exercise treatment trials.

Measuring appetitive conditioned responses in humans.
Clinical and preclinical findings suggest that individuals with abnormal responses to reward cues (stimuli associated with reward) may be at risk for maladaptive behaviors including obesity, addiction and depression. Our objective was to develop a new paradigm for producing appetitive conditioning using primary (food) rewards in humans, and investigate the equivalency of several outcomes previously used to measure appetitive responses to conditioned cues. We used an individualized food reward, and multimodal subjective, psychophysiological and behavioral measures of appetitive responses to a conditioned stimulus (CS) that predicted delivery of that food. We tested convergence among these measures of appetitive response, and relationships between these measures and action impulsivity, a putative correlate of appetitive conditioning. 90 healthy young adults participated. Although the paradigm produced robust appetitive conditioning in some measures, particularly psychophysiological ones, there were not strong correlations among measures of appetitive responses to the CS, as would be expected if they indexed a single underlying process. In addition, there was only one measure that related to impulsivity.

These results provide important information for translational researchers interested in appetitive conditioning, suggesting that various measures of appetitive conditioning cannot be treated interchangeably.

HUMAN AGING INFLUENCES NEURAL REWARD PROCESSING TO MAINTAIN ROBUST REWARD SENSITIVITY

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Annika Volkmer, Franziska Wagner, Minne Schreiber, Alexander Schmidt, Stefan Brodoehl, Carsten M. Klingner
Universitätsklinikum Jena, Department Of Neurology, Biomagnetic Center, Jena, Germany

Aging is associated with an overarching process that does not occur equally in all regions and particularly not in all brain regions. Neural processing of reward is considered as an influential factor in controlling individual's daily behavior. Comparative studies showed age-related neurocognitive changes and it remains unclear whether the aging brain is able to maintain functional integrity of the reward system. To investigate different activation patterns of elderly during prediction and receiving of reward, functional magnetic resonance images (fMRI) were acquired in 23 older (50-80 years) and 35 younger (19-31 years) healthy adults. While undergoing fMRI-measurements participants performed an incentive delay task offering monetary outcome (Monetary Incentive Delay Task). According to our behavioral results, age was associated with slower reaction times. Despite slower reaction times of elderly, reward sensitivity does not differ from that of the younger subsample. Therefore, our results suggest maintaining functional integrity of the aging reward system. Performing region of interest analyses, feedback of monetary reward revealed significant greater activation of reward-related brain structures in older adults compared to the younger group. These structures included left insula, right middle and inferior frontal gyrus as well as right middle cingulate gyrus. In contrast reward prediction led to enhanced activation of bilateral insula, caudate nucleus, right putamen and anterior cingulate cortex in the younger subsample. Our results indicate the older brain to react more sensitive to the receipt of reward. The different neural activation patterns suggest a compensation pattern of the aging brain underlying the preserved reward sensitivity.

UNDERSTANDING INDIVIDUAL DIFFERENCES IN REWARD-GUIDED LEARNING AS AN EFFICIENT ADAPTATION TO TASK UNCERTAINTY AND COMPUTATIONAL NOISE

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Bence Csaba Farkas[1], Pierre Jacquet[1], Vasilisa Skvortsova[2], Valentin Wyart[1]
[1]Ecole Normale Superieure, Laboratoire De Neurosciences Cognitives Et Computationnelles, Inserm U960, Département D'etudes Cognitives, Paris, France, [2]University College London, Max Planck Center For Computational Psychiatry And Ageing Research, London, United Kingdom

Humans have been shown to be capable of adjusting their learning rates in response to expected and unexpected uncertainty in the environment. Moreover, their inferences have also been shown to be subject to computational noise, driving exploratory decisions. However, it has not been investigated how these two parameters are set in a coordinated manner during reward guided learning. To fill this gap in our understanding, we have recruited 175 human subjects to take part in a decision-making task administered online, in which they had to take reward maximizing actions in an environment that was characterized by both expected and unexpected uncertainty. Their behaviour was modelled with a noisy Kalman filter to estimate individuals' perceived uncertainty, learning rates and computational noise levels. Our results indicate that learning rates and computational noise levels covary in a systematic manner, and that their covariation is guided by the perceived expected and unexpected uncertainty of subjects. Moreover, there is evidence for both state and trait like sources of inter-individual variability.

Dopamine modulates many component processes of cognition, including reinforcement learning (RL), working memory (WM), and memory consolidation (MC). Pinpointing the roles of dopamine in natural behaviour is therefore challenging, but critical, given its contributions to healthy and disordered cognition. We have begun addressing this challenge using a paradigm designed to assay RL, WM and MC in participants genotyped at rs2514218 and rs1076560, D2-receptor polymorphisms associated with psychiatric risk and altered receptor expression respectively. 125 healthy participants (21.5±3.5Y, 86 Female) performed an online probabilistic selection task (PST) adapted to incorporate different WM loads by varying the number of stimuli, with evening training and morning testing to assay overnight MC. The PST is a two-alternative forced choice task with stimuli presented in fixed pairs. Pairs differ in the reward probability contrast of the two stimuli. After learning to preferentially select higher reward probability stimuli, participants are tested on all permutations of stimulus pairs, with no reward feedback. Participants provided saliva samples for genotyping. Carriers of minor alleles for either rs2514218 or rs1076560 tended to show higher asymptotic learning phase accuracies, though this difference depended on PST version. Logistic regression analyses also indicate differential dependence on WM across PST versions and genotypes. MC manifested as improved performance during morning testing but appeared similar across groups. We are currently adapting a version of the Opponent-Actor Learning model (a dual learning system RL-based model) to relate these task- and genotype-dependent effects to dopaminergic mechanisms in basal-ganglia-thalamo-cortical circuits.

IDENTIFYING SIGN-TRACKING AND GOAL-TRACKING BEHAVIOURS IN HUMANS – AN EYE-TRACKING TRANSLATIONAL STUDY

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Larisa Dinu[1], Alexandra-Livia Georgescu[1], Bryan Singer[2], Paul Overton[3], Eleanor Dommett[1]
[1]King's College London, Psychology, London, United Kingdom, [2]University of Sussex, Psychology, Brighton, United Kingdom, [3]University of Sheffield, Psychology, Sheffield, United Kingdom

Aims: In Pavlovian conditioning, learnt behaviour varies according to the perceived value of environmental cues. For goal-trackers, the cue merely predicts a reward, whilst for sign-trackers, the cue holds incentive value. Sign-tracking can be maladaptive and is associated with impulsivity and attentional deficits. The sign-tracking-goal-tracking model is well-validated in animals, but more work is needed to explore these individual differences in humans. The study aimed to establish a Pavlovian conditioning paradigm to identify individuals who sign-track or goal-track. **Methods**: Eye movements of a sample of healthy adults (N=71, 18-35 years) were recorded using EyeLink1000 whilst performing a Pavlovian conditioning task, in which participants pressed a button to reveal the outcomes (monetary or neutral) paired with the visual cues shown (CS+ or CS-). Dwell time was measured for two areas of interest: sign (i.e. cue) and goal (i.e. reward). An eye-gaze index was computed based on the dwell time sign-to-goal ratio, with higher values indicating sign-tracking behaviour. **Results:** Sign- and goal-trackers were determined using a median split of the eye-gaze index (median=-.177), with sign-trackers displaying values above the median. Sign-trackers represented 45.1% (N=32) of the sample. The eye-gaze index was significantly higher for sign-trackers compared to goal-trackers in the CS+ trials (t=2.49, df=31, *p*=.019, d=.31, 95% CI [.07,.80]), but not in the CS- trials. **Conclusions:** We demonstrate that sign-tracking is a learnt behaviour associated with CS+ trials only. This holds translational potential for understanding individual differences in reward-learning, implicated in impulse control disorders, such as addictions.

RELATIVE VALUE LEARNING IS NOT WEIRD: LOSING MONEY AROUND THE WORLD WITH CONTEXT-DEPENDENT REINFORCEMENT LEARNING.

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Hernan Anllo
ENS, Dec, Paris, France

Recent findings pertaining to value encoding in reinforcement learning show that options that were deemed optimal in a given context will continue to be favored even when extrapolated to a context where they are no longer profitable. This economic version of the Ebbinghaus effect suggests that values are rescaled as a function of the range of available options, even when this adaptation leads to suboptimal choices. However, as with many other allegedly-robust economic behaviors, it is possible that this rescaling may not reflect a general property of decision-making, but rather some unique aspect of choice behavior present only in Western, Educated, Industrialized, Rich and Democratic (WEIRD) societies. Moreover, suboptimal choices could be potentially explained by risk-aversion behavior (e.g. favoring highest outcome probability rather than highest expected value), which is well known to differ between rich and developing countries. In the present work, we administered the 2-arm bandit reinforcement learning task previously shown to demonstrate such contextual effects, across 11 countries of markedly different socioeconomic and cultural makeup (Argentina, Iran, Russia, Japan, China, India, Israel, Chile, Morocco, France and US). Crucially, we added an explicit dimension to the task, where risk behind choices was explicitly declared. Our findings show that despite pronounced sociocultural differences, all participants presented evidence of context-dependent learning. The results was not explained by risk tolerance in the explicit task, which in turn, was moderately different across nations. These findings strengthen the idea that relative value learning is biologically hard coded and not a cultural artefact.

TEST-RETEST RELIABILITY IN HUMAN REINFORCEMENT LEARNING VERSUS SELF-REPORTED MEASURES

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Stefano Vrizzi[1], Anis Najar[1], Mael Lebreton[2], Stefano Palminteri[1]
[1]Ecole Normale Superieure, Laboratoire De Neurosciences Cognitives Et Computationnelles, Inserm U960, Département D'etudes Cognitives, Paris, France, [2]Paris School of Economics, Paris-jourdan Sciences Économiques, Paris, France

Aims Recent meta-analysis (Enkavi et al., 2019) showed that test-retest reliability of self-reported surveys is higher than in behavioural tasks. We aimed to test this result in reinforcement learning (RL). **Methods** We defined a behavioural class of measures as the accuracy scores in the learning contexts of a RL task (Palminteri et al., 2015). For self-reported measures, we defined two classes: propensity-based and clinical. The former comprised four behavioural inhibition system (BIS) and behavioural activation system (BAS) scales; the latter measured nicotine consumption, alcohol consumption, anxiety score and depression score. We compared variability within and between these three classes of measures on the same participants (N=169), with a retest six months later. **Results** We defined test-retest reliability as Pearson's correlation between test and retest across participants. Correlations were statistically significant for each variable ($p<0.01$). Reliability was low or very low for behavioural measures, but moderate and strong for both propensity and clinical measures.
Cross-correlation between variables showed that behavioural measures were essentially correlated only among themselves, while propensity and clinical measures were correlated within and between themselves.
Finally, plotting test-retest reliabilities with the associated Coefficient of Variation (CV) revealed a clear clustering of the three classes of measurement. While behavioural and propensity measures differed by reliability, clinical measures reported greater CV. **Conclusions** Altogether, reliability and cross-correlation results not only back-up and align with the evidence that self-reported measures capture more stable traits, but more importantly, they extend it to the field of human RL.

DISRUPTED FUNCTIONAL CONNECTIVITY IS ASSOCIATED WITH REDUCED REWARD SENSITIVITY AND LEARNING DEFICITS AFTER STROKE

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Jenny Rogenz, Franziska Wagner, Laura Opitz, Johanna Maas, Alexander Schmidt, Stefan Brodoehl, Otto W. Witte, Carsten M. Klingner
Universitätsklinikum Jena, Department Of Neurology, Biomagnetic Center, Jena, Germany

With a frequency of one stroke event every 40 seconds in the United States, stroke represents the leading cause of long-term disability worldwide (GBD 2016). To return stroke patients back to independence, a key feature to enhance rehabilitation efficiency is motor learning (Kitago and Krakauer 2013). About one third of stroke survivors suffer from apathy that is associated with reward insensitivity and negatively impacts rehabilitation outcome (Towfighi et al. 2017). One possible explanation is that stroke lesions fundamentally disrupt functional reward-network-interaction (Marsh et al. 2020, Oestreich et al. 2020). To test this hypothesis this study firstly aims to correlate both behavioral reward response and neuronal network connectivity in subacute stroke patients (n=27) compared to age-matched healthy controls (n=26). Reward system activity was analyzed using the Monetary-Incentive-Delay Task (MID, Knutson et al 2010). Corresponding effects on the level of brain-connectivity were analyzed with coherence analyses of magnetoencephalography (MEG) data. As a main result, stroke patients behaviourally show a significantly lower reward sensitivity and learning deficits in MID. They required greater monetary incentives than the healthy controls to increase their reaction speed compared to control conditions. These effects correlate with functional brain network connectivity changes in fronto-temporal regions depending on low reward magnitudes in stroke patients. In the future perspective, the understanding of this large variability in network responses following stroke provides perspectives for individual network readouts to achieve optimal therapeutic strategies. Hence, novel treatments poststroke are needed to reduce stroke-induced morbidity and to increase the patient’s and caregiver’s quality of life.

IMPAIRED REWARD PROCESSING IN CHRONIC STROKE SURVIVORS

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Minne Schreiber, Annika Volkmer, Alexander Schmidt, Stefan Brodoehl, Carsten M. Klingner, Franziska Wagner
Universitätsklinikum Jena, Department Of Neurology, Biomagnetic Center, Jena, Germany

Rehabilitation is essential for stroke patients to try to return to their premorbid functioning. Therefore reward-related learning keeps patients motivated repeating exercises. Based on our previous studies we know that reward sensitivity is reduced in acute state of stroke. Accordingly, we need a more detailed understanding of the reward system in chronic stroke survivors. The hypothesis that chronic stroke survivors show deficits in reward processing and altered reward networks was tested. Chronic stroke survivors (n=24, 100 ± 20.8 days post stroke) and healthy controls (n=23) underwent a functional magnetic resonance imaging (fMRI) scan during which they performed the Monetary Incentive Delay Task (MID). Two resting state acquisitions, one before and one after the paradigm, were acquired for connectivity analyses.
Behaviorally intact reward processing was established in the stroke and control group. Both required greater monetary reward to decrease their reaction time during the MID. However, fMRI data revealed alterations in neuronal function during reward processing. While activity in regions of positive reward decreased during prediction of reward in stroke survivors, they showed increasing activity during receiving of reward compared to healthy controls. E.g., the middle-frontal-gyrus as a key hub of reward decision making revealed significant differences. These data suggest that behaviorally chronic stroke survivors seemed to be recovered in functional reward processing, but different activation patterns may be associated with neuronal deficits. Stronger rewarding stimuli may be necessary to improve rehabilitation. We need further details about network changes, as these can act as potential compensation for reward processing.

A VIEW-BASED DECISION MECHANISM FOR REWARDS IN PRIMATE AMYGDALA

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Fabian Grabenhorst[1], Adrian Ponce-Alvarez[2], Alexandra Battaglia-Mayer[3], Gustavo Deco[2], Wolfram Schultz[4]
[1]University of Oxford, Experimental Psychology, Oxford, United Kingdom, [2]Universitat Pompeu Fabra, Department Of Technology And Information, Barcelona, Spain, [3]Sapienza University of Rome, Department Of Physiology And Pharmacology, Rome, Italy, [4]University of Cambridge, Physiology, Development And Neuroscience, Cambridge, United Kingdom

Primates forage visually by shifting their view between objects and deciding on the best reward before acting. Here we show that when monkeys made value-guided choices, amygdala neurons encoded their decisions in an abstract, purely internal representation defined by the monkey's view but not by specific object or reward properties. Across amygdala subdivisions, activity patterns evolved gradually from an object-specific value code to a transient, object-independent code in which currently viewed and last-viewed objects competed to form a view-based choice. Neural-network modelling identified a sequence of computations by which amygdala neurons implemented view-based decision-making and eventually recovered the chosen object's identity when the monkeys acted on their choice. These findings reveal a neural mechanism that derives object choices from abstract, view-based computations, suggesting an efficient solution for decision problems with many objects.

NUTRIENT-SENSITIVE REINFORCEMENT LEARNING IN RHESUS MONKEYS

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Fei-Yang Huang[1], Fabian Grabenhorst[1,2]
[1]University of Cambridge, Department Of Physiology, Development And Neuroscience, Cambridge, United Kingdom, [2]Wellcome Trust-MRC Institute of Metabolic Science, Addenbrooke's Hospital, Cambridge, United Kingdom

Animals adapt food choices to regulate nutrient intake for survival. In reinforcement learning (RL), animals choose by assigning values to options and update these values with experience. However, canonical RL models do not address how learning depends on biologically critical constituents of food rewards, such as nutrients. To address these questions, we trained two adult male rhesus monkeys (*Macaca mulatta*) to choose from binary food options with varying reward probabilities (monkey Ya: N = 4,684 trials; monkey Ym: N = 5,321 trials). These options were randomly drawn from four nutrient-defined liquids that differed only in fat or sugar content. All liquids were cued by fixed but novel visual stimuli within each session and were matched in flavor (blackcurrant or peach), temperature, and other ingredients (protein, salt, etc) to isolate the effects of individual nutrient content on learning and decision-making. We found that the monkeys learned faster from preferred nutrient rewards and chose them frequently even when they were associated with lower reward probability. Although more recent experiences generally had a stronger influence on choices, the impact of reward history depended on reward nutrient composition and individual nutrient preferences. Accordingly, we propose a nutrient-sensitive RL model that separately updates the value of fat and sugar to form scalar reward values that explain choices. Our findings suggest that preference for nutrients contributes to subjective valuation, learning, and choice of food rewards. Incorporating subjective nutrient values into RL models enhance their biological validity and help reveal unrecognized nutrient-specific learning and decision computations.

Pubmed:
34155111: Huang FY, Sutcliffe MPF, Grabenhorst F
Preferences for nutrients and sensory food qualities identify biological sources of economic values in monkeys.
Value is a foundational concept in reinforcement learning and economic choice theory. In these frameworks, individuals choose by assigning values to objects and learn by updating values with experience. These theories have been instrumental for revealing influences of probability, risk, and delay on choices. However, they do not explain how values are shaped by intrinsic properties of the choice objects themselves. Here, we investigated how economic value derives from the biologically critical components of foods: their nutrients and sensory qualities. When monkeys chose nutrient-defined liquids, they consistently preferred fat and sugar to low-nutrient alternatives. Rather than maximizing energy indiscriminately, they seemed to assign subjective values to specific nutrients, flexibly trading them against offered reward amounts. Nutrient-value functions accurately modeled these preferences, predicted choices across contexts, and accounted for individual differences. The monkeys' preferences shifted their daily nutrient balance away from dietary reference points, contrary to ecological foraging models but resembling human suboptimal eating in free-choice situations. To identify the sensory basis of nutrient values, we developed engineering tools that measured food textures on biological surfaces, mimicking oral conditions. Subjective valuations of two key texture parameters-viscosity and sliding friction-explained the monkeys' fat preferences, suggesting a texture-sensing mechanism for nutrient values. Extended reinforcement learning and choice models identified candidate neuronal mechanisms for nutrient-sensitive decision-making. These findings indicate that nutrients and food textures constitute critical reward components that shape economic values. Our nutrient-choice paradigm represents a promising tool for studying food-reward mechanisms in primates to better understand human-like eating behavior and obesity.

RATS ADAPT OPTIMALLY TO CHANGES IN REINFORCEMENT PROBABILITIES, STIMULUS PRESENTATION PROBABILITIES AND DISCRIMINATION DIFFICULTY IN A PERCEPTUAL DECISION MAKING TASK

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Luis De La Cuesta Ferrer[1], Christina Koß[2], Andrea Dietl[1], Frank Jäkel[2], Maik Stüttgen[1]

In a world full of uncertainty in which resources are scarce, animals need to categorize objects (e.g., edible vs. non-edible food items), track environmental variables, (e.g., food availability), and flexibly adapt to changing circumstances in order to efficiently guide action. In the lab, this can be studied by means of perceptual decision making tasks with blockwise changes of reinforcement schedules. In these tasks, statistical modelling of the environment allows computation of the optimal response strategy to serve as a benchmark for gauging subjects' performance. Indeed, several previous studies have reported that animals quickly adapt to changing contingencies, often even maximizing long-term reward. Nonetheless, the cognitive algorithm underlying adaptive behaviour in these situations is largely unknown and existing learning algorithms have not been systematically investigated. Here, we aimed at comparing three different learning models: an optimal account as calculated from Signal Detection Theory, a greedy income-based model (that only learns after rewards) and an error-based account (that only learns after errors). Rats were trained on a sound discrimination forced choice task. In several conditions, discrimination difficulty, stimulus presentation probability and reward probability were manipulated. The conditions were constructed such that the three different accounts yielded divergent predictions. We found that, despite rats' steady state performance was well explained by the optimal account, none of the mechanistic models tested here was able to explain how they did it, calling for further investigations into the cognitive algorithm underlying adaptive perceptual choice behaviour.

DIVERGENT ROLE OF NUCLEUS ACCUMBENS D2-MSN-VENTRAL PALLIDUM PROJECTIONS IN DIFFERENT PHASES OF MOTIVATED BEHAVIOR

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Carina Soares-Cunha
ICVS, University of Minho, School Of Medicine, Braga, Portugal

The nucleus accumbens (NAc) is key in regulating reward-seeking and motivated behaviors. The NAc receives dopamine signals from the ventral tegmental area (VTA), which acts predominantly via D1 or D2 dopamine receptors that are expressed by largely non-overlapping populations of medium spiny neurons (MSNs). These two MSN sub-populations project to different outputs: D1-MSNs project to the VTA, while both D1- and D2-MSNs project to the ventral pallidum (VP). In order to better understand the contribution of D2-MSN-VP projections in reward-related behaviors, we performed optical manipulation of these inputs during different segments of a progressive ratio task for food and in a free choice instrumental task. We show that cue-paired optogenetic activation of D2-MSN-VP neurons is sufficient to increase the breakpoint in a progressive ratio task, indicative of increased motivation. Optical inhibition results in the opposite behavioral effect. Interestingly, optical activation of D2-MSN-VP projections during reward delivery significantly decreases motivation; the opposite is observed for optical inhibition. In agreement, in the free choice instrumental task, animals prefer the lever that originates one pellet in opposition to pellet plus D2-MSN-VP optogenetic activation, and vice versa for optogenetic inhibition. In summary, D2-MS-VP projections bi-directionally modulate motivated behavior, depending on the timing of stimulation: activation of D2-MS-VP inputs during cue exposure increases motivation, while activation at reward delivery decreases motivation in distinct behavioral paradigms.

Laterodorsal tegmentum-ventral tegmental area projections encode positive reinforcement signals.
The laterodorsal tegmentum (LDT) is a brainstem nucleus classically involved in REM sleep and attention, and that has recently been associated with reward-related behaviors, as it controls the activity of ventral tegmental area (VTA) dopaminergic neurons, modulating dopamine release in the nucleus accumbens. To further understand the role of LDT-VTA inputs in reinforcement, we optogenetically manipulated these inputs during different behavioral paradigms in male rats. We found that in a two-choice instrumental task, optical activation of LDT-VTA projections shifts and amplifies preference to the laser-paired reward in comparison to an otherwise equal reward; the opposite was observed with inhibition experiments. In a progressive ratio task, LDT-VTA activation boosts motivation, that is, enhances the willingness to work to get the reward associated with LDT-VTA stimulation; and the reverse occurs when inhibiting these inputs. Animals abolished preference if the reward was omitted, suggesting that LDT-VTA stimulation adds/decreases value to the stimulation-paired reward. In addition, we show that LDT-VTA optical activation induces robust preference in the conditioned and real-time place preference tests, while optical inhibition induces aversion. The behavioral findings are supported by electrophysiological recordings and c-fos immunofluorescence correlates in downstream target regions. In LDT-VTA ChR2 animals, we observed an increase in the recruitment of lateral VTA dopamine neurons and D1 neurons from nucleus accumbens core and shell; whereas in LDT-VTA NpHR animals, D2 neurons appear to be preferentially recruited. Collectively, these data show that the LDT-VTA inputs encode positive reinforcement signals and are important for different dimensions of reward-related behaviors.

Nucleus accumbens medium spiny neurons subtypes signal both reward and aversion.
Deficits in decoding rewarding (and aversive) signals are present in several neuropsychiatric conditions such as depression and addiction, emphasising the importance of studying the underlying neural circuits in detail. One of the key regions of the reward circuit is the nucleus accumbens (NAc). The classical view on the field postulates that NAc dopamine receptor D1-expressing medium spiny neurons (D1-MSNs) convey reward signals, while dopamine receptor D2-expressing MSNs (D2-MSNs) encode aversion. Here, we show that both MSN subpopulations can drive reward and aversion, depending on their neuronal stimulation pattern. Brief D1- or D2-MSN optogenetic stimulation elicited positive reinforcement and enhanced cocaine conditioning. Conversely, prolonged activation induced aversion, and in the case of D2-MSNs, decreased cocaine conditioning. Brief stimulation was associated with increased ventral tegmenta area (VTA) dopaminergic tone either directly (for D1-MSNs) or indirectly via ventral pallidum (VP) (for D1- and D2-MSNs). Importantly, prolonged stimulation of either MSN subpopulation induced remarkably distinct electrophysiological effects in these target regions. We further show that blocking κ-opioid receptors in the VTA (but not in VP) abolishes the behavioral effects induced by D1-MSN prolonged stimulation. In turn, blocking δ-opioid receptors in the VP (but not in VTA) blocks the behavioral effects elicited by D2-MSN prolonged stimulation. Our findings demonstrate that D1- and D2-MSNs can bidirectionally control reward and aversion, explaining the existence of controversial studies in the field, and highlights that the proposed striatal functional opposition needs to be reconsidered.

Mild Prenatal Stress Causes Emotional and Brain Structural Modifications in Rats of Both Sexes.
Stress or high levels of glucocorticoids (GCs) during developmental periods is known to induce persistent effects in the neuroendocrine circuits that control stress response, which may underlie individuals' increased risk for developing neuropsychiatric conditions later in life, such as anxiety or depression. We developed a rat model (Wistar han) of mild exposure to unpredictable prenatal stress (PS), which consists in a 4-h stressor administered three times per week on a random basis; stressors include strobe lights, noise and restrain. Pregnant dams subjected to this protocol present disrupted circadian corticosterone secretion and increased corticosterone secretion upon acute stress exposure. Regarding progeny, both young adult (2 months old) male and female rats present increased levels of circulating corticosterone and hyperactivity of the hypothalamus-pituitary-adrenal axis to acute stress exposure. Both sexes present anxious- and depressive-like behaviors, shown by the decreased time spent in the open arms of the elevated plus maze (EPM) and in the light side of the light-dark box (LDB), and by increased immobility time in the forced swim test, respectively. Interestingly, these results were accompanied by structural modifications of the bed nucleus of stria terminalis (BNST) and hippocampus, as well as decreased norepinephrine and dopamine levels in the BNST, and serotonin levels in the hippocampus. In summary, we characterize a new model of mild PS, and show that stressful events during pregnancy can lead to long-lasting structural and neurochemical effects in the offspring, which affect behavior in adulthood.

Nucleus Accumbens Microcircuit Underlying D2-MSN-Driven Increase in Motivation.
The nucleus accumbens (NAc) plays a central role in reinforcement and motivation. Around 95% of the NAc neurons are medium spiny neurons (MSNs), divided into those expressing dopamine receptor D1 (D1R) or dopamine receptor D2 (D2R). Optogenetic activation of D2-MSNs increased motivation, whereas inhibition of these neurons produced the opposite effect. Yet, it is still unclear how activation of D2-MSNs affects other local neurons/interneurons or input terminals and how this contributes for motivation enhancement. To answer this question, in this work we combined optogenetic modulation of D2-MSNs with pharmacological delivery of specific neurotransmitter antagonists in rats. First, we showed that optogenetic activation of D2-MSNs increases motivation in a progressive ratio (PR) task. We demonstrated that this behavioral effect relies on cholinergic-dependent modulation of dopaminergic signalling of ventral tegmental area (VTA) terminals, which requires D1R and D2R signalling in the NAc. D2-MSN optogenetic activation decreased ventral pallidum (VP) activity, reducing the inhibitory tone to VTA, leading to increased dopaminergic activity. Importantly, optogenetic activation of D2-MSN terminals in the VP was sufficient to recapitulate the motivation enhancement. In summary, our data suggests that optogenetic stimulation of NAc D2-MSNs indirectly modulates VTA dopaminergic activity, contributing for increased motivation. Moreover, both types of dopamine receptors signalling in the NAc are required in order to produce the positive behavioral effects.

Activation of D2 dopamine receptor-expressing neurons in the nucleus accumbens increases motivation.
Striatal dopamine receptor D1-expressing neurons have been classically associated with positive reinforcement and reward, whereas D2 neurons are associated with negative reinforcement and aversion. Here we demonstrate that the pattern of

activation of D1 and D2 neurons in the nucleus accumbens (NAc) predicts motivational drive, and that optogenetic activation of either neuronal population enhances motivation in mice. Using a different approach in rats, we further show that activating NAc D2 neurons increases cue-induced motivational drive in control animals and in a model that presents anhedonia and motivational deficits; conversely, optogenetic inhibition of D2 neurons decreases motivation. Our results suggest that the classic view of D1-D2 functional antagonism does not hold true for all dimensions of reward-related behaviours, and that D2 neurons may play a more prominent pro-motivation role than originally anticipated.

Reappraising striatal D1- and D2-neurons in reward and aversion.
The striatum has been involved in complex behaviors such as motor control, learning, decision-making, reward and aversion. The striatum is mainly composed of medium spiny neurons (MSNs), typically divided into those expressing dopamine receptor D1, forming the so-called direct pathway, and those expressing D2 receptor (indirect pathway). For decades it has been proposed that these two populations exhibit opposing control over motor output, and recently, the same dichotomy has been proposed for valenced behaviors. Whereas D1-MSNs mediate reinforcement and reward, D2-MSNs have been associated with punishment and aversion. In this review we will discuss pharmacological, genetic and optogenetic studies that indicate that there is still controversy to what concerns the role of striatal D1- and D2-MSNs in this type of behaviors, highlighting the need to reconsider the early view that they mediate solely opposing aspects of valenced behaviour.

The motivational drive to natural rewards is modulated by prenatal glucocorticoid exposure.
Exposure to elevated levels of glucocorticoids (GCs) during neurodevelopment has been identified as a triggering factor for the development of reward-associated disorders in adulthood. Disturbances in the neural networks responsible for the complex processes that assign value to rewards and associated stimuli are critical for disorders such as depression, obsessive–compulsive disorders, obesity and addiction. Essential in the understanding on how cues influence behavior is the Pavlovian–instrumental transfer (PIT), a phenomenon that refers to the capacity of a Pavlovian stimulus that predicts a reward to elicit instrumental responses for that same reward. Here, we demonstrate that in utero exposure to GCs (iuGC) impairs both general and selective versions of the PIT paradigm, suggestive of deficits in motivational drive. The iuGC animals presented impaired neuronal activation pattern upon PIT performance in cortical and limbic regions, as well as morphometric changes and reduced levels of dopamine in prefrontal and orbitofrontal cortices, key regions involved in the integration of Pavlovian and instrumental stimuli. Normalization of dopamine levels rescued this behavior, a process that relied on D2/D3, but not D1, dopamine receptor activation. In summary, iuGC exposure programs the mesocorticolimbic dopaminergic circuitry, leading to a reduction in the attribution of the incentive salience to cues, in a dopamine-D2/D3-dependent manner. Ultimately, these results are important to understand how GCs bias incentive processes, a fact that is particularly relevant for disorders where differential attribution of incentive salience is critical.

PRENATAL GLUCOCORTICOID EXPOSURE ALTERS EFFORT DECISION MAKING AND TRIGGERS NUCLEUS ACCUMBENS AND ANTERIOR CINGULATE CORTEX FUNCTIONAL CHANGES

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Verónica Domingues
ICVS, University of Minho, School Of Medicine, Braga, Portugal

Individuals select actions based on cost-benefit to allocate resources into goal-directed actions. Different brain regions coordinate this complex decision, including the nucleus accumbens (NAc), anterior cingulate cortex (ACC) and ventral tegmental area (VTA). *In utero* exposure to glucocorticoids (iuGC) triggers prominent motivation deficits in adulthood, but the impact of this exposure in the ACC-NAc and/or ACC-VTA circuits is unknown. In this work, we tested adult iuGC-exposed animals on a classical motivation task and on an effort-based decision-making task. We also evaluated basal and evoked neuronal activity of the ACC, NAc and VTA. We show that iuGC exposure causes decreased motivation for food in a progressive ratio task and impaired effort-based decision-making in adulthood. These behavioral deficits were associated with reduced neuronal activation of the NAc and ACC, as evaluated through the number of c-fos+ neurons after task performance. Interestingly, iuGC treatment led to increased NAc and ACC basal neuronal activity. Optogenetic activation of ACC terminals in the NAc triggered a different response in iuGC animals in comparison to control group, while the ACC-VTA circuit seems to be preserved. In sum, these data suggest that iuGC animals present motivational and effort-based decision-making deficits that occur in parallel with ACC-NAc dysfunction.

Constitutive deficiency of the neurogenic hippocampal modulator AP2γ promotes anxiety-like behavior and cumulative memory deficits in mice from juvenile to adult periods.
The transcription factor activating protein two gamma (AP2γ) is an important regulator of neurogenesis both during embryonic development as well as in the postnatal brain, but its role for neurophysiology and behavior at distinct postnatal periods is still unclear. In this work, we explored the neurogenic, behavioral, and functional impact of a constitutive and heterozygous AP2γ deletion in mice from early postnatal development until adulthood. AP2γ deficiency promotes downregulation of hippocampal glutamatergic neurogenesis, altering the ontogeny of emotional and memory behaviors associated with hippocampus formation. The impairments induced by AP2γ constitutive deletion since early development leads to an anxious-like phenotype and memory impairments as early as the juvenile phase. These behavioral impairments either persist from the juvenile phase to adulthood or emerge in adult mice with deficits in behavioral flexibility and object location recognition. Collectively, we observed a progressive and cumulative impact of constitutive AP2γ deficiency on the hippocampal glutamatergic neurogenic process, as well as alterations on limbic-cortical connectivity, together with functional behavioral impairments. The results herein presented demonstrate the modulatory role exerted by the AP2γ transcription factor and the relevance of hippocampal neurogenesis in the development of emotional states and memory processes.

Resilience to stress and sex-specific remodeling of microglia and neuronal morphology in a rat model of anxiety and anhedonia.
Prenatal exposure to stress or glucocorticoids (GC) is associated with the appearance of psychiatric diseases later in life. Microglia, the immune cells of the brain, are altered in stress-related disorders. Synthetic GC such as dexamethasone (DEX) are commonly prescribed in case of preterm risk labour in order to promote fetal lung maturation. Recently, we reported long-lasting differences in microglia morphology in a model of exposure to DEX (iuDEX), that presents an anxious phenotype. However, it is still unclear if stress differentially affects iuDEX males and females. In this work, we evaluated how iuDEX animals of both sexes cope with chronic mild stress for 2 weeks. We evaluated emotional behavior and microglia and neuronal morphology in the dorsal hippocampus (dHIP) and (NAc), two brain regions involved in emotion-related disorders. We report that males and females prenatally exposed to DEX have better performance in anxiety- and depression-related behavioral tests after chronic stress exposure in adulthood than non-exposed animals. Interestingly, iuDEX animals present sex-dependent changes in microglia morphology in the dHIP (hypertrophy in females) and in the NAc (atrophy in females and hypertrophy in males). After chronic stress, these cells undergo sex-specific morphological remodeling. Paralleled to these alterations in cytoarchitecture of microglia, we report inter-regional differences in dendritic morphology in a sex-specific manner. iuDEX females present fewer complex neurons in the NAc, whereas iuDEX males presented less complex neuronal morphology in the dHIP. Interestingly, these alterations were modified by stress exposure. Our work shows that stressful events during pregnancy can exert a preserved sex-specific effect in adulthood. Although the role of the observed cellular remodeling is still unknown, sex-specific differences in microglia plasticity induced by long-term stress exposure may anticipate differences in drug efficacy in the context of stress-induced anxiety- or depression-related behaviors.

Glial cells in Parkinson´s disease: protective or deleterious?
Glial cells have been identified more than 100 years ago, and are known to play a key role in the central nervous system (CNS) function. A recent piece of evidence is emerging showing that in addition to the capacity of CNS modulation and homeostasis, glial cells are also being looked like as a promising cell source not only to study CNS pathologies initiation and progression but also to the establishment and development of new therapeutic strategies. Thus, in the present review, we will discuss the current evidence regarding glial cells' contribution to neurodegenerative diseases as Parkinson's disease, providing cellular, molecular, functional, and behavioral data supporting its active role in disease initiation, progression, and treatment. As so, considering their functional relevance, glial cells may be important to the understanding of the underlying mechanisms regarding neuronal-glial networks in neurodegeneration/regeneration processes, which may open new research opportunities for their future use as a target or treatment in human clinical trials.

Preclinical Comparison of Stem Cells Secretome and Levodopa Application in a 6-Hydroxydopamine Rat Model of Parkinson's Disease.
Parkinson's Disease (PD) is characterized by the massive loss of dopaminergic neurons, leading to the appearance of several motor impairments. Current pharmacological treatments, such as the use of levodopa, are yet unable to cure the disease. Therefore, there is a need for novel strategies, particularly those that can combine in an integrated manner neuroprotection and neuroregeneration properties. In vitro and in vivo models have recently revealed that the secretome of mesenchymal stem cells (MSCs) holds a promising potential for treating PD, given its effects on neural survival, proliferation, differentiation. In the present study, we aimed to access the impact of human bone marrow MSCs (hBM-MSCs) secretome in 6-hydroxydopamine (6-OHDA) PD model when compared to levodopa administration, by addressing animals' motor performance, and substantia nigra (SN), and striatum (STR) histological parameters by tyrosine hydroxylase (TH) expression. Results revealed that hBM-MSCs secretome per se appears to be a modulator of the dopaminergic system, enhancing TH-positive cells expression (e.g., dopaminergic neurons) and terminals both in the SN and STR when compared to the

untreated group 6-OHDA. Such finding was positively correlated with a significant amelioration of the motor outcomes of 6-OHDA PD animals (assessed by the staircase test). Thus, the present findings support hBM-MSCs secretome administration as a potential therapeutic tool in treating PD, and although we suggest candidate molecules (Trx1, SEMA7A, UCHL1, PEDF, BDNF, Clusterin, SDF-1, CypA, CypB, Cys C, VEGF, DJ-1, Gal-1, GDNF, CDH2, IL-6, HSP27, PRDX1, UBE3A, MMP-2, and GDN) and possible mechanisms of hBM-MSCs secretome-mediated effects, further detailed studies are needed to carefully and clearly define which players may be responsible for its therapeutic actions. By doing so, it will be reasonable to presume that potential treatments that can, per se, or in combination modulate or slow PD may lead to a rational design of new therapeutic or adjuvant strategies for its functional modeling and repair.

Role of laterodorsal tegmentum projections to nucleus accumbens in reward-related behaviors.
The laterodorsal tegmentum (LDT) is associated with reward considering that it modulates VTA neuronal activity, but recent anatomical evidence shows that the LDT also directly projects to nucleus accumbens (NAc). We show that the majority of LDT-NAc inputs are cholinergic, but there is also GABAergic and glutamatergic innervation; activation of LDT induces a predominantly excitatory response in the NAc. Non-selective optogenetic activation of LDT-NAc projections in rats enhances motivational drive and shifts preference to an otherwise equal reward; whereas inhibition of these projections induces the opposite. Activation of these projections also induces robust place preference. In mice, specific activation of LDT-NAc cholinergic inputs (but not glutamatergic or GABAergic) is sufficient to shift preference, increase motivation, and drive positive reinforcement in different behavioral paradigms. These results provide evidence that LDT-NAc projections play an important role in motivated behaviors and positive reinforcement, and that distinct neuronal populations differentially contribute for these behaviors.

ACTION PREDICTION ERROR, A VALUE FREE DOPAMINERGIC TEACHING SIGNAL, DRIVES SELECTIVE CORTICOSTRIATAL PLASTICITY DURING AN AUDITORY DISCRIMINATION TASK. II: BEHAVIORAL AND CAUSAL EVIDENCE.

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Frequency-specific plasticity in the posterior striatum (pStr) during auditory discrimination learning suggests it is the locus for forming and storing task-relevant associations. Dopamine signals, thought to reinforce these associations, have been reported to encode information about threat in the pStr, raising the question of how reward-guided associations are formed in this region. Here we show that pStr dopaminergic input is indeed critical for learning and forming frequency-specific associations. We propose a model where dopaminergic input to the pStr forms the value-free half of a dual value-based/value-free dopaminergic learning system. Chronic lesions of the pStr, or the pStr-projecting dopaminergic cells, result in identical learning deficits affecting later learning stages. This is consistent with our dual controller model where initial learning is driven by a value-based system and then rapidly consolidated in a value-free manner in the pStr. Supporting this, optogenetic inhibition of either the direct or the indirect pathways in pStr disrupt behavioural performance specifically in later stages of learning. In line with pStr-projecting dopamine providing a teaching signal we show using LFP recordings that these dopaminergic inputs are required for frequency-specific plasticity and that temporally-specific optogenetic manipulations of dopamine levels in pStr bias future behaviour. These results, together with our finding of an action-related and value-free dopaminergic signal in the pStr (see part I), suggest a model where stable state-action associations are formed in the pStr in a dopamine-dependent but value-free manner, leading to a more habitual behaviour.

ACTION PREDICTION ERROR, A VALUE-FREE DOPAMINERGIC TEACHING SIGNAL, DRIVES SELECTIVE CORTICOSTRIATAL PLASTICITY DURING AN AUDITORY DISCRIMINATION TASK. I: DOPAMINE RECORDINGS

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Francesca Greenstreet[1], Hernando Vergara[1], Sthitapranjya Pati[1], Laura Schwarz[1], Matthew Wisdom[1], Fred Marbach[1], Yvonne Johansson[1], Theodore Moskovitz[1], Claudia Clopath[2], Marcus Stephenson-Jones[1]

Experience dependent changes in corticostriatal plasticity are critical for reinforcement learning. In line with this, in an auditory frequency discrimination task, selective frequency-specific corticostriatal plasticity is observed in the posterior striatum (pStr). Dopamine reward prediction error signals are thought to provide a critical teaching signal for such corticostriatal modifications. However the dopaminergic input to the auditory striatum is reported to be activated by threat and not reward prediction error. How such a threat prediction error could help animals learn to transform sound into actions that will obtain reward is unclear. To address this we used photometry to record dopamine levels in the pStr of mice performing an auditory frequency discrimination task. Here we show that dopamine in the pStr encodes an action prediction error, a value free teaching signal that could be used to reinforce stable sound-action associations. pStr dopamine levels are correlated with the contralateral action, and show no variation to reward, outcome value or predicted value. Consistent with a prediction error the response to action is stimulus specific and decreases over training as the action becomes predicted by the auditory stimulus. The dopamine signal we observed in the pStr could be explained by an action prediction error model but not by other alternative models of dopaminergic activity including, rewards prediction error, movement, novelty or salience. Taking inspiration from computational models of habit formation we propose that this value-free teaching signal works in concert with canonical value-based dopaminergic teaching signals to consolidate stable state-action associations in the sensory striatum.

STRIATAL DOPAMINE ENCODES THE RELATIONSHIP BETWEEN ACTIONS AND REWARD

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Genevra Hart
University of New South Wales, Psychology, Kensington, Australia

Despite the well described role of dopamine in the striatum for motor learning and movement, its function in encoding actions and their outcomes for goal-directed action is less clear. Here, rats acquired two actions for distinct outcomes while we simultaneously recorded dopamine release in the dorsomedial striatum using dLight1.1 with fiber photometry, as these action-outcome associations were incremented and selectively degraded. Goal-directed actions generated a lateralized dopamine signal that reflected the strength of the action-outcome association, and tracked increments and decrements in the action-outcome contingency. In addition to this lateralized signal, dopamine signalled reward predictions, which were broadcast bilaterally during the action, and updated by a reward prediction error following exposure to the outcome. Striatal dopamine release, therefore, both directly modulates and updates encoding of the instrumental action-outcome association for goal-directed action.

IS MOTIVATION FOR PHYSICAL EXERCISE ENCODED BY MIDBRAIN DOPAMINERGIC NEURONS?

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Emma Mesguich[1], Maxime Come[2], Bastien Redon[1,3], Imane Hurel[1], Francisca Julio-Kalajzic[1], Philippe Faure[2], Giovanni Marsicano[1], Francis Chaouloff[1]
[1]Neurocentre Magendie, Bordeaux University, Inserm U1215, Bordeaux, France, [2]ESPCI, Brain Plasticity Lab Umr8249 Cnrs, Paris, France, [3]Geneva University, Département Des Neurosciences Fondamentales, Genève, Switzerland

Aims Our studies combining conditioned wheel-running and electrophysiology suggest that exercise motivation requires a cannabinoid type-1 receptor-mediated disinhibition of ventral tegmental area (VTA) dopaminergic (DA) activity (Muguruza et al., 2019; Medrano et al., 2021). However, direct evidence for a link between VTA DA activity and exercise motivation is still lacking. We thus aim at examining how midbrain DA neuronal activity varies with the intensity of the effort required to access a running wheel. ***Methods*** Operant chambers hosted a locked wheel surrounded by nose poke (NP) ports and light cues. In a first step, wheel unlocking was indicated by a light cue (Pavlovian rule). In a second series of experiments using instrumental conditioning, mice had access to the wheel following correct light cue-conditioned NP performance, i.e. under intra-session fixed ratio (FR)1 and FR5 reinforcement schedules. Our *in vivo* electrophysiology technique uses 16-channel extracellular recordings in the VTA of freely-moving mice trained before electrode implantation. ***Results*** Once mice learned the Pavlovian association, VTA DA neuronal activity increased during cue presentation, in keeping with the reward prediction error theory (Schultz et al. 1997). Having set up a conditioning protocol wherein mice learn within several sessions that wheel access is under alternate FR1/FR5 rules, ongoing experiments test whether VTA DA neuronal activity is effort-dependent. ***Conclusions*** We have first observed that VTA DA activity might be involved in the rewarding effect of running. We are now testing whether such an activity varies with the intensity of the effort needed to access that reward.

TASK-DEPENDENT ENSEMBLE CODING IN RAT MEDIAL PREFRONTAL CORTEX

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Ida V. Rautio[1], Fredrik Nevjen[2], David Klindt[2], Benjamin Dunn[2], Jonathan Whitlock[1]
[1]Norwegian University of Science and Technology (NTNU), Kavli Institute For Systems Neuroscience, Trondheim, Norway, [2]NTNU, Department Of Mathematical Sciences, Trondheim, Norway

The medial prefrontal cortex has been implicated in diverse cognitive processes such as attention, goal-related navigation, action-planning, social information processing, learning and strategy-switching. Previous work has shown that clear behavioural and cognitive correlates in the mPFC are less common at the single cell level, which often necessitates methods to uncover higher-dimensional aspects to give meaningful behavioral- or task-related interpretations of their findings. In an effort to better understand the apparent flexibility of this brain area, we have implemented a multi-task approach where animals repeatedly experience an open field foraging task and a bait-chasing task in the same arena, as well as a social context with a conspecific on a linear track, while we record from hundreds of neurons simultaneously using Neuropixel probes. Additionally, we employed precise 3D tracking to investigate potentially low-dimensional features like pose and movement in addition to the cognitive aspects of each context. Single neuron and population responses have so far shown sparse and unstable tuning to posture and movement, and the same for self-motion and spatial tuning. However, more complex task-specific behaviors, in particular the chasing task, elicit stronger, reliable spiking responses, and exhibit stable correlational structures at the ensemble level. Leveraging the multiple tasks to disentangle behavioral selectivity from the context, we aim to elucidate the extent to which the selectivity is unique and common in these seemingly distinct cognitive processes.

Examining the Subacute Effects of Mild Traumatic Brain Injury Using a Traditional and Computerized Neuropsychological Test Battery.
This study investigates subacute cognitive effects of mild traumatic brain injury (MTBI) in the Trondheim Mild TBI Study, as measured, in part, by the neuropsychological test battery of the Collaborative European NeuroTrauma Effectiveness Research in TBI (CENTER-TBI) program, including computerized tests from the Cambridge Neuropsychological Test Automated Battery (CANTAB) and traditional paper-and-pencil tests. We investigated whether cognitive function was associated with injury severity: intracranial traumatic lesions on neuroimaging, witnessed loss of consciousness (LOC), or post-traumatic amnesia (PTA) >1 h. Further, we explored which of the tests in the CENTER-TBI battery might be associated with the largest subacute effects of MTBI (i.e., at 2 weeks post-injury). We recruited 177 patients with MTBI (16-59 years of age) from a regional trauma center and an outpatient clinic,79 trauma control participants, and 81 community control participants. The MTBI group differed from community controls only on one traditional test of processing speed (coding; = 0.009, Cliff's delta [Δ] = 0.20). Patients with intracranial abnormalities performed worse than those without on a traditional test (phonemic verbal fluency; = 0.043, Δ = 0.27), and patients with LOC performed differently on the Attention Switching Task from the CANTAB (= 0.020, Δ = -0.20). Patients with PTA >1 h performed worse than those with <1 h on 10 measures, from traditional tests and the CANTAB (Δ = 0.33-0.20), likely attributable, at least in part, to pre-existing differences in intellectual functioning between groups. In general, those with MTBI had good neuropsychological outcome 2 weeks after injury and no particular CENTER-TBI computerized or traditional tests seemed to be more sensitive to subtle cognitive deficits.

DIFFERENTIAL DOPAMINE SIGNALLING IN VENTRAL AND DORSAL STRIATUM IN VIVO

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Freya Marijatta[1], Mark Walton[2], Peter Magill[1]
[1]University of Oxford, Mrc Brain Networks Dynamics Unit Ndcn, Oxford, United Kingdom, [2]University of Oxford, Experimental Psychology, Oxford, United Kingdom

Striatal dopamine signals encode information related to reward and movement, but the precise patterning of these signals can vary across striatal regions. Links between regional diversity and functional diversity in stratum are often simplified into a framework incorporating two main pathways originating from the dopaminergic midbrain; a ‘reward pathway’ that terminates in ventral striatum (or nucleus accumbens, NAc), and a ‘movement pathway’ terminating in dorsal striatum. To elucidate regional and functional heterogeneity in striatal dopamine signalling, fluorescence emitted from the genetically-encoded dopamine sensor dLight was photometrically recorded from the NAc and dorsal striatum of anaesthetised and awake mice. In anaesthetised mice, electrical stimulation of the dopaminergic midbrain across a wide parameter space was used to systematically investigate regional differences in evoked dLight fluorescence. Awake, head-fixed mice were trained in a treadmill-based go/no-go task and dLight photometry was then used to assess the extent to which each striatal region selectively encodes reward and movement during behavioural performance.

New, changing, and inherently variable environments force animals to address different sorts of uncertainty. These in turn, are associated with various aspects of behavioural and neural activity. Hippocampal place cells code in a behaviourally-relevant manner for aspects of space and reward. By inducing various forms of uncertainty in these two quantities, we sought to shed light on the ways that mice experience and accommodate the incompletely known. We designed a novel Uncertain Reward Task (URTask) in a virtual reality (VR) apparatus (figure1). Mice (six adults) were trained to run along a VR linear track and lick for a water reward. Different forms of uncertainty were manipulated by varying the distributions of reward locations and changing the virtual surround. Using two-photon calcium imaging, we recorded activities of place cells in CA1 along with mouse behaviour (licking and velocity) as uncertainty was induced and partially resolved by experience. Given inherently variable reward locations, animals tend to slow down and lick continuously within the expected reward zone (figure 2), and the place map within the reward zone becomes less spatially precise (figure 3). From limpid changes in reward locations, the behaviour requires a few trials to adjust to the new task configuration (figure 4), and the place map undergoes a higher degree of remapping (figure 5). Our data demonstrates that the URTask can engender different forms of uncertainty that produce different behavioural and neuronal adaptations. The URTask may therefore be used to investigate how the brain distinguishes and decodes varying forms of uncertainty.

DOPAMINE CORRELATES OF HABIT VERSUS GOAL-DIRECTED BEHAVIOR IN THE VENTRAL TEGMENTAL AREA

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Robin Magnard[1], Patricia Janak[1,2], Youna Vandaele[1]
[1]Johns Hopkins University, Psychological And Brain Sciences, Baltimore, United States of America, [2]Johns Hopkins School of Medicine, The Solomon H. Snyder Department Of Neuroscience, Baltimore, United States of America

Habitual performance is commonly considered in light of dorsolateral striatum and its nigral dopaminergic (DA) input. However, how ventral tegmental area DA neuron activity might also differentially signal habitual *versus* goal-directed performance remains largely unknown. To address this question, we tested rats in two operant procedures, a lever insertion fixed-ratio 5 (LI5) task and a lever retraction fixed-ratio 5 (LR5) task. Here, the timing of lever insertion (LI) and retraction (LR) is varied so that one is a relevant cue signaling reward (sucrose 20%) availability while the other cue is made irrelevant. We then used satiety-induced devaluation to test whether behavior was goal-directed or habitual. Finally, we compared activity of DA neurons *via in vivo* fiber photometry recording after VTA infusion of Cre- dependent GCaMP6f virus in adult TH-Cre rats performing either the LR5 or LI5 task. We found rats quickly developed habitual behavior and chunking in the LR5 task in which the LR cue predicts immediate reward delivery. We further observed rapid shifts in activation of DA VTA neurons from reward retrieval to the earlier LR cue, followed by decreases in cue-related DA signals across repeated trials as performance become automatic and habitual. In contrast, behavior in the LI5 task was goal-directed, and cue-induced DA activation remained relatively constant across trials and sessions, when reward availability was signaled by the LI cue, more distal from reward delivery. These results show manifest task differences in DA signaling that appear consistent with differences in habitual *versus* goal-directed control of behavior.

Nigrostriatal Dopaminergic Denervation Does Not Promote Impulsive Choice in the Rat: Implication for Impulse Control Disorders in Parkinson's Disease.
Impulse control disorders (ICDs) are frequent behavioral complications of dopaminergic (DA) replacement therapies (DRTs) in Parkinson's disease (PD). Impulsive choice, which refers to an inability to tolerate delays to reinforcement, has been identified as a core pathophysiological process of ICDs. Although impulsive choices are exacerbated in PD patients with ICDs under DRTs, some clinical and preclinical studies suggest that the DA denervation of the dorsal striatum induced by the neurodegenerative process as well as a pre-existing high impulsivity trait, may both contribute to the emergence of ICDs in PD. We therefore investigated in a preclinical model in rats, specifically designed to study PD-related non-motor symptoms, the effect of nigrostriatal DA denervation on impulsive choice, in relation to pre-existing levels of impulsivity, measured in a Delay Discounting Task (DDT). In this procedure, rats had the choice between responding for a small sucrose reinforcer delivered immediately, or a larger sucrose reinforcer, delivered after a 0, 5, 10 or 15 s delay. In two different versions of the task, the preference for the large reinforcer decreased as the delay increased. However, and in contrast to our initial hypothesis, this discounting effect was neither exacerbated by, or related to, the extent of the substantia nigra pars compacta (SNc) DA lesion, nor it was influenced by pre-existing variability in impulsive choice. These results therefore question the potential implication of the nigrostriatal DA system in impulsive choice, as well as the DA neurodegenerative process as a factor contributing significantly to the development of ICDs in PD.

Subthalamic Nucleus Stimulation Impairs Motivation: Implication for Apathy in Parkinson's Disease.
Apathy is one of the most disabling neuropsychiatric symptoms in Parkinson's disease (PD) patients and has a higher prevalence in patients under subthalamic nucleus deep brain stimulation. Indeed, despite its effectiveness for alleviating PD motor symptoms, its neuropsychiatric repercussions have not yet been fully uncovered. Because it can be alleviated by

dopaminergic therapies, especially D and D dopaminergic receptor agonists, the commonest explanation proposed for apathy after subthalamic nucleus deep brain stimulation is a too-strong reduction in dopaminergic treatments. The objective of this study was to determine whether subthalamic nucleus deep brain stimulation can induce apathetic behaviors, which remains an important matter of concern. We aimed to unambiguously address this question of the motivational effects of chronic subthalamic nucleus deep brain stimulation.

Trait Impulsivity and Anhedonia: Two Gateways for the Development of Impulse Control Disorders in Parkinson's Disease?
Apathy and impulsivity are two major comorbid syndromes of Parkinson's disease (PD) that may represent two extremes of a behavioral spectrum modulated by dopamine-dependent processes. PD is characterized by a progressive loss of dopaminergic neurons in the substantia nigra pars compacta to which are attributed the cardinal motor symptoms of the disorder. Dopamine replacement therapy (DRT), used widely to treat these motor symptoms, is often associated with deficits in hedonic processing and motivation, including apathy and depression, as well as impulse control disorders (ICDs). ICDs comprise pathological gambling, hypersexuality, compulsive shopping, binge eating, compulsive overuse of dopaminergic medication, and punding. More frequently observed in males with early onset PD, ICDs are associated not only with comorbid affective symptoms, such as depression and anxiety, but also with behavioral traits, such as novelty seeking and impulsivity, as well as with personal or familial history of alcohol use. This constellation of associated risk factors highlights the importance of inter-individual differences in the vulnerability to develop comorbid psychiatric disorders in PD patients. Additionally, withdrawal from DRT in patients with ICDs frequently unmasks a severe apathetic state, suggesting that apathy and ICDs may be caused by overlapping neurobiological mechanisms within the cortico-striato-thalamo-cortical networks. We suggest that altered hedonic and impulse control processes represent distinct prodromal substrates for the development of these psychiatric symptoms, the etiopathogenic mechanisms of which remain unknown. Specifically, we argue that deficits in hedonic and motivational states and impulse control are mediated by overlapping, yet dissociable, neural mechanisms that differentially interact with DRT to promote the emergence of ICDs in vulnerable individuals. Thus, we provide a novel heuristic framework for basic and clinical research to better define and treat comorbid ICDs in PD.

What can rodent models tell us about apathy and associated neuropsychiatric symptoms in Parkinson's disease?
In addition to classical motor symptoms, Parkinson's disease (PD) patients display incapacitating neuropsychiatric manifestations, such as apathy, anhedonia, depression and anxiety. These hitherto generally neglected non-motor symptoms, have gained increasing interest in medical and scientific communities over the last decade because of the extent of their negative impact on PD patients' quality of life. Although recent clinical and functional imaging studies have provided useful information, the pathophysiology of apathy and associated affective impairments remains elusive. Our aim in this review is to summarize and discuss recent advances in the development of rodent models of PD-related neuropsychiatric symptoms using neurotoxin lesion-based approaches. The data collected suggest that bilateral and partial lesions of the nigrostriatal system aimed at inducing reliable neuropsychiatric-like deficits while avoiding severe motor impairments that may interfere with behavioral evaluation, is a more selective and efficient strategy than medial forebrain bundle lesions. Moreover, of all the different classes of pharmacological agents, D2/D3 receptor agonists such as pramipexole appear to be the most efficient treatment for the wide range of behavioral deficits induced by dopaminergic lesions. Lesion-based rodent models, therefore, appear to be relevant tools for studying the pathophysiology of the non-motor symptoms of PD. Data accumulated so far confirm the causative role of dopaminergic depletion, especially in the nigrostriatal system, in the development of behavioral impairments related to apathy, depression and anxiety. They also put forward D2/D3 receptors as potential targets for the treatment of such neuropsychiatric symptoms in PD.

DISTRIBUTED NEURAL CODING OF MULTISENSORY VARIABLES AND TRIAL OUTCOME IN THE CORTICO-HIPPOCAMPAL HIERARCHY

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Julien Fiorilli[1], Pietro Marchesi[1], Thijs Ruikes[1], Gerjan Huis In 'T Veld[1], Rhys Buckton[1], Mariana Quintero[1], Ingrid Reiten[2], Jan Bjaalie[2], Cyriel Pennartz[1]
[1]University of Amsterdam, Cognitive And Systems Neuroscience, Amsterdam, Netherlands, [2]University of Oslo, Institute Of Basic Medical Sciences, Oslo, Norway

Neural circuits are believed to support adaptive behavior by integrating sensory input with reward and error-driven learning signals. How these signals are distributed across different levels of the cortico-hippocampal hierarchy remains poorly understood. We trained four rats on a multisensory object discrimination task and compared sensory and reward-driven responses from simultaneously recorded neurons in barrel cortex (S1BF, N=99), higher visual cortex (V2L, N=287), perirhinal cortex (PER, N=175) and hippocampus (HPC, N=202). We found that V2L neurons discharged after light onset, but not following whisker touch. A significant proportion of neurons was modulated by either of the two modalities in HPC (Touch: 16%; Light:10%), despite insignificant proportions of light or touch-modulated cells in PER. A significant proportion (9%) of V2L neurons differentiated between the objects during visual sampling; this object representation was not found in HPC or PER. Upon reward-poke entry, 16% of PER neurons differentiated between trial outcome (rewarded or unrewarded). In contrast to the other regions, this modulation preceded reward-delivery dependent changes in lick rate. These neurons did not merely react to reward delivery itself, because the majority of these neurons in fact discharged upon an unrewarded poke. Altogether, we report a surprising absence of object-identity representations in PER during sensory sampling. Instead, PER primarily represented information about choice outcome, especially in unrewarded trials. Our results support a distributed neural coding of multisensory variables in the cortico-hippocampal hierarchy during object sampling and reward processing, with a particularly important role for PER in signaling the absence an expected reward.

PHASIC DOPAMINE BUILDS AND REVEALS LATENT ATTRACTORS.

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Jérémie Naudé[1,2], Matthieu Sarazin[3], Sarah Mondoloni[1,4], Alexandre Mourot[1,5], Philippe Faure[1,5], Bruno Delord[3]
[1]CNRS, Neurosciences Paris Seine, Paris, France, [2]CNRS, Institut De Génomique Fonctionnelle, MONTPELLIER CEDEX , France, [3]CNRS, Institut Des Systèmes Intelligents Et De Robotique, PARIS CEDEX, France, [4]University of Lausanne, Department Of Fundamental Neuroscience, Lausanne, Switzerland, [5]ESPCI, Brain Plasticity Lab Umr8249 Cnrs, Paris, France

Transient dopamine (DA) neuron activity contributes to both future decisions (learning) and ongoing behavior (motivation), but reconciling these two roles remains challenging. The popular reinforcement learning theory interprets fast, phasic DA activity as a reward-related teaching signal. At the neuronal level, such role of DA in learning is thought to correspond to the gating of synaptic plasticity, effectively building neural representations of the value of actions leading to reward. By contrast, the role of phasic DA in motivation relies on modulating synaptic excitability online, but has proven hard to reconcile with reinforcement-learning accounts. We thus sought to characterize the dual role of DA in the framework of dynamical system theory, based on DA biophysical effects, and achieved a specific control of VTA DA with optogenetics to test predictions derived from our model. We considered mice navigating between places reinforced by DA stimulation, modeled by a recurrent neural network model of decision. Mice behavior could be explained by a synergy between plasticity and excitability effects on animals' internal goals. DA-gated synaptic plasticity reinforced synapses onto neurons encoding for the rewarded location, building a latent (i.e. not always expressed) attractor, which could be revealed by DA effects on synaptic excitability. We verified experimentally the model predictions that VTA photostimulation energizes, attracts and directs movements specifically toward a previously-rewarded location, without exerting any motor effects out of reward context. We thus propose that the motivational role of VTA DA is to widen the basin of DA-built, latent attractors; corresponding to DA expressing a potential goal.

BASAL GANGLIA OUTPUT AND THALAMIC CIRCUITS FOR CONTEXT DEPENDENT ANTICIPATION AND ACTION SIGNALING

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Mauricio Toro, Margarida Sousa, Sofia Castro E Almeida, Tiago Monteiro, Filipe Rodrigues, Margarida Pexirra, Joe Paton
Champalimaud Foundation, Champalimaud Research, Lisboa, Portugal

The expression of behavior is highly context-dependent. Prior knowledge about the environment is required to prepare and modulate action selection and execution. The basal ganglia (BG) are thought to contribute to this process through downstream influence on motor areas. However, little data exists regarding the interaction between BG and downstream targets during context-dependent action execution. Here, we studied the interaction between BG outputs and motor thalamus while rats performed delayed movements for varying reward. We trained rats to withhold cued, lateralized movements for variable delays until delivery of a go cue. Crucially, reward location alternated in blocks of trials, meaning that rightwards and leftwards movements were sometimes rewarded, sometimes not. Rats indicated their knowledge of impending reward by reacting and moving more quickly. Next, we simultaneously recorded neural activity from substantia nigra pars reticulata and VA/VL thalamus, and found that both regions carried signatures of reward-context preceding trial initiation, and reward expectation, movement direction, and their interaction before and during movement execution. We then modeled the development of these neural signals using a recurrent actor-critic reinforcement learning agent trained in the task. Surprisingly, we were only able to fully recapitulate behavior and neural activity using a multi-agent architecture with sparse access to state variables, reminiscent of parallel BG circuitry. More broadly, these results suggest distributed, parallel behavioral control as a possible pre-requisite for the expression of general features of context-dependent behavior.

MESOLIMBIC DOPAMINE NEURON STIMULATION INFLUENCE'S GOAL DIRECTED ACTION INITIATION AND RESTRAINT.

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

George Jenkins, Hironori Ishii, Emilie Werlen, Juan-Carlos Cerpa, Lauren Burgeno, Mark Walton
University of Oxford, Experimental Psychology, Oxford, United Kingdom

Aims: Previous studies have shown that dopamine release in the nucleus accumbens in response to reward predictive cues differs depending on the action required to obtain upcoming reward. When animals must initiate action, cue-evoked accumbal dopamine follows reward prediction error encoding, but when animals must restrain action to earn reward release is instead suppressed. To determine whether increased release of dopamine in the accumbens causally influences the likelihood of initiating action, we stimulated VTA dopamine neurones whilst animals were engaged in a Go/NoGo task. Methods TH-Cre rats were trained in a Go/NoGo task, where cues indicated whether animals had to either leave a nosepoke and make two lever presses (Go trials) or remain in the nosepoke for 1.7-1.9s (NoGo trials) to receive reward. Following transfection of midbrain dopamine neurons with AAV2-EF1a-ChR2 or AAV2-EF1a-GFP, a 20hz stimulation was delivered either shortly after the cue (50ms after cue) or later in the trial (800ms after cue). Results Stimulation of midbrain dopamine neurones impaired both the ability of animals to restrain action on NoGo trials, and to execute the correct action sequence on Go trials. These effects were only observed in animals expressing ChR2 and were present only when the stimulation was delivered shortly after cue presentation, not later in the trial. Conclusion These experiments indicate that dopamine release is not merely providing a readout of behaviour, but rather acts to shape online behaviour in situations when animals must either initiate or restrain action to obtain reward.

Cognitive flexibility is the ability to adaptively respond to changes in the environment. Neural processes involved in cognitive flexibility have been identified. However, it is less clear how animals determine the correct rules governing environmental changes and how rule acquisition is neurally implemented. Reinforcement learning (RL) is a powerful theory for understanding how animals choose actions to maximize reward. RL models provide a direct link to neural computations underlying reward-driven behavior. However, they predict learning should be slow and gradual, thus struggling to explain hallmarks of flexible behavior such as rapid rule learning in complex environments. To gain insight into how animals learn in such environments, we trained rats on a novel rule-switching task where correct choices require integrating information from different sensory modalities and memory of past choices. We found that, rather than learning complex, high-dimensional state-action-space mappings, rats follow general, low-dimensional strategies to test environmental features for their relevance to reward. We developed statistical methods to measure strategy-specific attention to task features during choice and learning. We found that rats focus attention on one specific feature at a time, switching attention abruptly to another feature when they accumulate enough evidence that the current strategy is unreliable. Furthermore, we found that an RL model where attention modulates both choice and learning is best at explaining animal behavior. Our findings support the notion that animals work around computational complexity in real-world environments by adapting attentional mechanisms that allow them to reduce task dimensionality, thus providing an explanation for rapid learning.

Coordinated Prefrontal State Transition Leads Extinction of Reward-Seeking Behaviors.
Extinction learning suppresses conditioned reward responses and is thus fundamental to adapt to changing environmental demands and to control excessive reward seeking. The medial prefrontal cortex (mPFC) monitors and controls conditioned reward responses. Abrupt transitions in mPFC activity anticipate changes in conditioned responses to altered contingencies. It remains, however, unknown whether such transitions are driven by the extinction of old behavioral strategies or by the acquisition of new competing ones. Using multiple single-unit recordings of mPFC in male rats, we studied the relationship between single-unit and population dynamics during extinction learning, using alcohol as a positive reinforcer in an operant conditioning paradigm. To examine the fine temporal relation between neural activity and behavior, we developed a novel behavioral model that allowed us to identify the number, onset, and duration of extinction-learning episodes in the behavior of each animal. We found that single-unit responses to conditioned stimuli changed even under stable experimental conditions and behavior. However, when behavioral responses to task contingencies had to be updated, unit-specific modulations became coordinated across the whole population, pushing the network into a new stable attractor state. Thus, extinction learning is not associated with suppressed mPFC responses to conditioned stimuli, but is anticipated by single-unit coordination into population-wide transitions of the internal state of the animal. The ability to suppress conditioned behaviors when no longer beneficial is fundamental for the survival of any organism. While pharmacological and optogenetic interventions have shown a critical involvement of the mPFC in the suppression of conditioned responses, the neural dynamics underlying such a process are still largely unknown. Combining novel analysis tools to describe behavior, single-neuron response, and population activity, we found that widespread changes in neuronal firing temporally coordinate across the whole mPFC population in anticipation of behavioral extinction. This coordination leads to a global transition in the internal state of the network, driving extinction of conditioned behavior.

Identifying nonlinear dynamical systems via generative recurrent neural networks with applications to fMRI.

A major tenet in theoretical neuroscience is that cognitive and behavioral processes are ultimately implemented in terms of the neural system dynamics. Accordingly, a major aim for the analysis of neurophysiological measurements should lie in the identification of the computational dynamics underlying task processing. Here we advance a state space model (SSM) based on generative piecewise-linear recurrent neural networks (PLRNN) to assess dynamics from neuroimaging data. In contrast to many other nonlinear time series models which have been proposed for reconstructing latent dynamics, our model is easily interpretable in neural terms, amenable to systematic dynamical systems analysis of the resulting set of equations, and can straightforwardly be transformed into an equivalent continuous-time dynamical system. The major contributions of this paper are the introduction of a new observation model suitable for functional magnetic resonance imaging (fMRI) coupled to the latent PLRNN, an efficient stepwise training procedure that forces the latent model to capture the 'true' underlying dynamics rather than just fitting (or predicting) the observations, and of an empirical measure based on the Kullback-Leibler divergence to evaluate from empirical time series how well this goal of approximating the underlying dynamics has been achieved. We validate and illustrate the power of our approach on simulated 'ground-truth' dynamical systems as well as on experimental fMRI time series, and demonstrate that the learnt dynamics harbors task-related nonlinear structure that a linear dynamical model fails to capture. Given that fMRI is one of the most common techniques for measuring brain activity non-invasively in human subjects, this approach may provide a novel step toward analyzing aberrant (nonlinear) dynamics for clinical assessment or neuroscientific research.

Detecting Multiple Change Points Using Adaptive Regression Splines With Application to Neural Recordings.
Time series, as frequently the case in neuroscience, are rarely stationary, but often exhibit abrupt changes due to attractor transitions or bifurcations in the dynamical systems producing them. A plethora of methods for detecting such in time series statistics have been developed over the years, in addition to test criteria to evaluate their significance. Issues to consider when developing change point analysis methods include computational demands, difficulties arising from either limited amount of data or a large number of covariates, and arriving at statistical tests with sufficient power to detect as many changes as contained in potentially high-dimensional time series. Here, a general method called is developed for detecting multiple change points in the mean of multivariate time series. The method's advantages over alternative approaches are demonstrated through a series of simulation experiments. This is followed by a real data application to neural recordings from rat medial prefrontal cortex during learning. Finally, the method's flexibility to incorporate useful features from state-of-the-art change point detection techniques is discussed, along with potential drawbacks and suggestions to remedy them.

Persistent Memory in Single Node Delay-Coupled Reservoir Computing.
Delays are ubiquitous in biological systems, ranging from genetic regulatory networks and synaptic conductances, to predator/pray population interactions. The evidence is mounting, not only to the presence of delays as physical constraints in signal propagation speed, but also to their functional role in providing dynamical diversity to the systems that comprise them. The latter observation in biological systems inspired the recent development of a computational architecture that harnesses this dynamical diversity, by delay-coupling a single nonlinear element to itself. This architecture is a particular realization of Reservoir Computing, where stimuli are injected into the system in time rather than in space as is the case with classical recurrent neural network realizations. This architecture also exhibits an internal memory which fades in time, an important prerequisite to the functioning of any reservoir computing device. However, fading memory is also a limitation to any computation that requires persistent storage. In order to overcome this limitation, the current work introduces an extended version to the single node Delay-Coupled Reservoir, that is based on trained linear feedback. We show by numerical simulations that adding task-specific linear feedback to the single node Delay-Coupled Reservoir extends the class of solvable tasks to those that require nonfading memory. We demonstrate, through several case studies, the ability of the extended system to carry out complex nonlinear computations that depend on past information, whereas the computational power of the system with fading memory alone quickly deteriorates. Our findings provide the theoretical basis for future physical realizations of a biologically-inspired ultrafast computing device with extended functionality.

Homeostatic plasticity for single node delay-coupled reservoir computing.
Supplementing a differential equation with delays results in an infinite-dimensional dynamical system. This property provides the basis for a reservoir computing architecture, where the recurrent neural network is replaced by a single nonlinear node, delay-coupled to itself. Instead of the spatial topology of a network, subunits in the delay-coupled reservoir are multiplexed in time along one delay span of the system. The computational power of the reservoir is contingent on this temporal multiplexing. Here, we learn optimal temporal multiplexing by means of a biologically inspired homeostatic plasticity

mechanism. Plasticity acts locally and changes the distances between the subunits along the delay, depending on how responsive these subunits are to the input. After analytically deriving the learning mechanism, we illustrate its role in improving the reservoir's computational power. To this end, we investigate, first, the increase of the reservoir's memory capacity. Second, we predict a NARMA-10 time series, showing that plasticity reduces the normalized root-mean-square error by more than 20%. Third, we discuss plasticity's influence on the reservoir's input-information capacity, the coupling strength between subunits, and the distribution of the readout coefficients.

Behavior control in the sensorimotor loop with short-term synaptic dynamics induced by self-regulating neurons.
The behavior and skills of living systems depend on the distributed control provided by specialized and highly recurrent neural networks. Learning and memory in these systems is mediated by a set of adaptation mechanisms, known collectively as neuronal plasticity. Translating principles of recurrent neural control and plasticity to artificial agents has seen major strides, but is usually hampered by the complex interactions between the agent's body and its environment. One of the important standing issues is for the agent to support multiple stable states of behavior, so that its behavioral repertoire matches the requirements imposed by these interactions. The agent also must have the capacity to switch between these states in time scales that are comparable to those by which sensory stimulation varies. Achieving this requires a mechanism of short-term memory that allows the neurocontroller to keep track of the recent history of its input, which finds its biological counterpart in short-term synaptic plasticity. This issue is approached here by deriving synaptic dynamics in recurrent neural networks. Neurons are introduced as self-regulating units with a rich repertoire of dynamics. They exhibit homeostatic properties for certain parameter domains, which result in a set of stable states and the required short-term memory. They can also operate as oscillators, which allow them to surpass the level of activity imposed by their homeostatic operation conditions. Neural systems endowed with the derived synaptic dynamics can be utilized for the neural behavior control of autonomous mobile agents. The resulting behavior depends also on the underlying network structure, which is either engineered or developed by evolutionary techniques. The effectiveness of these self-regulating units is demonstrated by controlling locomotion of a hexapod with 18 degrees of freedom, and obstacle-avoidance of a wheel-driven robot.

Spatiotemporal computations of an excitable and plastic brain: neuronal plasticity leads to noise-robust and noise-constructive computations.
It is a long-established fact that neuronal plasticity occupies the central role in generating neural function and computation. Nevertheless, no unifying account exists of how neurons in a recurrent cortical network learn to compute on temporally and spatially extended stimuli. However, these stimuli constitute the norm, rather than the exception, of the brain's input. Here, we introduce a geometric theory of learning spatiotemporal computations through neuronal plasticity. To that end, we rigorously formulate the problem of neural representations as a relation in space between stimulus-induced neural activity and the asymptotic dynamics of excitable cortical networks. Backed up by computer simulations and numerical analysis, we show that two canonical and widely spread forms of neuronal plasticity, that is, spike-timing-dependent synaptic plasticity and intrinsic plasticity, are both necessary for creating neural representations, such that these computations become realizable. Interestingly, the effects of these forms of plasticity on the emerging neural code relate to properties necessary for both combating and utilizing noise. The neural dynamics also exhibits features of the most likely stimulus in the network's spontaneous activity. These properties of the spatiotemporal neural code resulting from plasticity, having their grounding in nature, further consolidate the biological relevance of our findings.

CELLULAR DETERMINANTS OF SUBTHALAMIC FUNCTIONAL DIVERSITY

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Michaël Loureiro, Fabrice Chaudun, Nand Mule, Vahid Esmaeili, Anna Ramisch, Sabine Fièvre, Lucile Marion-Poll, Christian Lüscher
University of Geneva, Basic Neurosciences, Geneva, Switzerland

Aims. Deep brain stimulation of the subthalamic nucleus (STN) is used to treat motor symptoms in Parkinsonian patients with motor fluctuations. After prolonged stimulation, undesired side effects (e.g.anhedonia) may appear, which are believed to originate from a non specific stimulation of STN circuits mediating a variety of functions. A comprehensive description of the cellular diversity of the STN is lacking. Here we use complementary approaches to characterize the cellular determinants of STN functions. **Methods.**To determine the spatial organization of projection neurons within the STN, we performed dual retrograde tracings in mice in two established targets. To characterize STN neuronal subtypes, we then used single-nucleus-RNAseq. To study the correlations between neuronal activity and rewarding behaviors, we carried out in vivo recordings coupled with opto-tagging of STN projection neurons in an operant conditioning task where mice had to press a lever to obtain a rewarding solution. **Results.**Anatomical tracings showed that VP-projectors were concentrated ventrally in the STN. Conversely, SNR- and GPE-projector distribution did not show a dorso-ventral gradient. Gene expression analysis revealed 7 STN clusters with specific marker candidates. In vivo recording suggest the existence of at least 3 neuronal clusters based on the waveform and firing parameters. Furthermore, some neurons showed increased activity during rewarding actions. **Conclusion.**Ongoing experiments aim at linking the electrophysiological activity of STN clusters with their gene expression and to further explore their function during motor and rewarding behaviors. Altogether, our results hold promise for a better understanding of the cellular diversity and functional implications of the STN.

EVALUATION OF A TOUCHSCREEN ADAPTATION OF A RODENT REWARD-INDUCED BIAS ASSAY

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Nicholas Cherbanich, Emma Robinson
Bristol University, Physiology, Pharmacology And Neuroscience, Bristol, United Kingdom

AIMS: A recent study in an early life adversity model found a specific impairment in reward learning in a novel foraging-based task, independent of changes in reward sensitivity or motivation. In this study, we sought to test if the foraging task could be adapted to run in a touch-screen operant chamber. METHODS: The study used male Lister-hooded rats (n=14). Following initial training to establish the instrumental response, animals were pseudo-randomly presented with two pairs of images within the same session. For each pair of images, one was assigned correct and one incorrect but the value of the reward for the correct response was either high (3 reward pellets) or low (1 reward pellet). The association between the image and reward value was kept constant. Animals were tested over 14–22 sessions until they reached >70% accuracy and were then tested in a choice test protocol where high and low rewarded images were presented together with a randomised reinforcement schedule. RESULTS: Animals showed an increase in accuracy for each pair over time ($F_{7,189}$=10.83, p<0.001) but did not develop a bias towards the higher value image. In the choice test, there was a bias towards the high reward image (t_{13}=2.520, p<0.05). In a subsequent replication study in the same cohort using new images no bias was observed during learning or during the choice test. CONCLUSIONS: Animal's rate of learning in this touchscreen task was much slower than seen in the foraging-based and failed to develop a reliable reward-induced bias.

Behaviour exhibited by humans and other organisms is generally inconsistent and biased, and thus is often labelled irrational. However, the origins of this seemingly suboptimal behaviour remain elusive. We developed a behavioural task and normative framework to reveal how organisms should allocate their limited processing resources such that there is an advantage to being imprecise and biased for a given metabolic investment that guarantees maximal utility. We trained mice to perform a novel choice task based on ordinal comparisons of orientation stimuli. Additionally, we introduced trial-to-trial variability in the reliability of sensory stimuli and controlled the prior distribution of the sensory inputs in terms of presented orientations. Mice were trained in three different stimulus-reward association environments. This allowed us to model the allocation of sensory resources across the orientation space in each environment, and check whether it complies with the predictions of rational inattention theory. We found that mice act as rational-inattentive agents by adaptively allocating their sensory resources in a way that maximizes reward consumption in each stimulus-reward association environment. Surprisingly, perception to commonly occurring stimuli was relatively imprecise. However, this apparent statistical fallacy implies “awareness” and efficient adaptation to their neurocognitive limitations. Interestingly, distributional reinforcement learning mechanisms efficiently regulate sensory precision via top-down normalization. Furthermore, we found that pupil size contains information about reward expectancy of orientation stimuli in each sensory-reward association environment. These findings establish a neurobehavioral foundation for how organisms efficiently perceive and adapt to environmental states of the world within the constraints imposed by neurobiology.

BETA OSCILLATIONS IN THE MONKEY STRIATUM ENCODES REWARD PREDICTION ERROR

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Ruggero Basanisi[1], Kevin Marche[2], Etienne Combrisson[1], Paul Apicella[1], Andrea Brovelli[1]
[1]Institut de Neurosciences de la Timone (INT), Aix-marseille Université, Cnrs, Marseille, France, [2]Wellcome Center for Integrative Neuroimaging, Department Of Experimental Psychology,, Oxford, United Kingdom

Reward prediction errors (RPEs) reflect the difference between predicted and obtained rewards, and they are a building block of basic forms of reinforcement learning. RPE signals are encoded by the activity of midbrain dopaminergic neurons that innervate the striatum and frontal cortex, suggesting that RPE signals are integrated in cortico-basal ganglia circuits. In the current study, we investigated the participation of the different territories of the striatum in the encoding of RPE. To do so, we recorded local field potentials (LFPs) in the striatum of two rhesus monkeys performing a task involving a choice among options for movement with different reward probabilities. The trial-by-trial evolution of RPE was estimated using a reinforcement learning model fitted on monkeys' choice behavior. We found that changes in beta band oscillations (15-30 Hz) during the outcome period appear consistent with RPE encoding. Moreover, the learning-relevant outcome information contained in beta oscillations increased along a dorsolateral-to-ventromedial gradient. These region-specific changes in LFP activity suggest a relationship between beta oscillations in the striatum and the evaluation of outcome based on reward feedback, highlighting a specific contribution of the ventral striatum to the updating of choice behavior.

THE VAGUS NERVE SCALES NATURAL AND RECREATIONAL REWARDS

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Oriane Onimus[1], Julien Castel[1], Faustine Arrivet[2], Nicolas Heck[3], Serge Luquet[1], Giuseppe Gangarossa[1]
[1]Université de Paris, Unité De Biologie Fonctionnelle Et Adaptative, PARIS, France, [2]Sorbonne Université, Neuroscience Paris Seine, PARIS, France, [3]Sorbonne Université, Neuroscience Paris Seine, Paris, France

Interoception is a fundamental physiological property which allows the brain to be constantly informed about the homeostatic state of peripheral organs. Among a plethora of interoceptive mediators, the vagus nerve represents the main fast neuronal relay, thus ensuring the rapid and dynamic bidirectional communication between the periphery and the brain. Indeed, recent breakthroughs have highlighted the key role of the vagus nerve in governing food reward-associated events and eating disorders. However, the functional underpinnings of this “extended circuit” remain still elusive. Here, we hypothesize that the gut-to-brain vagal axis may serve as an integrative (holistic) lever to gate the hedonic and homeostatic effects of natural (food) and recreational (drugs of abuse) stimuli, thereby playing a permissive role in the development of reward-based dysfunctions such as eating disorders and drug addiction. Using a wide array of approaches (motivated behaviours, *in vivo* Ca^{2+} and dopamine imaging, metabolic efficiency, immunofluorescence, structural neuronal morphology), we have gathered compelling evidence indicating that the vagus nerve plays a pivotal role in scaling the reward processes associated to natural as well as recreational stimuli. In fact, disruption of the vagus nerve led to profound adaptations of the dopamine (DA) system which represents the cornerstone central circuit underlying reward and reinforcement events. In conclusion, our results reveal that the gut-to-brain vagal axis represents an interesting and innovative target which may pave the way to new therapeutic strategies for reward-based disorders.

CONTEXT-DEPENDENT REWARD AND AVERSIVE MEMORIES IN THE VENTRAL HIPPOCAMPUS

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Joana Duarte, Robin Nguyen, Stéphane Ciocchi
University of Bern, Laboratory Of Systems Neuroscience, Department Of Physiology, Bern, Switzerland

Acquiring and exploiting memories of rewarding and aversive experiences is critical for animal survival. Memory-guided behavior depends on the brain's capability to simultaneously construct salient emotional experiences and internal representations of encountered spatial environments. The ventral hippocampus (vHip) is a high-order cortical area involved in emotional behaviors associated with rewarding and aversive experiences. However, the neuronal dynamics and circuits within the vHip underlying the formation of context-dependent emotional memories remain poorly understood. In this study, using *in vivo* single-unit recordings in freely-moving mice during a contextual reward- and fear conditioning paradigm, we found that neuronal activity in vHip discriminates between emotional contexts with distinct valence. Contextual neuronal activity in vHip did preferentially form in emotion-contingent contexts after learning and a support-vector-machine based classifier was able to predict context identity. We next identified which pre-synaptic input to vHip mediate the formation of emotional contextual memories. To do so, we optogenetically manipulated the locus coeruleus (LC), a brain region known to release noradrenalin and regulate hippocampal plasticity and learning. We observed that suppression of LC activity in vHip during learning impaired contextual reward memory formation, although contextual fear memory was preserved. These findings identify selective neuronal activity patterns in vHip underlying emotional contextual memories and provide evidence that synaptic inputs from the LC to vHip plays a key role in contextual reward memory.

Microglia cytoarchitecture in the brain of adenosine A receptor knockout mice: Brain region and sex specificities.
Microglia cells exert a critical role in brain development, mainly supported by their immune functions, which predicts an impact on the genesis of psychiatric disorders. In fact, microglia stress during gestation is, for instance, associated with chronic anxiety and cognitive deficits accompanied by long-lasting, region- and sex-specific changes in microglia morphology. We recently reported that the pattern of microglia morphologic plasticity, which is sex-determined, impacts on anxious-like behaviour and cognition. We also reported that the pharmacologic blockade of adenosine A receptors (A R) is able to reshape microglia morphology, in a sex-specific manner and with behavioural sequelae. In order to better understand the role of A R in the sex differentiation of microglia, we now compared their morphology in wild-type and A R knockout male and female C57BL/6 mice in two cardinal brain regions implicated in anxiety-like behaviour and cognition, the prefrontal cortex (PFC) and the dorsal hippocampus (dHIP). We report interregional differences between PFC and dHIP in a sex-specific manner: while males presented more complex microglia in the dHIP, microglia from females had a more complex morphology in the PFC. Surprisingly, the genetic deletion of A R did not alter these sex differences, but promoted the exclusive remodelling (increase in complexity) in PFC microglia from females. These findings further support the existence of a heterogeneous microglial network, distinct between sexes and brain regions, and help characterizing the role of A R in the sex- and brain region-specific morphologic differentiation of microglia.

Region-specific control of microglia by adenosine A receptors: uncoupling anxiety and associated cognitive deficits in female rats.
Epidemiologic studies have provided compelling evidence that prenatal stress, through excessive maternal glucocorticoids exposure, is associated with psychiatric disorders later in life. We have recently reported that anxiety associated with prenatal exposure to dexamethasone (DEX, a synthetic glucocorticoid) correlates with a gender-specific remodeling of microglia in the medial prefrontal cortex (mPFC), a core brain region in anxiety-related disorders. Gender differences in microglia morphology, the higher prevalence of anxiety in women and the negative impact of anxiety in cognition, led us to specifically

evaluate cognitive behavior and associated circuits (namely mPFC-dorsal hippocampus, dHIP), as well as microglia morphology in female rats prenatally exposed to dexamethasone (in utero DEX, iuDEX). We report that iuDEX impaired recognition memory and deteriorated neuronal synchronization between mPFC and dHIP. These functional deficits are paralleled by microglia hyper-ramification in the dHIP and decreased ramification in the mPFC, showing a heterogeneous remodeling of microglia morphology, both postnatally and at adulthood in different brain regions, that differently affect mood and cognition. The chronic blockade of adenosine A receptors (A R), which are core regulators of microglia morphology and physiology, ameliorated the cognitive deficits, but not the anxiety-like behavior. Notably, A R blockade rectified both microglia morphology in the dHIP and the lack of mPFC-dHIP synchronization, further heralding their role in cognitive function.

Differential suppression of the ipsi- and contralateral nociceptive reflexes in the neonatal rat spinal cord by agonists of μ-, δ- and κ-opioid receptors.
Nociceptive discharges caused by the unilateral tissue damage are processed in the spinal cord by both ipsi- and contralateral neuronal circuits. The mechanisms of the neurotransmitter control of this bilateral excitation spread is poorly understood. Spinally administered opiates are known to suppress nociceptive transmission and nociceptive withdrawal reflexes. Here we investigated whether three major types of opioid receptors are involved in the bilateral control of the spinal nociceptive sensorimotor processing. Effects of the μ-, δ- and κ-opioid receptor agonists on the ipsi- and contralateral nociceptive reflexes were studied by recording slow ventral root potentials in an isolated spinal cord preparation of the new-born rat. Absolute levels of expression of the opioid genes were analyzed by the droplet digital PCR. Ipsi- and contralateral slow ventral root potentials were most strongly suppressed by the μ-opioid receptor agonist DAMGO, by 63% and 85%, followed by the κ-opioid receptor agonist U-50488H, by 44% and 73%, and δ-opioid receptor agonist leucine-enkephalin, by 27% and 49%, respectively. All these agonists suppressed stronger contra- than ipsilateral responses. Naloxone prevented effects of the agonists indicating that they act through opioid receptors, which, as we show, are expressed in the neonatal spinal cord at the levels similar to those in adults. Thus, opioid receptor agonists suppress the segmental nociceptive reflexes. Stronger contralateral effects suggest that the endogenous opioid system regulates sensorimotor processing in the spinal commissural pathways. These effects of opioids may be relevant for treatment of symmetric clinical pain symptoms caused by unilateral tissue injury.

The Dyslexia-susceptibility Protein KIAA0319 Inhibits Axon Growth Through Smad2 Signaling.
KIAA0319 is a transmembrane protein associated with dyslexia with a presumed role in neuronal migration. Here we show that KIAA0319 expression is not restricted to the brain but also occurs in sensory and spinal cord neurons, increasing from early postnatal stages to adulthood and being downregulated by injury. This suggested that KIAA0319 participates in functions unrelated to neuronal migration. Supporting this hypothesis, overexpression of KIAA0319 repressed axon growth in hippocampal and dorsal root ganglia neurons; the intracellular domain of KIAA0319 was sufficient to elicit this effect. A similar inhibitory effect was observed in vivo as axon regeneration was impaired after transduction of sensory neurons with KIAA0319. Conversely, the deletion of Kiaa0319 in neurons increased neurite outgrowth in vitro and improved axon regeneration in vivo. At the mechanistic level, KIAA0319 engaged the JAK2-SH2B1 pathway to activate Smad2, which played a central role in KIAA0319-mediated repression of axon growth. In summary, we establish KIAA0319 as a novel player in axon growth and regeneration with the ability to repress the intrinsic growth potential of axons. This study describes a novel regulatory mechanism operating during peripheral nervous system and central nervous system axon growth, and offers novel targets for the development of effective therapies to promote axon regeneration.

Depression as a Glial-Based Synaptic Dysfunction.
Recent studies combining pharmacological, behavioral, electrophysiological and molecular approaches indicate that depression results from maladaptive neuroplastic processes occurring in defined frontolimbic circuits responsible for emotional processing such as the prefrontal cortex, hippocampus, amygdala and ventral striatum. However, the exact mechanisms controlling synaptic plasticity that are disrupted to trigger depressive conditions have not been elucidated. Since glial cells (astrocytes and microglia) tightly and dynamically interact with synapses, engaging a bi-directional communication critical for the processing of synaptic information, we now revisit the role of glial cells in the etiology of depression focusing on a dysfunction of the "quad-partite" synapse. This interest is supported by the observations that depressive-like conditions are associated with a decreased density and hypofunction of astrocytes and with an increased microglia "activation" in

frontolimbic regions, which is expected to contribute for the synaptic dysfunction present in depression. Furthermore, the traditional culprits of depression (glucocorticoids, biogenic amines, brain-derived neurotrophic factor, BDNF) affect glia functioning, whereas antidepressant treatments (serotonin-selective reuptake inhibitors, SSRIs, electroshocks, deep brain stimulation) recover glia functioning. In this context of a quad-partite synapse, systems modulating glia-synapse bidirectional communication-such as the purinergic neuromodulation system operated by adenosine 5'-triphosphate (ATP) and adenosine-emerge as promising candidates to "re-normalize" synaptic function by combining direct synaptic effects with an ability to also control astrocyte and microglia function. This proposed triple action of purines to control aberrant synaptic function illustrates the rationale to consider the interference with glia dysfunction as a mechanism of action driving the design of future pharmacological tools to manage depression.

Experimental investigations have suggested that humans perceive received rewards in a context-dependent manner. More precisely, rewards are rescaled as a function of the maximal and minimal values received in the same context, a process referred to as range-adaptation. We here set out to explore what could be the advantage of performing range-adaptation from a computational point of view. We used computational modeling to compare a classical reinforcement learning algorithm (Q-Learning) with a new reinforcement learning algorithm that implements range-adaptation. This revealed that performing range-adaptation allows the algorithm to reach a high performance for rewards of any magnitude; on the contrary, the baseline algorithm reaches a high performance only a certain range of magnitudes. We analytically demonstrate that these results are explained by the incapacity of the baseline model to efficiently address the exploration-exploitation dilemma. Indeed, the optimal value of the parameter that controls the degree of exploration depends on the rewards' magnitude, thus a fixed value cannot be suited for any magnitude. We then show that performing range-adaptation acts as a dynamic update of the exploration parameter, maintaining it close to its optimal value for any magnitude. Finally, we show that these results can be extended to multi-step reinforcement learning tasks, i.e. tasks in which future rewards must be anticipated. We conclude by discussing how these results could contribute to research in artificial intelligence, on top of providing insights as to why humans implement range-

adaptation.

ALTERED REWARD-MOTIVATION PROCESSING OF THE TALLYHO/JNGJ MOUSE MODEL IN OPERANT LEARNING TASK IS ASSOCIATED WITH INSULIN SIGNALLING MECHANISMS

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Mairead Sullivan[1], Jeffrey Glennon[1], Sarita Dam[2], Charlotte Oomen[2], Ilse Van De Vondervoort[2], Joao Paulo Rodrigues[3]
[1]University College Dublin, Physiology, Dublin, Ireland, [2]RadboundUMC, Cognitive Neuroscience, Nijmegen, Netherlands, [3]Universidade Federal de Juiz de Fora, School Of Medicine, -, Brazil

Behavioural inflexibility is a debilitating feature of numerous psychiatric disorders, impairing ability to change behavioural strategy to match environmental reward. Insulin signalling has been implicated in Obsessive-Compulsive Disorder, with TALLYHO/JngJ mouse models of Type 2 diabetes showing impaired spontaneous alteration and increased anxiety. Here, we assessed extinction learning, the ability to inhibit previously-rewarded behaviour in TALLYHO/JngJ mice and their SWR/J controls. TALLYHO/JngJ mice acquire the task similar to controls (51.77 ± 18.07 vs 50.13 ± 16.37) but extinguish responses more rapidly (27.81 ± 2.30 vs 38.73 ± 2.79), show greater omissions (21.81 ± 0.70 vs 18.38 ± 0.84) and require more time (567.9 ± 3.83 vs 549.6 ± 5.95) for task completion following reward removal. Transcriptomic analysis in cerebellum shows significantly reduced expression in TALLYHO/JngJ of IGF1R (0.41 ± 0.03 vs 0.51 ± 0.03) and KCNQ1 (0.30 ± 0.027 vs 0.41 ± 0.03), two genes implicated in insulin signalling, with a significant positive correlation between expression levels and the extinction response. This suggests a link between reward-motivation processing and insulinergic signalling. Insulin controls not only blood glucose and lipid metabolism but also is involved in inflammation. Ongoing inflammatory proteomics work in blood sera and matching brain regions involved in compulsive and reward-related behaviour (anterior cingulate cortex and nucleus accumbens) is underway to map onto the extinction phenotype.

CODING AND CONTROL OF GOAL-DIRECTED BEHAVIOR BY AMYGDALA

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Julien Courtin
FMI, Neurosciences, Basel, Switzerland

Acting to achieve goals depends on the ability to motivate specific behaviors. By definition, instrumental goal-directed actions are oriented toward specific outcomes and are sensitive to variations in outcome value and action-outcome contingency. However, the underlying neuronal mechanisms that encode and maintain such parameters are poorly understood. Here we used calcium imaging and optogenetic manipulations in basolateral amygdala of freely moving mice performing non-cued, self-paced instrumental goal-directed actions to receive and consume rewards. We show that distinct neuronal activity patterns sequentially represent the entire action-consumption behavioral sequence. Whereas action-associated patterns integrate the identity, value and expectancy of pursued goals, consumption-associated patterns reflect the identity and value of experienced outcomes. Thus, the interplay between these patterns allows the maintenance of specific motivational states necessary to adaptively direct behavior toward prospective rewards. Finally, by tracking the neuronal activity of same neurons over a multi-phase behavioral task we show that such motivational states allow the transfer and reinstatement of specific memories.

A neuronal mechanism for motivational control of behavior.
Acting to achieve goals depends on the ability to motivate specific behaviors based on their predicted consequences given an individual's internal state. However, the underlying neuronal mechanisms that encode and maintain such specific motivational control of behavior are poorly understood. Here, we used Ca imaging and optogenetic manipulations in the basolateral amygdala of freely moving mice performing noncued, self-paced instrumental goal-directed actions to receive and consume rewards. We found that distinct neuronal activity patterns sequentially represent the entire action-consumption behavioral sequence. Whereas action-associated patterns integrated the identity, value, and expectancy of pursued goals, consumption-associated patterns reflected the identity and value of experienced outcomes. Thus, the interplay between these patterns allows the maintenance of specific motivational states necessary to adaptively direct behavior toward prospective rewards.

Adaptive disinhibitory gating by VIP interneurons permits associative learning.
Learning drives behavioral adaptations necessary for survival. While plasticity of excitatory projection neurons during associative learning has been extensively studied, little is known about the contributions of local interneurons. Using fear conditioning as a model for associative learning, we found that behaviorally relevant, salient stimuli cause learning by tapping into a local microcircuit consisting of precisely connected subtypes of inhibitory interneurons. By employing deep-brain calcium imaging and optogenetics, we demonstrate that vasoactive intestinal peptide (VIP)-expressing interneurons in the basolateral amygdala are activated by aversive events and provide a mandatory disinhibitory signal for associative learning. Notably, VIP interneuron responses during learning are strongly modulated by expectations. Our findings indicate that VIP interneurons are a central component of a dynamic circuit motif that mediates adaptive disinhibitory gating to specifically learn about unexpected, salient events, thereby ensuring appropriate behavioral adaptations.

A competitive inhibitory circuit for selection of active and passive fear responses.
When faced with threat, the survival of an organism is contingent upon the selection of appropriate active or passive behavioural responses. Freezing is an evolutionarily conserved passive fear response that has been used extensively to study the neuronal mechanisms of fear and fear conditioning in rodents. However, rodents also exhibit active responses such

as flight under natural conditions. The central amygdala (CEA) is a forebrain structure vital for the acquisition and expression of conditioned fear responses, and the role of specific neuronal sub-populations of the CEA in freezing behaviour is well-established. Whether the CEA is also involved in flight behaviour, and how neuronal circuits for active and passive fear behaviour interact within the CEA, are not yet understood. Here, using in vivo optogenetics and extracellular recordings of identified cell types in a behavioural model in which mice switch between conditioned freezing and flight, we show that active and passive fear responses are mediated by distinct and mutually inhibitory CEA neurons. Cells expressing corticotropin-releasing factor (CRF) mediate conditioned flight, and activation of somatostatin-positive (SOM) neurons initiates passive freezing behaviour. Moreover, we find that the balance between conditioned flight and freezing behaviour is regulated by means of local inhibitory connections between CRF and SOM neurons, indicating that the selection of appropriate behavioural responses to threat is based on competitive interactions between two defined populations of inhibitory neurons, a circuit motif allowing for rapid and flexible action selection.

Prefrontal neuronal assemblies temporally control fear behaviour.
Precise spike timing through the coordination and synchronization of neuronal assemblies is an efficient and flexible coding mechanism for sensory and cognitive processing. In cortical and subcortical areas, the formation of cell assemblies critically depends on neuronal oscillations, which can precisely control the timing of spiking activity. Whereas this form of coding has been described for sensory processing and spatial learning, its role in encoding emotional behaviour remains unknown. Fear behaviour relies on the activation of distributed structures, among which the dorsal medial prefrontal cortex (dmPFC) is known to be critical for fear memory expression. In the dmPFC, the phasic activation of neurons to threat-predicting cues, a spike-rate coding mechanism, correlates with conditioned fear responses and supports the discrimination between aversive and neutral stimuli. However, this mechanism does not account for freezing observed outside stimuli presentations, and the contribution of a general spike-time coding mechanism for freezing in the dmPFC remains to be established. Here we use a combination of single-unit and local field potential recordings along with optogenetic manipulations to show that, in the dmPFC, expression of conditioned fear is causally related to the organization of neurons into functional assemblies. During fear behaviour, the development of 4 Hz oscillations coincides with the activation of assemblies nested in the ascending phase of the oscillation. The selective optogenetic inhibition of dmPFC neurons during the ascending or descending phases of this oscillation blocks and promotes conditioned fear responses, respectively. These results identify a novel phase-specific coding mechanism, which dynamically regulates the development of dmPFC assemblies to control the precise timing of fear responses.

4-Hz oscillations synchronize prefrontal-amygdala circuits during fear behavior.
Fear expression relies on the coordinated activity of prefrontal and amygdala circuits, yet the mechanisms allowing long-range network synchronization during fear remain unknown. Using a combination of extracellular recordings, pharmacological and optogenetic manipulations, we found that freezing, a behavioral expression of fear, temporally coincided with the development of sustained, internally generated 4-Hz oscillations in prefrontal-amygdala circuits. 4-Hz oscillations predict freezing onset and offset and synchronize prefrontal-amygdala circuits. Optogenetic induction of prefrontal 4-Hz oscillations coordinates prefrontal-amygdala activity and elicits fear behavior. These results unravel a sustained oscillatory mechanism mediating prefrontal-amygdala coupling during fear behavior.

Prefrontal parvalbumin interneurons shape neuronal activity to drive fear expression.
Synchronization of spiking activity in neuronal networks is a fundamental process that enables the precise transmission of information to drive behavioural responses. In cortical areas, synchronization of principal-neuron spiking activity is an effective mechanism for information coding that is regulated by GABA (γ-aminobutyric acid)-ergic interneurons through the generation of neuronal oscillations. Although neuronal synchrony has been demonstrated to be crucial for sensory, motor and cognitive processing, it has not been investigated at the level of defined circuits involved in the control of emotional behaviour. Converging evidence indicates that fear behaviour is regulated by the dorsomedial prefrontal cortex (dmPFC). This control over fear behaviour relies on the activation of specific prefrontal projections to the basolateral complex of the amygdala (BLA), a structure that encodes associative fear memories. However, it remains to be established how the precise temporal control of fear behaviour is achieved at the level of prefrontal circuits. Here we use single-unit recordings and optogenetic manipulations in behaving mice to show that fear expression is causally related to the phasic inhibition of

prefrontal parvalbumin interneurons (PVINs). Inhibition of PVIN activity disinhibits prefrontal projection neurons and synchronizes their firing by resetting local theta oscillations, leading to fear expression. Our results identify two complementary neuronal mechanisms mediated by PVINs that precisely coordinate and enhance the neuronal activity of prefrontal projection neurons to drive fear expression.

Persistence of amygdala gamma oscillations during extinction learning predicts spontaneous fear recovery.
Extinction of auditory fear conditioning induces a temporary inhibition of conditioned fear responses that can spontaneously reappear with the passage of time. Several lines of evidence indicate that extinction learning relies on the recruitment of specific neuronal populations within the basolateral amygdala. In contrast, post-extinction spontaneous fear recovery is thought to result from deficits in the consolidation of extinction memory within prefrontal neuronal circuits. Interestingly, recent data indicates that the strength of gamma oscillations in the basolateral amygdala during auditory fear conditioning correlates with retrieval of conditioned fear responses. In the present manuscript we evaluated the hypothesis that post-extinction spontaneous fear recovery might depend on the maintenance of gamma oscillations within the basolateral amygdala by using single unit and local field potential recordings in behaving mice. Our results indicate that gamma oscillations in the basolateral amygdala were enhanced following fear conditioning, whereas during extinction learning gamma profiles were more heterogeneous despite similar extinction learning rates. Remarkably, variations in the strength of gamma power within the basolateral amygdala between early and late stages of extinction linearly predicted the level of post-extinction spontaneous fear recovery. These data suggest that maintenance of gamma oscillations in the basolateral amygdala during extinction learning is a strong predictive factor of long term spontaneous fear recovery.

REWARD SIGNAL CONTROLS THE SPEED OF EVOLVING POPULATION DYNAMICS IN MOUSE POSTERIOR PARIETAL CORTEX

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Benjamin Goolsby[1], Karim Oweiss[2]
[1]University of Florida, Biomedical Engineering, Gainesville, United States of America, [2]University of Florida, Electrical Eng, Biomedical Eng And Neuroscience, Gainesville, United States of America

When rewards are immediately available, sensory-guided action selection typically occurs with little to no delay. In contrast, memory-guided action selection could be slower when rewards are delayed or unavailable. Individual neurons in association cortex have been shown to exhibit mixed selectivity towards sensory and choice variables, but how reward presence or absence influences the encoding of these variables at the population level remains largely unknown. Here we investigated the role of posterior parietal cortex (PPC) neurons in stimulus categorization and choice selectivity conditioned on reward availability. We trained mice on an auditory categorization task under two contexts in which reward was either immediately available (context 1) or delayed (context 2). We first found that PPC population dynamics encode the reward state (present or absent) independent of stimulus or choice variables. We further found that population dynamics evolve at different speeds in state space depending on whether reward was immediately available (context 1) or delayed (context 2). This difference in speed could not be entirely explained by changes in stimulus only, decision only or stimulus-decision components in the neural activity. Our results suggest a novel mechanism whereby the reward signal controls the mnemonic representation of task variables to maintain economic neural activity states that can be rapidly and reliably readout by other downstream areas at the time of action selection.

CONVERGENT AND DIVERGENT CIRCUITRY OF CENTRAL AMYGDALA FOR PROCESSING ADDICTIVE AND NATURAL REWARDS

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Łukasz Bijoch[1], Joanna Klos[2], Leszek Kaczmarek[3], Anna Beroun[1]
[1]Nencki Institute Of Experimental Biology PAS, Laboratory Of Neuronal Plasticity, Laboratory Of Neurobiology, Nencki-embl Partnership For Neural Plasticity And Brain Disorders – Braincity, Warsaw, Poland, [2]Max Planck Institute for Biological Intelligence, Bonhoeffer Lab, Planegg, Germany, [3]Nencki Institute of Experimental Biology, Laboratory Of Neurobiology, Nencki-embl Partnership For Neural Plasticity And Brain Disorders – Braincity, Warsaw, Poland

Since few years, it is claimed that drug addiction should be considered as a specific form of learning as it creates changes in neural networks by strengthening or weakening some of neuronal connections - synapses. Similar modifications occur during natural reward learning and it is believed that these are spots in the brain where information- engrams, are encoded. It was deliberated that drugs of abuse hijack these engrams to create extremely durable forms of memories. Thus, in this study we were testing how much similarities shares the initial exposure to addictive substances with natural form of learning. As a mice model of “addictive” learning we chose cocaine intraperitoneal injections, while sucrose self-administration mimicked the natural form of learning. Series of electrophysiology and immunohistochemical experiments were performed on a reward-related brain structure: Central Amygdala with its medial (CeM) and lateral (CeL) parts. Our results indicate that indeed both cocaine IP injection and sugar administration cause rapid (already two hours after the exposure) plastic changes and c-Fos expression in CeM. On the other hand, cocaine additionally triggers plasticity in CeL. Interestingly, electrophysiology experiments unraveled, that neurons in CeL, but not in CeM, diminish their activity upon cocaine exposure. Together, we found common and divergent pathways in central amygdala for natural and addictive rewards processing.

REDUCED CONTEXT LEARNING IN OLDER ADULTS

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Nadège Bault[1], Stefano Palminteri[2], Giorgio Coricelli[3]
[1]University of Plymouth, School Of Psychology, Plymouth, United Kingdom, [2]École Normale Supérieure - PSL Research University, Département D'etudes Cognitives, Paris, France, [3]University of Southern California, Economics And Psychology, Los Angeles, United States of America

Aging is associated with increased susceptibility to fraud and impairments in financial decision making. To be an effective financial decision maker, in addition to learning how to gain reward, one must also learn how to avoid losses. We use behavioral and computational methods to investigate the computational mechanisms underlying reward and punishment learning in older adults and to study the effect of aging to the ability to correctly represent the choice context. The results of our experiments indicate that, over time, younger adults learn to adjust based on context such that in loss contexts, having a no loss outcome triggers reinforcement-learning processes that allow them to learn as effectively about avoiding losses as gaining rewards. In contrast, our behavioral findings indicate that older adults show selective impairments in learning to avoid losses. This age-related impairment could either be due to impairments in the ability to learn about the decision context (i.e. impaired context learning) or to a more general 'positivity effect' in which they attend relatively less to negative than positive outcomes. We develop and test computational models to identify the contribution of different types of learning mechanisms to these age differences. In particular, we compare the degree to which impairments in learning about the context versus a bias to attend more to positive than negative feedback can account for older adults' learning patterns.

ELECTROENCEPHALOGRAPHIC CORRELATES OF CONTINUOUS FEEDBACK PROCESSING

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Cameron Hassall, Yan Yan, Laurence Hunt
University of Oxford, Department Of Psychiatry, Oxford, United Kingdom

Feedback processing is commonly studied by analyzing the brain's response to discrete events. However, the neural correlates of continuous feedback processing are less understood. Recent animal work suggests that moment-to-moment changes in reward are tracked by slowly ramping midbrain dopaminergic activity. Our goal was to identify a candidate electroencephalographic (EEG) measure of continuous reward tracking in humans. Twenty participants completed a stimulus-response learning task in which reward increased or decreased gradually. Continuous reward elicited EEG activity consistent with a component of the event-related potential (ERP) previously linked to slowly ramping dopaminergic activity. Importantly, reward-related activity depended on outcome expectancy. Consistent with a reward prediction error, activity for expected continuous rewards was reduced compared to activity for unexpected continuous rewards. These results demonstrate the possibility of using human scalp-recorded potentials to track continuous feedback processing.

ACUPUNCTURE DECREASES BRAIN TEMPERATURE INDUCED BY METHAMPHETAMINE VIA RMTG

POSTER SESSION 01 - SECTION: REWARD PROCESSING AND REINFORCEMENT LEARNING

Namjun Kim, Bong Hyo Lee
Daegu Haany University, College Of Korean Medicin, Daegu, Korea, Republic of

Aims: Methamphetamine (METH) is a representative psychostimulant that has been abused worldwide. The reinforcing effects of METH is known to stronger than any other abused drug due to its neuronal action to the dopamine release in the nucleus accumbens (NAc). The present study examined if acupuncture could suppress METH-induced increase of brain temperature and a possible neuronal mechanism was also investigated. **Methods:** Male SD rats were anesthetized with sodium pentobarbital (50 mg/kg) and placed at a stereotaxic apparatus. Rats were subjected for the implantation of thermometer in the NAc of the mesolimbic system. Temperature was recorded for 60 minutes. Acupuncture treatments at each acupoint bilaterally immediately after METH infusion. For the electronic lesion, electrodes were inserted into each target area. **Results:** Acute administration of MTEH increased the temperature in the NAc of mesolimbic system. However, acupuncture inhibited this increase of brain temperature when stimulated at HT7, but not at TE9. In addition, this inhibitory effect of acupuncture at HT7 disappeared when the RMTg was blocked by electronic lesion. But other areas couldn't block HT7 effect. **Conclusion:** Acupuncture at HT7 inhibited the increase of brain temperature in the NAc by MTEH and this inhibition of acupuncture was blocked by the lesion of the RMTg. Results of the present study suggest that acupuncture at HT7 can be a useful therapy for the MTEH addiction. **Key words:** Acupuncture, HT7, Methamphetamine, RMTg, NAc, Brain temperature.

Aims Preclinical research has become progressively complex due to diverse and/or conflicting reported results, generating a reproducibility crisis in the field. Without knowing, scientists may dismiss critical factors that influence the planning and outcome of a study. To address this problem, "PEERS", an open-access online platform, was constructed to advise scientists on which experimental factors and variables are most likely to affect the outcome of a test or model and must be considered during design, execution, and reporting stages. Methods "PEERS" was constructed by identifying commonly utilised *in vivo* and *in vitro* protocols in neuroscience followed by the generation of an extensive list of factors deemed critical for their outcome, based on published literature. Furthermore, with "PEERS" we developed a structured and transparent system for rating the strength of evidence related to each identified factor and its relevance for a specific method/model. Results So far, certain protocols were chosen for the working prototype as a proof-of-concept. Here, we describe the Open Field paradigm in rodents and demonstrate the selection of factors specific to the experimental setup and details of the rating system. Lastly, we provide evidence on how "PEERS" supports a community-driven approach to grade evidence and add protocols to the platform. Conclusions Collectively, by aiding scientists to search for specific factors relevant to their experiments constructively and to report results in a standardised and adequate manner, "PEERS" will serve as a collaborative exchange and analysis tool to elevate data robustness and validity, as well as reproducibility of preclinical research.

[Pharmacology of ketamine and esketamine as rapid-acting antidepressants].
The lack of utter efficacy and fast action of commonly used antidepressants that selectively target the monoaminergic neurotransmission has led to the exploration of ketamine's actions. Ketamine's antidepressant effect was firstly described in 1973 and nowadays its therapeutic value as a fast- and long- lasting antidepressant has been extensively established. Ketamine is an antagonist of the N-Methyl-D-aspartate receptor (NMDAR) and its main mechanism of action via NMDAR inhibition expressed in GABAergic (gamma-Aminobutyric acid, GABA) interneurons may be relayed to its antidepressant effects. This review aims to describe the pharmacokinetic and pharmacodynamic profile of ketamine when used for treatment-resistant depression. Moreover, ketamine is a racemic mixture consisting of two enantiomers, R- and S- ketamine. We describe the pharmacology of esketamine, along with the guidelines for effective and safe intranasal administration of esketamine. Lastly, this review presents sex differences in preclinical and clinical studies of ketamine and esketamine administration.

PEERS - An Open Science "Platform for the Exchange of Experimental Research Standards" in Biomedicine.
Laboratory workflows and preclinical models have become increasingly diverse and complex. Confronted with the dilemma of a multitude of information with ambiguous relevance for their specific experiments, scientists run the risk of overlooking critical factors that can influence the planning, conduct and results of studies and that should have been considered . To

address this problem, we developed "PEERS" (Platform for the Exchange of Experimental Research Standards), an open-access online platform that is built to aid scientists in determining which experimental factors and variables are most likely to affect the outcome of a specific test, model or assay and therefore ought to be considered during the design, execution and reporting stages. The PEERS database is categorized into and experiments and provides lists of factors derived from scientific literature that have been deemed critical for experimentation. The platform is based on a structured and transparent system for rating the strength of evidence related to each identified factor and its relevance for a specific method/model. In this context, the rating procedure will not solely be limited to the PEERS working group but will also allow for a community-based grading of evidence. We here describe a working prototype using the Open Field paradigm in rodents and present the selection of factors specific to each experimental setup and the rating system. PEERS not only offers users the possibility to search for information to facilitate experimental rigor, but also draws on the engagement of the scientific community to actively expand the information contained within the platform. Collectively, by helping scientists search for specific factors relevant to their experiments, and to share experimental knowledge in a standardized manner, PEERS will serve as a collaborative exchange and analysis tool to enhance data validity and robustness as well as the reproducibility of preclinical research. PEERS offers a vetted, independent tool by which to judge the quality of information available on a certain test or model, identifies knowledge gaps and provides guidance on the key methodological considerations that should be prioritized to ensure that preclinical research is conducted to the highest standards and best practice.

Antidepressants' effects on testosterone and estrogens: What do we know?
Various antidepressants are commonly used to treat depression and anxiety disorders, and sex differences have been identified in their efficacy and side effects. Steroids, such as estrogens and testosterone, both in the periphery and locally in the brain, are regarded as important modulators of these sex differences. This review presents published data from preclinical and clinical studies that measure testosterone and estrogen level changes during and/or after acute or chronic administration of different antidepressants. The majority of studies show an interaction between sex hormones and antidepressants on sexual function and behavior, or in depressive symptom alleviation. However, most of the studies omit to investigate antidepressants' effects on circulating levels of gonadal hormones. From data reviewed herein, it is evident that most antidepressants can influence testosterone and estrogen levels. Still, the evidence is conflicting with some studies showing an increase, others decrease or no effect. Most studies are conducted in male animals or humans, underscoring the importance of considering sex as an important variable in such investigations, especially as depression and anxiety disorders are more common in women than men. Therefore, research is needed to elucidate the extent to which antidepressants can influence both peripheral and brain levels of testosterone and estrogens, in males and females, and whether this impacts the effectiveness or side effects of antidepressants.

Multi-scale network imaging in a mouse model of amyloidosis.
The adult neocortex is not hard-wired but instead retains the capacity to reorganise across multiple spatial scales long into adulthood. Plastic reorganisation occurs at the level of mesoscopic sensory maps, functional neuronal assemblies and synaptic ensembles and is thought to be a critical feature of neuronal network function. Here, we describe a series of approaches that use calcium imaging to measure network reorganisation across multiple spatial scales in vivo. At the mesoscopic level, we demonstrate that sensory activity can be measured in animals undergoing longitudinal behavioural assessment involving automated touchscreen tasks. At the cellular level, we show that network dynamics can be longitudinally measured at both stable and transient functional assemblies. At the level of single synapses, we show that functional subcellular calcium imaging approaches can be used to measure synaptic ensembles of dendritic spines in vivo. Finally, we demonstrate that all three levels of imaging can be spatially related to local pathology in a preclinical rodent model of amyloidosis. We propose that multi-scale in vivo calcium imaging can be used to measure parallel plasticity processes operating across multiple spatial scales in both the healthy brain and preclinical models of disease.

Cognitive disturbances in the cuprizone model of multiple sclerosis.
Cognitive problems frequently accompany neurological manifestations of multiple sclerosis (MS). However, during screening of preclinical candidates, assessments of behaviour in mouse models of MS typically focus on locomotor activity. In the present study, we analysed cognitive behaviour of 9 to 10-week-old female C57Bl/6J mice orally administered with the toxin cuprizone that induces demyelination, a characteristic feature of MS. Animals received 400 mg/kg cuprizone daily for 2 or

4 weeks, and their performance was compared with that of vehicle-treated mice. Cuprizone-treated animals showed multiple deficits in short touchscreen-based operant tasks: they responded more slowly to visual stimuli, rewards and made more errors in a simple rule-learning task. In contextual/cued fear conditioning experiments, cuprizone-treated mice showed significantly lower levels of contextual freezing than vehicle-treated mice. Diffusion tensor imaging showed treatment-dependent changes in fractional anisotropy as well as in axial and mean diffusivities in different white matter areas. Lower values of fractional anisotropy and axial diffusivity in cuprizone-treated mice indicated developing demyelination and/or axonal damage. Several diffusion tensor imaging measurements correlated with learning parameters. Our results show that translational touchscreen operant tests and fear conditioning paradigms can reliably detect cognitive consequences of cuprizone treatment. The suggested experimental approach enables screening novel MS drug candidates in longitudinal experiments for their ability to improve pathological changes in brain structure and reverse cognitive deficits.

Automated classification of self-grooming in mice using open-source software.
Manual analysis of behavior is labor intensive and subject to inter-rater variability. Although considerable progress in automation of analysis has been made, complex behavior such as grooming still lacks satisfactory automated quantification.

Comprehensive and ethologically-relevant cognitive and behavioural phenotyping in rodent experiments is essential to deciphering the neural basis of animal cognition. Existing tests are often labour-intensive, time-consuming and lack specificity in their readouts. Furthermore, the results of these tests usually compare effects between groups and cannot distinguish differences between individual animals. To address these shortcomings, we developed a novel fully automated AI-based mouse phenotyping system ('smartKage'). Our system integrates T-maze spatial alternation, novel-object recognition (NOR) and object-in-place recognition (OPR) cognitive tests that can be run long-term (>12 months) continuously and in parallel without any interference from the Experimenter in an animal's home-cage environment. In addition to cognitive assessment, the smartKage measures other behavioural outcomes such as sleep and activity patterns, exercise and food and water consumption. In line with the results reported in the conventional tests, we showed that T-maze performance declines with inter-trial interval and the spatial working-memory spans up to 10 min. Furthermore, the object exploration time increases with introduction of a 'novel object' or with changing location of a familiar object. Importantly, in double-blind experiments we showed that using the smartKage in combination with a brief testing on a standard T-maze we were able to separate hippocampal-lesioned, entorhinal-lesioned and sham controls with perfect accuracy on the individual animal basis, which has never been previously achieved. Finally, we demonstrate the utility of the smartKage for translational applications by conducting cognitive and behavioural phenotyping in popular Alzheimer's disease mouse models (APP^{NL-G-F} and Tau^{PS19}).

First effects of rising amyloid-β in transgenic mouse brain: synaptic transmission and gene expression.
Detecting and treating Alzheimer's disease, before cognitive deficits occur, has become the health challenge of our time. The earliest known event in Alzheimer's disease is rising amyloid-β. Previous studies have suggested that effects on synaptic transmission may precede plaque deposition. Here we report how relative levels of different soluble amyloid-β peptides in hippocampus, preceding plaque deposition, relate to synaptic and genomic changes. Immunoprecipitation-mass spectrometry was used to measure the early rise of different amyloid-β peptides in a mouse model of increasing amyloid-β ('TASTPM', transgenic for familial Alzheimer's disease genes APP/PSEN1). In the third postnatal week, several amyloid-β peptides were above the limit of detection, including amyloid-β40, amyloid-β38 and amyloid-β42 with an intensity ratio of 6:3:2, respectively. By 2 months amyloid-β levels had only increased by 50% and although the ratio of the different peptides remained constant, the first changes in synaptic currents, compared to wild-type mice could be detected with patch-clamp recordings. Between 2 and 4 months old, levels of amyloid-β40 rose by ~7-fold, but amyloid-β42 rose by 25-fold, increasing the amyloid-β42:amyloid-β40 ratio to 1:1. Only at 4 months did plaque deposition become detectable and only in some mice; however, synaptic changes were evident in all hippocampal fields. These changes included increased glutamate release probability ($P < 0.001$, n = 7-9; consistent with the proposed physiological effect of amyloid-β) and loss of spontaneous action potential-mediated activity in the cornu ammonis 1 (CA1) and dentate gyrus regions of the hippocampus ($P < 0.001$, n = 7). Hence synaptic changes occur when the amyloid-β levels and amyloid-β42:amyloid-β40 ratio are still low compared to those necessary for plaque deposition. Genome-wide microarray analysis revealed changes in gene expression at 2-4 months including synaptic genes being strongly affected but often showing significant changes only by 4 months. We thus

demonstrate that, in a mouse model of rising amyloid-β, the initial deposition of plaques does not occur until several months after the first amyloid-β becomes detectable but coincides with a rapid acceleration in the rise of amyloid-β levels and the amyloid-β42:amyloid-β40 ratio. Prior to acceleration, however, there is already a pronounced synaptic dysfunction, reflected as changes in synaptic transmission and altered gene expression, indicating that restoring synaptic function early in the disease progression may represent the earliest possible target for intervention in the onset of Alzheimer's disease.

Neuronal and Peripheral Pentraxins Modify Glutamate Release and may Interact in Blood-Brain Barrier Failure.
Neuronal pentraxin 1 (NPTX1) has been implicated in Alzheimer's disease, being present in and around dystrophic neurons in plaques, affecting glutamatergic transmission postsynaptically and mediating effects of amyloidβ. Here, we confirm the presence of NPTX1 around plaques in postmortem Alzheimer's disease brain and report that acutely applied human NPTX1 increases paired-pulse ratio at mouse CA3-CA1 hippocampal synapses, indicating a decrease in glutamate release. In contrast, chronic exposure to NPTX1, NPTX2, or NPTX receptor decreases paired-pulse ratio, mimicking some of the earliest changes in mice expressing familial Alzheimer's disease genes. The peripheral pentraxin, serum amyloid P component (SAP), causes similar synaptic effects to NPTX1. The presence of SAP on amyloid plaques in Alzheimer's disease confirms that it can enter the brain. We show that SAP and neuronal pentraxins can interact and that SAP can enter the brain if the blood-brain barrier is compromised, suggesting that peripheral pentraxins could affect central synaptic transmission via this interaction, especially in the event of blood-brain barrier breakdown.

Structure and organization of heteromeric AMPA-type glutamate receptors.
AMPA-type glutamate receptors (AMPARs), which are central mediators of rapid neurotransmission and synaptic plasticity, predominantly exist as heteromers of the subunits GluA1 to GluA4. Here we report the first AMPAR heteromer structures, which deviate substantially from existing GluA2 homomer structures. Crystal structures of the GluA2/3 and GluA2/4 N-terminal domains reveal a novel compact conformation with an alternating arrangement of the four subunits around a central axis. This organization is confirmed by cysteine cross-linking in full-length receptors, and it permitted us to determine the structure of an intact GluA2/3 receptor by cryogenic electron microscopy. Two models in the ligand-free state, at resolutions of 8.25 and 10.3 angstroms, exhibit substantial vertical compression and close associations between domain layers, reminiscent of N-methyl-D-aspartate receptors. Model 1 resembles a resting state and model 2 a desensitized state, thus providing snapshots of gating transitions in the nominal absence of ligand. Our data reveal organizational features of heteromeric AMPARs and provide a framework to decipher AMPAR architecture and signaling.

Architecture of the heteromeric GluA1/2 AMPA receptor in complex with the auxiliary subunit TARP γ8.
AMPA-type glutamate receptors (AMPARs) mediate excitatory neurotransmission and are central regulators of synaptic plasticity, a molecular mechanism underlying learning and memory. Although AMPARs act predominantly as heteromers, structural studies have focused on homomeric assemblies. Here, we present a cryo-electron microscopy structure of the heteromeric GluA1/2 receptor associated with two transmembrane AMPAR regulatory protein (TARP) γ8 auxiliary subunits, the principal AMPAR complex at hippocampal synapses. Within the receptor, the core subunits arrange to give the GluA2 subunit dominant control of gating. This structure reveals the geometry of the Q/R site that controls calcium flux, suggests association of TARP-stabilized lipids, and demonstrates that the extracellular loop of γ8 modulates gating by selectively interacting with the GluA2 ligand-binding domain. Collectively, this structure provides a blueprint for deciphering the signal transduction mechanisms of synaptic AMPARs.

AMPA receptor anchoring at CA1 synapses is determined by N-terminal domain and TARP γ8 interactions.
AMPA receptor (AMPAR) abundance and positioning at excitatory synapses regulates the strength of transmission. Changes in AMPAR localisation can enact synaptic plasticity, allowing long-term information storage, and is therefore tightly controlled. Multiple mechanisms regulating AMPAR synaptic anchoring have been described, but with limited coherence or comparison between reports, our understanding of this process is unclear. Here, combining synaptic recordings from mouse hippocampal slices and super-resolution imaging in dissociated cultures, we compare the contributions of three AMPAR interaction domains controlling transmission at hippocampal CA1 synapses. We show that the AMPAR C-termini play only a modulatory role, whereas the extracellular N-terminal domain (NTD) and PDZ interactions of the auxiliary subunit TARP γ8 are both crucial, and each is sufficient to maintain transmission. Our data support a model in which γ8 accumulates AMPARs at the

postsynaptic density, where the NTD further tunes their positioning. This interplay between cytosolic (TARP γ8) and synaptic cleft (NTD) interactions provides versatility to regulate synaptic transmission and plasticity.
Nat Commun, 2021; 12
28290985: Watson JF, Ho H, Greger IH
Synaptic transmission and plasticity require AMPA receptor anchoring via its N-terminal domain.
AMPA-type glutamate receptors (AMPARs) mediate fast excitatory neurotransmission and are selectively recruited during activity-dependent plasticity to increase synaptic strength. A prerequisite for faithful signal transmission is the positioning and clustering of AMPARs at postsynaptic sites. The mechanisms underlying this positioning have largely been ascribed to the receptor cytoplasmic C-termini and to AMPAR-associated auxiliary subunits, both interacting with the postsynaptic scaffold. Here, using mouse organotypic hippocampal slices, we show that the extracellular AMPAR N-terminal domain (NTD), which projects midway into the synaptic cleft, plays a fundamental role in this process. This highly sequence-diverse domain mediates synaptic anchoring in a subunit-selective manner. Receptors lacking the NTD exhibit increased mobility in synapses, depress synaptic transmission and are unable to sustain long-term potentiation (LTP). Thus, synaptic transmission and the expression of LTP are dependent upon an AMPAR anchoring mechanism that is driven by the NTD.

An inhalation anaesthesia approach for neonatal mice allowing streamlined stereotactic injection in the brain.
Investigating brain function requires tools and techniques to visualise, modify and manipulate neuronal tissue. One powerful and popular method is intracerebral injection of customised viruses, allowing expression of exogenous transgenes. This technique is a standard procedure for adult mice, and is used by laboratories worldwide. Use of neonatal animals in scientific research allows investigation of developing tissues and enables long-term study of cell populations. However, procedures on neonatal mice are more challenging, due to the lack of reliable methods and apparatus for anaesthesia of these animals.

Mechanisms underlying TARP modulation of the GluA1/2-γ8 AMPA receptor.
AMPA-type glutamate receptors (AMPARs) mediate rapid signal transmission at excitatory synapses in the brain. Glutamate binding to the receptor's ligand-binding domains (LBDs) leads to ion channel activation and desensitization. Gating kinetics shape synaptic transmission and are strongly modulated by transmembrane AMPAR regulatory proteins (TARPs) through currently incompletely resolved mechanisms. Here, electron cryo-microscopy structures of the GluA1/2 TARP-γ8 complex, in both open and desensitized states (at 3.5 Å), reveal state-selective engagement of the LBDs by the large TARP-γ8 loop ('β1'), elucidating how this TARP stabilizes specific gating states. We further show how TARPs alter channel rectification, by interacting with the pore helix of the selectivity filter. Lastly, we reveal that the Q/R-editing site couples the channel constriction at the filter entrance to the gate, and forms the major cation binding site in the conduction path. Our results provide a mechanistic framework of how TARPs modulate AMPAR gating and conductance.

CLOSED-LOOP SYSTEM FOR REAL-TIME COMPULSIVE BEHAVIOR DETECTION AND WIRELESS OPTOGENETIC STIMULATION IN OBSESSIVE-COMPULSIVE DISORDER MOUSE MODEL

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Patricia Silva[1,2,3], Patricia Monteiro[2,3], Luis Jacinto[2,3]
[1]Center for Microelectromechanical Systems (CMEMS), Department Of Industrial Electronics, Guimarães, Portugal, [2]University of Minho, Life And Health Sciences Research Institute (icvs) / School Of Medicine, Braga, Portugal, [3]PT Government Associate Laboratory, Icvs/3b's, Braga/Guimarães, Portugal

Obsessive-Compulsive Disorder (OCD) is a prevalent neuropsychiatric disorder characterized by recurrent intrusive thoughts (obsessions) that can lead to repetitive behaviors (compulsions), which can cause significant disruption of daily activities. To simultaneously study the neuronal circuits involved in OCD and test novel therapies, it is critical to develop methodologies that can automatically detect and/or predict compulsive behavior and allow effective modulation of relevant brain circuits with temporal precision. Thus, we developed a closed-loop system that combines computer vision and machine learning approaches for effective real-time detection of compulsive/repetitive behaviors, which are coupled with wirelessly controlled optogenetic brain stimulation in the *Sapap3* KO mouse model of OCD. Accurate online detection of repetitive behavioral motifs, such as face grooming, was achieved by combining DeepLabCut for real-time animal body part tracking with supervised extraction of kinematic behavioral features and classification of behavioral states with Support Vector Machines (SVM). To reduce/correct body part tracking outlier labels that can skew behavioral classification, different correction and smoothing strategies including average, median and Kalman filters were also tested. Online detection of repetitive behavior triggers a small wireless optical brain stimulator that delivers light to the brain for low-latency optogenetic stimulation. The brain stimulator consists of an implanted microscale inorganic lightemitting diode (μ-ILED) and battery-powered external electronics for Bluetooth Low Energy communication in a lightweight PCB. This new closed-loop system allows a direct assessment of the impact of brain circuit manipulations in compulsive behavior, contributing to the elucidation of the brain circuits involved in OCD and novel therapies developments.

BLUEBERRY: PROVIDING WIRELESS OPTOGENETIC FEEDBACK IN FREELY MOVING ANIMALS BASED ON REAL-TIME BEHAVIORAL TRACKING

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Ali Nourizonoz, Gregorio Galinanes, Raphaël Thurnherr, Sébastien Pellat, Daniel Huber
University of Geneva, Department Of Basic Neuroscience, Geneva, Switzerland

Optogenetics has been extensively used by neuroscientists in a quest to manipulate neuronal activity in different brain areas and study their causal link to behavior. Applications widely vary from head-fixed settings, where stable optical access to the brain is necessary, to freely moving scenarios where maintaining natural sensory-motor variables are crucial. Thanks to recent technological advances in wireless communication, optogenetic stimulation devices can be controlled remotely, allowing to extend freely moving studies to multi-animal setups or complex three dimensional environments. However, the relatively high cost and the lack of open source systems has placed constraints on the current wireless optogenetic devices. Here we present the BlueBerry, an open source, low cost (30$) multi-channel optogenetic device controlled and programmed remotely using Bluetooth Low Energy (BLE) protocol. The light and compact design (1.4gr - 11 x 15 x 6 mm) of the BlueBerry makes it an ideal candidate for real-time optogenetic application in freely roaming small animals such as mice or small primates. We illustrate the capability of the BlueBerry system combined with other open source frameworks such as EthoLoop (www.etholoop.org) for freely moving mice in two different experimental settings: 1) stimulation of the ventral tegmental area (VTA) to reinforce execution of specific type of behavior repeatedly in naturalistic 3D environments and 2) stimulation of somatosensory cortex in a “infinity-Y-maze” solving task where the mouse has to transform the artificial sensory feedbacks into navigation decisions (left or right) at every intersection.

EthoLoop: automated closed-loop neuroethology in naturalistic environments.
Accurate tracking and analysis of animal behavior is crucial for modern systems neuroscience. However, following freely moving animals in naturalistic, three-dimensional (3D) or nocturnal environments remains a major challenge. Here, we present EthoLoop, a framework for studying the neuroethology of freely roaming animals. Combining real-time optical tracking and behavioral analysis with remote-controlled stimulus-reward boxes, this system allows direct interactions with animals in their habitat. EthoLoop continuously provides close-up views of the tracked individuals and thus allows high-resolution behavioral analysis using deep-learning methods. The behaviors detected on the fly can be automatically reinforced either by classical conditioning or by optogenetic stimulation via wirelessly controlled portable devices. Finally, by combining 3D tracking with wireless neurophysiology we demonstrate the existence of place-cell-like activity in the hippocampus of freely moving primates. Taken together, we show that the EthoLoop framework enables interactive, well-controlled and reproducible neuroethological studies in large-field naturalistic settings.

A common computational principle for vibrotactile pitch perception in mouse and human.
We live surrounded by vibrations generated by moving objects. These oscillatory stimuli propagate through solid substrates, are sensed by mechanoreceptors in our body and give rise to perceptual attributes such as vibrotactile pitch (i.e. the perception of how high or low a vibration's frequency is). Here, we establish a mechanistic relationship between vibrotactile pitch perception and the physical properties of vibrations using behavioral tasks, in which vibratory stimuli were delivered to the human fingertip or the mouse forelimb. The resulting perceptual reports were analyzed with a model demonstrating that physically different combinations of vibration frequencies and amplitudes can produce equal pitch perception. We found that the perceptually indistinguishable but physically different stimuli follow a common computational principle in mouse and human. It dictates that vibrotactile pitch perception is shifted with increases in amplitude toward the frequency of highest vibrotactile sensitivity. These findings suggest the existence of a fundamental relationship between the seemingly unrelated

concepts of spectral sensitivity and pitch perception.

A NEW MINI-VR AND DUAL-WHEEL PLATFORM FOR CLOSED-LOOP MOTOR LEARNING AND ADAPTATION IN MICE

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Sebastien Hausmann[1], Gary Kane[2], Mackenzie Mathis[2]
[1]EPFL, Bmi/cnp, Geneva, Switzerland, [2]Harvard University, Rowland Institute, Cambridge, United States of America

We live in environments that are constantly changing, and as a result, our motor commands need to be continually adapted to account for changing sensory inputs. Visual inputs are easy to control and manipulate, making visual-adaptation an ideal way to study the neural mechanisms of motor adaptation. In particular, modern virtual reality platforms paired with tractable models such as mice, are ideally suited. Yet current approaches rely on either open or closed loop approaches where mice run on an air-supported styrofoam ball, limiting the ability to perform perturbations across the body axis. To tackle this, we developed a novel fully closed-loop split-wheel virtual reality (VR) and mini-VR "headset" for mice to study specific types of visuomotor adaptations. The virtual environment is displayed in a "mini-VR" system, and to navigate in the virtual environment the mice must rotate two wheels placed ipsilaterally underneath their limbs. Moving the wheels synchronously during locomotion therefore directly translates in navigating straight in the virtual environment. Thus, an imposed visual perturbation can modulate each wheel independently to shift the overall angle of movement in the VR world. We show that mice can learn to navigate on this split wheel VR system within 14 days and when challenged with a visual perturbation they can rapidly adapt within 100 trials and show classical signatures of adaptive behavior.

THE HELICO MAZE TO STUDY EARLY LEARNING AND SUBCATEGORIES OF LONG-TERM MEMORY IN MICE

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

François S. Roman[1], Guy Escoffier[2], Martine Migliorati[2], Melinda Rahrah[2], Charles Roman[2], Michel Khrestchatisky[2]
[1]INP Institut de Neurophysiopathologie, Umr 7051 Cnrs - Aix-marseille Université Neurobiologie Des Processus Mnésiques Aix-marseille Université – Faculté De Médecine/campus Timone –, Marseille Cedex , France, [2]INP Institut de Neurophysiopathologie, Umr 7051 Cnrs - Aix-marseille Université Neurobiologie Des Processus Mnésiques Aix-marseille Université – Faculté De Médecine/campus Timone –, Marseille Cedex, France

Aims: The Helico Maze (HM) was developed to study procedural and reference subcategories of long-term memory as early as possible in the mouse. Methods: BALB/c AnNCrl (BALB), C57BL/6JRj (C57) and DBA/2 JRj (DBA) mice were 8 weeks old at the beginning of training on this new apparatus. Results: The three strains learned how to use the HM (procedural memory), and they then learned and remembered four odor-reward associations (reference memory). The three strains differed in the number of correct responses. BALB mice showed better performance than C57 and DBA mice. The results of the first trials of each session revealed that only the BALB and C57 mice remembered the odor-reward associations. DBA mice, well-known having hippocampal circuitry dysfunctioning, needed to relearn the associations each day. Conclusions: With this new maze, the number of olfactory cue-reward associations was increased from 2 to 4 in comparison to a previous olfactory tubing maze. Consequently, a supplementary effort of memory was required, and the chance level was decreased from 50 % to 25 %. Thus, the HM can be considered to measure the hippocampus-dependent behavior of the mouse, allowing to study, as early as possible in young mice, the different subcategories of long-term memory, such as those observed in humans. In addition, using the Helico Maze may open new avenues to validate efficacy of treatments that target early events related neurodegenerative diseases.

INTRODUCTION: Accumulation of aberrantly processed and misfolded proteins into aggregates causes proteotoxic stress in neuronal cells, resulting in long-term deleterious effects and neurodegeneration, associated to several diseases. **AIM:** This work addresses an unmet medical need: the lack of effective treatment for aging-associated neurodegenerative diseases (ND). **METHODS:** Here, we established an automated assay to screen for small molecules able to act as enhancers of protein folding and homeostasis capacity, that reduce proteotoxic stress in a whole organism, using motor activity after heat-shock (HS) as a readout. For this purpose, we used a transgenic model of a polyglutamine disease, a strain expressing a Firefly-Luciferase folding sensor, and Wild-type animals, evaluating their motor function in the basal situation and during post-HS recovery. The protocol developed consisted in exposing animals to 60 min of HS at 37ºC, after which their motor activity was measured in an automated manner, for 15h, using an automated movement detector. **RESULTS:** The HS of 60 min caused paralysis, however, all *C. elegans* models tested were still able to recover close to baseline levels 15h post-HS. Using this newly established protocol, we found that the pharmacologic and genetic modulation of serotonergic signaling prevented proteotoxic damage and significantly increased motor function recovery. **CONCLUSION:** Currently, we are screening libraries of novel and repurposed compounds, for which some of the molecular targets have been genetically defined. This should allow the identification of novel candidate therapeutics and a deeper understanding of the biological pathways underlying proteotoxic stress, of relevance to many human diseases.

Novel Machado-Joseph disease-modifying genes and pathways identified by whole-exome sequencing.
Machado-Joseph disease (MJD/SCA3) is a neurodegenerative polyglutamine disorder exhibiting a wide spectrum of phenotypes. The abnormal size of the (CAG)n at ATXN3 explains ~55% of the age at onset variance, suggesting the involvement of other factors, namely genetic modifiers, whose identification remains limited. Our aim was to find novel genetic modifiers, analyse their epistatic effects and identify disease-modifying pathways contributing to MJD variable expressivity. We performed whole-exome sequencing in a discovery sample of four age at onset concordant and four discordant first-degree relative pairs of Azorean patients, to identify candidate variants which genotypes differed for each discordant pair but were shared in each concordant pair. Variants identified by this approach were then tested in an independent multi-origin cohort of 282 MJD patients. Whole-exome sequencing identified 233 candidate variants, from which 82 variants in 53 genes were prioritized for downstream analysis. Eighteen disease-modifying pathways were identified; two of the most enriched pathways were relevant for the nervous system, namely the neuregulin signaling and the agrin interactions at neuromuscular junction. Variants at PARD3, NFKB1, CHD5, ACTG1, CFAP57, DLGAP2, ITGB1, DIDO1 and CERS4 modulate age at onset in MJD, with those identified in CFAP57, ACTG1 and DIDO1 showing consistent effects across cohorts of different geographical origins. Network analyses of the nine novel MJD modifiers highlighted several important molecular interactions, including genes/proteins previously related with MJD pathogenesis, namely between ACTG1/APOE and VCP/ITGB1. We describe novel pathways, modifiers, and their interaction partners, providing a broad molecular portrait of age at onset modulation to be further exploited as new disease-modifying targets for MJD and related diseases.

Identification of the 5-HT serotonin receptor as a novel therapeutic target in a C. elegans model of Machado-Joseph disease.
Machado-Joseph disease (MJD) or Spinocerebellar ataxia type 3 (SCA3) is a progressive neurodegenerative disorder that affects movement coordination leading to a premature death. Despite several efforts, no disease-modifying treatment is yet available for this disease. Previous studies pinpointed the modulation of serotonergic signaling, through pharmacological inhibition of the serotonin transporter SERT, as a promising therapeutic approach for MJD/SCA3. Here, we describe the 5-HT receptor as a novel therapeutic target in MJD, using a C. elegans model of ATXN3 proteotoxicity. Chronic and acute administration of befiradol (also known as NLX-112), a highly specific 5-HT agonist, rescued motor function and suppressed mutant ATXN3 aggregation. This action required the 5-HT receptor orthologue in the nematode, SER-4. Tandospirone, a clinically tested 5-HT receptor partial agonist, showed a limited impact on animals' motor dysfunction on acute administration and a broader receptor activation profile upon chronic treatment, its effect depending on 5-HT but also on the 5-HT/SER-5 and 5-HT/SER-7 receptors. Our results support high potency and specificity of befiradol for activation of 5-HT/SER-4 receptors and highlight the contribution of the auto- and hetero-receptor function to the therapeutic outcome in this MJD model. Our study deepens the understanding of serotonergic signaling modulation in the suppression of ATXN3 proteotoxicity and suggests that a potent and selective 5-HT receptor agonist such as befiradol could constitute a promising therapeutic agent for MJD.

Data on the effects of spp. and spp. plant extracts in models of genetically determined neurodegenerative diseases.
Here, we present the data on the biological effects of spp. and spp. plant extracts in () models of neurodegenerative diseases, which is related to the work presented in the article "Neurotherapeutic effect of spp. leaf extracts in models of tauopathy and polyglutamine disease: role of the glutathione redox cycle" [1]. This dataset was generated to define non-toxic concentrations of these plant extracts and to assess their impact on the motor phenotype and oxidative stress resistance of transgenic models of two genetically defined neurodegenerative diseases: Machado-Joseph disease and Frontotemporal dementia with Parkinsonism associated to the chromosome 17. The impact of the plant extracts on toxicity was assessed using the food-clearance assay, absorbance being measured daily for seven days at 595 nm to quantify () strain OP50 bacteria consumption. Worm length and motor behaviour, including spontaneous and stimulated movement, were analysed using videos acquired with an Olympus SZX7 stereomicroscope with an integrated camera (Olympus SC30) and processed using the Image J® software and the Wrmtrck plugin. The resistance to oxidative stress induced by 240 µM juglone was assessed by determining the percentage of live animals after 1 hour of exposure.

Neurotherapeutic effect of Hyptis spp. leaf extracts in Caenorhabditis elegans models of tauopathy and polyglutamine disease: Role of the glutathione redox cycle.
Hyptis suaveolens (HS), Hyptis pectinata (HP) and Hyptis marrubioides (HM) are plants used in folk medicine for treatment of several diseases. Here, we tested the in vivo antioxidant and neuroprotective potential of methanolic extracts from these plants, containing several rosmarinic acid derivatives and isoquercetin. In C. elegans, HS, HP and HM leaf extracts enhanced the antioxidant responses through the induction of specific antioxidant enzymes and demonstrated neurotherapeutic potential in transgenic models of genetically determined human neurodegenerative diseases - Frontotemporal dementia with parkinsonism linked to chromosome 17 and Machado-Joseph disease. Chronic treatment of disease models with HS, HP and HM leaf extracts improved the animals' motor function and increased their tolerance to an oxidative insult. The restorative effect of HM extract in motor performance of both disease models required the presence of glutathione reductase (gsr-1), an enzyme that assures the glutathione redox cycle, highlighting the role of this pathway and unveiling a common candidate therapeutic target for these diseases. Our findings strengthen the relevance of plant-derived bioactive compound discovery for neurodegenerative disorders that remain without effective treatment.

A VERSATILE OPEN SOURCE 1-PHOTON IMAGING PLATFORM FOR INVESTIGATING THE NEURONAL CORRELATES OF BEHAVIOURAL FLEXIBILITY

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Brice De La Crompe[1,2,3], Megan Schneck[1,2,3], Florian Steenbergen[1,2,3], Artur Schneider[1,2,3], Ilka Diester[1,2,3,4]
[1]Albert-Ludwigs-Universität, Optophysiology - Optogenetics And Neurophysiology, Freiburg, Germany, [2]Albert-Ludwigs-Universität, Freiburg, Germany, Faculty Of Biology, Institute Of Biology Iii, Freiburg, Germany, [3]Albert-Ludwigs-Universität, Freiburg, Germany, Imbit // Brainlinks-brainoolsuniversity Of Freiburg, Freiburg, Germany, [4]Albert-Ludwigs-Universität, Bernstein Center For Computational Neuroscience, Freiburg, Germany

In order to survive in a complex and changing environment, animals have to adapt their behaviour. This ability is called behavioural flexibility and is classically evaluated by a reversal learning paradigm. During such a paradigm, the animals adapt their behaviour according to a change in the reward contingencies, allowing an investigation of complex cognitive functions, ranging from outcome expectancies to motor adaptation. Here, we describe FreiBox, a versatile, low-cost (~750 Euros) and open-source platform allowing us to investigate the neuronal correlates of behavioural flexibility with 1-photon Calcium imaging. It is an Arduino-based setup, integrating a new licking sensor for detecting directional licking in a behavioural task, controlled by a custom-built Python interface. We show that the Arduino is able to track mouse licking behaviour in real time and to control task events in a sub-millisecond timescale allowing both discriminative and serial reversal learning tasks. To complete our setup for freely-moving animals, we also developed and validated a cost-effective commutator (<150 Euros), which is crucial for calcium imaging with the Miniscope v4 and measuring electrophysiological signals with Neuropixel probes. Finally, we demonstrate that FreiBox can be used in combination with 1-photon imaging and other open-source initiatives (e.g. openEphys) to form a versatile platform for exploring the neuronal substrates of licking-based behaviour in mice. In summary, FreiBox and our low-cost commutator complement the recently emerging battery of open-source initiatives, opening new avenues to investigate behavioural flexibility with a specific focus on Calcium imaging in mice involved in a reversal learning paradigm.

Translocator protein (18 kDa) mapping with [125I]-CLINDE in the quinolinic acid rat model of excitotoxicity: a longitudinal comparison with microglial activation, astrogliosis, and neuronal death.
Excitotoxicity leads to an inflammatory reaction involving an overexpression of: translocator protein 18 kDa (TSPO) in cerebral microglia and astrocytes. Therefore, we performed ex vivo explorations with [125]-CLINDE, a TSPO-specific radioligand, to follow the time course of TSPO expression, in parallel with lesion progression, over 90 days after induction of cerebral excitotoxicity in rats intrastriatally injected with quinolinic acid. Biodistribution data showed a significant increase in CLINDE uptake on the injured side from 1 days postlesion (dpl); the maximal striatal binding values evidenced a plateau between 7 and 30 dpl. [125I]-CLINDE binding was displaced from the lesion by PK11195, suggesting TSPO specificity. These results were confirmed by ex vivo autoradiography. Combined immunohistochemical studies showed a marked increase in microglial expression in the lesion, peaking at 14 dpl, and astrocytic reactivity enhanced at 7 and 14 dpl, whereas a prominent neuronal cell loss was observed. At 90 dpl, CLINDE binding and immunoreactivity targeting activated microglia, astrogliosis, and neuronal cell density returned to a basal level. These results show that both neuroinflammation and neuronal loss profiles occurred concomitantly and appeared to be transitory processes. These findings provide the possibility of a therapeutic temporal window to compare the differential effects of antiinflammatory treatments in slowing down neurodegeneration in this rodent model, with potential applications to humans.

Inhibiting Lateral Habenula Improves L-DOPA-Induced Dyskinesia.
A systematic search of brain nuclei putatively involved in L-3,4-dihydroxyphenylalanine (L-DOPA)-induced dyskinesia (LID) in Parkinson's disease shed light, notably, upon the lateral habenula (LHb), which displayed an overexpression of the ΔFosB, ARC, and Zif268 immediate-early genes only in rats experiencing abnormal involuntary movements (AIMs). We thus

hypothesized that LHb might play a role in LID.

The globus pallidus orchestrates abnormal network dynamics in a model of Parkinsonism.
The dynamical properties of cortico-basal ganglia (CBG) circuits are dramatically altered following the loss of dopamine in Parkinson's disease (PD). The neural circuit dysfunctions associated with PD include spike-rate alteration concomitant with excessive oscillatory spike-synchronization in the beta frequency range (12-30 Hz). Which neuronal circuits orchestrate and propagate these abnormal neural dynamics in CBG remains unknown. In this work, we combine in vivo electrophysiological recordings with advanced optogenetic manipulations in normal and 6-OHDA rats to shed light on the mechanistic principle underlying circuit dysfunction in PD. Our results show that abnormal neural dynamics present in a rat model of PD do not rely on cortical or subthalamic nucleus activity but critically dependent on globus pallidus (GP) integrity. Our findings highlight the pivotal role played by the GP which operates as a hub nucleus capable of orchestrating firing rate and synchronization changes across CBG circuits both in normal and pathological conditions.

A Disynaptic Circuit in the Globus Pallidus Controls Locomotion Inhibition.
The basal ganglia (BG) inhibit movements through two independent circuits: the striatal neuron-indirect and the subthalamic nucleus-hyperdirect pathways. These pathways exert opposite effects onto external globus pallidus (GPe) neurons, whose functional importance as a relay has changed drastically with the discovery of two distinct cell types, namely the prototypic and the arkypallidal neurons. However, little is known about the synaptic connectivity scheme of different GPe neurons toward both motor-suppressing pathways, as well as how opposite changes in GPe neuronal activity relate to locomotion inhibition. Here, we optogenetically dissect the input organizations of prototypic and arkypallidal neurons and further define the circuit mechanism and behavioral outcome associated with activation of the indirect or hyperdirect pathways. This work reveals that arkypallidal neurons are part of a novel disynaptic feedback loop differentially recruited by the indirect or hyperdirect pathways and that broadcasts inhibitory control onto locomotion only when arkypallidal neurons increase their activity.

Functional interrogation of neural circuits with virally transmitted optogenetic tools.
The vertebrate brain comprises a plethora of cell types connected by intertwined pathways. Optogenetics enriches the neuroscientific tool set for disentangling these neuronal circuits in a manner which exceeds the spatio-temporal precision of previously existing techniques. Technically, optogenetics can be divided in three types of optical and genetic combinations: (1) it is primarily understood as the manipulation of the activity of genetically modified cells (typically neurons) with light, i.e. optical actuators. (2) A second combination refers to visualizing the activity of genetically modified cells (again typically neurons), i.e. optical sensors. (3) A completely different interpretation of optogenetics refers to the light activated expression of a genetically induced construct. Here, we focus on the first two types of optogenetics, i.e. the optical actuators and sensors in an attempt to give an overview into the topic. We first cover methods to express opsins into neurons and introduce strategies of targeting specific neuronal populations in different animal species. We then summarize combinations of optogenetics with behavioral read out and neuronal imaging. Finally, we give an overview of the current state-of-the-art and an outlook on future perspectives.

ELECTROCHEMICAL APTAMER-BASED BIOSENSORS ENABLE IN-BRAIN DRUG CONCENTRATION-BEHAVIORAL RESPONSE ANALYSES.

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Tod Kippin
University of California, Santa Barbara, Psychological & Brain Sciences, Santa Barabara, United States Minor Outlying Islands

Drugs exert their behavioral effects via concentration-dependent actions upon neural circuits. However, to date, there has been relatively limited attention to the role pharmacokinetics plays in psychopharmacology because, amongst other factors, the temporal resolution with which we can measure these compounds is *orders of magnitude* too slow to capture the concentrations associated with altered physiological processes. For instance, procaine and cocaine are psychoactive compounds that have short half-lives and elicit highly dynamic behavioral effects upon intravenous administration making determination of the relation between in-brain concentration and on-going behavior challenging. Thus motivated, we adopted electrochemical aptamer-based sensors (E-AB sensors) to the task of measuring drugs in-situ and in real-time in awake, freely behaving animals. Here, we report EAB sensors that exhibit sufficient sensitivity, appropriate temporal resolution (~12s), and stable drift characteristics to fully resolve pharmacokinetics of procaine and cocaine in the brains of rats. These data combined with standard locomotor measurements enable detailed analyses of the relations between in-brain concentration and behavioral response for individual male and female subjects. In parallel, we employed EAB-supported feedback-control of drug delivery to produce constant in-brain drug concentrations to remove individual differences in PK as well as examine within-session neurobehavioral adaptations caused by drug exposure. In conclusion, we have developed technology capable of determining individual, in-brain pharmacokinetics of psychoactive drugs in behaving animals that can enable concentration-response analyses.

Estimating the pose of multiple animals is a challenging computer vision problem: frequent interactions cause occlusions and complicate the association of detected keypoints to the correct individuals, as well as having highly similar looking animals that interact more closely than in typical multi-human benchmarking datasets. To take up this challenge, we build on DeepLabCut, an open source pose estimation toolbox, and provide high-performance animal assembly and tracking—features required for multi-animal scenarios. We propose a multi-task architecture that predicts multiple conditional random fields and therefore can predict keypoints, within-animal body part connections ("limbs"), as well as animal identity. Advantageously, the definition of an animal's skeleton, i.e. the list of limbs that will be used for assembly, is data-driven, thus requiring no user input. Furthermore, we integrate the ability to predict an animal's identity to assist tracking (in case of occlusions). We illustrate the power of this framework with four datasets varying in complexity, which we release to serve as a benchmark for future algorithm development.

Behavioral differences among individuals are ubiquitous in animal studies. When consistent across time and contexts, they define animal personality. In adulthood, environmental factors, such as social context, play a major role in personality adaptation. However, the underlying neurophysiological mechanisms are poorly understood and bring promising leads towards understanding inter-individual differences in vulnerability to drugs. We aim at unraveling the social determinants of inter-individual variability and drug vulnerability, using a semi-natural multi-environment, “Souris City”, where mice are living in large social groups and individually tracked for several weeks. This system combines a compartmentalized social homecage and a T-maze with individual access. It allows us to observe correlations between decision-making strategies in the T-maze, and behavioral traits in the social zone, and thus to describe individual profiles. Using juxtacellular recordings in anaesthetized mice, we found that individuals with distinct behavioral traits in Souris-City also display differences in the spontaneous activity of their Ventral Tegmental Area (VTA) dopaminergic (DA) neurons. We next investigated whether these mice also showed differences in their response to nicotine exposure, by recording VTA DA neurons responses to intravenous nicotine injections. Using c-fos immunoreactivity in cleared whole brains, we further sought for inter-individual differences in global responses of brain structures to intraperitoneal nicotine injections. Finally, we looked into the impact of nicotine intake on individual behavior, either through voluntary consumption in Souris City, or by chronic administration via subcutaneous osmotic pumps. This combinatorial approach allows to address key questions on individual personality and vulnerability to nicotine.

A LEARNING ASSAY FOR HEAD-FIXED WALKING FLIES

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Andres Flores-Valle, Johannes Seelig
Max Planck Society, Max Planck Institute For Neurobiology Of Behavior, Bonn, Germany

Understanding the function of sleep is hindered by the extended nature of sleep control circuits over many brain areas and by the many different brain functions that are impacted by sleep. In the brain of Drosophila, multiple neural populations have been identified that are important for sleep control. In the central complex, an area in the center of the fly brain, sleep control circuits interact with circuits that have well characterized functions in the context of navigation as well as memory. Based on the fly connectome as well as the dynamics of the relevant neural populations, which are known thanks to electrophysiology and calcium imaging experiments, we developed a computational model of the interaction of sleep control and navigation circuits [Flores-Valle et al., Plos. Comp. Biol., 2021]. How memory circuits interact with sleep or navigation circuits in the fly brain is however only little understood and mostly only through computational modeling. Constraining such models requires experimental paradigms that allow investigating neural dynamics underlying sleep and learning. This necessitates recording neural activity in behaving animals over multiple timescales, including bouts of wakefulness and sleep while the animal is engaged in a learning task. In particular, such an approach needs a reliable learning paradigm that can be implemented in tethered flies and can therefore be combined with neural recordings. Here, we develop a novel learning paradigm for tethered walking flies and use it for analyzing the function of putative learning circuits in the Drosophila brain.

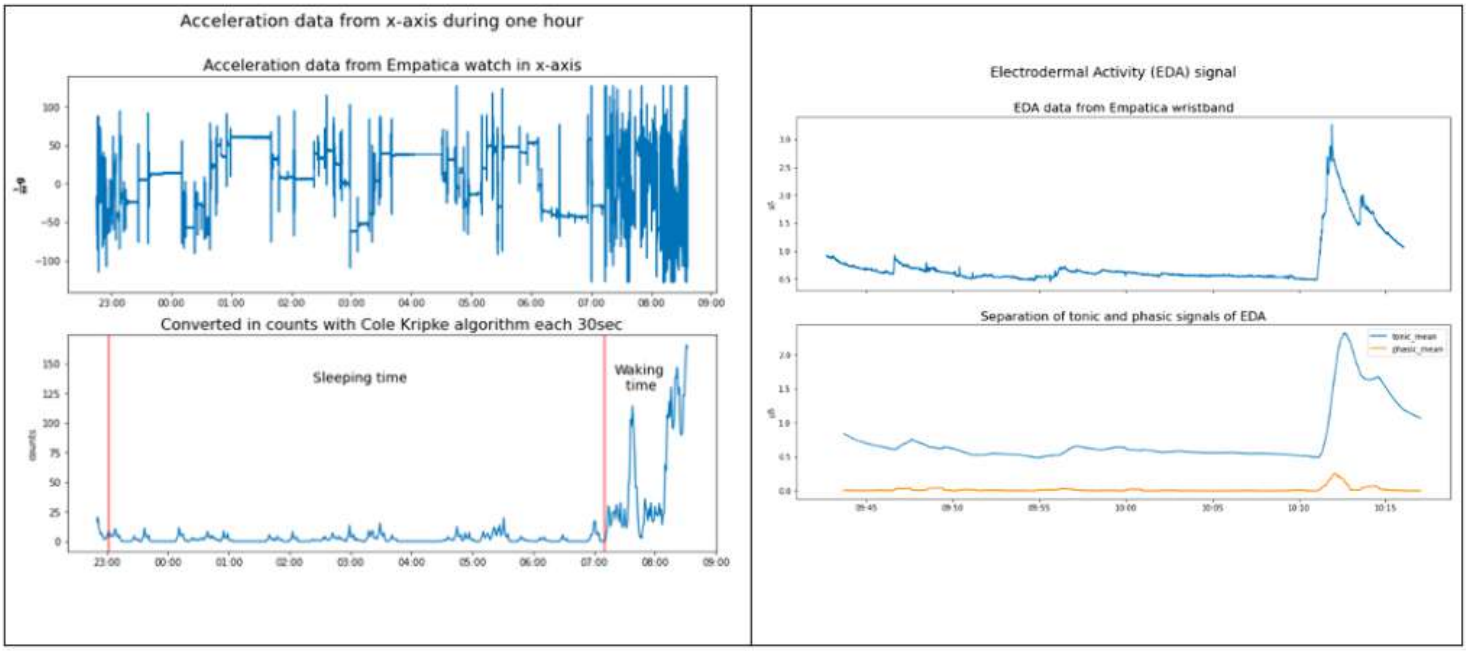
ECOCAPTURE@HOME: DEVELOPMENT OF AN ASSESSMENT METHOD FOR APATHY IN EVERYDAY LIFE CONDITIONS, TARGETED TOWARDS PATIENTS WITH NEURODEGENERATIVE DISEASES AND THEIR CAREGIVERS.

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Idil Sezer, Valérie Godefroy, Mathilde Boucly, Armelle Rametti-Lacroux, Arabella Bouzigues, Raffaella Migliaccio, Richard Lévy, Bénédicte Batrancourt
Sorbonne Université, Paris Brain Institute – Institut du Cerveau – ICM, Inserm U1127, CNRS UMR 7225, AP-HP, Hôpital Pitié Salpêtrière, Paris, France

Aims: Apathy is the most frequent behavioral syndrome in neurological diseases and is associated with high levels of distress both in patients and their caregivers. As the current assessment of apathy is biased by subjectivity, we have developed a research program to objectively assess apathy under ecological conditions. In this program, the ECOCAPTURE@HOME study aims to: 1/ measure behavioral markers of apathy from data collected in patient-caregiver dyads in everyday life conditions, and 2/ predict the psychological status of the patient-caregiver dyad from these markers of apathy. **Methods:** The ECOCAPTURE@HOME method will be applied on 40 patient-caregiver dyads (patients with behavioral variant frontotemporal dementia or Alzheimer's Disease) and 20 healthy control dyads. Each dyad will be monitored for 28 consecutive days, in particular through the remote collection of passive data from the Empatica E4 wristband, a wearable device providing real-time physiological data (acceleration, heart rate, electrodermal activity). Using these sensor data, our first goal is to develop algorithms to extract behavioral metrics reflecting assumed markers of apathy: daytime activity, quality of sleep, emotional arousal. **Results:** Preliminary results of ECOCAPTURE@HOME in pilot subjects (n = 10) will be detailed. Sensor data will be computed to extract behavioral metrics (e.g., activity counts/day, time awake/asleep, tonic and phasic phase of
EDA).



Conclusions: We are developing a method that leverages the capabilities of physiological sensors to detect apathy. This method should contribute to the remote follow-up of patient's apathy and caregiver's status, thus laying the foundation for a personalized therapeutic program.

WILLIAM JAMES' THEORY OF EMOTION: WHAT WAS JAMES'S INITIAL RESPONSE TO LANGE'S THEORY OF EMOTION?

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Toshihiko Sato
Nagano University, Social Welfare, Ueda, Japan

William James (1884), an American philosopher and psychologist, and Carl Lange (1885), a Danish physician, proposed their independent theories of emotion in the late 19th century. Their theories were prominent contributions to affective neuroscience and the psychology of emotion. They emphasized the role of afferent neural input, information transmitted from various peripheral body responses to the brain, to produce subjective experiences of emotion. Although their theories of emotions were similar in content and commonly referred to as the "James–Lange" theory of emotion, the two paradigms had different academic backgrounds. For example, James published his theoretical paper "What is an emotion?" in a philosophical journal, *Mind*. At the same time, Lange's monograph included new theoretical ideas of emotions and clinical observations. In this presentation, the author will elucidate how James responded to Lange's theory of emotion in James's famous book, *The Principles of Psychology*, in 1890 and discuss how Lange's theory influenced later versions of James's theories of emotions. At first, James seemed to be stimulated and encouraged by reading the contents of Lange's monograph. He quoted several sentences from Lange's monograph five times, including a description of expressions of grief, and used part of these phrases to explain the reflex mechanisms of emotions in *Principles*. On the other hand, while James agreed with Lange's theory in general, James did not compromise Lange's key concept regarding the crucial role of the vasomotor center in the brain.

GENE THERAPY RESEARCH AND THE BRAIN: IS AFRICA ETHICALLY, LEGALLY AND SOCIALLY READY?

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

George Wanderi
University of Nairobi, School Of Medicine, Nairobi, Kenya

Interventional modalities that include gene therapy and stem cell techniques for treating neurological disorders affecting the central nervous system (CNS) are rapidly growing in developed nations. They are largely driven by well-funded and organized academic and research institution with collaborations across the borders. Gene therapy for example, can result in a stable or inducible expression of transgene(s), and can allow a nearly specific expression in target cells. It has been used successfully in gene knockout approach for Huntington's disease. In this review, we will discuss the social implications of such techniques with respect to socio-cultural norms in many African nations from 2003 to present. We will discuss the legal implications of such advancements in the context of identity, scientific regulation and communication, capacity building and clinical opportunities for collaborative research across the African continent. **Keywords:** gene therapy, central nervous system, viral vector, gene regulation, brain disease, culture, Africa

RESPONSIBILITY ISSUES RAISED BY NEUROTECHNOLOGIES IN LIGHT OF ETHICS AND PHILOSOPHY.

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Laure Tabouy
CESP-U1018-Inserm, Université Paris-Saclay, UVSQ, Team Ethics And Epistemology Research, Villejuif Cedex, France

What kind of world do we want? How far can and should we go? Several European and international projects aiming at advancing the knowledge of the brain by combining the expertise of neuroscience research with that of computer science research are making it possible to miniaturize, make more efficient and more effective invasive and non-invasive neurotechnologies. Developed in research laboratories as well as in private companies, and already marketed to the general public in good health, the boundary between medical and non-medical uses is becoming very porous, with different objectives and investments. The acceleration of these innovations makes it essential to reflect on the societal, ethical and legal issues at stake, in particular on the notion of responsibility. The design of interdisciplinary safeguards, evaluation and monitoring systems, and the definition of governance adapted to the sociological, ethical and legal values of the countries involved are currently being developed worldwide. It is around the need to agree on the notion of social responsibility that neuroethics is called for by the OECD Council through its recommendation n°0457 of 2019 on responsible innovation in neurotechnologies. Reflecting on the notion of responsibility in the light of the philosopher will bring a non-negligible lighting to approach responsibility. It is thus by summoning Hans Jonas, Ernst Bloch, Hannah Arendt, Paul Ricoeur and Heather Douglas, but also by using neuroethics and existing laws and recommendations that this work around social responsibility concerning neurotechnologies has taken shape.

A CRITICAL STUDY OF SOME NEUROSCIENTIFIC STUDIES ON FREEWILL

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Sam (Seyed Amir Mohammad) Moosavi (Moosavi Jashni)
Missing Institution, Missing Department, Tehran, Iran

Since neuroscientific studies have been established, several disciplines have utilized their findings and this has changed our understanding of the world in many ways. But the study of high cortical functions like, judgment, language, reasoning, decision-making, and so on, require a multidisciplinary approach, for these functions have a socio-politico-cultural nature, and, disciplinary approaches (including a neuroscientific one) is not adequate and sufficient to answer complex questions of such a subject-matter. One of the fields that has been seriously affected by neuroscience and also requires multidisciplinary research is the freewill. Some of the logical, epistemological, ethical, social, and political consequences of these studies are so vital that increase the importance of precise and even obsessive verification of their methodology, research design, and implementation or the act of doing the experiment. Ever since science has become disciplinary, some of the related studies have become like separate islands, while taking a stand in any of these fields requires a transdisciplinary approach. Also, in addition to interaction between the disciplines, the findings of different disciplines sometimes suffer from logical opposition, and, at times some findings are in contradiction with the principles, assumptions, rules, and other findings of the same field. In this study, some of the famous neuroscientific studies' methodologies and findings will be critically examined and the logical opposition between their findings and some dogmas of modern thinking (including the scientific method) will be discussed. For this purpose, reflective analysis and review article methods have been used.

PEER COMMUNITY IN NEUROSCIENCE

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Florent Lebon[1], Mahesh Karnani[2], Marion Mercier[3], Vincent Magloire[3], Thibaut Sesia[4], Ian Greenhouse[5]
[1]University of Bourgogne Franche-Comté, Inserm U1093, Dijon, France, [2]Vrije Universiteit Amsterdam, Faculty Of Earth And Life Sciences, Amsterdam, Netherlands, [3]University College London, Faculty Of Brain Sciences, London, United Kingdom, [4]University Hospital of Cologne, Stereotaxy And Functional Neurosurgery Animal Laboratory, Cologne, Germany, [5]University of Oregon, Human Physiology, Eugene, United States of America

The dissemination of results and new technologies in neuroscience is rapidly evolving from an exclusive and fee-oriented publishing system towards more open, free and independent strategies for sharing knowledge. In this context, preprint servers such as bioRxiv answer a very real scientific need by enabling the rapid, free and easy dissemination of findings, regardless of whether these are novel, replicated, or showcasing negative results. In 2019, we launched Peer Community In (PCI) Circuit Neuroscience, a platform that provides rigorous evaluation and validation of preprints in this subfield of neuroscience, at no cost for authors and readers. As neuroscience is the largest subject category on bioRxiv, and a highly interdisciplinary field, we recently launched PCI Neuroscience (PCI Neuro). It now covers research topics such as neural circuits, synaptic physiology, neuroanatomy but also behavioral neuroscience, cognitive neuroscience, sensorimotor functions, and others, using a variety of techniques (behavioral testing, electrophysiology, neuroimaging, brain stimulation, neuromodulation, computational modeling, etc.). At this poster we discuss PCI Neuro's mission, how it works, and why it is an essential initiative in this new era of open science. To contribute to this grass-roots community effort, you can sign up online at https://neuro.peercommunityin.org/. We want to hear all of your opinions so please stop by to talk to us!

WHY MEN RAPE: PERSPECTIVES FROM INCARCERATED RAPISTS IN A KWAZULU-NATAL PRISON

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Lihle Qulu[1], Relebohile Relebohile Moletsane[2], Abigail Wilkinson[1,3], Jani Nothling[4], Lindokuhle Ngubane[5]
[1]Stellenbosch University, Human Physiology, cape town, South Africa, [2]University Of KwaZulu-Natal, Centre For Visual Methodologies For Social Change, cape town, South Africa, [3]University Of KwaZulu-Natal, Psychology, Pietermaritzburg, South Africa, [4]South African Medical Research Counsel, Research Capacity, cape town, South Africa, [5]University Of KwaZulu-Natal, Human Physiology, Durban, South Africa

South Africa is one of the leading countries in the world that records high rate of crimes against women and children especially on sexual violence. South African government have implemented numerous initiatives to curb the escalating rate of sexual violence, but the effect is minimal. This study aimed to investigate the experiences and social factors influencing the behavior of rape incarcerated men in KwaZulu-Natal prison. An interpretative and exploratory qualitative research design consisted of purposive sampling was used to select eighteen sex offenders. Data was obtained from face-to-face interviews and analyzed using Thematic analysis to identify and describe six themes, (1) the way perpetrators understood rape, (2) childhood trauma and adverse events, (3) substance abuse, (4) perceptions of gender roles, (5) avoiding responsibility, and (6) recidivism. The findings revealed that all sex perpetrators have been exposed to at least one childhood trauma and adversity. Some perpetrators of child rape described the act as consensual and did not consider it as rape. Most participants avoided taking responsibility for their actions and blamed the victim, victim family, alcohol use, traditional gender roles and transactional sex. Recidivism was common to perpetrators with previous conviction for rape, physical assault, theft etc. The findings demonstrated a complex personality dynamic involved in the cycle of abuse and the evolution of criminal behavior, starting as a victim and ending as a perpetrator. This study provides a foundational understanding of the rape perpetration which may be used to further explore the psychology and neurobiology of the rape perpetrators.

The Pathogenesis of Fever-Induced Febrile Seizures and Its Current State.
Febrile seizures, commonly in children between the ages of 3 months to 5 years, are a neurological abnormality characterized by neuronal hyper-excitability, that occur as a result of an increased core body temperature during a fever, which was caused by an underlying systemic infection. Such infections cause the immune system to elicit an inflammatory response resulting in the release of cytokines from macrophages. The cytokines such as interleukin (IL)- 1β, IL-6, and tumour necrosis factor-α (TNF-α) combat the infection in the localized area ultimately spilling over into circulation resulting in elevated cytokine levels. The cytokines, along with pathogen-associated molecular patterns (PAMPs) expressed on pathogens for example, lipopolysaccharide (LPS), interact with the blood brain barrier (BBB) causing a 'leaky' BBB which facilitates cytokines and LPS entry into the central nervous system. The cytokines activate the microglia which release their own cytokines, specifically IL1β. IL-β interacts with the brain endothelium resulting in the activation of cyclooxygenase 2 which catalyzes the production of prostaglandin 2 (PGE2). PGE2 enters the hypothalamic region and induces a fever. Abnormally increased IL-1β levels also progressively increases excitatory (glutamatergic) neurotransmission, and decreases inhibitory (GABAergic) neurotransmission, thus mediating the pathogenesis of convulsions. Current treatments for febrile seizures present with side effects that are detrimental to health, which fosters the need for an alternative, more affordable treatment with fewer adverse side effects, and 1 that is easily accessible, especially in low income areas that are also affected by other underlying socio-economic factors, in which febrile seizures are of growing concern.

BURNOUT EVALUATION IN THE HEALTHCARE WORKERS DURING THE COVID-19

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Diana Galletta, Vittorio Freda, Roberta Rossi, Alessandro Vellucci, Niccolo' Solini, Maria Stella Vescio, Claudio Caiazza, Ester Picillo
Unit of Psychiatry and Psychology, 'federico Ii' University Hospital, Naples, Italy

Background: Healthcare workers burnout is an under-recognized and under-reported problem, characterized by a state of mental exhaustion, detachment, and a decreased sense of personal accomplishment. Methods: A three months observational study will take place in the A.O.U. “Federico II”, Naples. The participants sample will be divided into three groups of healthcare workers: medical doctors (MD), nursing staff (NS) and unlicensed assistive personnel (UAP). Data will be collected both at the baseline (March to May 2022) and at the endpoint (March to May 2023). We will administer an Occupational Anamnesis (OA), the Link Burnout Questionnaire (24-LBQ), the Perceived Stress Scale (10-PSS) and the Work Ability Index (7-WAI), in order to evaluate their work-related stress. Results: Overall 400 workers agreed to participate to our observational study. The overall purpose of the study is to evaluate if there is a significant mean difference between the score of the three groups and if the variations between the baseline and the endpoint scores are significant. The other goal is to verify the correlations between the moderators of the OA and the scores of MD, NS and UAP. Conclusions: We expect to find a significant mean difference between the scores within the three groups and a significant mean difference between the baseline and the endpoint scores among the healthcare workers. We also suppose some of the moderators might have a significant correlation with the results of LBQ, PSS and WAI.

STRESS AND SLEEP DISORDERS AMONG INTERNATIONAL MEDICAL STUDENTS IN GEORGIA

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Irine Sakhelashvili[1], Karen Spruyt[2]
[1]Ilia State University, Tengiz Onianil Laboratory Of Sleep-wakefulness Study, Tbilisi, Georgia, [2]Inserm, Université De Paris, Neurodiderot, Paris, France

Introduction: This study estimated prevalence rates of daytime sleepiness, stress, and pre-sleep arousals among international medical students by gender studying in Georgia. **Methods:** 207 international medical students of the European University (Georgia) participated in the study (November-December, 2018). Participants completed the Epworth Sleepiness Scale (ESS), Pre-Sleep Arousal Scale (PSAS), and Student-Life Stress Inventory (SLSI). **Results:** The average age of the participants was 21.31±2.27 years; 44.4% (92) were women. Most study participants reported higher-than-normal values in all categories of stress and sleep studied. A quarter of students (25.12%) reported excessive daytime sleepiness which was more common in male students. 97.1% of students reported high pre-sleep arousal. Also a high frequency of stress levels has been reported across all stress categories in 78% of participants; 79.9% in men, 87.8% in women. Nearly all (98.06%) participants reported high levels of total SLSI scores, however more women than men experienced a stressful student life. **Conclusion:** Foreign medical students in Georgia experience sleep problems and stress. Further research is needed to assess the relationship between sleep and stress parameters and identify predictors. But it is clear that universities need to implement preventive strategies to help international medical students. **Keywords:** Sleep; stress; daytime sleepiness; pre-sleep arousal, international medical student

Insomnia, Pre-Sleep Arousal, Psychosocial Factors and Changes in Sleep Pattern during the Second Wave Lockdown of the COVID-19 Pandemic in Georgia.
Studies performed across the COVID-19 pandemic waves point to the persistent impact of the pandemic on sleep and mental health. We expand these data by examining insomnia, pre-sleep arousal, psychosocial factors, and retrospective changes in sleep pattern during the COVID-19 second wave lockdown period in Georgia. Data were collected through an online survey (= 1117). The prevalence rate of probable insomnia disorder was 24.2%. Clinically relevant somatic and cognitive pre-sleep arousal was present in 49.8% and 58.0% of participants, and high levels of anxiety, depression and social isolation were found in 47.0%, 37.3%, 47.2% of respondents, respectively. We observed high prevalence rates of worse sleep quality, delayed bedtimes and risetimes, longer sleep latencies, higher awakenings and shorter sleep durations, relative to the pre-pandemic period. COVID-19-infected participants showed more severe sleep and mental problems. Specific predictors differentially affected insomnia, somatic and cognitive pre-sleep arousal. Depression and COVID-19 infection emerged as vulnerability factors for pre-sleep arousal, which, in turn, was associated with a higher predisposition to insomnia disorder. We confirm the strong deteriorating impact of the COVID-19 pandemic on sleep and psychosocial well-being during the second wave lockdown period. The specific association between pre-sleep arousal, insomnia, and psychosocial factors is of clinical relevance for the prevention of severity and persistence of sleep and mental problems across the repeated lockdown/reopening waves. Modulation of pre-sleep arousal may prove beneficial to implement targeted interventions.

Longitudinal assessment of NREM sleep EEG in typically developing and medication-free ADHD adolescents: first year results.
Clinical observation and structural MRI studies suggest that delayed brain maturation is a major cause of attention deficit hyperactivity disorder (ADHD). Sleep electroencephalogram (EEG) which exhibits major changes across adolescence provides an opportunity to investigate brain electrophysiology evidence for maturational delay. We present data from an ongoing longitudinal study of sleep EEG in medication-free ADHD and typically developing adolescents to investigate brain

electrophysiological evidence for this maturational delay.

Relationship between Sleep Disorders and Health Related Quality of Life-Results from the Georgia SOMNUS Study.
The extent to which sleep disorders are associated with impairment of health-related quality of life (HRQoL) is poorly described in the developing world. We investigated the prevalence and severity of various sleep disorders and their associations with HRQoL in an urban Georgian population. 395 volunteers (20⁻60 years) completed Pittsburgh Sleep Quality Index, Epworth Sleepiness Scale, STOP-Bang questionnaire, Insomnia Severity Index, Beck Depression Inventory-Short Form, and Short Form Health Survey (SF-12). Socio-demographic data and body mass index (BMI) were obtained. The prevalence of sleep disorders and their association with HRQoL was considerable. All SF-12 components and physical and mental component summaries (PCS, MCS) were significantly lower in poor sleepers, subjects with daytime sleepiness, apnea risk, or insomnia. Insomnia and apnea severity were also associated with lower scores on most SF-12 dimensions. The effect of insomnia severity was more pronounced on MCS, while apnea severity-on PCS. Hierarchical analyses showed that after controlling for potential confounding factors (demographics, depression, BMI), sleep quality significantly increased model's predictive power with an R^2 change (ΔR^2) by 3.5% for PCS (adjusted $R^2 = 0.27$) and by 2.9% for MCS (adjusted $R^2 = 0.48$); for the other SF-12 components ΔR^2 ranged between 1.4% and 4.6%. ESS, STOP-Bang, ISI scores, all exerted clear effects on PCS and MCS in an individual regression models. Our results confirm and extend the findings of studies from Western societies and strongly support the importance of sleep for HRQoL. Elaboration of intervention programs designed to strengthen sleep-related health care and thereof HRQoL is especially important in the developing world.

Sleep quality among internally displaced Georgian adolescents and population-based controls.
Sleep problems in children and adolescents are a significant public health concern and may be linked to a variety of psychoemotional difficulties. This study aimed to evaluate sleep quality and associated factors in conflict-affected Georgian adolescents after 9 months of forced displacement. Thirty-three internally displaced adolescents (mean age 11.4 years) and 33 adolescents (mean age 10.8 years) from the general population completed the Epworth Sleepiness Scale and the Children's Depression Inventory (CDI). Parents completed the Children's Sleep-Wake Scale and provided information on their socioeconomic status (SES) and the adolescents' sleep behavior, academic performance, and peer social relationships. The groups differed significantly in sleep quality, peer relationships, SES, and CDI scores. In the internally displaced group, the only significant predictor of sleep quality was SES, which increased the predictive capacity of the model (demographic and psychosocial variables) by 20% in the hierarchical analyses. The most significant predictor in the non-internally displaced group was CDI. This research indicates that displacement may affect sleep quality and psychosocial functioning. The importance of family SES as a contributing factor to displaced adolescents' poor sleep quality is highlighted. An integrated approach designed to improve the psychosocial environment of internally displaced adolescents is needed for their protection.

NEUROETHICS GUIDANCE DOCUMENTS: PRINCIPLES, ANALYSIS, AND IMPLEMENTATION STRATEGIES

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Lucy Tournas[1], Karen Rommelfanger[2], Matthew O'Shaughnessy[3], Walter Johnson[4], Christopher Rozell[5]
[1]Arizona State University, School Of Life Sciences, Tempe, United States of America, [2]Emory University, School Of Medicine Departments Of Neurology And Psychiatry & Behavioral Sciences, Atlanta, United States of America, [3]Georgia Tech, School Of Electrical & Computer Engineering, Atlanta, United States of America, [4]Australian National University, School Of Regulation And Global Governance (regnet), Acton, Australia, [5]Georgia Institute of Technology, School Of Electrical & Computer Engineering, Atlanta, United States of America

Innovations in neurotechnologies have ignited conversations about ethics around the world, with implications for researchers, policymakers, and the private sector. The human rights impacts of neurotechnologies have drawn the attention of United Nations bodies; nearly 40 states are tasked with implementing the Organization for Economic Co-operation and Development's principles for responsible innovation in neurotechnology; and the United States is considering placing export controls on brain-computer interfaces. Against this backdrop, we offer the first review and analysis of neuroethics guidance documents recently issued by prominent government, private, and academic groups, focusing on commonalities and divergences in articulated goals; envisioned roles and responsibilities of different stakeholder groups; and the suggested role of the public. Drawing on lessons from the governance of other emerging technologies, we suggest implementation and evaluation strategies to guide practitioners and policymakers in operationalizing these ethical norms in research, business, and policy settings.

BEHAVIORAL TESTS ASSESSING NEUROPSYCHIATRIC ENDOPHENOTYPES IN ADOLESCENT MICE REVEAL STRAIN- AND SEX-SPECIFIC EFFECTS

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Claudia Pitzer[1], Barbara Kurpiers[1], Ahmed Eltokhi[2]
[1]University of Heidelberg, Interdisciplinary Neurobehavioral Core, heidelberg, Germany, [2]University of Washington, Department Of Pharmacology, Seattle, United States of America

Neuropsychiatric disorders including autism spectrum disorder, schizophrenia, attention deficit hyperactivity, and depression can be efficiently modeled and assessed in rodents via different sets of behavioral tests. Although adolescence is known to be a sensitive developmental stage for neuropsychiatric disorders in humans, most behavioral test batteries in the literature were performed in adult mice of different ages, missing valuable phenotypic information related to the effect of synaptic maturation during development and increasing the variabilities of the results between different studies. In a set of multiple studies, we explored the possibility of performing behavioral tests assessing different endophenotypes of neuropsychiatric disorders in very young male and female wild-type mice from three strains, C57BL/6N, DBA/2, and FVB/N. The tested endophenotypes included anxiety, social behaviors, cognitive functions, motor abnormalities and depression, covering the main behavioral impairments that occur in neuropsychiatric disorders. The results of our studies showed mainly that most of these endophenotypes can be assessed reliably in young adolescent mice, even the complex learning and memory functions. Additionally, our analysis revealed that these three strains displayed significant differences under certain behavioral paradigms. Although these tests were performed before puberty, mice revealed some sex-related differences in specific behavioral tests and depending on the tested strain. Our results provide new insights into discrete behaviors during development and emphasize the crucial importance of the genetic background, sex, and experimental settings in the age-dependent regulation of different behaviors related to neuropsychiatric disorders.

THE NEED FOR PRESERVATION OF MEDICAL DECISION MAKING WITH DIMINISHED COGNITIVE CAPACITY

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Jennifer Jin
Emory University, Bioethics, Atlanta, United States of America

Alzheimer's Disease (AD) and other neurodegenerative dementias are reaching epidemic proportions. Because of the way AD impacts brain pathology and pathways associated with higher level cognitive functions, a diagnosis can often lead to a presumed compromise in independent decision-making. This can call into question an impaired individual's ability to make sound medical decisions. However, decision-making capacity should not be treated as a binary concept, and simply having AD does not mean individuals are completely unable to make their own decisions regarding their medical care. Studies suggest that with assistance from tools and protocols, individuals with cognitive compromise can still demonstrate understanding and make independent decisions. To explore underlying assumptions regarding medical decision-making capacity in individuals with AD, we performed a neuroethical analysis with qualitative interviews, which revealed recurrent themes and knowledge gaps across four broad themes: 1. examination and evaluation of medical agency, 2. assignment of surrogacy, 3. current cognitive exams, 4. communication with various stakeholders about medical agency. We found that people generally need more time with diagnostic information to make lifestyle decisions and implement necessary changes to ensure their desires for the future. Impacted individuals and their families were not being equipped with important information needed to make such big decisions. This can create tension and distrust between the stakeholders involved but can be easily remedied by placing a greater emphasis on notifying patients early enough with the necessary information regarding their diagnosis and prognosis to process through them and discuss with their families on how to move forward.

Behavioral core facilities are becoming key features in academic institutes, because they provide expertise and specialized services for researchers within the field of neuroscience. Uppsala University Behavioral Facility (UUBF; https://www.uu.se/en/research/research-platforms/uubf/) is a non-profit core facility supported by the Faculty of Medicine and Pharmacy, Uppsala University, Sweden. With employed personnel, UUBF's main aims are to provide administration- and organization services for internal and external research groups. UUBF is a unique infrastructure, because it includes support and expertise for three of the most common vertebrate model organisms: mouse, rat and fishes (mainly focused on zebrafish), and also involve researchers investigating insect behaviors. UUBF provide equipment and protocols for behavioral experiments and assists with research in the range of species and methodologies used within UUBF. Examples include setting up behavioral tests for new species, behavioral and optogenetic integrations, and welfare studies as well as deep learning (DeepLabCut) approaches and statistical methodologies. UUBF also provides assistance with data analysis, interpretation of results, writing of ethical applications and training and guidance in experimental design. Furthermore, UUBF offers graduate courses on animal behavior e.g. "How to study behavior in vertebrates with focus on fish and rodents", and administers the Swedish Society for Neuroscience. You are welcome to contact UUBF (uubf@farmbio.uu.se) for discussing your future behavioral experiments.

DEVELOPMENT OF DIGITAL SENSITIVITY SCALE: DIGITAL LITERACY AND DIGITAL EFFICACY SELF-ASSESSMENT

POSTER SESSION 01 - SECTION: NEUROSCIENCE TOOLS, TECHNIQUES & ETHICS

Jin Young Park, Hae In Park, Ji Seon Ahn, Seul Bit Pi, Min Jeong Cho
Yongin Severance Hospital, Yonsei University College Of Medicine, Dept. Of Psychiatry, Yongin-si, Korea, Republic of

Introduction: This study reconceptualizes the definition of digital literacy and derives factors in order to develop a measurement tool for digital literacy, which is suitable for contemporary societies, while presenting self-efficacy as a personal characteristic that is expected to affect the use of digital technology based on related prior research. Method: As a result of an online survey conducted on 475 university students, 3 factors and 13 questions out of 18 preliminary questions for which the suitability index satisfies the standard were selected with exploratory and confirmatory factor analysis on the digital literacy measurement. 2 factors and 7 questions out of 9 preliminary questions for which the suitability index satisfies the standard were selected through exploratory and confirmatory factor analysis on the digital efficacy measurement. Results: 3 factors of digital literacy consisted of 6 questions of general use, 4 questions of digital attitude, and 3 questions of digital apply, and 2 factors of digital efficacy consisted of 4 questions of digital confidence and 3 questions of digital anxiety. A total of 20 questions were selected with the measurement tool of digital sensitivity. The developed measurement tool showed good results in reliability and validity evaluation and was verified as a suitable tool to measure digital literacy and digital efficacy. Conclusion The digital sensitivity measurement developed in this study can be usefully used to measure one's digital literacy in the form of self-diagnosis and to identify the individual's attitude toward digital technology use and resistance factors to the use of digital technology.

Funding: This work was supported by the Korea Medical Device Development Fund grant funded by the Korea government (the Ministry of Science and ICT, the Ministry of Trade, Industry and Energy, the Ministry of Health & Welfare, the Ministry of Food and Drug Safety) (Project Number: 1711138277, KMDF_PR_20200901_0143).

SPIKING NEURAL NETWORK SIMULATIONS REVEAL THE ROLE OF PLACE AND GRID CELLS IN SPATIAL LEARNING

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Behnam Ghazinouri, Mohammadreza Mohagheghi Nejad, Yorick Sens, Sen Cheng
Ruhr-Universität Bochum, Faculty Of Computer Science, Bochum, Germany

Much is known about the neural representations of space, e.g. place cells (PC) in the hippocampus and grid cells (GC) in the medial entorhinal cortex. However, the functional role of these neural spatial representations in driving behavior remains unclear. We therefore developed a spiking neural network model to study the role of PC and GC representations in spatial learning in a closed-loop simulation. The task was similar to the Morris-Watermaze, i.e., an artificial agent had to find a hidden goal in an open-field environment. The network consisted of either PCs or GCs, which projected to action selection neurons that formed a ring attractor. The location of the activity bump in this network determined the movement directions. We found that smaller place field sizes lead to better learning performance at the cost of requiring more PCs to tile the environment. Similarly, learning with GCs that have smaller grid spacings and smaller fields was superior to learning with large grid spacings. Since GCs have multiple firing fields, their spatial representation is ambiguous. As a result, we expected learning performance based on GC inputs to be lower, as compared to using PC inputs. Surprisingly, this was not the case. This counterintuitive result might be due to the fact that superpositions of multiple periodic grid maps results in unique representations of the spatial locations in the environment. Our work therefore shows that the function of neural representations does not simply follow common intuition and more computational modeling is required.

COMPUTATIONAL TOOL FOR COMPARING DEVELOPMENT OF CELLULAR-SCALE NETWORK ACTIVITY FROM MICROELECTRODE ARRAY (MEA) RECORDINGS OF 2D NEURONAL CULTURES AND 3D HUMAN CEREBRAL ORGANOIDS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Susanna Mierau[1,2,3], Timothy Sit[4], Rachael Feord[1], Alexander Dunn[1], Jeremi Chabros[1], Elise Chang[1], Yin Yuan[1], David Oluigbo[2], Leo Nagy[1], Lance Burn[1], Hugo Smith[1], Erik Hemberg[5], Martin Hemberg[2,3], Madeline Lancaster[6], Andras Lakatos[7], Guillaume Hennequin[8], Stephen Eglen[9], Ole Paulsen[1]
[1]University of Cambridge, Physiology, Development And Neuroscience, Cambridge, United Kingdom, [2]Brigham & Women's Hospital, Neurology, Boston, United States of America, [3]Harvard Medical School, Neurology, Boston, United States of America, [4]University College London, Sainsbury Wellcome Centre, London, United Kingdom, [5]Massachusetts Institute of Technology, Csail, Cambridge, United States of America, [6]MRC Laboratory of Molecular Biology, Cell Biology, Cambridge, United Kingdom, [7]University of Cambridge, Cambridge Centre For Brain Repair, Cambridge, United Kingdom, [8]University of Cambridge, Engineering, Cambridge, United Kingdom, [9]University of Cambridge, Applied Mathematics & Theoretical Physics, Cambridge, United Kingdom

Microelectrode array (MEA) recordings are commonly used to compare neuronal activity in cultures. Yet MEA recordings can also reveal cellular-scale network activity in 2D cultures (Downes et al, 2012; Schroeter et al, 2015) and 3D human cerebral organoids (Giandomenico et al, 2019; Szebenyi et al, 2021). Graph theoretical metrics are frequently applied at larger spatial scales to model whole brain networks. However, few computational tools are available to assist neurobiologists in identifying cellular-scale network effects. Our aim is to provide a diagnostic tool for batch analysis of MEA experiments for comparing network function over time and conditions (e.g., genetic mutation). We created a MATLAB analysis pipeline for raw voltage time-series acquired from single- (Multichannel System) or multi-well MEAs (Axion). First, multiple threshold- and/or template-based spike detection methods can be compared, including our novel electrode-specific custom wavelets. Second, spiking and bursting activity are compared at the electrode and well/array level. Third, functional connectivity is inferred using the spike time tiling coefficient (Cutts & Eglen, 2014) and probabilistic thresholding to determine significant connections between activity observed at electrode pairs. Fourth, graph theoretical and other network metrics are compared by age and condition. Our pipeline reveals differences in spike and burst firing upon electrical or optogenetic stimulation. It recapitulates age-related differences in network topology from published data. In sum, the pipeline enables new users to perform MEA analysis beyond measures of activity or correlation alone to identify differences in network topology and roles of individual nodes in network activity.

INVESTIGATING LONG-TERM CONTEXT OF LANGUAGE MODELS ON BRAIN ACTIVITY DURING NARRATIVES LISTENING IN FMRI

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Subba Reddy Oota, Frederic Alexandre, Xavier Hinaut
Inria-Research, Computer Science, Bordeaux, France

An interesting way to evaluate the representations obtained with machine learning language models is to compared them with human brain recordings. Encoding models have been used to partially predict fMRI recordings of different areas given the features of language models (such as Transformers). However, these models still lack long-term cognitive plausibility as well as insights on the underlying neural substrate mechanisms: e.g. how their representations differ across model layer depth and longer contexts. We study the influence of context representations of different language models such as sequence-based models: Long short-term memory networks (LSTMs), ELMo, and a popular pretrained Transformer language model (Longformer). In particular, we study how the internal hidden representations of such models are aligned with the fMRI brain activity. We use fMRI recordings of subjects listening to narrative stories to interpret word and sequence embedding representations. We further investigate how the representations of language model layers reveal better semantic context during listening. One of the novelties is that we look at several hidden states of LSTMs: cell and output gate states. Our computational experiments provide the following cognitive insights: (i) LSTM cell states are better aligned with brain recordings than LSTM output gate states: the cell state activity can represent more long-term information; (ii) the representations of ELMo and Longformer display a good predictive performance across brain regions for listening stimuli; (iii) Posterior Medial Cortex (PMC), Temporo-Parieto-Occipital junction (TPOJ) and Dorsal Frontal Lobe (DFL) have higher correlation versus Early Auditory (EAC) and Auditory Association Cortex

(AAC).

A three-layered model of primate prefrontal cortex encodes identity and abstract categorical structure of behavioral sequences.
Categorical encoding is crucial for mastering large bodies of related sensory-motor experiences, but what is its neural substrate? In an effort to respond to this question, recent single-unit recording studies in the macaque lateral prefrontal cortex (LPFC) have demonstrated two characteristic forms of neural encoding of the sequential structure of the animal's sensory-motor experience. One population of neurons encodes the specific behavioral sequences. A second population of neurons encodes the sequence category (e.g. ABAB, AABB or AAAA) and does not differentiate sequences within the category (Shima, K., Isoda, M., Mushiake, H., Tanji, J., 2007. Categorization of behavioural sequences in the prefrontal cortex. Nature 445, 315-318.). Interestingly these neurons are intermingled in the lateral prefrontal cortex, and not topographically segregated. Thus, LPFC may provide a neurophysiological basis for sensorimotor categorization. Here we report on a neural network simulation study that reproduces and explains these results. We model a cortical circuit composed of three layers (infragranular, granular, and supragranular) of 5*5 leaky integrator neurons with a sigmoidal output function, and we examine 1000 such circuits running in parallel. Crucially the three layers are interconnected with recurrent connections, thus producing a dynamical system that is inherently sensitive to the spatiotemporal structure of the sequential inputs. The model is presented with 11 four-element sequences following Shima et al. We isolated one subpopulation of neurons each of whose activity predicts individual sequences, and a second population that predicts category independent of the specific sequence. We argue that a richly interconnected cortical circuit is capable of internally generating a neural representation of category membership, thus significantly extending the scope of recurrent network computation. In order to demonstrate that these representations can be used to create an explicit categorization capability, we introduced an additional neural structure

corresponding to the striatum. We showed that via cortico-striatal plasticity, neurons in the striatum could produce an explicit representation both of the identity of each sequence, and its category membership.

Real-time parallel processing of grammatical structure in the fronto-striatal system: a recurrent network simulation study using reservoir computing.
Sentence processing takes place in real-time. Previous words in the sentence can influence the processing of the current word in the timescale of hundreds of milliseconds. Recent neurophysiological studies in humans suggest that the fronto-striatal system (frontal cortex, and striatum--the major input locus of the basal ganglia) plays a crucial role in this process. The current research provides a possible explanation of how certain aspects of this real-time processing can occur, based on the dynamics of recurrent cortical networks, and plasticity in the cortico-striatal system. We simulate prefrontal area BA47 as a recurrent network that receives on-line input about word categories during sentence processing, with plastic connections between cortex and striatum. We exploit the homology between the cortico-striatal system and reservoir computing, where recurrent frontal cortical networks are the reservoir, and plastic cortico-striatal synapses are the readout. The system is trained on sentence-meaning pairs, where meaning is coded as activation in the striatum corresponding to the roles that different nouns and verbs play in the sentences. The model learns an extended set of grammatical constructions, and demonstrates the ability to generalize to novel constructions. It demonstrates how early in the sentence, a parallel set of predictions are made concerning the meaning, which are then confirmed or updated as the processing of the input sentence proceeds. It demonstrates how on-line responses to words are influenced by previous words in the sentence, and by previous sentences in the discourse, providing new insight into the neurophysiology of the P600 ERP scalp response to grammatical complexity. This demonstrates that a recurrent neural network can decode grammatical structure from sentences in real-time in order to generate a predictive representation of the meaning of the sentences. This can provide insight into the underlying mechanisms of human cortico-striatal function in sentence processing.

Hierarchical-Task Reservoir for Online Semantic Analysis From Continuous Speech.
In this article, we propose a novel architecture called hierarchical-task reservoir (HTR) suitable for real-time applications for which different levels of abstraction are available. We apply it to semantic role labeling (SRL) based on continuous speech recognition. Taking inspiration from the brain, this demonstrates the hierarchies of representations from perceptive to integrative areas, and we consider a hierarchy of four subtasks with increasing levels of abstraction (phone, word, part-of-speech (POS), and semantic role tags). These tasks are progressively learned by the layers of the HTR architecture. Interestingly, quantitative and qualitative results show that the hierarchical-task approach provides an advantage to improve the prediction. In particular, the qualitative results show that a shallow or a hierarchical reservoir, considered as baselines, does not produce estimations as good as the HTR model would. Moreover, we show that it is possible to further improve the accuracy of the model by designing skip connections and by considering word embedding (WE) in the internal representations. Overall, the HTR outperformed the other state-of-the-art reservoir-based approaches and it resulted in extremely efficient with respect to typical recurrent neural networks (RNNs) in deep learning (DL) [e.g., long short term memory (LSTMs)]. The HTR architecture is proposed as a step toward the modeling of online and hierarchical processes at work in the brain during language comprehension.

A Robust Model of Gated Working Memory.
Gated working memory is defined as the capacity of holding arbitrary information at any time in order to be used at a later time. Based on electrophysiological recordings, several computational models have tackled the problem using dedicated and explicit mechanisms. We propose instead to consider an implicit mechanism based on a random recurrent neural network. We introduce a robust yet simple reservoir model of gated working memory with instantaneous updates. The model is able to store an arbitrary real value at random time over an extended period of time. The dynamics of the model is a line attractor that learns to exploit reentry and a nonlinearity during the training phase using only a few representative values. A deeper study of the model shows that there is actually a large range of hyperparameters for which the results hold (e.g., number of neurons, sparsity, global weight scaling) such that any large enough population, mixing excitatory and inhibitory neurons, can quickly learn to realize such gated working memory. In a nutshell, with a minimal set of hypotheses, we show that we can have a robust model of working memory. This suggests this property could be an implicit property of any random population, that can be acquired through learning. Furthermore, considering working memory to be a physically open but functionally closed system, we give account on some counterintuitive electrophysiological recordings.

Corticostriatal response selection in sentence production: Insights from neural network simulation with reservoir computing.
Language production requires selection of the appropriate sentence structure to accommodate the communication goal of the speaker - the transmission of a particular meaning. Here we consider event meanings, in terms of predicates and thematic roles, and we address the problem that a given event can be described from multiple perspectives, which poses a problem of response selection. We present a model of response selection in sentence production that is inspired by the primate corticostriatal system. The model is implemented in the context of reservoir computing where the reservoir - a recurrent neural network with fixed connections - corresponds to cortex, and the readout corresponds to the striatum. We demonstrate robust learning, and generalization properties of the model, and demonstrate its cross linguistic capabilities in English and Japanese. The results contribute to the argument that the corticostriatal system plays a role in response selection in language production, and to the stance that reservoir computing is a valid potential model of corticostriatal processing.

Exploring the acquisition and production of grammatical constructions through human-robot interaction with echo state networks.
One of the principal functions of human language is to allow people to coordinate joint action. This includes the description of events, requests for action, and their organization in time. A crucial component of language acquisition is learning the grammatical structures that allow the expression of such complex meaning related to physical events. The current research investigates the learning of grammatical constructions and their temporal organization in the context of human-robot physical interaction with the embodied sensorimotor humanoid platform, the iCub. We demonstrate three noteworthy phenomena. First, a recurrent network model is used in conjunction with this robotic platform to learn the mappings between grammatical forms and predicate-argument representations of meanings related to events, and the robot's execution of these events in time. Second, this learning mechanism functions in the inverse sense, i.e., in a language production mode, where rather than executing commanded actions, the robot will describe the results of human generated actions. Finally, we collect data from naïve subjects who interact with the robot via spoken language, and demonstrate significant learning and generalization results. This allows us to conclude that such a neural language learning system not only helps to characterize and understand some aspects of human language acquisition, but also that it can be useful in adaptive human-robot interaction.

NEURONAL DYNAMICS IN THE CEREBELLUM DURING REACHING

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Stefano Bettani
ENS, Ibens, Paris, France

The cerebellum is a fundamental structure of the hindbrain, and it is essential for the coordination of movements, balance and motor learning. Cerebellar computations are performed within functional microzones that process information in parallel and form distinct output streams. In the cerebellar cortex, sets of neighboring Purkinje cells belonging to the same microzone are organized in parasagittal bands. How neuronal activity is coordinated within each microzone is currently unknown. In this study, we have recorded simultaneously sets of neighboring cells activated during fast forelimb voluntary movements. Neighboring Purkinje cells exhibit millisecond-timescale synchrony during motor execution. This synchrony is maintained, embedded in high-frequency oscillations, during sleep and active exploration, suggesting that recurrent inhibition continuously shapes the correlations between neighboring cells. Our results indicate that during a fast and complex movement, local assemblies of Purkinje cells, whose projections converge in the cerebellar nuclei, dynamically form at the millisecond time scale and will thus produce very transient episodes of inhibition in the cerebellar nuclei. Thanks to a novel approach based on penalized likelihood fits of the discharge of neurons we were able to discriminate the correlations at different time scales and obtain confidence intervals for the significance of such correlations.

SENSORY REPRESENTATION VARIABILITY DURING NEURODEVELOPMENT IN FRAGILE X SYNDROME

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Beatriz Mizusaki[1], Nazim Kourdougli[2], Anand Suresh[2], Carlos Portera-Cailliau[2], Cian O'Donnell[3]
[1]University of Bristol, School Of Computer Science, Electrical And Electronic Engineering, And Engineering Maths, Bristol, United Kingdom, [2]David Geffen School of Medicine at UCLA, Department Of Neurology, Los Angeles, United States of America, [3]Magee Campus - Ulster University, School Of Computing, Engineering And Intelligent Systems, Derry, United Kingdom

Atypical sensory processing, including hypersensitivity to tactile, visual or auditory stimuli, is a common challenge across Autism Spectrum Disorders (ASD). It can affect behavioural performance on sensory discrimination tasks and lead to various other symptoms, such as anxiety, attention deficit, and learning disability. Recent studies in humans have associated this trait with high trial-to-trial variability in responses to sensory stimuli, as recorded by EEG and fMRI; however, the underlying circuit mechanisms are not yet well understood. We studied the *Fmr1* knockout (*Fmr1*$^{-/-}$) mouse model of Fragile-X Syndrome, the most common single-gene (FMR1) cause of ASD, to identify analogous alterations at the level of neural population coding. We performed longitudinal in vivo 2-photon calcium imaging to record spontaneous and whisker-evoked activity in layer 2/3 neurons in primary somatosensory cortex (S1) of lightly anaesthetised wild-type (WT) and *Fmr1*$^{-/-}$ mice. Repeated bouts of whisker stimuli (1 sec-long, every 3 sec) were delivered at physiologically natural frequencies (5 or 10 Hz). Our experimental design enabled the tracking of individual neuron activity across a critical window of S1 development between P14 and P19, which coincides with high expression of *Fmr1*. We found that, despite similar overall statistics, within-animal heterogeneity in neuronal activity was greater in *Fmr1*$^{-/-}$ mice. Although decoding accuracy (how well the L2/3 population could discriminate the stimuli) was similar between WT and *Fmr1*$^{-/-}$ mice at both ages, we observed different dynamics during the inter-stimulus intervals, in the time scale of seconds. We suggest a relation to observed differences in response attenuation and reliability.

In a stochastic and uncertain world, learning is difficult. Nonetheless, humans estimate the probability of future events with remarkable accuracy based on past observations. The Bayesian brain hypothesis posits that the human brain uses uncertainty (or conversely, confidence) to update its beliefs and make predictions. **Aim:** The current study aims to characterize the neural representation of confidence during probabilistic learning in the human brain. **Methods:** We measured the neural activity of 26 human adults during a probability-learning task with 7T fMRI. Participants were shown binary sequences of visual stimuli drawn from a Bernoulli process whose generative probabilities changed abruptly and without notice. Subjects were instructed to learn those probabilities and to occasionally report them along with their estimation confidence. We analyzed the latent variables of learning with a Bayesian ideal observer model that distinguishes confidence from prediction, predictability and surprise. **Results:** Reported probability estimates and confidence levels correlated with the Bayesian solution. fMRI analyses revealed the existence of a frontoparietal network whose activity is 1) sensitive to confidence (linearly correlated), 2) specific to confidence rather than confounded with surprise and predictability (included as covariates, and whose correlates did not overlap with those of confidence at the subject-level), 3) invariant to which item is predicted in the sequence, and 4) functional because it predicts subjective confidence reports. **Conclusions:** By locating neural correlates of confidence that meet four general criteria of neural representations (sensitivity, specificity, invariance and functionality), our findings contribute to the understanding of the neural mechanisms of probabilistic learning.

THETA CYCLE SKIPPING IN SEPTAL NUCLEI DURING EXECUTION OF SPATIAL ALTERNATION TASK

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Katarzyna Bzymek[1,2], Fabian Kloosterman[1,2,3,4]
[1]KU Leuven, Faculty Of Psychology & Educational Sciences, Leuven, Belgium, [2]Neuro-Electronics Research Flanders, Nerf, Heverlee, Belgium, [3]Interuniversity Microelectronics Centre, Imec, Leuven, Belgium, [4]Vlaams Instituut voor Biotechnologie, Vib, Leuven, Belgium

The ability to navigate the environment in search for food and shelter is crucial for the survival of mammals. An internal representation of the environment – or map – allows animals to evaluate multiple routes and adapt their navigation strategy to current needs and future goals. This spatial cognition depends on position-related activity in the hippocampal formation. Septal nuclei receive strong projections from hippocampus, therefore it is a very good candidate to link different aspects of spatial information between hippocampal formation and other brain regions. In this study, we compared the spatial firing properties of cells in different subdivisions of the septal region in rats that performed a spatial alternation task. Using a chronically implanted Neuropixels probe, we recorded from 1561 cells in lateral septum (LS), medial septum (MS) and septohippocampal nuclei (SHi). We observed that during locomotion, intrinsic theta rhythmicity (6-12 Hz) of cells was strongest in the dorsal LS and MS, and weaker in the SHi. We identified cells in dorsal LS and SHi that fired on alternate theta cycles (cycle skipping cells). We found more skipping cells on the outbound journeys, with a vast majority firing on alternate theta cycle while the animal approached the choice point. In contrast, very few cells in MS showed theta cycle skipping behavior. Finally, we observed that cells in dorsal LS convey more spatial information than cells in other septal subdivisions. These results highlight the functional complexity of the septal region and suggest that different subregions have distinct contributions to spatial navigation.

Aims. Primates can represent task rules in an abstract format and re-use these codes in novel contexts to facilitate learning. Although advances have been made in elucidating the neuronal geometry of these codes, how such representations emerge in the prefrontal cortex (PFC) over learning is still poorly understood. Here, we explored learning-induced changes to the dynamics of the macaque PFC using a learning paradigm that encourages abstraction and generalisation of task rules (XOR). *Methods*. We developed new, theoretically principled metrics to measure how the selectivity of cells to task variables changes over learning. Critically, we compared two models of selectivity: (1) *random mixed selectivity*, which assumes that cell selectivity is randomly distributed in the space spanned by both linear and nonlinear mixtures of task variables, and (2) *optimal structured mixed selectivity*, which we derived mathematically and confirmed using simulations, in which linear selectivity is precisely balanced with nonlinear selectivity to optimally perform an XOR task. *Results*. When animals learned a single XOR mapping, we found that selectivity profiles diverged from random towards the optimal model. When an additional XOR mapping was introduced, previously learned cell selectivity remained non-random, and selectivity for the new mapping also converged towards the optimal, non-random, model. *Conclusions.* We found that PFC cells became functionally similar over learning. Our results also indicate that to solve an XOR mapping, non-linear selectivity strikes a balance with linear selectivity. This solution was generalised across different instances of the same rule allowing for an abstract task structure to be utilised.

Self-face and emotional faces-are they alike?
The image of one's own face is a particularly distinctive feature of the self. The self-face differs from other faces not only in respect of its familiarity but also in respect of its subjective emotional significance and saliency. The current study aimed at elucidating similarities/dissimilarities between processing of one's own face and emotional faces: happy faces (based on the self-positive bias) and fearful faces (because of their high perceptual saliency, a feature shared with self-face). Electroencephalogram data were collected in the group of 30 participants who performed a simple detection task. Event-related potential analyses indicated significantly increased P3 and late positive potential amplitudes to the self-face in comparison to all other faces: fearful, happy and neutral. Permutation tests confirmed the differences between the self-face and all three types of other faces for numerous electrode sites and in broad time windows. Representational similarity analysis, in turn, revealed distinct processing of the self-face and did not provide any evidence in favour of similarities between the self-face and emotional (either negative or positive) faces. These findings strongly suggest that the self-face processing do not resemble those of emotional faces, thus implying that prioritized self-referential processing is driven by the subjective relevance of one's own face.

Unconscious perception of one's own name modulates amplitude of the P3B ERP component.
The P3 event-related potential has been known for over 50 years, but its function is still a matter of ongoing debate. Current theories interpret P3b either as a correlate of perceptual consciousness, or as reflecting cognitive processes, like working memory and executive functions. Unexpectedly, recent studies indicate that P3b might occur in response to unconsciously

presented stimuli which, if further replicated, will be important for defining its functional role. Therefore, in the present study we investigated the P3b component in response to participants' own name - a stimulus which is subjectively extremely salient and known to evoke a robust P3b response. The self-name and control (other) names were presented supra- and subliminally (backward-masked), in a subjective rating task and in a forced-choice identification task. We found that a consciously perceived self-name evoked a P3b of larger amplitude than the other-name in both tasks, which confirms that the self-name was processed preferentially. When the self-name was presented subliminally it was associated with larger P3b amplitude than the other-name in the identification task, but not in the subjective rating task. This indicates that a salient stimulus can in principle modulate the P3b amplitude even when processed outside of awareness, but also that subliminal processing depends on the task-set and top-down factors. Taken as a whole, our results provide evidence against the interpretation of P3b as a correlate of consciousness (and more generally conflict with the Global Workspace Theory) and will allow a more precise description of the relation between P3b and cognitive processes.

Unconscious Detection of One's Own Image.
A key mechanism behind preferential processing of self-related information might be an early and automatic capture of attention. Therefore, the present study tested a hypothesis that one's own face will attract bottom-up attention even without conscious identification. To test this, we used a dot-probe paradigm with electrophysiological recordings, in which participants (N = 18) viewed masked and unmasked pairs of faces (other, self) presented laterally. Analysis of the sensitivity measure d ' indicated that faces were not consciously identified in the masked condition. A clear N2 posterior-contralateral (N2pc) component (a neural marker of attention shifts) was found in both the masked and unmasked conditions, revealing that one's own face automatically captures attention when processed unconsciously. Therefore, our study (a) demonstrates that self-related information is boosted at an early (preconscious) stage of processing, (b) identifies further features (beyond simple physical ones) that cause automatic attention capture, and (c) provides further evidence for the dissociative nature of attention and consciousness.

The impact of self-esteem on the preferential processing of self-related information: Electrophysiological correlates of explicit self vs. other evaluation.
Preferential processing of self-related information is a well-documented phenomenon on both the behavioral and neural levels. However, the impact of self-esteem on this self-preference has not been studied in a systematic way. Here, the electrophysiological correlates of explicit self-reflection were investigated in individuals with low (LSE) and high self-esteem (HSE). Participants evaluated trait adjectives in reference to the self or to an "other" person (close-other, famous) while EEG was recorded. The analysis of event-related potentials focused on the late positive component (LPC), which exhibits a fronto-central distribution and latency over 500 ms. In both LSE and HSE groups, the amplitudes of LPC were enhanced in the self condition when compared to control conditions (both close-other and famous). Crucially, LPC amplitudes in the HSE group were significantly higher than in the LSE group. Moreover, the self-preference effect, defined as the difference between amplitudes of LPC associated with the evaluation of words in relation to oneself vs. other people, was significantly higher in the HSE group than in the LSE group. Overall, our findings indicate that people with high self-esteem tend to engage in self-referential processing to a higher extent.

29375456: Wójcik MJ, Nowicka MM, Kotlewska I, Nowicka A
Self-face Captures, Holds, and Biases Attention.
The implicit self-recognition process may take place already in the pre-attentive stages of perception. After a silent stimulus has captured attention, it is passed on to the attentive stage where it can affect decision making and responding. Numerous studies show that the presence of self-referential information affects almost every cognitive level. These effects may share a common and fundamental basis in an attentional mechanism, conceptualized as attentional bias: the exaggerated deployment of attentional resources to a salient stimulus. A gold standard in attentional bias research is the dot-probe paradigm. In this task, a prominent stimulus (cue) and a neutral stimulus are presented in different spatial locations, followed by the presentation of a target. In the current study we aimed at investigating whether the self-face captures, holds and biases attention when presented as a task-irrelevant stimulus. In two dot-probe experiments coupled with the event-related potential (ERP) technique we analyzed the following relevant ERPs components: N2pc and SPCN which reflect attentional shifts and the maintenance of attention, respectively. An inter-stimulus interval separating face-cues and probes (800 ms) was introduced only in the first experiment. In line with our predictions, in Experiment 1 the self-face elicited the N2pc and the SPCN component. In Experiment 2 in addition to N2pc, an attentional bias was observed. Our results indicate that unintentional self-face processing disables the top-down control setting to filter out distractors, thus leading to the

engagement of attentional resources and visual short-term memory.

CORRELATION PATTERNS IN WORKING-MEMORY TASKS: FMRI FRACTAL AND SPECTRAL ANALYSIS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Jeremi Ochab[1], Marcin Wątorek[2], Anna Ceglarek[3], Koryna Lewandowska[3], Barbara Sikora-Wachowicz[3], Magdalena Fąfrowicz[3], Tadeusz Marek[3], Paweł Oświęcimka[2]
[1]Institute of Theoretical Physics, Jagiellonian University, Theory Of Complex Systems Department, Krakow, Poland, [2]Jagiellonian University, Institute Of Theoretical Physics, Kraków, Poland, [3]Institute of Applied Psychology, Jagiellonian University, Department Of Cognitive Neuroscience And Neuroergonomics, Krakow, Poland

We study differences in fMRI correlation patterns of short-term memory distortions. We considered resting state (RS) and four experimental tasks: two visual-verbal (V; based on lists of semantically or phonetically associated words) and two non-verbal (NV; based on pictures of similar objects) in memorisation and retrieval phases.
Since functional activations have a non-trivial temporal and spatial correlation structure, we quantified the regional activity (116-region AAL atlas) with the Hurst exponent, detrended fluctuation analysis and non-linear cross-correlations (CC). Collective behaviour of CC was analysed through eigenvalues of their matrices using a novel method of grouping them according to eigenvector similarity across subjects. The signals in specific occipital lobe areas depended both on the type of experimental tasks and on information memorisation or retrieval. A particularly apparent difference was visible between memorisation in V and NV tasks. In the former, for some brain regions in the Visual II RS network, the Hurst exponents are very close to 0.5, indicating a lack of linear temporal correlations; in the latter, we observe persistent behaviour. The reduction of exponents in tasks relative to the spontaneous brain activity in RS is significant in many brain areas. We additionally uncovered regionally coordinated changes by comparing CC eigenvalue distributions. They showed the greatest differences between: RS and other tasks, memorisation and retrieval, V and NV tasks. We confirmed that temporal correlations are a clear regionally dependent discriminant of tasks and that, methodologically, the non-linear correlations are more sensitive to differences than linear ones and grouped eigenvalues to ungrouped.

EVENT-RELATED VARIABILITY IS MODULATED BY TASK AND DEVELOPMENT

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Shruti Naik[1], Parvaneh Adibpour[2], Jessica Dubois[2,3], Ghislaine Dehaene-Lambertz[2], Battaglia Demian[1,4]
[1]Aix-Marseille Université, Institute For Systems Neuroscience, Marseille, France, [2]UNICOG, Neurospin Paris-saclay, Gif/Yvette, France, [3]Inserm, Neurodiderot Unit, Gif-sur-Yvette, France, [4]University of Strasbourg, Usias, Strasbourg, France

In carefully designed experiments, cognitive scientists interpret mean event-related potentials (ERP) in terms of cognitive operations. However, the huge signal variability from one trial to the next, questions the representability of such mean events. Here we explored whether this variability is an unwanted noise, or an informative part of the neural response. We took advantage of the rapid changes in the visual system during human infancy and analyzed the variability of visual responses to central and lateralized faces in 2-to 6-month-old infants and adults using high-density electroencephalography (EEG). We observed that that the effects of stimulus on the spontaneous background fluctuations is only "modulatory" rather than determinant. I.e. Neural trajectories of individual trials always remain very far from ERP components, only moderately bending their direction with a substantial temporal jitter across trials. In infants nonetheless, the temporal structure of these weak modulations depend on the difficulty of the task at hand possibly dependent on the top-down attention at this age. Dynamical systems interpretation of these results allows us to suggest that the Event-Related Potential (ERP) components act as weakly attracting modes of a low-dimensional energy landscape in which neural trajectories are transiently constrained due to stimulus arrival.However, single trial trajectories displayed characteristic patterns of acceleration and deceleration when approaching ERP components, as if they were under the active influence of steering forces causing transient attraction and stabilization. Our approaches to characterize Event Related Variability (ERV) allows more faithful description of ERPs in terms of brain state kinematics of neural trajectories.

DOES THE BRAIN CARE ABOUT AVERAGES? A SIMPLE TEST

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Alejandro Tlaie[1], Katharine Shapcott[1], Paul Tiesinga[2], Marieke Schölvinck[3], Martha Havenith[4]
[1]Ernst Strüngmann Institute for Neuroscience in Cooperation with Max Planck Society, Zero Noise Lab, Frankfurt, Germany, [2]Radboud University, Neuroinformatics/donders Institute, Nijmegen, Netherlands, [3]Ernst Strüngmann Institute, Havenith & Schölvinck Lab, Frankfurt, Germany, [4]Ernst Strüngmann Institute for Neuroscience in Cooperation with Max Planck Society, Zero Noise Lab, Frankfurt am Main, Germany

Trial-averaged metrics, e.g. tuning curves or population response vectors, are a basic and ubiquitous way of characterizing neuronal activity. But how relevant are such trial-averaged responses to neuronal computation itself? Here we present a simple test to estimate whether average responses reflect aspects of neuronal activity that contribute to neuronal processing. The test probes two assumptions inherent in the usage of average neuronal metrics: 1. Reliability: Neuronal responses repeat consistently enough across trials that the averageresponse template remains recognizable to downstream regions. 2. Behavioural relevance: If a single-trial response is more similar to the average template, it will be easier for the animal to respond correctly. We apply this test to a large publicly available data set featuring electrophysiological recordings from 71 brain areas in behaving mice. We show that single-trial responses were less correlated to the average response template than would be expected if they represented discrete versions of the template. Moreover, single-trial responses could not be clearly assigned to the template of one stimulus over another. Crucially, better-matched single-trial responses did not predict correct behaviour. We conclude that in this dataset, average responses do not seem particularly relevant to neuronal computation, and we encourage other researchers to apply similar tests when using trial-averaged neuronal metrics.

INTRINSIC NEURAL EXCITABILITY INDUCES TIME-DEPENDENT OVERLAP OF MEMORY ENGRAMS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Geoffroy Delamare, Douglas Feitosa Tomé, Claudia Clopath
Imperial College London, Bioengineering, London, United Kingdom

Memories are thought to be stored in neural ensembles known as engrams that are specifically reactivated during memory recall. According to recent studies, memory engrams of two events that happened close in time tend to overlap in the hippocampus and the amygdala, and this overlap has been shown to support memory linking. It has been hypothesised that these overlaps arise from the mechanisms that regulate memory allocation itself, involving neural excitability, but the exact process remains unclear. Indeed, most theoretical studies focus on synaptic plasticity and little is known about the role of intrinsic plasticity, which could be mediated by neural excitability and serve as a complementary mechanism for forming memory engrams. Here, we developed a rate-based model that includes neural excitability as a variable threshold of the firing rate input-output function. We obtained overlapping memory engrams for contexts that are presented close in time, consistent with experimental studies. Moreover, we showed that increasing the initial excitability of a subset of neurons just before presenting a context biases the memory allocation to these neurons. We then explored the role of global inhibition as a way of controlling competition between neurons from two ensembles. These results have identified the possible mechanisms underlying the role of intrinsic excitability in memory allocation and linking, and now allow for predictions regarding the dynamics of memory engrams.

A DUAL PATHWAY ARCHITECTURE FOR VOCAL LEARNING IN SONGBIRDS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Remya Sankar[1], Nicolas Rougier[2], Arthur Leblois[3]
[1]INRIA-Bordeaux, Mnemosyne, Talence, France, [2]Inria BSO, Mnemosyne, Talence, France, [3]CNRS - Université de Bordeaux, Neuroscience, Bordeaux, France

Juvenile songbirds learn to imitate adult vocalizations. This behaviour is governed by a dedicated neural circuitry, comprising a cortical pathway required for vocal production and a parallel basal ganglia-thalamo-cortical (BG) pathway necessary for plasticity. The BG pathway induces variability in production during vocal exploration, receives a performance signal via midbrain dopaminergic projections and drives a motor bias that rectifies errors. This dopamine-modulated change in vocal output is gradually consolidated within the cortical pathway. Reinforcement learning has been hypothesized to underlie such sensorimotor learning. However, pure RL approaches may result in non-optimal solutions under uneven reward contours in a continuous action space. We re-interpret the role of the dual pathway architecture in songbirds to address these limitations. We posit that the BG pathway conducts exploration by inducing large daily jumps in vocal exploration. As the cortical pathway matures, it gradually consolidates BG reward-modulated exploration using Hebbian learning. We demonstrate how this process essentially implements simulated annealing. The dual pathway architecture converges at the global optimum in a number of trials, comparable with the learning period of songbirds (60 days, 1000 trials per day). We further emulate an experimental protocol to induce plasticity in adults by locally modulating the reward profile around the global optimum, post-convergence. As observed empirically, the network adapts to this change in reward contour and modifies its vocal exploration profile. To further test this interpretation, we contrast with ongoing electro-physiological investigations in the output nuclei of these two pathways, in zebra finches subjected to a distorted feedback protocol.

A REALISTIC SPIKING CEREBELLAR MODEL IN CLOSED-LOOP PREDICTS THE UNDERLYING NEURAL MECHANISMS OF EYEBLINK CONDITIONING IN BEHAVING HEALTHY AND PATHOLOGICAL MICE

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Alice Geminiani[1], Claudia Casellato[1], Henk-Jan Boele[2,3], Alessandra Pedrocchi[4], Chris De Zeeuw[2,5], Egidio D'Angelo[1,6]
[1]University of Pavia, Department Of Brain And Behavioral Sciences, Pavia, Italy, [2]Erasmus Medical Center, Department Of Neuroscience, Rotterdam, Netherlands, [3]Princeton University, Neuroscience Institute, Princeton, United States of America, [4]Politecnico di Milano, Department Of Electronics, Information And Bioengineering, Milan, Italy, [5]Netherlands Institute for Neuroscience, Cerebellar Coordination & Cognition - De Zeeuw Group, Amsterdam, Netherlands, [6]IRCCS Mondino Foundation, Brain Connectivity Center, Pavia, Italy

During Eye-Blink Classical Conditioning (EBCC), the cerebellum learns to associate two time-locked stimuli, such that a conditioned stimulus can elicit a motor response (eyelid closure) anticipating the action of the unconditioned stimulus. Experimental findings suggest that this association results from integration of multiple neuronal and synaptic mechanisms in the cerebellar cortex, which regulate the Deep Cerebellar Nuclei (DCN) output and hence the behavioural response. Here, we used a data-driven Spiking Neural Network (SNN) of the cerebellum in a control loop to test the empirical hypothesis that plasticity in the inhibitory molecular layer is crucial for EBCC. The SNN was reconstructed from neuronal densities in different layers, morphological and geometrical features of the circuit and local connectivity rules (Fig. 1A). Neurons were represented as advanced point models, retaining the main electroresponsive features of cerebellar neurons. By exploiting *ad hoc* Spike-Timing Dependent Plasticity (STDP) rules, parallel fiber-Purkinje cell (pf-PC) and parallel fiber-Molecular Layer Interneuron (pf-MLI) connections underwent long-term plasticity driving learning. The model reproduced the EBCC learning curve with neural activities quite similar to those recorded in mice (Fig. 1B). By switching-off pf-PC STDP and MLI inhibition to reproduce mutant mice alterations, learning was compromised, matching the dysfunctional behavioural curves observed in experiments. Our simulations demonstrate that plasticity in the MLI inhibitory pathway is indeed necessary and sufficient to account for a prominent component of learning in EBCC. Distributed cortical plasticity, feedforward inhibition to PC, and DCN rebound bursting were identified as key elements for learning, eventually compensating for localized lesions.

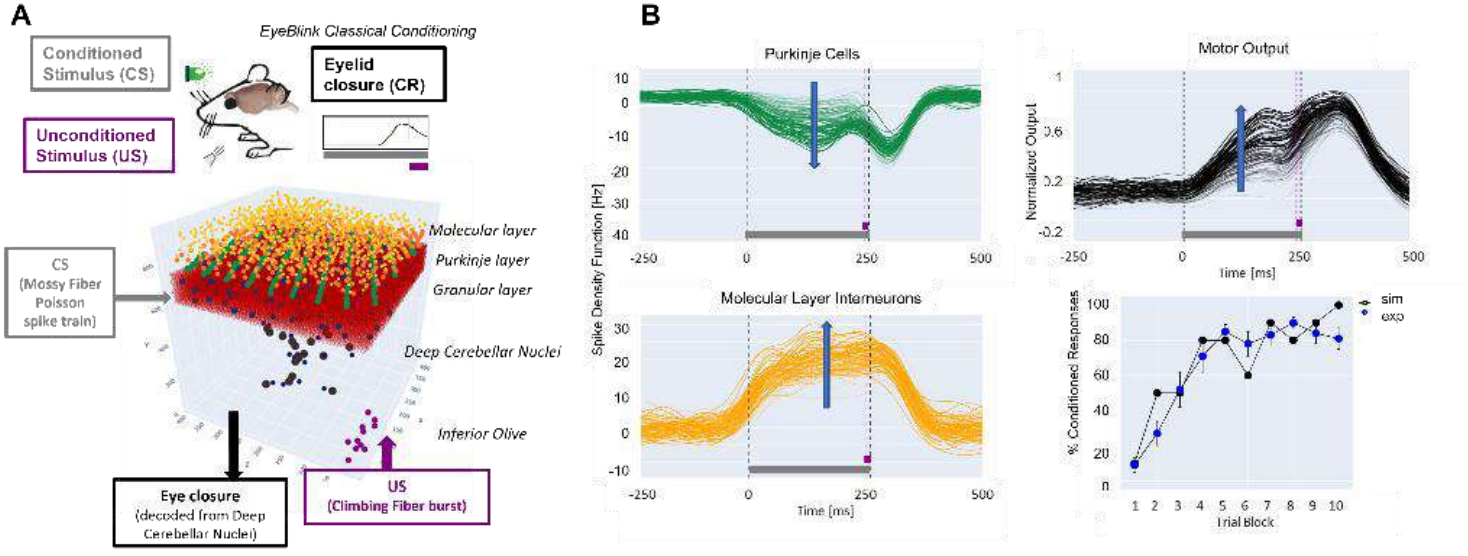

Figure 1. SNN simulations of EyeBlink Conditioning. (A) Schematic representation of EBC, cerebellar SNN with cerebellar cortex, nuclei and Inferior Olive volumes, input/output EBC signals encoding/decoding in the network neural populations. (B) EBC simulations in control conditions, with Spike Density Function of PC and MLI changing throughout learning trials (from light to dark colours), output motor response decoded from DCN activity (from light to dark black lines) and corresponding percentage of conditioned responses throughout trial blocks, comparing simulation and mice experiments.

A Multiple-Plasticity Spiking Neural Network Embedded in a Closed-Loop Control System to Model Cerebellar Pathologies.
The cerebellum plays a crucial role in sensorimotor control and cerebellar disorders compromise adaptation and learning of motor responses. However, the link between alterations at network level and cerebellar dysfunction is still unclear. In principle, this understanding would benefit of the development of an artificial system embedding the salient neuronal and plastic properties of the cerebellum and operating in closed-loop. To this aim, we have exploited a realistic spiking computational model of the cerebellum to analyze the network correlates of cerebellar impairment. The model was modified to reproduce three different damages of the cerebellar cortex: (i) a loss of the main output neurons (Purkinje Cells), (ii) a lesion to the main cerebellar afferents (Mossy Fibers), and (iii) a damage to a major mechanism of synaptic plasticity (Long Term Depression). The modified network models were challenged with an Eye-Blink Classical Conditioning test, a standard learning paradigm used to evaluate cerebellar impairment, in which the outcome was compared to reference results obtained in human or animal experiments. In all cases, the model reproduced the partial and delayed conditioning typical of the pathologies, indicating that an intact cerebellar cortex functionality is required to accelerate learning by transferring acquired information to the cerebellar nuclei. Interestingly, depending on the type of lesion, the redistribution of synaptic plasticity and response timing varied greatly generating specific adaptation patterns. Thus, not only the present work extends the generalization capabilities of the cerebellar spiking model to pathological cases, but also predicts how changes at the neuronal level are distributed across the network, making it usable to infer cerebellar circuit alterations occurring in cerebellar pathologies.

Healthy and pathological cerebellar Spiking Neural Networks in Vestibulo-Ocular Reflex.
Since the Marr-Albus model, computational neuroscientists have been developing a variety of models of the cerebellum, with different approaches and features. In this work, we developed and tested realistic artificial Spiking Neural Networks inspired to this brain region. We tested in computational simulations of the Vestibulo-Ocular Reflex protocol three different models: a network equipped with a single plasticity site, at the cortical level; a network equipped with a distributed plasticity, at both cortical and nuclear levels; a network with a pathological plasticity mechanism at the cortical level. We analyzed the learning performance of the three different models, highlighting the behavioral differences among them. We proved that the model with a distributed plasticity produces a faster and more accurate cerebellar response, especially during a second session of acquisition, compared with the single plasticity model. Furthermore, the pathological model shows an impaired learning capability in Vestibulo-Ocular Reflex acquisition, as found in neurophysiological studies. The effect of the different plasticity conditions, which change fast and slow dynamics, memory consolidation and, in general, learning capabilities of the cerebellar network, explains differences in the behavioral outcome.

Complex Dynamics in Simplified Neuronal Models: Reproducing Golgi Cell Electroresponsiveness.
Brain neurons exhibit complex electroresponsive properties - including intrinsic subthreshold oscillations and pacemaking, resonance and phase-reset - which are thought to play a critical role in controlling neural network dynamics. Although these properties emerge from detailed representations of molecular-level mechanisms in "realistic" models, they cannot usually be generated by simplified neuronal models (although these may show spike-frequency adaptation and bursting). We report here that this whole set of properties can be generated by the (E-GLIF) neuron model. E-GLIF derives from the GLIF model family and is therefore mono-compartmental, keeps the limited computational load typical of a linear low-dimensional system, admits analytical solutions and can be tuned through gradient-descent algorithms. Importantly, E-GLIF is designed to maintain a correspondence between model parameters and neuronal membrane mechanisms through a minimum set of equations. In order to test its potential, E-GLIF was used to model a specific neuron showing rich and complex electroresponsiveness, the cerebellar Golgi cell, and was validated against experimental electrophysiological data recorded from Golgi cells in acute cerebellar slices. During simulations, E-GLIF was activated by stimulus patterns, including current steps and synaptic inputs, identical to those used for the experiments. The results demonstrate that E-GLIF can reproduce the whole set of complex neuronal dynamics typical of these neurons - including intensity-frequency curves, spike-frequency adaptation, post-inhibitory rebound bursting, spontaneous subthreshold oscillations, resonance, and phase-reset - providing a new effective tool to investigate brain dynamics in large-scale simulations.

Complex Electroresponsive Dynamics in Olivocerebellar Neurons Represented With Extended-Generalized Leaky Integrate and Fire Models.

The neurons of the olivocerebellar circuit exhibit complex electroresponsive dynamics, which are thought to play a fundamental role for network entraining, plasticity induction, signal processing, and noise filtering. In order to reproduce these properties in single-point neuron models, we have optimized the Extended-Generalized Leaky Integrate and Fire (E-GLIF) neuron through a multi-objective gradient-based algorithm targeting the desired input-output relationships. In this way, E-GLIF was tuned toward the unique input-output properties of Golgi cells, granule cells, Purkinje cells, molecular layer interneurons, deep cerebellar nuclei cells, and inferior olivary cells. E-GLIF proved able to simulate the complex cell-specific electroresponsive dynamics of the main olivocerebellar neurons including pacemaking, adaptation, bursting, post-inhibitory rebound excitation, subthreshold oscillations, resonance, and phase reset. The integration of these E-GLIF point-neuron models into olivocerebellar Spiking Neural Networks will allow to evaluate the impact of complex electroresponsive dynamics at the higher scales, up to motor behavior, in closed-loop simulations of sensorimotor tasks.

Response Dynamics in an Olivocerebellar Spiking Neural Network With Non-linear Neuron Properties.
Sensorimotor signals are integrated and processed by the cerebellar circuit to predict accurate control of actions. In order to investigate how single neuron dynamics and geometrical modular connectivity affect cerebellar processing, we have built an olivocerebellar Spiking Neural Network (SNN) based on a novel simplification algorithm for single point models (Extended Generalized Leaky Integrate and Fire, EGLIF) capturing essential non-linear neuronal dynamics (e.g., pacemaking, bursting, adaptation, oscillation and resonance). EGLIF models specifically tuned for each neuron type were embedded into an olivocerebellar scaffold reproducing realistic spatial organization and physiological convergence and divergence ratios of connections. In order to emulate the circuit involved in an eye blink response to two associated stimuli, we modeled two adjacent olivocerebellar microcomplexes with a common mossy fiber input but different climbing fiber inputs (either on or off). EGLIF-SNN model simulations revealed the emergence of fundamental response properties in Purkinje cells (burst-pause) and deep nuclei cells (pause-burst) similar to those reported . The expression of these properties depended on the specific activation of climbing fibers in the microcomplexes and did not emerge with scaffold models using simplified point neurons. This result supports the importance of embedding SNNs with realistic neuronal dynamics and appropriate connectivity and anticipates the scale-up of EGLIF-SNN and the embedding of plasticity rules required to investigate cerebellar functioning at multiple scales.

DATA-DRIVEN MODEL OF MULTI-PROTEIN ACTIVITY OUTLINES SYNAPTIC PLASTICITY RULES

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Yuhong Liu[1], Jennifer Krummeich[2], Susann Schweiger-Seemann[2], Tatjana Tchumatchenko[1,3]
[1]University Medical Center of the Johannes Gutenberg University, Institute Of Physiological Chemistry, Mainz, Germany, [2]University Medical Center of the Johannes Gutenberg University, Institute Of Human Genetics, Mainz, Germany, [3]University of Bonn Medical Center, Institute Of Experimental Epileptology And Cognition Research, Bonn, Germany

Despite the circuit function that drives memory and learning being an area of intense study over the last decades, the exact mechanisms that underlie the function are not fully understood. Using data-driven modeling techniques, we aim to develop an experimentally testable computational framework that links dendritic molecular dynamics to synaptic plasticity rules, ultimately bridging this knowledge gap. Using data obtained from the mouse model of Tuberous Sclerosis (TSC) Disease, associated with learning disabilities and autistic behavior, we study the disturbed synaptic plasticity and hyperactive mammalian target of rapamycin (mTOR) signaling pathway that regulates protein synthesis. Comparing the difference in synaptic composition between wild type (WT) and mutants (MT), related to mTOR hyperactivity, gives us insight into the crucial characteristics that drive synaptic plasticity and allows us to build an effective computational model. After analyzing both homogenates and synaptosomes from WT and MT mice at discrete timepoints during early development, we discovered a complex temporal dynamic network involving multiple potentially interacting proteins. Thus, we were able to construct a mathematical framework consisting of a system of Ordinary Differential Equations (ODE) that can (1) explain the interaction among synaptic proteins participating in the mTOR pathway, revealing the mechanism underlying the observed protein activity and (2) fill in information about experimentally unobserved timepoints. In conclusion, our work shows how the experimentally observed protein concentrations in WT and MT can be used to gain insight into the underlying protein interaction network and the dynamics across timepoints.

WORLD STRUCTURE INFERENCE BY HIPPOCAMPAL REPLAY

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Zhenrui Liao[1,2], Darian Hadjiabadi[3], Satoshi Terada[2], Ivan Soltesz[4], Attila Losonczy[1]
[1]Columbia University, Zuckerman Institute, New York, United States of America, [2]Columbia University Medical Center, Department Of Neuroscience, New York, United States of America, [3]Stanford University, Bioengineering, Stanford, United States of America, [4]Stanford University, Neurosurgery, Stanford, United States of America

Memory consolidation assimilates noisy experiences into a cognitive map of the world. This process requires the replay of learned sequences in the hippocampus, though the content of these sequences remains controversial. Recent work has shown that the statistics of replay deviate significantly from those of experience: stimuli which are experientially salient may be either selected or suppressed from replay. We propose a parsimonious novel mechanism for this phenomenon: the use of the symmetric spike-time dependent plasticity rule (sSTDP), previously reported at CA3 excitatory synapses, to remodel inhibitory synapses as well. We show using three levels of modeling--spiking network, detailed biophysical, and abstract normative--that this mechanism enables efficient inference of the latent statistical structure of the world given noisy observations. We develop a mathematical theory of how sSTDP shapes sequence dynamics in a recurrent network, and prove that replay, viewed as a statistical estimator of a latent sequence, converges asymptotically to the true sequence. Finally, we make a number of predictions illustrating the power of inhibitory plasticity as a conceptual advance in our understanding of hippocampal dynamics and memory consolidation, foremost that CA3 replay consolidates "world structure'' rather than specific experience. Our experimental and theoretical work here outlines a potential direct link between the synaptic and cognitive levels of memory consolidation.

Adaptive stimulus selection for consolidation in the hippocampus.
Associative memories guide behavioural adaptation by binding together outcome-predictive sensory stimuli. However, in a feature-rich environment, only a subset of stimuli may predict a desired outcome. How neural circuits enable behavioural adaptation by selectively and durably representing subsets of sensory stimuli that are pertinent to a specific outcome is not known. We investigated this feature selection process in the hippocampus during memory acquisition and subsequent consolidation. Two-photon calcium imaging of CA3 axonal projections to CA1 combined with simultaneous local field potential recordings revealed that CA3 projections that encode behaviourally informative sensory stimuli were selectively recruited during the memory replay events that underlie hippocampal memory consolidation. These axonal projections formed sequential assemblies that conjunctively link sensory features to spatial location and thus reward proximity. By contrast, axons encoding uninformative, peripatetic sensory cues were notably suppressed during memory replay. Thus, while the hippocampus comprehensively encodes the real-time sensory environment, it implements a flexible filtering mechanism to maximize the utility of memories destined for long-term storage. We propose that utility-dependent recruitment of sensory experience during memory consolidation is a general coding principle for associative learning.

Recruitment and inhibitory action of hippocampal axo-axonic cells during behavior.
The axon initial segment of hippocampal pyramidal cells is a key subcellular compartment for action potential generation, under GABAergic control by the "chandelier" or axo-axonic cells (AACs). Although AACs are the only cellular source of GABA targeting the initial segment, their in vivo activity patterns and influence over pyramidal cell dynamics are not well understood. We achieved cell-type-specific genetic access to AACs in mice and show that AACs in the hippocampal area CA1 are synchronously activated by episodes of locomotion or whisking during rest. Bidirectional intervention experiments in head-restrained mice performing a random foraging task revealed that AACs inhibit CA1 pyramidal cells, indicating that the effect of GABA on the initial segments in the hippocampus is inhibitory in vivo. Finally, optogenetic inhibition of AACs at specific track locations induced remapping of pyramidal cell place fields. These results demonstrate brain-state-specific dynamics of a

critical inhibitory controller of cortical circuits.

Maximally selective single-cell target for circuit control in epilepsy models.
Neurological and psychiatric disorders are associated with pathological neural dynamics. The fundamental connectivity patterns of cell-cell communication networks that enable pathological dynamics to emerge remain unknown. Here, we studied epileptic circuits using a newly developed computational pipeline that leveraged single-cell calcium imaging of larval zebrafish and chronically epileptic mice, biologically constrained effective connectivity modeling, and higher-order motif-focused network analysis. We uncovered a novel functional cell type that preferentially emerged in the preseizure state, the superhub, that was unusually richly connected to the rest of the network through feedforward motifs, critically enhancing downstream excitation. Perturbation simulations indicated that disconnecting superhubs was significantly more effective in stabilizing epileptic circuits than disconnecting hub cells that were defined traditionally by connection count. In the dentate gyrus of chronically epileptic mice, superhubs were predominately modeled adult-born granule cells. Collectively, these results predict a new maximally selective and minimally invasive cellular target for seizure control.

Vasoactive Intestinal Polypeptide-Expressing Interneurons in the Hippocampus Support Goal-Oriented Spatial Learning.
Diverse computations in the neocortex are aided by specialized GABAergic interneurons (INs), which selectively target other INs. However, much less is known about how these canonical disinhibitory circuit motifs contribute to network operations supporting spatial navigation and learning in the hippocampus. Using chronic two-photon calcium imaging in mice performing random foraging or goal-oriented learning tasks, we found that vasoactive intestinal polypeptide-expressing (VIP), disinhibitory INs in hippocampal area CA1 form functional subpopulations defined by their modulation by behavioral states and task demands. Optogenetic manipulations of VIP INs and computational modeling further showed that VIP disinhibition is necessary for goal-directed learning and related reorganization of hippocampal pyramidal cell population dynamics. Our results demonstrate that disinhibitory circuits in the hippocampus play an active role in supporting spatial learning. VIDEO ABSTRACT.

Impaired hippocampal place cell dynamics in a mouse model of the 22q11.2 deletion.
Hippocampal place cells represent the cellular substrate of episodic memory. Place cell ensembles reorganize to support learning but must also maintain stable representations to facilitate memory recall. Despite extensive research, the learning-related role of place cell dynamics in health and disease remains elusive. Using chronic two-photon Ca imaging in hippocampal area CA1 of wild-type and Df(16)A mice, an animal model of 22q11.2 deletion syndrome, one of the most common genetic risk factors for cognitive dysfunction and schizophrenia, we found that goal-oriented learning in wild-type mice was supported by stable spatial maps and robust remapping of place fields toward the goal location. Df(16)A mice showed a significant learning deficit accompanied by reduced spatial map stability and the absence of goal-directed place cell reorganization. These results expand our understanding of the hippocampal ensemble dynamics supporting cognitive flexibility and demonstrate their importance in a model of 22q11.2-associated cognitive dysfunction.

Hippocampal adult-born granule cells drive network activity in a mouse model of chronic temporal lobe epilepsy.
Temporal lobe epilepsy (TLE) is characterized by recurrent seizures driven by synchronous neuronal activity. The reorganization of the dentate gyrus (DG) in TLE may create pathological conduction pathways for synchronous discharges in the temporal lobe, though critical microcircuit-level detail is missing from this pathophysiological intuition. In particular, the relative contribution of adult-born (abGC) and mature (mGC) granule cells to epileptiform network events remains unknown. We assess dynamics of abGCs and mGCs during interictal epileptiform discharges (IEDs) in mice with TLE as well as sharp-wave ripples (SPW-Rs) in healthy mice, and find that abGCs and mGCs are desynchronized and differentially recruited by IEDs compared to SPW-Rs. We introduce a neural topic model to explain these observations, and find that epileptic DG networks organize into disjoint, cell-type specific pathological ensembles in which abGCs play an outsized role. Our results characterize identified GC subpopulation dynamics in TLE, and reveal a specific contribution of abGCs to IEDs.

CO-TUNED, BALANCED EXCITATION AND INHIBITION IN OLFACTORY MEMORY NETWORKS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Claire Meissner-Bernard, Rainer Friedrich, Friedemann Zenke
Friedrich Miescher Institute for biomedical research, Neurobiology, Basel, Switzerland

Odor memories are exceptionally robust and essential for the survival of many species. In rodents, the olfactory cortex shows features of an autoassociative memory network and plays a key role in the retrieval of olfactory memories. Interestingly, the telencephalic area Dp, the zebrafish homolog of olfactory cortex, transiently enters a state of precise balance during the presentation of an odor. This state is characterized by large synaptic conductances (relative to the resting conductance) and by co-tuning of excitation and inhibition in odor space and in time at the level of individual neurons. Our aim is to understand how this precise balance affects memory function. For this purpose, we build a simplified, yet biologically plausible spiking neural network model of Dp using experimental observations as constraints. Co-tuning of excitation and inhibition is achieved when we structure and increase connectivity among ensembles of both excitatory and inhibitory neurons, which could reflect the formation of olfactory memories. This corroborates recent evidence from other species which suggests that memory traces are not purely encoded by excitatory neurons, as classically described. We then investigate the benefits of co-tuning for olfactory and memory processing. Among others, tuned inhibition stabilizes activity and enhances the retrieval of stored information from partial or degraded sensory inputs, which is relevant in light of the instability of the olfactory environment. These findings provide valuable insights into the computations performed by the olfactory cortex, and into general effects of balanced state dynamics in associative memory networks.

Private, subjective beliefs about uncertainty have been found to have idiosyncratic computational and neural substrates yet, humans share such beliefs seamlessly and cooperate successfully. Bringing together decision making under uncertainty and interpersonal alignment in communication, we examined the neuro-computational basis of the relationship between privately-held and socially-shared uncertainty. Examining confidence-speed-accuracy tradeoff in uncertainty-ridden perceptual decisions under social vs isolated context, we found that shared (i.e., reported confidence) and subjective (inferred from pupillometry) uncertainty dynamically followed social information. An attractor neural network model incorporating social information as top-down additive input captured the observed behavior and spontaneously demonstrated the emergence of confidence matching in virtual dyadic simulations. Electroencephalography showed that social exchange of confidence modulated the neural signature of evidence accumulation in the central parietal cortex and produced a sustained a top-down flow of information from prefrontal to parietal cortex. Our findings offer a neural population model for interpersonal alignment of shared beliefs.

MODELING REWARD-DRIVEN DECISION MAKING USING BIOPHYSICALLY REALISTIC ADEX MEAN-FIELD MODELS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Emre Baspinar[1], Gloria Cecchini[2], Michael Depass[2], Ignasi Cos[2], Ruben Moreno-Bote[3], Alain Destexhe[1]
[1]CNRS, Paris-Saclay University, Neuropsi, Saclay, France, [2]Universitat de Barcelona, Mathematics, Barcelona, Spain, [3]Universitat Pompeu Fabra, Center For Brain And Cognition, Barcelona, Spain

The Adaptive Exponential (AdEx) mean-field framework describes the averaged neuronal population behavior modeled by AdEx network. In the case of cerebral cortex, AdEx networks are used to model two cell types: Regular Spiking (RS) neurons, displaying spike-frequency adaptation as observed in excitatory pyramidal neurons, and Fast Spiking (FS) neurons, with no adaptation, as observed in inhibitory interneurons. AdEx networks are high dimensional, complex and difficult to analyze. AdEx mean-field models are low dimensional, simpler and easier to analyze compared to networks, yet they approximate closely the network dynamics, motivating our choice of model. Here, we extend the AdEx mean-field framework to model two networks of excitatory-inhibitory neurons, representing two cortical columns, and interconnected with excitatory connections contacting both RS and FS cells. Thus, this connection scheme introduces bicolumnar competition. Each column represents a pool of neurons making the decision in favor of one of two choices represented by two partially filled bars on a computer screen. Task is based on maximizing total reward provided at the end of each episode consisting of a number of trials. The total reward depends on the coherency between choices of the subject and implemented strategy. A reward-driven online learning mechanism allows the model to capture the implemented strategy, as well as subject exploratory behavior. We compare simulation results to performance data obtained from human subjects. Finally, this model provides a biophysical ground for simpler phenomenological models proposed for similar decision-making tasks and can be applied to neurophysiological data obtained from the monkey brain.

DON’T STOP THE TRAINING: CONTINUOUSLY-UPDATING SELF-SUPERVISED ALGORITHMS BEST ACCOUNT FOR AUDITORY RESPONSES IN THE CORTEX.

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Pierre Orhan, Jean-Rémi King, Yves Boubenec
Ecole Normale Superieure, Lsp, Paris, France

Cortical responses to sensory inputs are history dependent, taking into accounts a wide context. Frozen deep neural network exhibit sensory representations that do not integrate this wider context. Numerous studies have shown that these representations are similar to those of the mammalian in that their activations linearly map onto cortical responses to the same sensory inputs. However, it is unclear if unfrozen artificial networks integrate historical content like the brain. To address this issue, we analyze the brain responses of two ferret auditory cortices recorded with functional UltraSound imaging (fUS), while the animals were presented with 320 10\,s sounds. We compare these brain responses to the activations of Wav2vec 2.0, a self-supervised neural network pretrained with 960\,h of speech, and input with the same 320 sounds. Critically, we evaluate Wav2vec 2.0 under two distinct modes: (i) "Pretrained", where the same model is used for all sounds, and (ii) "Continuous Update", where the weights of the pretrained model are modified with back-propagation after every sound, presented in the same order as the ferrets. Our results show that the Continuous-Update mode leads Wav2Vec 2.0 to generate activations that are more similar to the brain than a Pretrained Wav2Vec 2.0 or than other control models using different training modes. These results suggest that the trial-by-trial modifications of self-supervised algorithms induced by back-propagation aligns with the corresponding fluctuations of cortical responses to sounds. Our finding thus provides empirical evidence of a common learning mechanism between self-supervised models and the mammalian cortex during sound processing.

HOW CEREBELLAR ARCHITECTURE FACILITATES RAPID ONLINE LEARNING

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Adriana Perez Rotondo[1], Dhruva Raman[1], Timothy O'Leary[2]
[1]University of Cambridge, Engineering, Cambridge, United Kingdom, [2]University of Cambridge, Department Of Engineering, Cambridge, United Kingdom

The cerebellum is critically involved in motor control, refining trajectories as movements are being executed. This requires fast, online learning. What features of cerebellar circuit structure make it particularly suited to online learning? The cerebellum has a distinctive circuit architecture in which each mossy fibre input typically projects to 250 granule cells, a population that comprises more than half of the neurons in the brain. Each granule cell forms ~4 synapses with mossy fibres. The main hypotheses for this sparse input expansion are that it facilitates pattern separation and smooth function approximation. However, we currently lack a theory that explains why this architecture is suited to online motor learning. We show that the large input expansion allows rapid and accurate learning in an online context. We consider a cerebellar-like network with sparse connections that map low-dimensional inputs into a high-dimensional internal, 'granule cell' layer. The network is tasked with simultaneously learning an internal model of a motor system, and using this model to better control motor output. Learning online introduces a narrow time window that severely limits the information available for synaptic plasticity mechanisms to appropriately adjust synaptic weights. We find that the effect of having limited information depends on the spread of the eigenvalues Hessian of the task error. As the input expansion increases, the geometry of the error surface becomes more favourable for online learning, diminishing the effect of information error and allowing for faster learning.

The electrical stimulation of peripheral nerves is used in various pathological contexts, from functional/sensory rehabilitation, to chronic pains and epilepsy[1]. Among the techniques inducing specific axonal response, the high-frequency (>kHz) conduction-block has been of growing interest[2] and have also been approved for post-amputation pain syndrome. However, this technique generates unwanted onset response at the start of the stimulation[3]. [4] proposed to reduce onset response by controlling the sodium channel closed-states proportions. Our aim was to develop an optimization algorithm that minimises the parasitic effect induced by the onset response. We developed an approach using recognized models[3] enabling correct quantification of the onset-response as observed in-vivo. We minimise the onset-response phenomenologically, based on spike counting. This results in a highly non-linear problem that we treated using Particle Swarm Optimization. Stimuli were coded using sinusoidal high-frequency modulated by an envelope coded with piecewise-splines. Our formulation of the problem enabled the optimization algorithm to converge and find a solution of enveloppe generating no onset-response. Moreover, we obtained several solutions, thus proving the non-uniqueness of such stimuli. We explored the solutions regularity. This opens the perspective of only-blocking stimulation. Our current work is to apply optimization algorithms on large fascicule to explore the minimization of the onset-response at the nerve-level and in-vivo validation of these waveshapes. DIFFERENCES IN POPULATION SPARSITY CAN EXPLAIN DIFFERENT MEMORY CONSOLIDATION SPEEDS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Naomi Auer, Richard Kempter
Humboldt-Universität zu Berlin, Institute Of Biology, Berlin, Germany

During systems memory consolidation, memories that were first stored in the hippocampus are transferred to the neocortex where they can survive for much longer time periods. The speed and success of such a learning process in the neocortex can vary [Tse et al., Science (2007)]. Our work aims at explaining the relation between the learning/consolidation speed of a network and its population sparsity. We address this question theoretically by using a feedforward network model to which uncorrelated input patterns are successively presented. Following a Hebbian learning scenario, synapses between active input and output neurons are turned on with a chosen transition probability; a fixed connectivity level is maintained by turning others off. An output sparsity level is enforced by imposing an activation threshold on the output neurons. We compute the storage capacity as the number of subsequent patterns that can be stored before a memory can't be successfully retrieved anymore [e.g. Leibold/Kempter, Cerebral Cortex (2008)]. We find that the optimal transition probability strongly depends on the sparsity level - the sparser the output, the higher the optimal transition probability. Thus, for sparse representations, the system can obtain a high storage capacity while learning/consolidating fast. We conclude that, in the context of systems memory consolidation, the consolidation process could be faster for memories that are related to sparser (than usual) representations in neocortical areas. This could guide us towards a neurophysiological understanding of so-called schemas - supposed knowledge bases in the neocortex which facilitate the consolidation of new schema-consistent memories.

Exploratory behaviour in a novel environment is altered when rewards or punishments are introduced. Despite appearing as opposites, these conditions cannot be modelled symmetrically. Reward will favour approach and multiple occasions to reinforce this knowledge, while punishment will generate as few visits as possible, thus minimal opportunities to learn from direct exposure. Hippocampal replays are reactivations of neuronal activity in place cells that represent spatially and temporary coherent paths and that play a fundamental role in spatial memory and learning. We suggest that hippocampal replay mechanisms are critical in avoidance learning tasks since they act as compensation mechanisms to overcome the sampling bias towards reward. To assess this hypothesis, we have designed a new experimental protocol where 8 mice are exposed to a negative stimulus, always in the end of the same arm of an U-shape maze, after being able to explore the entire maze freely. Then, we developed a computational behavioural model for the exploration of the mice prior to the stimuli, that also includes a Reinforcement Learning (RL) component that intervenes in the avoidance learning phase. After fitting the model on the data and performing model comparison, we found that standard RL cannot account for mice behaviour in the post-learning phase of the task, but RL with replay can better replicate the behaviour. In future works, the same method will be applied on reward-conditioning data in the same task, to compare the relative contribution of hippocampal replay in learning punishment or reward.

TEMPORAL CONTINUITY AND LEARNING AUDITORY OBJECTS: IMPLICATIONS FOR SOLVING THE “COCKTAIL PARTY PROBLEM” AND AUDITORY PERCEPTION

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Ronald Ditullio[1], Chetan Parthiban[1], Eugenio Piasini[2], Vijay Balasubramanian[1], Yale Cohen[1]
[1]University of Pennsylvannia, Computational Neuroscience Initiative, Philadelphia, United States of America, [2]SISSA, Cognitive Neuroscience, Trieste, Italy

A fundamental problem animals face is the unsupervised/minimally supervised learning of objects. Auditory objects present special challenges because they superpose, as opposed to occlude, and because of the large variability within auditory categories. A famous example of the challenge of learning and discriminating auditory objects is the “cocktail party problem”', learning and discriminating vocalizations amid the clutter of many similar stimuli. The mechanisms by which the brain solves this problem are not fully elucidated. One solution suggested by efficient coding theory is that neural circuits exploit the statistical regularities of the environment to solve perceptual tasks. Temporal regularities are a defining feature of many ethologically relevant stimuli, such as human speech and animal vocalizations. Accordingly, we hypothesize that efficient learning and discrimination of auditory objects can be achieved by training circuits to extract temporal regularities features. It follows from this hypothesis that unsupervised learning of the temporal regularities in stimuli (e.g., vocalizations), can support learning to discriminate between different vocalizations. To this end, we applied Slow Feature Analysis (SFA) to extract temporally regular features, i.e., those that vary in time as slowly as possible, from macaque vocalizations. Consistent with our hypothesis, we found that a linear classifier could discriminate effectively between vocalizations projected onto only five of the features found by SFA. These results suggest that the ``slow'' temporal features of auditory stimuli may be sufficient for parsing auditory scenes, providing a powerful computational mechanism that the brain utilizes for auditory perception.

We investigate the role of inhibition in structuring new neural assemblies following a learning phase in the brain. Although many studies have been devoted to this subject, few of them have considered the specific role of inhibitory neurons. Therefore, this work aims at studying the impact of inhibition in adaptive neural networks. In particular we focus on the role of synchronized dynamics for the creation and maintenance of structural modules in the brain circuits.
Specifically, we considered an excitatory-inhibitory neural network made of θ-neurons with plastic Hebbian synapses. The learning process is mimicked by stimulating different areas of the network with temporal alternating external stimuli. This stimulation process leads to the emergence of modular structures. Then, the network dynamics is analysed after the learning phase revealing the maintenance of co-active neural assemblies over the long term.
We show that the presence of inhibitory neurons controls the emergence of the modular structures and their maintenance in the resting phase following the learning period. Furthermore, we demonstrate that the number of inhibitory neurons in the network is directly related to the maximal number of neural assemblies that can be maintained.
These results support the idea that inhibition has a direct impact on the memory capacity of a neural network.

REVISITING THE CEREBELLAR MEMORY CONSOLIDATION MECHANISM FROM AI PERSPECTIVE: THE CEREBELLUM AS A DUAL LEARNING MACHINE

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Hyojin Bae[1], Jewoo Seo[2], Sang Jeong Kim[2], Chang-Eop Kim[1]

The cerebellum is known for the critical site for motor learning, and many studies have been conducted to explore the neural circuits and mechanisms responsible for the memory formation and consolidation. Although they have provided detailed observations in several cerebellum-dependent motor learning paradigms, our knowledge of the underlying processes remains fragmentary. In this study, we employ statistical learning theory in machine learning to propose a novel framework that can explain why and how the cerebellum learns and consolidates memories by transfer mechanism. We model the cerebellar system as dual learning machine which composed of two systems with different dimensions-cerebellar cortex and vestibular nuclei. The cerebellar cortex represents a “complex” system, which can be characterized as complex representation, fast adaptation, but relatively large overheads. The vestibular nuclei represent a “simple” system, which can be characterized as simple representation, slow adaption, but low overheads. Based on modified empirical risk minimization theory, we predicted that adaptive learning occurs first in the cerebellar cortex and simple components are then transferred to the vestibular nuclei, and the extent and timing of the transfer can vary depending on the task difficulty. Predictions were validated with both computer simulation and optomotor behavioral experiments. In this study, we tried to model and interpret the cerebellar system from the machine learning perspective. This framework can provide a comprehensive understanding on the cerebellar learning and contribute to further elucidating the essence of cerebellar computations.

MODELING NEUROMODULATORY-MEDIATED MODIFICATIONS OF CALCIUM-BASED PLASTICITY RULES THAT PREVENT HOMEOSTATIC RESET DURING SWITCHES IN FIRING ACTIVITY

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Kathleen Jacquerie, Caroline Minne, Juliette Ponnet, Nora Benghalem, Guillaume Drion
University of Liege, Department Of Electrical Engineering And Computer Science, Liege, Belgium

Synaptic plasticity refers to the ability of neurons to change their connections based on the correlation level in the activity of neighboring neurons. In parallel, neuron activity is affected by brain states. For example, during wake-sleep cycles, neurons switch from tonic to bursting activity. This firing pattern fluctuation is organized by neuromodulators - signaling molecules that induce reversible changes in functional properties of neurons or synapses. In our previous work, we have shown that synaptic plasticity rules such as triplet [Pfister,2006] and calcium-dependent models [Graupner,2016; Shouval,2002] are *not compatible* with switches in firing patterns. Using a conductance-based model robust to neuromodulation and synaptic plasticity [Jacquerie,2021], we built a cortical network to study the evolution of synaptic weights during switches in firing activity. We reproduced experimental plasticity protocol validated in wakefulness. Then, switching the network from tonic to burst without any modification of the synaptic rule leads to a *homeostatic reset*. All synaptic weights converge towards the same basal value whatever the rule due to neuromodulation of neuronal activity. This reset is overcome in the triplet model thanks to neuromodulators that alter the shape of the spike-time dependent curve as demonstrated in [Gonzalez-Ruedas,2018]. To uncover the biological mechanisms of this change, we translated this modification in calcium-based rules by neuromodulating the calcium thresholds, potentiation and depression levels, as well as the learning rates. Our model is a powerful tool that leads the way to unravel biological explanations of the bursting activity role during sleep and its support on the down-selection mechanism.

SYNAPSES LEARN TO UTILIZE RELEASE NOISE TO PREDICT POSTSYNAPTIC DYNAMICS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

David Kappel[1], Christian Tetzlaff[2]
[1]Ruhr-Universität Bochum, Institut Für Neuroinformatik, Bochum, Germany, [2]University Medical Center Göttingen, Department Of Computational Synaptic Physiology, Göttingen, Germany

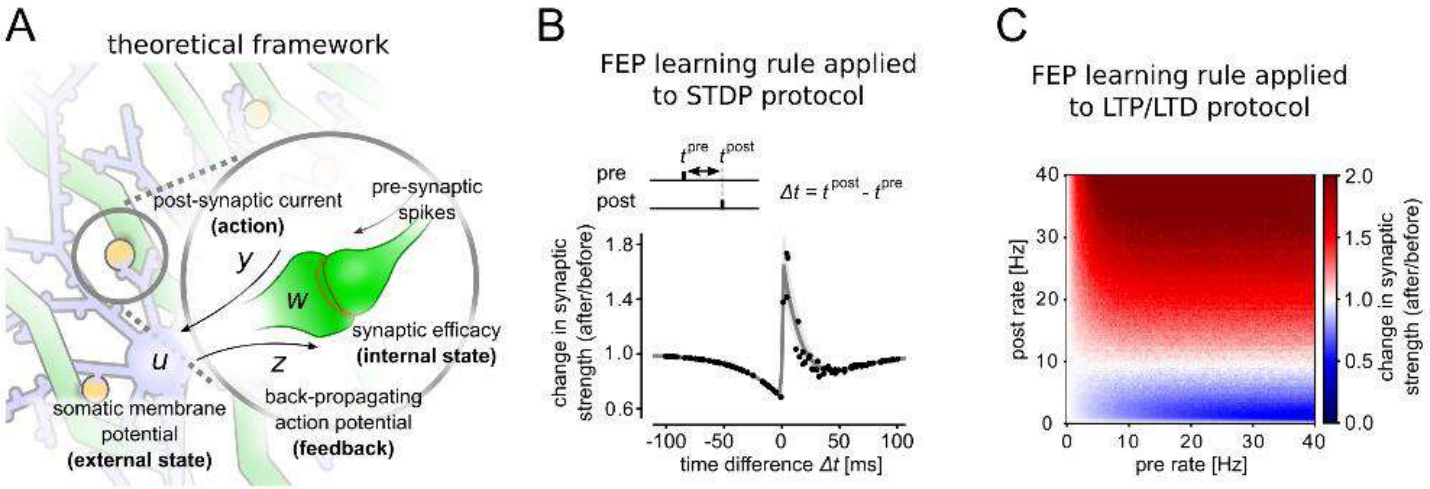

Fig.1: *Illustration of the theoretical framework and predicted synaptic learning rules.* Synapses in the brain are highly noisy, which leads to a large trial-by-trial variability in post-synaptic currents (PSCs). Given how costly synapses are in terms of energy consumption, these high levels of noise are surprising. In this theoretical study we establish the role of the experimentally found high levels of PSC noise to encode uncertainties about the post-synaptic activity and to efficiently use the sparse information provided by back-propagating action potentials. Furthermore, we show how synaptic release noise can be utilized as a computational resource to probe the behavior of the post-synaptic neuron. To arrive at our results we applied the Free Energy Principle (FEP) – a mathematical framework to describe the behavior of organisms and neural networks - for the first time to the level of individual synapses that communicate with the soma of the post-synaptic neuron (Fig.1A). In recent years there has been an increasing number of studies to show that the FEP can explain brain activity on different spatial and temporal scales. In this study we treat arguably the lowest level by considering the interaction of individual synapses with their environment. Using this approach we derive a synaptic learning rule from first principles that resembles experimentally well-established plasticity mechanisms and make precise predictions for future experiments (see Fig.1B,C). In addition, our synaptic FEP model allows us to show how neuronal systems utilize the unreliability of synaptic release to master behaviorally ambiguous situations.

FUNCTIONAL CONSEQUENCES OF TWO-PHASE SYNAPTIC PLASTICITY FOR CODING, ORGANIZATION, AND PRIMING OF LONG-TERM MEMORY REPRESENTATIONS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Jannik Luboeinski[1,2], Andrew Lehr[1,2], Christian Tetzlaff[1,2]
[1]III. Institute of Physics - Biophysics, University of Göttingen, Department Of Computational Neuroscience, Göttingen, Germany, [2]Institute of Neuro- and Sensory Physiology, University Medical Center Göttingen, Department Of Computational Synaptic Physiology, Göttingen, Germany

In the brain, groups of neurons with particularly strong synaptic connections are linked to memory representations. These so-called Hebbian cell assemblies are formed by synaptic plasticity and consolidated by synaptic tagging and capture (STC), influenced by diverse neuromodulatory signals. In order to characterize the impact of these mechanisms on long-term memory, their functional role at the level of neuronal networks needs to be understood. To this end, we employed a biologically detailed model of a recurrent network of spiking neurons featuring synaptic plasticity and neuromodulator-dependent STC. Thereby, we modeled and investigated the learning, consolidation, and recall of long-term memory representations. First, we found that the amount of an abstract neuromodulator present during consolidation can retroactively control the degree to which rate-based and spike timing-based information is stored in the network. Second, we found that the topological organization of multiple memory representations, determined by learning and consolidation, has diverse effects on memory functionality. Third, we identified a mechanism that enables the priming of a memory representation on a timescale of minutes to hours. We quantified these effects by using measures derived from the neuronal spiking activity in the network. Our findings demonstrate how STC along with other synaptic and neuronal mechanisms enables rich cognitive functionality. This may provide an explanatory basis for known long-term memory effects such as switching between the storing of semantic and episodic information, recency in free recall tasks, retroactive interference and enhanced recall caused by similarity of memories, and priming.

Nonlinear response characteristics of neural networks and single neurons undergoing optogenetic excitation.
Optogenetic stimulation has become the method of choice for investigating neural computation in populations of neurons. Optogenetic experiments often aim to elicit a network response by stimulating specific groups of neurons. However, this is complicated by the fact that optogenetic stimulation is nonlinear, more light does not always equal to more spikes, and neurons that are not directly but indirectly stimulated could have a major impact on how networks respond to optogenetic stimulation. To clarify how optogenetic excitation of some neurons alters the network dynamics, we studied the temporal and spatial response of individual neurons and recurrent neural networks. In individual neurons, we find that neurons show a monotonic, saturating rate response to increasing light intensity and a nonmonotonic rate response to increasing pulse frequency. At the network level, we find that Gaussian light beams elicit spatial firing rate responses that are substantially broader than the stimulus profile. In summary, our analysis and our network simulation code allow us to predict the outcome of an optogenetic experiment and to assess whether the observed effects can be attributed to direct or indirect stimulation of neurons.

Memory consolidation and improvement by synaptic tagging and capture in recurrent neural networks.
The synaptic-tagging-and-capture (STC) hypothesis formulates that at each synapse the concurrence of a tag with protein synthesis yields the maintenance of changes induced by synaptic plasticity. This hypothesis provides a biological principle underlying the synaptic consolidation of memories that is not verified for recurrent neural circuits. We developed a theoretical model integrating the mechanisms underlying the STC hypothesis with calcium-based synaptic plasticity in a recurrent spiking neural network. In the model, calcium-based synaptic plasticity yields the formation of strongly interconnected cell assemblies encoding memories, followed by consolidation through the STC mechanisms. Furthermore, we show for the first time that STC mechanisms modify the storage of memories such that after several hours memory recall is significantly improved. We

identify two contributing processes: a merely time-dependent passive improvement, and an active improvement during recall. The described characteristics can provide a new principle for storing information in biological and artificial neural circuits. Commun Biol, 2021; 4

With frequent exposure to novelty, it is imperative that the brain is capable of rapidly adapting in order to execute appropriate responses to new situations. In deep artificial neural networks, adaptive learning rules are used to provide fast learning but whether the brain employs similar strategies remains unknown. Here, we propose a model of the cholinergic system as an adaptive learning system that modulates long-term synaptic plasticity in cortical microcircuits across multiple brain areas. In this model, the cholinergic system integrates backprop-like local prediction error signals to modulate credit assignment across a multi-layered cortical network of pyramidal cells and feedback somatostatin interneurons. We incorporated different adaptive methods (Adagrad and RMSprop) from machine learning into our cholinergic model and tested diffuse cholinergic modulation at the neuron, layer and network levels on benchmark pattern recognition tasks. Our results show that modulation at the level of neurons and layers achieves similar learning performance compared to standard adaptive methods which require synapse-specific modulation. This demonstrates that the relative diffuse nature of cholinergic neuromodulation may be sufficient for effective adaptive learning. Furthermore, our model predicts that such adaptive credit assignment can only be achieved if cholinergic modulation jointly controls excitatory and inhibitory synapses in cortical networks. Experimental testing of this prediction using in vitro slice electrophysiology indicated that acetylcholine reduces the output of optogenetically identified feedback somatostatin interneurons highlighting its control of feedback inhibition. Overall, we demonstrate how incorporation of neuromodulatory signals into credit assignment processes can lead to efficient adaptive learning in the brain.

NEUROPHYSIOLOGICALLY-INSPIRED COMPUTATIONAL MODEL OF THE VISUAL RECOGNITION OF SOCIAL BEHAVIOR AND INTENT.

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Albert Mukovskiy[1], Mohammad Hovaidi-Ardestani[1], Alessandro Salatiello[1], Michael Stettler[1], Rufin Vogels[2], Martin Giese[1]
[1]Hertie Institute for Clinical Brain Research, University Clinic Tübingen, Sect. For Computational Sensomotorics, Dept. Of Cognitive Neurology, Tübingen, Germany, [2]KU Leuven, Department Of Neuroscience, Leuven, Belgium

AIMS: Humans recognize social interactions and intentions from videos of moving abstract stimuli, including simple geometric figures (Heider & Simmel, 1944). The neural machinery supporting such social interaction perception is completely unclear. Here, we present a physiologically plausible neural model of social interaction recognition that identifies social interactions in videos of simple geometric figures and fully articulating animal avatars, moving in naturalistic environments. METHODS: We generated the trajectories for both geometric and animal avatars using an algorithm based on a dynamical model of human navigation (Hovaidi-Ardestani, et al., 2018, Warren, 2006). Our neural recognition model combines a Deep Neural Network, realizing a shape-recognition pathway (VGG16), with a top-level neural network that integrates RBFs, motion energy detectors, and dynamic neural fields. The model implements robust tracking of interacting agents based on interaction-specific visual features (relative position, speed, acceleration, and orientation). RESULTS: A simple neural classifier, trained to predict social interaction categories from the features extracted by our neural recognition model, makes predictions that resemble those observed in previous psychophysical experiments on social interaction recognition from abstract (Salatiello, et al. 2021) and naturalistic videos. CONCLUSION: The model demonstrates that recognition of social interactions can be achieved by simple physiologically plausible neural mechanisms and makes testable predictions about single-cell and population activity patterns in relevant brain areas. ROBUST DECISION-MAKING: NON-LINEAR NEURAL RESPONSIVENESS CAN ENHANCE STIMULUS INFORMATION

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Jochen Braun[1], Anna Levina[2], Michele Giugliano[3]
[1]Otto-von-Guericke University, Institute Of Biology, Magdeburg, Germany, [2]University of Tübingen, Mathematics And Natural Science, Tübingen, Germany, [3]International School of Advanced Studies (SISSA), Neurobiology, Trieste, Italy

Sensory decision-making typically involves a choice between multiple alternatives and the evidence supporting each alternative may comprise some number of independent signals (*e.g.*, from different receptive fields). To make an optimal choice, all signals supporting each alternative must be integrated before the results can be compared. In the brain, sensory signals are integrated and represented by downstream neural responses that perform a non-linear transformation of sensory input. Here we report that choice performance can be more accurate when it relies on integrated (averaged) neural responses rather than on integrated (averaged) noisy sensory signals, at odds with the common-sense expectation that any neural processing should degrade sensory information. The improvement is obtained when sensory signals *s* are drawn from heavy-tailed (non-Gaussian) distributions *P(s)* and when non-linear neural response functions $\Psi(s)$ broadly match $\delta_s \ln P(s)$. As proof-of-principle, we devised a decision-making toy-model in which a separate population of spiking neurons represented evidence for each alternative. Specifically, we simulated responses of integrate-and-fire neurons to uncorrelated synaptic inputs, with variance encoding an independent 'sensory signal'. In this toy framework, integrating neural responses rather than sensory signals more than doubled choice performance, depending on assumptions. The intuitive reason for this improvement is that compressive (saturating) responsiveness reduces the influence of outlier signals. Although not widely known in neuroscience, this effect is exploited routinely in engineering and statistics by preprocessing samples with non-linear "influence functions" [*e.g.*, Huber, Ronchetti (2009) *Robust Statistics*, John Wiley & Sons]. An intriguing question for further work is whether neural response functions *in vivo* match or adapt to heavy-tailed input distributions.

THE ROLE OF THE SUPERIOR COLLICULUS IN ATTENTION DEMANDING TASKS: A COMPUTATIONAL MODEL

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Abbas Al Ali[1,2], Florian Röhrbein[1], Fred Hamker[2]
[1]Chemnitz University of Technology, Neurorobotics, Chemnitz, Germany, [2]Chemnitz University of Technology, Artificial Intelligence, Chemnitz, Germany

Experimental work has revealed "*attention deficits without cortical neuronal deficits"* in experiments in which animals performed a motion detection task and 'decided' to or not to press a button (Alexandre Zénon and Richard J. Krauzlis, Nature 2012). Transient inactivation in the superior colliculus (SC) disturbed the performance whilst cortical attentional signals remained unaffected. The question of how the SC affects the performance is still open. To advance our understanding of the temporal structure of involved brain areas' signals and the unknown critical role of the SC in accomplishing the task we aimed at a system-level modeling of the behavioral task dynamics. The complexity of both the task and the connections between involved cortical and subcortical areas is approached by a simplistic modular modeling paradigm using neuron-like units enabling the inclusion of the SC, the basal ganglia, the visual cortex and the motor cortex. We hypothesize a SC-role as a critical component in a spatial working memory system biasing the decision making process. With the aid of our hypothesized model we discuss this possibility and show simulation results supporting this idea. The presented model helps sketching the *temporal structure* of the trial and serves as a *computational template* that — due to its modularity — can be flexibly adapted and extended.

VOXELWISE ENCODING MODEL REVEALS 2D KEY POINTS LIKE REPRESENTATION IN EXTRASTRIATE BODY AREA.

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Giuseppe Marrazzo[1], Federico De Martino[1,2], Agustin Lage Castellanos[1,3], Maarten Vaessen[1], Beatrice De Gelder[1,4]
[1]Maastricht University, Faculty Of Psychology And Neuroscience, Maastricht, Netherlands, [2]Center for Magnetic Resonance Research, Department Of Radiology, Minneapolis, United States of America, [3]Cuban Center for Neuroscience, Department Of Neuroinformatics, La Habana, Cuba, [4]University College London, Department Of Computer Science, London, United Kingdom

Aim: Currently, the extrastriate body area (EBA) is considered to be an object category area that represents body stimuli. However, our understanding of body posture shows a gap between processing of low-level features and high-level semantic categories. This mid-level gap might be filled by the role played by EBA in the processing of body postures. In this study, we used voxelwise encoding model to investigate the role of EBA in body processing. **Methods:** Twenty participants viewed body stimuli while 7T fMRI responses were recorded. The stimuli were generated using a variational autoencoder (VAE), via random sampling from the latent space parameters from 3 different viewpoints. The fMRI response was modeled using several features extracted from the stimuli, such as VAE representation (encoding/decoding layers, latent space), 2D/3D coordinates of key joints (kp2d/kp3d), pixel space (Gabor like representation). The fMRI predicted responses from each model were generated via banded ridge regression using crossvalidation. **Results:** Results show a pattern of responses across visual cortex with Gabor and kp2d model which best predict responses to our stimuli. Specifically, the Gabor representation shows higher prediction accuracy in early visual occipital area as opposed to the kp2d representation which shows higher prediction accuracy in high-level temporal areas such as EBA. Furthermore, kp2d model (viewpoint variant) shows higher accuracy in EBA than kp3d model (viewpoint invariant). **Conclusion:** These findings suggest that EBA codes for specific features of the body, which in the case of kp2d model, are the joints position, and that this representation is viewpoint variant.

A CEREBELLO-CORTICAL RECURRENT NEURAL NETWORK FOR PROBING THE CEREBELLUM ROLE IN MOTOR LEARNING

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Leonardo Agueci[1], N Alex Cayco Gajic[2]
[1]École Normale Supérieure, Département D'études Cognitives, Paris, France, [2]École Normale Supérieure, Université Paris Sciences et Lettres, Département D'Études Cognitives, Paris, France

The motor cortex and the cerebellum are key regions involved in motor learning and adaptation. Based on its excitatory feedforward connectivity, classic theories of cerebellar function posit that it performs sensorimotor pattern separation and predicts the sensory consequences of movement. The motor cortex, on the other hand, has been hypothesised to use its recurrent connectivity to generate rich dynamics that can control complex movements. While these two regions have traditionally been studied in isolation, recent technological advances have made it now possible to access large populations of neurons in both regions simultaneously. Recent studies based on these techniques have demonstrated that coordinated cerebello-cortical activity is critical for motor control. As a result, the development of models that incorporate both cerebellar and neocortical dynamics is crucial. Towards this end, we leverage recurrent neural networks (RNNs), a machine learning model recently used to study neocortical engagement in complex tasks. We extend traditional RNNs to additionally incorporate a cerebellar module with feedforward divergent-convergent architecture, and train these networks to perform motor and cognitive tasks. The resulting RNN may be used as a model to study the structural pathways and functional interactions linking these regions, and can help to understand how the neocortex and the cerebellum coordinate during behaviour.

A MODEL OF HIPPOCAMPAL REPLAY DRIVEN BY EXPERIENCE AND ENVIRONMENTAL STRUCTURE FOR NEAR-OPTIMAL LEARNING

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Nicolas Diekmann[1], Sen Cheng[2]
[1]Ruhr-Universität Bochum, Institute For Neural Computation, Faculty Of Computer Science, Bochum, Germany, [2]Ruhr-Universität Bochum, Faculty Of Computer Science, Bochum, Germany

Hippocampal replay during awake resting states and sleep is thought to play an important role in learning and consolidation. Consistent with this function, tentative evidence suggests that replay sequences adapt to changing spatial constraints (Widloski & Foster, 2022). However, other studies suggest that replay does not always reflect the animal's previous behavior. For instance, the statistics of replay was found to resemble random walks (Stella et al., 2019), represent shortcuts that the animals had never taken (Gupta et al., 2010), and represent trajectories through regions that the animals had seen, but never explored (Ólafsdóttir et al., 2015). It is unclear how these different types of sequences are generated and what functions they serve. We address these questions in a computational study using reinforcement learning (RL). We propose a mechanism that reactivates experiences stochastically according to their priority ratings based on three variables: 1. Experience strength, 2. experience similarity and 3. inhibition of return. The relative importance of these variables differs depending on the statistics of experience and the environmental structure. This replay mechanism, together with the stochasticity of replay generates the diverse types of replay mentioned above. Importantly, this mechanism facilitates learning in spatial navigation tasks. Training an RL agent with replay sequences generated by our model outperforms training with random replay, and performs close to the state-of-the-art, but biologically unrealistic, model by Mattar & Daw (2018). In conclusion, different types of replay can be generated by a unified mechanism, which appears to be optimized to drive spatial learning.

PLACE AND GRID CELL NAVIGATION IN MULTIPLE ENVIRONMENTS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Vemund Schøyen[1], Mikkel Lepperød[2,3], Anders Malthe-Sørenssen[3], Konstantin Holzhausen[3], Markus Pettersen[3]
[1]University of Oslo, Department Of Biosciences, Oslo, Norway, [2]Simula, Research Laboratory, Oslo, Norway, [3]University of Oslo, Department Of Physics, Oslo, Norway

Recently, artificial recurrent neural networks (RNNs) trained to do path integration have been shown to emergently produce putative grid cells. Place and grid cells are known to remap in response to new environments. Specifically, place cells globally remap (randomly) while grid cells with the same spacing and scale appear to randomly translate and rotate in concert. We address how the emergent grid cells in the RNN model respond to changes in the environment, modelled by place cell global remapping. In particular we address, (i) whether the model produces grid cell patterns when required to learn multiple environments, (ii) how these patterns respond to different environments and if they reproduce biologically plausible grid cell remapping behaviour. Using the same methodology, we also unpack the generalisation capabilities of the grid cell network. For example, if the grid cells form a general path integrator, then the grid cell network should be invariant to arbitrary environments. In this work, we describe whether the model can effectively perform path integration in arbitrarily many environments, and how the dynamics that form grid cell patterns are impacted by an increasing number of environments. This work investigates emergent general computational modules which is of interest to AI research in areas such as transfer learning. Moreover, extending the model to include remapping will reveal either (i) an incomplete model of how place and grid cells can navigate in a seemingly arbitrary number of environments, or (ii) give theoretical insights into the functional role of remapping.

USING DEEP NEURAL NETWORKS TO MEASURE MULTI-DAY DYNAMICS OF DISTRIBUTED LIMBIC-CORTICAL SPATIAL REPRESENTATIONS IN LOCAL FIELD POTENTIALS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Kipp Freud[1], Matt Jones[2], Nathan Lepora[3], Cian O'Donnell[4]
[1]University of Bristol, Computer Science, Bristol, United Kingdom, [2]University of Bristol, School Of Physiology, Pharmacology And Neuroscience, Bristol, United Kingdom, [3]University of Bristol, Engineering Mathematics, Bristol, United Kingdom, [4]Magee Campus-Ulster University, School Of Computing, Engineering And Intelligent Systems, Londonderry, United Kingdom

AIMS We propose a machine learning approach to quantifying multi-day stability of neural representations in local field potential (LFP) data. Our test case focuses on spatial information encoding in adult rat hippocampus (CA1), prelimbic (PrL) and parietal (PC) cortex. METHODS We trained deep neural networks (DNN) to decode position from wavelet decomposition images of LFP simultaneously recorded from CA1, PrL and PC of four rats. Data were collected while each rat learned a maze-based memory and decision-making task over >20 days, with different DNN trained using data from separate days. By calculating the decoding accuracy of a DNN trained on data from different days, we quantified the representational stability of spatial encoding in these brain regions. RESULTS Our analysis yielded three main results; first, that decoding error in all brain regions increases monotonically as time between training and testing day is increased. Second, that stability of same-day location representations increases over learning. Lastly, that stability differs significantly between brain regions, with the most stable location representations emerging in parietal cortex. CONCLUSION This method enables a holistic, unbiased analysis of neural codes, requiring only minimally-processed LFP input and negating sampling or sorting bias inherent in spike-based metrics. Tracking neural representations over multi-day timescales reveals differential stability across hippocampus and neocortex, and quantifying representational drift for distinct frequency bands has potential to yield mechanistic insights into the nature of distributed information coding.

DIMENSIONAL CAUSALITY ANALYSIS METHOD ON EVOKED EPILEPTIC ACTIVITY IN VITRO

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Zoltán Somogyvári[1], Marcell Stippinger[1], Zsigmond Benkő[1], Ádám Zlatniczki[1], Attila Bencze[1], Kinga Moldován[2], Katalin Szádeczky-Kardoss[2], Sándor Borbély[3], Ildikó Világi[2], András Telcs[1]

In recent years, we have developed a new causality analysis method named Dimensional Causality (DC), which is capable to detect and distinguish all basic forms of causal connections between two dynamical systems, based on observed time series: DC can detect directed causal connections, circular or bidirectional connection and can distinguish them from the two unconnected systems driven by a hidden common cause, or confounder. While the efficacy of the method has been demonstrated on time series from simulated dynamical systems here we validate our method on in vitro measurements, where the form of the causal connection is more or less well known. LFP and Intrinsic Optical Signal (IOS) were recorded during evoked epileptic activity in vitro, evoked by magnesium-free Ringer-solution. In our earlier study, we have shown that Sugihara's cross-convergent mapping (CCM) method detects directed causal relationship from the LFP towards the IOS activity without detectable signs of a feedback effect. However, CCM can not distinguish the directed connection from the effect of a confounder. Furthermore, the outcome of the CCM was ambiguous, one had to consider the time delay of the effect to get to a clear conclusion. DC analysis showed a clear unidirectional causal connection from the LFP to the IOS in most of the cases, especially in the first period of the evoked seizure-like activity. Note, that the direction of the causal connection was inferred without considering any observable time delay of the effect.

A STATISTICAL PHYSICS THEORY OF HUMAN ADAPTIVE BEHAVIOR

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Constantin Vaillant-Tenzer[1], Etienne Koechlin[2]
[1]Ecole Normale Supérieure - PSL, Lnc2 - Département D'études Cognitives, Paris, France, [2]INSERM and Ecole Normale Supérieure - PSL, Lnc2 - Département D'études Cognitives, Paris, France

Human exhibit impressive adaptive behavior in various environments. However, a unifying theory accounting for basic principles underlying human adaptive behavior is lacking. We propose a statistical physics theory describing adaptive behavior based on the following postulate: actions are chosen to maximize knowledge acquisition within internal world models about the environment under energetic resources constraints. Through differential calculus and Dirichlet series, we derived a unique choice distribution optimally balancing exploration and exploitation behavior. We applied this model to multi-armed bandits and investigated the dynamics of behaviors over time. We will experimentally test model predictions through online experiments.

PROBABILISTIC PATH INTEGRATION, LOCALIZATION AND PLANNING IN THE HIPPOCAMPUS THROUGH DISTRIBUTED DISTRIBUTIONAL CODING

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Mehrdad Salmasi, Maneesh Sahani
University College London, Gatsby Computational Neuroscience Unit, London, United Kingdom

Aim: Positional information is available from many sensory modalities, but each is imperfect, and accurate navigation depends on integrating, representing and reasoning with the resultant positional uncertainty. We suggest that posterior probabilities over location are encoded by distributed distributional codes (DDC), and show that probabilistic path integration, localization and planning can be performed using the DDC representation. The modeled DDC neurons capture the dynamics of hippocampal CA1 and CA3 neurons. Methods: Distributed distributional coding (DDC) proposes that probability distributions are represented by the expected values of a set of encoding functions. We model navigation by probabilistic inference in a generative model, and encode the posterior over the current location by “filtering DDC” neurons, and the posterior over the next location by “predictive DDC” neurons. We implement probabilistic localisation, prediction, and structural learning through the activity of these DDC neurons. Results: Filtering DDC neurons show rapid spatial tuning in a new environment. In contrast, formation of place fields in predictive DDC neurons is gradual; fields emerge only after learning the structure of the environment. Furthermore, the tuning functions of both filtering and predictive DDC neurons are skewed backwards by further exploration, with larger skewness in predictive DDC neurons. These results are juxtaposed with the gradual formation and high skewness of place fields in CA3, and rapid formation and lower skewness of fields in CA1. Conclusions: DDC representation of positional uncertainty provides a framework for inference and learning in hippocampal navigation and explains some of the dynamics of CA1 and CA3 neurons.

ENCODING OF BEHAVIOUR BY PAIRWISE NEURONAL INTERACTIONS CORRELATES WITH REPRESENTATIONAL DRIFT

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Kristine Heiney[1,2,3], Mónika Józsa[1], Michael Rule[1], Stefano Nichele[3,4], Timothy O'Leary[1]
[1]University of Cambridge, Department Of Engineering, Cambridge, United Kingdom, [2]Norwegian University of Science and Technology, Department Of Computer Science, Trondheim, Norway, [3]Oslo Metropolitan University, Department Of Computer Science, Oslo, Norway, [4]Østfold University College, Department Of Computer Science And Communication, Halden, Norway

In some brain areas, populations of neurons can change their behavioural tuning gradually over days. At the single cell level, the rate of this drift varies considerably, raising the question: Does the amount of information contained in interactions between cells predict how much they drift? We reanalysed data from Driscoll et al. (2017), in which the activity of mouse posterior parietal cortex (PPC) neurons was tracked over weeks as mice performed a learned navigation task.

We quantified the informativeness of pairwise interactions by measuring the mutual information between behaviour and pairwise neuronal responses, relative to a conditionally shuffled baseline. This conditional shuffling preserves the tuning of single cells while destroying noise correlations or higher-order dependencies in a pair. The amount of pairwise information relative to this baseline can be synergistic (positive) or redundant (negative).

After thresholding these measures, we found that neurons with high average pairwise redundancy typically also showed greater average pairwise synergy. Furthermore, the average redundancy was positively correlated with tuning stability, more strongly than was single-cell informativeness. This suggests that redundant subpopulations of neurons form a more stable 'backbone' that is less susceptible to drift and more informative about behaviour on average. Thus, redundant coupling is more predictive of stable tuning than the information conveyed about behaviour at the single cell level.

EMBODIED SPIKING MUSHROOM BODY MODEL FOR THE INVESTIGATION OF ANT NAVIGATION

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Oluwaseyi Jesusanmi[1], Amany Amin[2], Thomas Nowotny[3]
[1]University of Sussex, Sussex Neuroscience, Life Sciences, Brighton, United Kingdom, [2]University of Sussex, School Of Engineering And Informatics, Brighton, United Kingdom, [3]University of Sussex, Sussex Neuroscience, School Of Engineering And Informatics, Brighton, United Kingdom

Introduction: Ants are efficient navigators; they have small brains but can forage over large distances. Replicating the neural circuitry that underlies this, will increase our knowledge on how brains can represent the environment, while giving inspiration for energy-efficient robot navigation systems. **Aims:** Produce a spiking neural network (SNN) model of the mushroom body (MB), a region of Hymenoptera brains vital in spatial learning. Train and test the MB model on images from foraging routes of wild ants and compare to the performance of the model on a robot. **Methods:** To build the MB model we used the GPU-accelerated SNN library PyGeNN. To train it, we presented it with many route lengths as different series of images. To test the model, we presented it with rotations of images from the training routes and found which angles the model categorised as familiar to get a heading direction. **Results:** We found our model acted similarly to a rotational image difference function, where unfamiliarity produces increased responses. On the natural dataset, we found the MB model could only learn short routes of approximately 25 images. However, on the robot, it was able to learn a 100-image route. **Conclusions:** Our real-time model is sufficient to navigate routes of reasonable length. The discrepancy between simulation and robot performance may be due to differences in input image statistics. This inspires our current work to build ant navigation experiments that can be easily replicated in a simulated environment, for improved comparison between real-world and simulated experiments.

NEUROMODULATION VIA IONIC ACTUATION OF POTASSIUM: AN IN SILICO STUDY

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Claudio Verardo[1], Leandro Julian Mele[1], Renaud Jolivet[2], Michele Giugliano[3], Luca Selmi[4], Pierpaolo Palestri[1]
[1]University of Udine, Polytechnic Department Of Engineering And Architecture, Udine, Italy, [2]Maastricht University, Maastricht Centre For Systems Biology, Maastricht, Netherlands, [3]International School of Advanced Studies (SISSA), Neuroscience Area, Trieste, Italy, [4]University of Modena and Reggio Emilia, Department Of Engineering "enzo Ferrari", Modena, Italy

Aims. The concentration of potassium K^+ in the extracellular environment is a crucial modulator of neuronal excitability. Recent advances in the technology of ionic actuators are enabling spatiotemporal resolution at the scale of neuronal cells and action potentials, thereby holding the promise of making the control of K^+ concentration a viable neuromodulation modality. In this regard, *in silico* studies are pivotal to understand the possibilities offered by such technology. *Methods.* To this aim, we first introduce a theoretical framework based on the Hodgkin-Huxley formalism and bifurcation analysis. We then propose a computational approach to couple the circuit-level description of neural membranes with the finite element modeling (FEM) of ionic transport in cellular fluids and ionic actuators. As case studies, we assume cortical neurons as target cells and PEDOT:PSS-coated electrodes as iontronic transducers. *Results.* Bifurcation analysis suggests a differential K^+-induced modulation of neural excitability, depending on the targeted cell. Remarkably, K^+-induced tonic spiking is not for granted. Simulations enable to assess if neural activity is elicited or inhibited by the ionic actuator as a function of the extracellular geometry, the profile of ionic actuation, and the physical parameters of the actuator. Examples are shown considering a 3D model of a neuronal soma and a planar electrode. *Conclusion.* These efforts may shed light on how neural activity can be shaped by targeting extracellular K^+ and represent a first step towards design-oriented studies of ionic actuators.

ACTIVE DENDRITES CAN SUPPORT RELIABLE SPIKING COMPUTATIONS

POSTER SESSION 01 - SECTION: COMPUTATIONAL NEUROSCIENCE OF LEARNING AND MEMORY

Thomas Burger[1], M. Rule[2], Timothy O'Leary[2]
[1]University of Cambridge, Engineering, Cambridge, United Kingdom, [2]University of Cambridge, Department Of Engineering, Cambridge, United Kingdom

Dendritic action potentials exhibit long plateaus of many milliseconds, lasting much longer than axonal spikes. On the other hand, the nervous system often has to be fast to facilitate rapid actions and decision making. Furthermore, cortical neurons are often in a high conductance state in vivo, shortening the membrane timeconstant and leading to very short integration windows of a few milliseconds. This raises the question of why slow dendritic plateaus exist in a system that with very short timeconstants elsewhere. Previous work has hypothesized that this timescale separation could facilitate the detection of temporal spiking patterns. Here we propose an alternative role for active dendrites in enabling the reliable integration of asynchronous spikes. We develop a physiologically grounded model in which the extended duration of dendritic spikes equips each dendrite with a memory of incoming signals, effectively buffering temporal jitter in the spike timings of incoming spikes. With our abstract model of a neuron whose dendrites exhibit plateau potentials, we demonstrate that this allows a neuron to integrate asynchronous input spikes. We show that the qualitative behaviour of this model maps onto a detailed biophysical model, where dendritic spikes plateaus are mediated by NMDA receptors. We then use the simplified model to show how active dendrites can make network-level spiking computations reliable and robust to noise and parameter uncertainty. Lastly, we demonstrate nontrivial computations via simulation of a network solving a classification task, in which decisions occur quickly, reliably, and with a low number of spikes.

NETWORK DIMENSIONALITY OF HIPPOCAMPAL POPULATION ACTIVITY DURING CONTINUOUS NOVELTY DETECTION

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Manfredi Castelli, Demi Brizee, Giuseppe P. Gava, Vitor Lopes-Dos-Santos, David Dupret
University of Oxford, Mrc Brain Network Dynamics Unit (ndcn), Oxford, United Kingdom

The structured firing activity of hippocampal neurons allows to process and integrate new information in memory. Notably, during active exploration, neural coordination in the theta-band (5-12Hz) is sparse, suggesting a high degree of dimensionality in information representation. On the other hand, the neural population fires in a synchronised manner during sharp wave/ripple (SWR) (150-250Hz) events during post-exploration sleep/rest, suggesting that mnemonic information is defined within a lower dimensional space. However, the extent to which changes in the dimensionality of population-level firing preserves structural information across behavioural states remains unknown. Here, we investigate how continuous integration of place-object information alters the dimensionality of the hippocampal population activity. We first report preliminary results showing that short timescale neuronal co-firing increases in post-task sleep, with the population activity space becoming lower dimensional. Furthermore, we investigated the offline reactivation of waking firing patterns during post-task individual SWR events. We found that as more information is integrated, spatial reactivation maps increase their selectivity and their dimensionality. We discuss how future work will assess how continual information integration affects the geometry of the network across behavioural states.

MODULATION OF IN VITRO CORTICAL NETWORKS BY MECHANICAL PERTURBATION OF INDIVIDUAL NEURONS

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Bogdana Cepkenovic[1,2], Vanessa Maybeck[1], Andreas Offenhäusser[1]
[1]Forschungszentrum Jülich GmbH, Ibi-3, Jülich, Germany, [2]RWTH Aachen University, Department Of Biology, Aachen, Germany

Recent investigations of network responses to a stimulus point to the ability to modulate a network at the single neuron level. Different perturbation modalities, ranging from single-cell electrical stimulation to focal damage, modulate the local network's firing dynamics and functional topology. With a growing body of evidence revealing that the target neurons respond to mechanical stimulation, we examined the neuronal network behavior upon mechanical stimulus. Specifically, we investigated to what extent a patch-clamp-induced mechanical perturbation influences the activity in the local network of dissociated rat cortical neurons. Simultaneous patch-clamp and calcium imaging experiments demonstrated that patch-pipette mediated mechanical stimulus induces calcium plateaus in targeted neurons, and on average in about 30% of neighbors in 0.185 mm^2. Interestingly, the initiation and propagation of these responses are independent of the neuron's spiking, as the calcium plateaus persisted after the pharmacological block of action potentials and synapses. However, combined electrophysiology experiments demonstrated a bursting activity during the mechanical perturbation, suggesting that the underlying mechanisms induce action potentials. To investigate the impact of patch-clamp-induced perturbation on the network's functional topology, we assessed the effective network connectivity before and after the mechanical stimulus. Here we show that a single mechanical perturbation reduces the network's ability to integrate information, with the recovery time of around 10 minutes. These findings indicate the potential use of mechanostimulation in network manipulation, while concurrently emphasizing the restrictions in the application of patch-clamp for network investigations.

Coordination between the hippocampus and the neocortex during sleep has been shown to promote memory consolidation and may play a crucial role in connecting memories which were not directly experienced together. To investigate this role, we used multi-unit electrophysiology and calcium imaging in freely moving mice during a multi-day inference task. We show that reinstatement in cortical and hippocampal areas supports inferential reasoning and, using immunohistochemistry, highlight the inhibitory and disinhibitory circuits which may control this process.

The zebrafish larva (danio rerio) optic tectum detects and processes visual stimuli, and generates appropriate motor behavior. Its spontaneous dynamics show a spatiotemporal structure organized in distinct functional neuronal assemblies (groups of highly correlated, co-firing neurons). Recent studies have shown that retinal inputs are dispensable for the development of these assemblies. Hence, to understand the functional role of these assemblies, it is necessary to disrupt their functional connectivity (FC). Here, we use an *mecp2*-null fish which has abnormal tectal activity to address this question. We used two-photon calcium imaging to simultaneously record hundreds of neurons of the periventricular layer of the optic tectum of both wild-type and *mepc2*-null larvae. We detected the assemblies by combining principal component analysis (PCA) and factor analysis for categorization of correlated neurons. To study the tectal FC, we measured the neural response to light spots at four different positions. Finally, we developed a behavioral setup to study prey capture of both fish. The results show that the number of neuronal assemblies of the wild type is higher than that of the *mecp2*-null. In contrast, the average number of neurons per assembly were higher in the *mecp2*-null. By using a linear decoder, we found that *mecp2*-null neural population decoding was at chance level. The spatiotemporal structure of the spontaneous activity is degraded in the *mecp2*-null larvae. This fact has not only implications in the processing of visual stimuli; it strongly affects the ability of the larvae to distinguish large objects that may represent predators.

RAPID ODOR PROCESSING BY LAYER 2 SUBCIRCUITS IN LATERAL ENTORHINAL CORTEX

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Sebastian Bitzenhofer[1], Jeffry Isaacson[2]
[1]University Medical Center Hamburg-Eppendorf, Developmental Neurophysiology, Hamburg, Germany, [2]University of California, San Diego, Department Of Neurosciences, La Jolla, United States of America

Olfactory information is encoded in lateral entorhinal cortex (LEC) by two classes of layer 2 (L2) principal neurons: fan and pyramidal cells. However, the functional properties of L2 cells and how they contribute to odor coding are unclear. Here, we show in awake mice that L2 cells respond to odors early during single sniffs and that LEC is essential for rapid discrimination of both odor identity and intensity. Population analyses of L2 ensembles reveals that rate coding distinguishes odor identity, but firing rates are only weakly concentration-dependent and changes in spike timing can represent odor intensity. L2 principal cells differ in afferent olfactory input and connectivity with inhibitory circuits and the relative timing of pyramidal and fan cell spikes provides a temporal code for odor intensity. Downstream, intensity is encoded purely by spike timing in hippocampal CA1. Together, these results reveal the unique processing of odor information by LEC subcircuits and highlight the importance of temporal coding in higher olfactory areas.

ELUCIDATING THE NEURAL CORRELATES OF COST-BENEFIT DECISIONS IN A RAT CORTICO-BASAL GANGLIA NETWORK

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Oliver Haermson[1], Isaac Grennan[2,3], Brook Perry[3], Robert Toth[4], Sanjay Manohar[1], Mark Walton[1], Andrew Sharott[4]
[1]University of Oxford, Experimental Psychology, Oxford, United Kingdom, [2]University of Oxford, Ndcn, Oxford, United Kingdom, [3]University of Oxford, Mrc Brain Network Dynamics Unit, Nuffield Department Of Clinical Neurosciences (ndcn), Oxford, United Kingdom, [4]University of Oxford, Mrc Brain Network Dynamics Unit, Nuffield Department Of Clinical Neurosciences, Oxford, United Kingdom

Aims Adaptive value-guided decision-making often requires weighing-up of costs and benefits of pursuing an available opportunity. While several brain areas have been detected that are important for this behaviour, little is currently known regarding how the decision variables are represented and evolve on the single cell and population levels *across* medial prefrontal cortex and the associated basal ganglia circuitry within the confines of a single behavioural paradigm. **Methods** We developed a novel cost-benefit "accept-reject" task for rats, in which rats choose whether or not to run to the end of a corridor to collect reward based on the prospective reward (4 different levels, varied trial-by-trial, signalled by auditory cues) and effort cost (3 different levels, varied over blocks of trials, implemented with barriers placed in the corridor that needed to be scaled to reach the reward zone). Rats (n=5) were implanted with a driveable micro-electrode array targeting medial orbitofrontal cortex, anterior cingulate cortex, dorsomedial striatum, ventral pallidum, and subthalamic nucleus and recordings were performed as rats performed the task. **Results** Behavioural data (n=13) demonstrated a positive effect of reward and a negative influence of effort on run likelihood, without an interaction between the two. Outcome devaluation strongly reduced preference for any offer. Preliminary analysis of electrophysiology data (n=2; 164 cells per region on average) suggests heterogenous reward and effort coding on run and omit trials distributed across the network. **Conclusions** We have successfully established a pipeline that allows us to probe the neural correlates of cost-benefit decisions across brain networks.

5-HT receptor perturbation has bidirectional influence over instrumental vigour and restraint.
The serotonin (5-HT) system, particularly the 5-HT receptor, has consistently been implicated in behavioural control. However, while some studies have focused on the role 5-HT receptors play in regulating motivation to work for reward, others have highlighted its importance in response restraint. To date, it is unclear how 5-HT transmission at this receptor regulates the balance of response invigoration and restraint in anticipation of future reward. In addition, it remains to be established how 5-HT receptors gate the influence of internal versus cue-driven processes over reward-guided actions. To elucidate these issues, we investigated the effects of administering the 5-HT receptor antagonist SB242084, both systemically and directly into the nucleus accumbens core (NAcC), in rats performing a Go/No-Go task for small or large rewards. The results were compared to the administration of d-amphetamine into the NAcC, which has previously been shown to promote behavioural activation. Systemic perturbation of 5-HT receptors-but crucially not intra-NAcC infusions-consistently boosted rats' performance and instrumental vigour on Go trials when they were required to act. Concomitantly, systemic administration also reduced their ability to withhold responding for rewards on No-Go trials, particularly late in the holding period. Notably, these effects were often apparent only when the reward on offer was small. By contrast, inducing a hyperdopaminergic state in the NAcC with d-amphetamine strongly impaired response restraint on No-Go trials both early and late in the holding period, as well as speeding action initiation. Together, these findings suggest that 5-HT receptor transmission, outside the NAcC, shapes the vigour of ongoing goal-directed action as well as the likelihood of responding as a function of expected reward.

Assessment of oxidative stress in serum by d-ROMs test.
Assessment of oxidative stress is an important but technically challenging procedure in medical and biological research. The

reactive oxygen metabolites (d-ROMs) test is a simple assay marketed for analyzing the total amount of hydroperoxides in serum via the Fenton's reaction. Earlier reports have raised a suspicion that a part of the signal detected in the assay comes from sources other than metabolites generated by oxidative stress. The aim of this study was to identify which serum components interfere with the d-ROMs signal. By application of sodium azide, ethylenediaminetetraacetic acid, sodium dodecylsulphate, varying temperature, and spiking endogenous substances we demonstrate that in the case of mammalian sera the assay determines ceruloplasmin (CP) activity with potential interferences from hydroperoxides, iron level, thiols, and albumin. In sera of avian species hydroperoxides contribute more to the test outcome, but the CP part is insensitive to inhibition by azide. In conclusion, this assay has deficiencies in terms of detecting realistic concentrations of hydroperoxides, is mostly measuring CP and is also interfered with other serum components, making it very difficult to interpret in most biological systems.

CONTEXTUAL OVER-EATING INDUCES TOPOLOGICAL DISTORTION OF THE HIPPOCAMPAL NETWORK

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Laura Lefèvre, Giuseppe P. Gava, Vitor Lopes-Dos-Santos, Katja Hartwich, Pavel Perestenko, David Dupret
University of Oxford, Mrc Brain Network Dynamics Unit, Oxford, United Kingdom

New cognitive challenges require overcoming old routines that memories of salient past experiences invigorate. However, the network-level neuronal operations that underlie cross-memory interaction are unclear. To address this, here we monitor hippocampal CA1 ensembles in mice that continually process new stimuli (objects) within an environment previously associated with palatable food intake. We found that robust contextual over-eating proactively interferes with subsequent object-place memory, decreasing selectivity of object-place population representation. By analysing the structure of population activity, we found that robust food-context memory induces a network state of heightened neuronal co-activity. This topological alteration developed through repeated contextual feeding, preventing further integration of mnemonic patterns for continued object discrimination. These findings suggest a functional principle of memory circuits where sparse population firing structure permits flexible integration and interaction of memories, which contextual over-eating can compromise.

SPATIAL CODING BY SOMATOSTATIN AND NEUROTENSIN NEURONS IN THE LATERAL SEPTUM

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Robson Scheffer Teixeira[1], Francisco Bernal[1,2], Letizia Moscato[1,2], Tatiana Korotkova[1,2]
[1]University of Cologne, Institute For Vegetative Physiology - Faculty Of Medicine, Cologne, Germany, [2]Max Planck Institute, Metabolism Research, Cologne, Germany

The animal's ability to remember the location of rewarding and/or aversive stimuli is crucial for survival. The lateral septum (LS) integrates information about environmental stimuli and internal states signals to weigh the expression of different behavioral outcomes, like food-seeking, social recognition, locomotion, and anxiety-like behaviors. Here we used single cell, deep-brain calcium imaging in freely moving mice to investigate two GABAergic neuronal populations identified in the LS, neurotensin (Nts) and somatostatin (Sst) neurons. Mice explored an enclosure containing rewarding stimuli, or a non-rewarded enclosure. We found that a subset of Sst and Nts cells shows spatial, location-restricted activity. Sst neurons exhibited a higher percentage of place cells, a higher mutual information and a higher place field stability than Nts neurons. Further, Sst neurons showed a higher percentage of reward-associated cells and a higher reward-type selectivity. Our results suggest the involvement of a subset of LS neurons in the spatial and reward-related coding. We gratefully acknowledge support by the ERC Consolidator Grant (772994, FeedHypNet, to T.K.) and DFG (SFB1089 and EXC2030-CECAD, to T.K., 233886668-GRK1960, to F.S.).

GLUTAMATERGIC AFFERENTS TO THE NUCLEUS ACCUMBENS INTEGRATE OUTCOMES IN REWARD-LEARNING.

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Eshaan Iyer[1], Jessie Muir[1], Brenda Namuhoranye[2], Rosemary Bagot[3,4]
[1]McGill University, Integrated Program In Neuroscience, Montréal, Canada, [2]McGill University, Cognitive Science, Montréal, Canada, [3]McGill University, Psychology, Montréal, Canada, [4]McGill University, Ludmer Centre For Neuroinformatics And Mental Health, Montréal, Canada

Aims. Alterations in reward learning are associated with psychopathologies such as depression. The nucleus accumbens (NAc) is implicated in motivation and reward as well as depression, integrating input from a range of afferents including the ventral hippocampus (vHip) and the medial prefrontal cortex (mPFC). However, the role of these glutamatergic inputs to the NAc in reward learning remains relatively unexplored. **Methods.** Using frame-projected independent-fiber photometry, we recorded population-level activity of NAc afferents from the mPFC and the vHip in male and female mice in a two-armed bandit task. We estimated reward expectation and prediction error by fitting a dual learning rate reinforcement learning model to each animal's observed behavior and probed relationships between neural activity and behavior. **Results.** Both neural projections dynamically encode information about trial outcome and outcome history, with notable pathway-way specific time-dependent trajectories. Rewarded vs non-rewarded outcomes are associated with suppression in the mPFC and vHIP following a choice, with vHIP suppression emerging at a longer delay following choice. Additionally, we found a relationship between neural activity preceding a choice and an animal's modeled expectation of reward on a given trial as well as between post-choice neural activity and reward prediction error, further implicating these projections in tracking outcomes over time. **Conclusions**. Together, these findings demonstrate that mPFC and vHip projections to the NAc integrate outcomes over time in reward learning. Given evidence implicating these pathways in depression-like states, our results may suggest that these neural circuits could contribute to alterations in reward learning observed in psychopathologies.

Ambiguity and conflict: Dissecting uncertainty in decision-making.
Making decisions is fundamental to how we navigate, survive, and thrive in our environment. The quality of information used to support decisions is rarely perfect. Many decisions are made under conditions of uncertainty, arising from ambiguous or conflicting information. Conflict and ambiguity, though conceptually distinct, both generate uncertainty, a commonality that has led to overlapping and inconsistent terminology in the literature. Evidence from human and animal research suggests a behavioral dissociation in responding to conflict and ambiguity. This dissociation can be studied through the implementation of spatial or operant tasks in rodents which find close parallels in gambling tasks in humans. Pharmacological manipulations in rodents and fMRI studies in humans further suggest a dissociation in the neural processing of conflict and ambiguity such that fronto-striato-parietal circuits may be most important for interpreting ambiguous information, while the ventral striatum and ventral hippocampus are critical for resolving conflicting information. Overall, the neural representation and resolution of conflict and ambiguity remain relatively understudied despite the fundamental importance of these processes to understanding decision-making. We highlight the need for further research to differentiate these related yet distinct processes through implementation of carefully designed behavioral tasks with neural circuit-dissection techniques and the potential to pursue translational research between rodents and humans. Ventral Hippocampal Afferents to Nucleus Accumbens Encode Both Latent Vulnerability and Stress-Induced Susceptibility.
Stress is a major risk factor for depression, but not everyone responds to stress in the same way. Identifying why certain individuals are more susceptible is essential for targeted treatment and prevention. In rodents, nucleus accumbens (NAc) afferents from the ventral hippocampus (vHIP) are implicated in stress-induced susceptibility, but little is known about how this pathway might encode future vulnerability or specific behavioral phenotypes.

Probing relationships between reinforcement learning and simple behavioral strategies to understand probabilistic reward learning.

Reinforcement learning (RL) and win stay/lose shift model accounts of decision making are both widely used to describe how individuals learn about and interact with rewarding environments. Though mutually informative, these accounts are often conceptualized as independent processes and so the potential relationships between win stay/lose shift tendencies and RL parameters have not been explored.

NEURAL POPULATION REPRESENTATION OF PLACE-ITEM EXPERIENCES IN THE HIPPOCAMPAL NETWORK

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Giuseppe Pietro Gava[1], Pavel Perestenko[2], David Dupret[2]

A critical feature to thrive in a complex environment is the ability to form strong representations of salient locations important to satisfy basic needs. The hippocampus is a brain region crucial to learning and memory, however the network-level mechanisms that support the co-existence of multiple memories and their relation to saliency are unclear. To address these questions, here we monitor over multiple days large-scale ensembles of hippocampal CA1 neurons simultaneously in mice exploring a star-shaped maze where basic needs (e.g., eat, drink, sleep, run and socially interact) are met. Using a combination of network science and population dynamics manifold analyses, we investigate the dynamics of the network-level representation of discrete locations and items featuring such a complex environment. We observe that network representations become sparser and more resilient as the animal gains across-days experience of stable place-item relationships. These preliminary findings allow discussing the complexity of the multivariate hippocampal network-level representation and their underpinning mechanisms by which heterogeneous environmental features are simultaneously encoded.

Integrating new memories into the hippocampal network activity space.
By investigating the topology of neuronal co-activity, we found that mnemonic information spans multiple operational axes in the mouse hippocampus network. High-activity principal cells form the core of each memory along a first axis, segregating spatial contexts and novelty. Low-activity cells join co-activity motifs across behavioral events and enable their crosstalk along two other axes. This reveals an organizational principle for continuous integration and interaction of hippocampal memories.

Place Cells in Head-Fixed Mice Navigating a Floating Real-World Environment.
The hippocampal place cell system in rodents has provided a major paradigm for the scientific investigation of memory function and dysfunction. Place cells have been observed in area CA1 of the hippocampus of both freely moving animals, and of head-fixed animals navigating in virtual reality environments. However, spatial coding in virtual reality preparations has been observed to be impaired. Here we show that the use of a real-world environment system for head-fixed mice, consisting of an air-floating track with proximal cues, provides some advantages over virtual reality systems for the study of spatial memory. We imaged the hippocampus of head-fixed mice injected with the genetically encoded calcium indicator GCaMP6s while they navigated circularly constrained or open environments on the floating platform. We observed consistent place tuning in a substantial fraction of cells despite the absence of distal visual cues. Place fields remapped when animals entered a different environment. When animals re-entered the same environment, place fields typically remapped over a time period of multiple days, faster than in freely moving preparations, but comparable with virtual reality. Spatial information rates were within the range observed in freely moving mice. Manifold analysis indicated that spatial information could be extracted from a low-dimensional subspace of the neural population dynamics. This is the first demonstration of place cells in head-fixed mice navigating on an air-lifted real-world platform, validating its use for the study of brain circuits involved in memory and affected by neurodegenerative disorders.

Neural codes - Necessary but not sufficient for understanding brain function.
Brains are information processing systems whose operational principles ultimately cannot be understood without resource to information theory. We suggest that understanding how external signals are represented in the brain is a necessary step

towards employing further engineering tools (such as control theory) to understand the information processing performed by brain circuits during behaviour.

Encoding of locomotion kinematics in the mouse cerebellum.
The cerebellum is involved in coordinating motor behaviour, but how the cerebellar network regulates locomotion is still not well understood. We characterised the activity of putative cerebellar Purkinje cells, Golgi cells and mossy fibres in awake mice engaged in an active locomotion task, using high-density silicon electrode arrays. Analysis of the activity of over 300 neurons in response to locomotion revealed that the majority of cells (53%) were significantly modulated by phase of the stepping cycle. However, in contrast to studies involving passive locomotion on a treadmill, we found that a high proportion of cells (45%) were tuned to the speed of locomotion, and 19% were tuned to yaw movements. The activity of neurons in the cerebellar vermis provided more information about future speed of locomotion than about past or present speed, suggesting a motor, rather than purely sensory, role. We were able to accurately decode the speed of locomotion with a simple linear algorithm, with only a relatively small number of well-chosen cells needed, irrespective of cell class. Our observations suggest that behavioural state modulates cerebellar sensorimotor integration, and advocate a role for the cerebellar vermis in control of high-level locomotor kinematic parameters such as speed and yaw.

NEURAL MANIFOLDS IN HUMAN SUPERIOR TEMPORAL GYRUS SCAFFOLD SPEECH PHONOLOGICAL PROCESSING

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Pavo Orepic[1], Wilson Truccolo[2], Anne-Lise Giraud[1], Timothée Proix[1]
[1]University of Geneva, Department Of Basic Neurosciences, Geneva, Switzerland, [2]Brown University, Department Of Neuroscience, Providence, United States of America

Recent work in early sensory and motor cortices has shown that functionally-relevant population activity can be represented as a set of trajectories confined to a low-dimensional neural manifold, a subspace spanned by the patterns of correlated neuronal activity. However, it remains unknown whether the same encoding principles apply to speech comprehension, a multi-level hierarchical neural processing that integrates several cognitive functions. We analyzed population activity recorded with a microelectrode Utah array implanted in the anterior superior temporal gyrus (aSTG) of a patient with pharmacoresistant epilepsy, and sought after a speech-associated neural manifold. We applied dimensionality reduction methods to the single and multiunit activity collected while the patient performed several auditory tasks encompassing a rich repertoire of stimuli. Our preliminary results show that distinct linguistic units (e.g., words, syllables, and phonemes) could be represented as distinct trajectories on a low-dimensional neural manifold. Moreover, our analysis suggests that differences in the dynamics of the trajectories spanned on the aSTG manifold preferably account for the variability present in the phonetic features of the stimuli. These findings extend previous work on single-neuron to neuronal population response to auditory stimuli in the aSTG, and shed new light on neuronal dynamics during speech processing by uncovering phoneme-specific trajectories confined to a speech-associated neural manifold.

EEG Spatiotemporal Patterns Underlying Self-other Voice Discrimination.
There is growing evidence showing that the representation of the human "self" recruits special systems across different functions and modalities. Compared to self-face and self-body representations, few studies have investigated neural underpinnings specific to self-voice. Moreover, self-voice stimuli in those studies were consistently presented through air and lacking bone conduction, rendering the sound of self-voice stimuli different to the self-voice heard during natural speech. Here, we combined psychophysics, voice-morphing technology, and high-density EEG in order to identify the spatiotemporal patterns underlying self-other voice discrimination (SOVD) in a population of 26 healthy participants, both with air- and bone-conducted stimuli. We identified a self-voice-specific EEG topographic map occurring around 345 ms post-stimulus and activating a network involving insula, cingulate cortex, and medial temporal lobe structures. Occurrence of this map was modulated both with SOVD task performance and bone conduction. Specifically, the better participants performed at SOVD task, the less frequently they activated this network. In addition, the same network was recruited less frequently with bone conduction, which, accordingly, increased the SOVD task performance. This work could have an important clinical impact. Indeed, it reveals neural correlates of SOVD impairments, believed to account for auditory-verbal hallucinations, a common and highly distressing psychiatric symptom.

Breathing affects self-other voice discrimination in a bodily state associated with somatic passivity.
A growing number of studies have focused on identifying cognitive processes that are modulated by interoceptive signals, particularly in relation to the respiratory or cardiac cycle. Considering the fundamental role of interoception in bodily self-consciousness, we here investigated whether interoceptive signals also impact self-voice perception. We applied an interactive, robotic paradigm associated with somatic passivity (a bodily state characterized by illusory misattribution of self-generated touches to someone else) to investigate whether somatic passivity impacts self-voice perception as a function of concurrent interoceptive signals. Participants' breathing and heartbeat signals were recorded while they performed two self-voice tasks (self-other voice discrimination and loudness perception) and while simultaneously experiencing two robotic conditions (somatic passivity condition; control condition). Our data reveal that respiration, but not cardiac activity, affects

self-voice perception: participants were better at discriminating self-voice from another person's voice during the inspiration phase of the respiration cycle. Moreover, breathing effects were prominent in participants experiencing somatic passivity and a different task with the same stimuli (i.e., judging the loudness and not identity of the voices) was unaffected by breathing. Combining interoception and voice perception with self-monitoring framework, these data extend findings on breathing-dependent changes in perception and cognition to self-related processing.

Sense of agency for intracortical brain-machine interfaces.
Intracortical brain-machine interfaces decode motor commands from neural signals and translate them into actions, enabling movement for paralysed individuals. The subjective sense of agency associated with actions generated via intracortical brain-machine interfaces, the neural mechanisms involved and its clinical relevance are currently unknown. By experimentally manipulating the coherence between decoded motor commands and sensory feedback in a tetraplegic individual using a brain-machine interface, we provide evidence that primary motor cortex processes sensory feedback, sensorimotor conflicts and subjective states of actions generated via the brain-machine interface. Neural signals processing the sense of agency affected the proficiency of the brain-machine interface, underlining the clinical potential of the present approach. These findings show that primary motor cortex encodes information related to action and sensing, but also sensorimotor and subjective agency signals, which in turn are relevant for clinical applications of brain-machine interfaces.

Sensorimotor conflicts induce somatic passivity and louden quiet voices in healthy listeners.
Sensorimotor conflicts are known to alter the perception of accompanying sensory signals, and deficits in sensory attenuation have been observed in schizophrenia. In the auditory domain, self-generated tones or voices (compared to tones or voices presented passively or with temporal delays) have been associated with changes in loudness perception and attenuated neural responses. It has been argued that for sensory signals to be attenuated, predicted and sensory consequences must have a consistent spatiotemporal relationship, between button presses and reafferent signals, via predictive sensory signaling, a process altered in schizophrenia. Here, we investigated auditory sensory attenuation for a series of morphed voices while healthy participants applied sensorimotor stimulations that had no spatiotemporal relationship to the voice stimuli and that have been shown to induce mild psychosis-like phenomena. In two independent groups of participants, we report a loudening of silent voices and found this effect only during maximal sensorimotor conflicts (versus several control conditions). Importantly, conflicting sensorimotor stimulation also induced a mild psychosis-like state in the form of somatic passivity and participants who experienced stronger passivity lacked the sensorimotor loudening effect. We argue that this conflict-related sensorimotor loudness amplification may represent a reduction of auditory self-attenuation that is lacking in participants experiencing a concomitant mild psychosis-like state. We interpret our results within the framework of the comparator model of sensorimotor control, and discuss the implications of our findings regarding passivity experiences and hallucinations in schizophrenia.

The perspectives of mapping and monitoring of the sense of self in neurosurgical patients.
Surgical treatment of tumors, epileptic foci or of vascular origin, requires a detailed individual pre-surgical workup and intra-operative surveillance of brain functions to minimize the risk of post-surgical neurological deficits and decline of quality of life. Most attention is attributed to language, motor functions, and perception. However, higher cognitive functions such as social cognition, personality, and the sense of self may be affected by brain surgery. To date, the precise localization and the network patterns of brain regions involved in such functions are not yet fully understood, making the assessment of risks of related post-surgical deficits difficult. It is in the interest of neurosurgeons to understand with which neural systems related to selfhood and personality they are interfering during surgery. Recent neuroscience research using virtual reality and clinical observations suggest that the insular cortex, medial prefrontal cortex, and temporo-parietal junction are important components of a neural system dedicated to self-consciousness based on multisensory bodily processing, including exteroceptive and interoceptive cues (bodily self-consciousness (BSC)). Here, we argue that combined extra- and intra-operative approaches using targeted cognitive testing, functional imaging and EEG, virtual reality, combined with multisensory stimulations, may contribute to the assessment of the BSC and related cognitive aspects. Although the usefulness of particular biomarkers, such as cardiac and respiratory signals linked to virtual reality, and of heartbeat evoked potentials as a surrogate marker for intactness of multisensory integration for intra-operative monitoring has to be proved, systemic and automatized testing of BSC in neurosurgical patients will improve future surgical outcome.

Enhancing analgesic spinal cord stimulation for chronic pain with personalized immersive virtual reality.
Spinal cord stimulation (SCS) is an approved treatment for truncal and limb neuropathic pain. However, pain relief is often suboptimal and SCS efficacy may reduce over time, requiring sometimes the addition of other pain therapies, stimulator revision, or even explantation. We designed and tested a new procedure by combining SCS with immersive virtual reality (VR) to enable analgesia in patients with chronic leg pain. We coupled SCS and VR by linking SCS-induced paresthesia with personalized visual bodily feedback that was provided by VR and matched to the spatiotemporal patterns of SCS-induced paresthesia. In this cross-sectional prospective interventional study, 15 patients with severe chronic pain and an SCS implant underwent congruent SCS-VR (personalized visual feedback of the perceived SCS-induced paresthesia displayed on the patient's virtual body) and 2 control conditions (incongruent SCS-VR and VR alone). We demonstrate the efficacy of neuromodulation-enhanced VR for the treatment of chronic pain by showing that congruent SCS-VR reduced pain ratings on average by 44%. Spinal cord stimulation-VR analgesia was stronger than that in both control conditions (enabling stronger analgesic effects than incongruent SCS-VR analgesia or VR alone) and kept increasing over successive stimulations, revealing the selectivity and consistency of the observed effects. We also show that analgesia persists after congruent SCS-VR had stopped, indicating carry over effects and underlining its therapeutic potential. Linking latest VR technology with recent insights from the neuroscience of body perception and SCS neuromodulation, our personalized new SCS-VR platform highlights the impact of immersive digiceutical therapies for chronic pain.Registration: clinicaltrials.gov, Identifier: NCT02970006.

PREDICTIVE ODOR REINSTATEMENT IN PRIMARY OLFACTORY CORTEX

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Tor Stensola[1], Hanne Stensola[1], Megha Patwa[2], Eric Dewitt[2], Zachary Mainen[2]
[1]University of Agder, Faculty Of Health And Sport Sciences, Kristiansand, Norway, [2]Champalimaud Centre for the Unknown, Champalimaud Neuroscience Programme, Lisboa, Portugal

While primary sensory areas are robustly activated by sensory input signals, both theory and experiment suggest that the same cortices are modulated by internally generated activity. Predictive coding theories propose that sensory cortical responses incorporate comparisons between incoming sensory signals and expectations generated by internal models of the sensory scene. Yet several aspects of how sensory expectation is expressed in sensory circuits remain unclear. A fundamental question is whether distinct prediction effects accompany functional and anatomical differences between sensory modalities. The primary olfactory cortex (OC) receives unpatterned sensory inputs via the main olfactory bulb, and OC responses to odors reflect local associative dynamics more so than input activity. How sensory predictions are implemented in this system is not well understood. To address this, we chronically recorded neural populations in the mouse OC during presentation of odor pairs without reinforcement. 12 odors were systematically paired to establish stimulus-specific sensory predictions. In a subset of trials, the second odor was either presented alone (unpredicted) or omitted. After odor pairing, we observed changes to odor responses in both single cells and on the population level. Prediction-matched responses were bidirectionally modulated across the neural population, and became decodable from neural activity prior to odor onset. Surprisingly, after just one session, we observed reinstatement of the predicted odor representation instead of a mismatch response in trials where the predicted odor was omitted. These data indicate that prediction generates activity in the primary olfactory cortex that differs from what has been observed in other sensory modalities.

AIMS: A major question in neuroscience is inferring neural representations without relying on external information. A dominating approach has been looking for external inputs that maximally explain firing rate and timing variability. Coupling large-scale single-cell recordings with unsupervised machine learning techniques provides unique opportunities to challenge this perspective. **METHODS:** Here, we combine miniscope calcium imaging of CA1 neurons and dimensionality reduction methods to investigate the representational dynamics of the hippocampus, using spatial navigation as the ground truth. **RESULTS:** We show that during a forced-alternation task in a linear track, neural population activity in the mouse hippocampus can be constrained to a low-dimensional subspace (i.e. a neural manifold) in which both continuous (position) and discrete (direction) task-specific variables are jointly mapped. Moreover, when mice perform the alternation task on consecutive days, the manifold topology remains stable, even when recording from different sets of neurons. To gain interpretability, we trained various decoders to predict the animal's position during the task, using either the original neural population firing rates or the low-dimensional manifold activity as inputs. A comparative analysis of different dimensionality reduction methods highlighted their varying performance when inferring space representations from neural manifolds. Moreover, when adding complexity to the behavioural task (e.g. rotation of the maze in the room), this approach facilitates the evaluation of the stability and adaptation of the inferred internal representations. **CONCLUSION:** Our results reveal the more promising strategies for unbiased inference of internal hippocampal neural representations, offering new insights into the representational dynamics of the hippocampus.

GABAergic signaling to astrocytes in the prefrontal cortex sustains goal-directed behaviors.
GABA interneurons play a critical role in higher brain functions. Astrocytic glial cells interact with synapses throughout the whole brain and are recognized as regulatory elements of excitatory synaptic transmission. However, it is largely unknown how GABAergic interneurons and astrocytes interact and contribute to stable performance of complex behaviors. Here, we found that genetic ablation of GABA receptors in medial prefrontal cortex astrocytes altered low-gamma oscillations and firing properties of cortical neurons, which affected goal-directed behaviors. Remarkably, working memory deficits were restored by optogenetic stimulation of astrocytes with melanopsin. Furthermore, melanopsin-activated astrocytes in wild-type mice enhanced the firing rate of cortical neurons and gamma oscillations, as well as improved cognition. Therefore, our work identifies astrocytes as a hub for controlling inhibition in cortical circuits, providing a novel pathway for the behaviorally relevant midrange time-scale regulation of cortical information processing and consistent goal-directed behaviors.

Reduced Insulin-Like Growth Factor-I Effects in the Basal Forebrain of Aging Mouse.
It is known that aging is frequently accompanied by a decline in cognition. Furthermore, aging is associated with lower serum IGF-I levels that may contribute to this deterioration. We studied the effect of IGF-I in neurons of the horizontal diagonal band of Broca (HDB) of young (≤6 months old) and old (≥20-month-old) mice to determine if changes in the response of these neurons to IGF-I occur along with aging. Local injection of IGF-I in the HDB nucleus increased their neuronal activity and induced fast oscillatory activity in the electrocorticogram (ECoG). Furthermore, IGF-I facilitated tactile responses in the primary somatosensory cortex elicited by air-puffs delivered in the whiskers. These excitatory effects decreased in old mice. Immunohistochemistry showed that cholinergic HDB neurons express IGF-I receptors and that IGF-I injection increased the expression of c-fos in young, but not in old animals. IGF-I increased the activity of optogenetically-identified cholinergic

neurons in young animals, suggesting that most of the IGF-I-induced excitatory effects were mediated by activation of these neurons. Effects of aging were partially ameliorated by chronic IGF-I treatment in old mice. The present findings suggest that reduced IGF-I activity in old animals participates in age-associated changes in cortical activity.

PREMOTOR AND MOTOR CORTICAL DYNAMICS DURING SKILLED MOTOR LEARNING

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Yangfan Peng[1], Jessica Myatt[1], Sasha Tinelli[1], Armin Lak[2], Andrew Sharott[1]
[1]University of Oxford, Mrc Brain Network Dynamics Unit, Nuffield Department Of Clinical Neurosciences, Oxford, United Kingdom, [2]University of Oxford, Dpag, Oxford, United Kingdom

Many regions of the central nervous system contribute to motor control, but skilled motor learning is dependent on the motor cortex. Spiking in motor cortical circuits is reorganised during learning to coordinate different movements into a single action guided by the outcome of previous actions. It has been shown that, as motor performance improves, more neurons become recruited, and that the activity of these neurons becomes increasingly correlated. It is not yet clear to what extent such spatiotemporal refinement of cortical population dynamics results from changes in long-range inputs or emerge at the local microcircuit level. We performed high-density electrophysiological recordings across multiple motor regions in head-fixed mice during learning of a skilled forelimb reaching task. Mice showed increased task performance over consecutive days and movement kinematics are being analysed using automated pose estimation. We observed extensive recruitment of neurons in premotor and motor cortex during the reaching task. These data allowed detailed characterisation of the evolution of coordinated activity patterns within and across motor cortices as skilled movement was refined. This will help to disentangle the contribution of local and long-range connections during cortical learning.

A LATENT VARIABLE MODEL USING FEATURE SHARING, FOR NEURAL STATE SPACE DISCOVERY

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Martin Bjerke, David Klindt, Claudia Battistin, Benjamin Dunn
Norwegian University of Science and Technology, Department Of Mathematical Sciences, Trondheim, Norway

Due to the recent advances in neural recording techniques, the number of simultaneously recordable neurons available is at an all-time high. Abundant amounts of data has generated a demand for models that are able to recover interpretable underlying latent structures from large neural populations, so-called Latent Variable Models. However, many of these models are prone to finding only locally optimal solutions, with a heavy dependency on initialisation and neuron selection. In our work, we propose novel priors, constraining the model to assume a common shape for the tuning curves, referred to as feature sharing in related work, which acts a strong but reasonable prior. Said priors are easily enforced using splines to model the neural response functions, which we combine with a variational autoencoder framework for latent variable encoding. This allows us to infer latent variables and tuning curves using less data, as well as providing a more stable inference procedure, with the feature sharing prior lessening the model's dependency on the initialisation. Furthermore, our model also enables the detection of multiple ensembles, allowing for multiple latent variables with parametric, selective neuron inclusion. Finally, we show that where feature sharing and ensemble detection are applicable, such as in the cases of tuning to head direction and spatial position (grid cells), we are able to recover latent trajectories on various manifolds from both simulated and real data.

NEURONAL ACTIVITY IN THE MEDIAL ENTORHINAL CORTEX IS COORDINATED WITH THALAMIC HEAD-DIRECTION CELLS DURING SLEEP.

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Gilberto Vite, Adrien Peyrache
Montreal Neurological Institute - McGill University, Faculty Of Medicine, Montreal, Canada

Aims: Flexible navigation requires signals that are updated irrespective of the external conditions. The demonstration that pairwise coordination of both grid and head-direction (HD) cells is maintained during sleep when external inputs are largely reduced, has provided experimental evidence for attractor dynamics in these systems. Specifically, this was shown separately for the HD cells of the anterodorsal nucleus (ADN) of the thalamus and for HD and grid cells of the medial entorhinal cortex (MEC). Inactivation studies previously showed that ADN HD cells are necessary for normal grid cell activity, begging the question of the exact role of the thalamic HD cells in MEC population activity. To address this problem, we performed simultaneous recording of thalamic HD cells and the MEC. **Methods:** We implanted 32-channel and 32 or 64-channel probes into ADn and MEC respectively. The recordings consisted of a 2h sleep session, 30 mins exploration, followed by another 2h sleep session. **Results:** We analyzed 35 pairs of ADN-MEC HD cells. The coordination of ADN-MEC HD cell pairs was preserved during all phases of sleep, NREM and REM, the angular offset of the preferred direction during wake predicting the correlation during sleep, **Conclusions:** Our findings suggest that the HD signal is coherent across multiple areas of the brain's navigation system across all brain states. As ADN certainly exerts more influence on its cortical targets than it is itself influenced by cortical feedback, it is thus possible that the attractor dynamics observed in the MEC are inherited from upstream coherent activity.

Histological and diffusion-weighted magnetic resonance imaging data from normal and degenerated optic nerve and chiasm of the rat.
Diffusion-weighted magnetic resonance imaging (dMRI) is widely used to infer microstructural characteristics of tissue, particularly in cerebral white matter. Histological validation of the metrics derived from dMRI methods are needed to fully characterize their ability to capture biologically-relevant histological features non-invasively. The data described here were used to correlate metrics derived from dMRI and quantitative histology in an animal model of axonal degeneration ("Histological validation of per-bundle water diffusion metrics within a region of fiber crossing following axonal degeneration" [1]). Unilateral retinal ischemia/reperfusion was induced in 10 rats, by the elevation of pressure of the anterior chamber of the eye for 90 min. Five rats were used as controls. After five weeks, injured animals were intracardially perfused to analyze the optic nerves and chiasm with dMRI and histology. This resulted in 15 brain scans, each with 80 diffusion-sensitizing gradient directions with b = 2000 and 2500 s/mm and 20 non-diffusion-weighted images (b = 0 s/mm), with isometric voxel resolution of 125 μm. Histological sections were obtained after dMRI. Optical microscopy photomicrographs of the optic nerves (stained with toluidine blue) are available, as well as their corresponding automatic segmentations of axons and myelin.
Data Brief, 2019; 26

Histological validation of per-bundle water diffusion metrics within a region of fiber crossing following axonal degeneration.
Micro-architectural characteristics of white matter can be inferred through analysis of diffusion-weighted magnetic resonance imaging (dMRI). The diffusion-dependent signal can be analyzed through several methods, with the tensor model being the most frequently used due to its straightforward interpretation and low requirements for acquisition parameters. While valuable information can be gained from the tensor-derived metrics in regions of homogeneous tissue organization, this model does not provide reliable microstructural information at crossing fiber regions, which are pervasive throughout human white matter. Several multiple fiber models have been proposed that seem to overcome the limitations of the tensor, with few providing per-bundle dMRI-derived metrics. However, biological interpretations of such metrics are limited by the lack of histological

confirmation. To this end, we developed a straightforward biological validation framework. Unilateral retinal ischemia was induced in ten rats, which resulted in axonal (Wallerian) degeneration of the corresponding optic nerve, while the contralateral was left intact; the intact and injured axonal populations meet at the optic chiasm as they cross the midline, generating a fiber crossing region in which each population has different diffusion properties. Five rats served as controls. High-resolution ex vivo dMRI was acquired five weeks after experimental procedures. We correlated and compared histology to per-bundle descriptors derived from three methodologies for dMRI analysis (constrained spherical deconvolution and two multi-tensor representations). We found a tight correlation between axonal density (as evaluated through automatic segmentation of histological sections) with per-bundle apparent fiber density and fractional anisotropy (derived from dMRI). The multi-fiber methods explored were able to correctly identify the damaged fiber populations in a region of fiber crossings (chiasm). Our results provide validation of metrics that bring substantial and clinically useful information about white-matter tissue at crossing fiber regions. Our proposed framework is useful to validate other current and future dMRI methods.

SPARSE CHAOS AND LOCALIZATION IN THE DYNAMICS OF NEURONAL CIRCUITS

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Mohammadreza Soltanipour[1,2], Rainer Engelken[3], Fred Wolf[1,2]
[1]Göttingen Campus Institute for Dynamics of Biological Networks, Physics Of Biological Systems, Göttingen, Germany, [2]Max Planck Institute for Dynamics and Self-Organization, Physics Of Biological Systems, Göttingen, Germany, [3]Columbia University, Mortimer B. Zuckerman Mind Brain Behavior Institute, New York, United States of America

Nerve impulses, the currency of information flows in the brain, are generated by an instability of the neuronal membrane potential dynamics. Neuronal circuits exhibit collective chaos that appears essential for learning, memory, sensory processing, and motor control. What controls the nature and intensity of collective chaos in neuronal circuits, however, is not well understood. Here we use computational ergodic theory to demonstrate that basic features of nerve impulse generation profoundly affect collective chaos in neuronal circuits. Numerically exact calculations of Lyapunov spectra, Kolmogorov-Sinai-entropy, and upper and lower bounds on attractor dimension show that changes in nerve impulse generation in individual neurons only moderately modify rate of information encoding but qualitatively transform phase space structure, reducing the number of unstable manifolds, Kolmogorov-Sinai-entropy, and attractor dimension by orders of magnitude. Beyond a critical point, marked by a localization transition of the leading covariant Lyapunov vector, the network exhibits sparse chaos: extended periods of near stable dynamics interrupted by short bursts of intense chaos. Analysis of large networks with more realistic structure indicate the generality of these findings. In cortical circuits biophysics appears tuned to this regime of episodic chaos. Our results demonstrate a tight link between fundamental features of single neuron biophysics and the collective dynamics of cortical circuits and suggest that the machinery of nerve impulse generation is tailored to enhance circuit controllability and information flow. PERCEPTION AND PROPAGATION OF ACTIVITY THROUGH THE CORTICAL HIERARCHY IS DETERMINED BY NEURAL VARIABILITY

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Matthias Loidolt[1,2], James Rowland[2], Thijs Van Der Plas[2], Robert Lees[2], Joshua Keeling[2], Jonas Dehning[1], Thomas Akam[3], Viola Priesemann[1], Adam Packer[2]

The brains of higher organisms are composed of anatomically and functionally distinct regions performing specialised tasks; but regions do not operate in isolation. Orchestration of complex behaviours requires communication between brain regions, but how neural activity dynamics are organised to facilitate reliable transmission is not well understood. We studied this process directly by generating neural activity that propagates between brain regions and drives behaviour, allowing us to assess how populations of neurons in sensory cortex cooperate to transmit information. We achieved this by imaging two hierarchically organised and densely interconnected regions, the primary and secondary somatosensory cortex (S1 and S2) in mice while performing two-photon photostimulation of S1 neurons and assigning behavioural salience to the photostimulation. We found that the probability of perception is determined not only by the strength of the photostimulation signal, but also by the variability of S1 neural activity. Therefore, maximising the signal-to-noise ratio of the stimulus representation in cortex is critical to its continued propagation downstream. Further, we show that propagated, behaviourally salient activity elicits balanced, persistent, and generalised activation of the downstream region. Hence, our work adds to existing understanding of cortical function by identifying how population activity is formatted to ensure robust transmission of information, allowing specialised brain regions to communicate and coordinate behaviour.

The challenges of containing SARS-CoV-2 via test-trace-and-isolate.
Without a cure, vaccine, or proven long-term immunity against SARS-CoV-2, test-trace-and-isolate (TTI) strategies present a promising tool to contain its spread. For any TTI strategy, however, mitigation is challenged by pre- and asymptomatic transmission, TTI-avoiders, and undetected spreaders, which strongly contribute to "hidden" infection chains. Here, we study a semi-analytical model and identify two tipping points between controlled and uncontrolled spread: (1) the behavior-driven reproduction number [Formula: see text] of the hidden chains becomes too large to be compensated by the TTI capabilities, and (2) the number of new infections exceeds the tracing capacity. Both trigger a self-accelerating spread. We investigate how these tipping points depend on challenges like limited cooperation, missing contacts, and imperfect isolation. Our results suggest that TTI alone is insufficient to contain an otherwise unhindered spread of SARS-CoV-2, implying that complementary measures like social distancing and improved hygiene remain necessary.

In the interconnected mammalian cortex, the dimensionality of firing patterns is confined to a lower dimensional space. Generally, neurons in a population are constrained by the local circuit and display strong correlations. Thus, local spiking activity tends to be highly coupled. This behaviour has been assessed inside a single cortical area, but not between different cortical areas. Since neurons are likewise constrained by meso- and macro-scale connectivity, we further investigate interareal coupling. We ask if the population coupling strength is correlated to any functional relation between primary visual cortex, somatosensory cortex, perirhinal cortex and hippocampal CA1 region. Next, we ask if internal coupling is predictive for external coupling. We analyse the level of population coupling with the spike-triggered population rate: a convolution of a single unit's firing-rate with a target population. We assess the level of population coupling between different areas. We see different dynamics in population coupling within-areas versus between-areas. Generally, interareal coupling strength is low, but a small subset of units per area shows significant coupling between areas. We find correlations between within and between-area coupling, thought these are weak. Furthermore, we find divergent coupling between areas in comparison to anatomical connections. In hippocampus, spatial selectivity is negatively correlated with coupling. Different behavioural states affect coupling in divergent ways, with decreased coupling within al areas during sleeping conditions, and only the sleeping hippocampus shows significantly decrease coupling to other areas. Overall, SNPC offers an important window on cell-to-population synchronization in multi-area networks.

MOSSY CELLS ORTHOGONALLY COMPRESS HIPPOCAMPAL INFORMATION

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Ayako Ouchi, Yuji Ikegaya
The University of Tokyo, Graduate School Of Pharmaceutical Sciences, Tokyo, Japan

Neuronal activity in the hippocampal CA3 region is disynaptically transmitted to the dentate gyrus via hilar mossy cells, which are extremely fewer in number than CA3 pyramidal cells and dentate granule cells and constitute a bottleneck middle layer. How this small layer relays hippocampal information remains unknown. We previously demonstrated that the subthreshold membrane potentials (*V*ms) of mossy cells reflect the activity of hippocampal sharp waves (SWs)/ ripples initiated in the CA3 subregion in acute hippocampal slices. Moreover, we observed the weak correlation between Δ*V*ms and the SW amplitudes which implies that the mossy cell ensembles may collectively encode information of SWs. We thus hypothesized that the SW waveforms were predictable from a set of the *V*m responses in mossy cells. In this study, we simultaneously performed *in vitro* whole-cell recordings from up to five mossy cells in hippocampal slices and *in vivo* whole-cell recordings from a mossy cell from anesthetized mice. Using machine learning analysis, we succeeded in predicting SW waveforms from the *V*m dynamics of 1-5 mossy cells more precisely than was expected by chance, and found that the use of more mossy cells was correlated with a better SW prediction. Remarkably, spatial entropy analysis revealed the orthogonal coding by mossy cell populations, which are analogous to data compression in information engineering. Therefore, we conclude that SW activity is densely compressed in the MC layer and that the MC layer may serve as a biological bottleneck layer in hippocampal computations.

PRINCIPLES UNDERLYING INFORMATION FLOW ACROSS THE ENTIRE BRAIN OF THE ZEBRAFISH

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Emiliano Marachlian, German Sumbre, Louis Dannatt
Ecole Normale Superieure, L'institut De Biologie, Paris, France

Our knowledge of how the brain works, although growing, has always been constrained by our limited capability of measuring it. Previously, through work on individual brain regions, it has been shown that information can be stored through functional clusters of neurons (assemblies). However, it remains unclear how the brain represents information as a whole and how information flows through it. To study neuronal assemblies and their sequences, we recorded spontaneous and stimuli triggered neuronal activity in the whole brain of zebrafish larvae, while simultaneously recording free tail movement. We found a large variability in the characteristics of the functional assemblies. Although we found evidence of compact and local assemblies, most assemblies were sparse and spanned the entire brain. As a measure of information flow, we will present a Markov model of assembly transitions to create a functional graph network allowing topological analysis. The functional network shows distribution degree compatible with scale free. From this graph we identified the role of individual assemblies, some acting as information hubs connecting different brain regions. We additionally carried out and exhaustive characterization of the activation sequences triggered spontaneously, from visual and auditory stimuli and during different behavioral motives. In sum we will present for the first time a rich description of whole brain assemblies and assemblies' sequences.

REVEALING LATENT KNOWLEDGE IN CORTICAL NETWORKS DURING GOAL-DIRECTED LEARNING

POSTER SESSION 01 - SECTION: NEURONAL POPULATION CODING AND DYNAMICS

Céline Drieu[1], Ziyi Zhu[2], Aaron Wang[1], Kylie Fuller[1], Sarah Elnozahy[1], Kishore Kuchibhotla[1]
[1]Johns Hopkins University, Department Of Psychological And Brain Sciences, Baltimore, United States of America, [2]Johns Hopkins University, Department Of Neuroscience, Baltimore, United States of America

Behavioral performance during goal-directed learning is typically measured in the presence of reinforcement. In this context, learning has been described as a slow process with high inter-subject variability. Exploration of the neural mechanisms, therefore, has focused on identifying dynamics concomitant with these slow performance improvements. Recent work, however, has shown that task acquisition is much faster and more stereotyped than previously thought. Performance was evaluated daily in reinforced and non-reinforced ('probe') trials. These probe trials revealed a rapid and stereotyped acquisition of task contingencies early in learning which was only expressed much later in reinforced trials. Here we ask whether and how sensory cortical networks encode and control the acquisition of this latent knowledge. We used longitudinal, two-photon calcium imaging of the same large population of excitatory neurons in layer II/III of the auditory cortex (AC) while mice learned an auditory Go/No-Go task. We used unsupervised low-rank tensor decomposition to uncover low-dimensional network dynamics at different timescales. We identified a subset of neurons that were initially S+-driven but then shifted to firing at the time of reward, suggesting a role in reward learning. Another subset of S−-responsive neurons exhibited a rapid enhancement of their stimulus-driven response, suggesting a role in behavioral inhibition. Optogenetic silencing of the AC on reinforced trials led to a striking delay in the acquisition of stimulus-action associations. Overall, our work argues that latent task knowledge emerges rapidly in the AC and is crucial for goal-directed learning.

Nested sequences of hippocampal assemblies during behavior support subsequent sleep replay.
Consolidation of spatial and episodic memories is thought to rely on replay of neuronal activity sequences during sleep. However, the network dynamics underlying the initial storage of memories during wakefulness have never been tested. Although slow, behavioral time scale sequences have been claimed to sustain sequential memory formation, fast ("theta") time scale sequences, nested within slow sequences, could be instrumental. We found that in rats traveling passively on a model train, place cells formed behavioral time scale sequences but theta sequences were degraded, resulting in impaired subsequent sleep replay. In contrast, when the rats actively ran on a treadmill while being transported on the train, place cells generated clear theta sequences and accurate trajectory replay during sleep. Our results support the view that nested sequences underlie the initial formation of memory traces subsequently consolidated during sleep.

Hippocampal Sequences During Exploration: Mechanisms and Functions.
Although the hippocampus plays a critical role in spatial and episodic memories, the mechanisms underlying memory formation, stabilization, and recall for adaptive behavior remain relatively unknown. During exploration, within single cycles of the ongoing theta rhythm that dominates hippocampal local field potentials, place cells form precisely ordered sequences of activity. These neural sequences result from the integration of both external inputs conveying sensory-motor information, and intrinsic network dynamics possibly related to memory processes. Their endogenous replay during subsequent sleep is critical for memory consolidation. The present review discusses possible mechanisms and functions of hippocampal theta sequences during exploration. We present several lines of evidence suggesting that these neural sequences play a key role in information processing and support the formation of initial memory traces, and discuss potential functional distinctions between neural sequences emerging during theta vs. awake sharp-wave ripples.

Reversed theta sequences of hippocampal cell assemblies during backward travel.
Hippocampal cell assemblies coding for past, present and future events form theta-timescale (~100 ms) sequences that

represent spatio-temporal episodes. However, the underlying mechanisms remain largely unknown. We recorded hippocampal and entorhinal cortical activity as rats experienced backward travel on a model train. Although the firing fields of place cells remained stable, the order in which they were activated in the theta sequence was reversed during backward travel. Thus, hippocampal cell assemblies coordinated their relative timing to correctly predict the sequential traversal of place fields in reverse order. At the single-cell level, theta phase represented distance traveled through the field, even though the head of the rat was oriented opposite to travel direction and entorhinal head-direction cells maintained their preferred firing direction. Our results challenge most theoretical models of theta sequence generation in the hippocampus.

PREDICTING SPATIAL BEHAVIOR FROM COMPLEX HIPPOCAMPAL OSCILLATORY CODES

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Vincent Douchamps[1], Matteo Di Volo[2,3], Alessandro Torcini[3], Battaglia Demian[4,5], Romain Goutagny[1]
[1]Université de Strasbourg / CNRS, Lnca, Strasbourg, France, [2]University of Parma, Department Of Medicine And Surgery, Parma, Italy, [3]Université de Cergy-Pontoise, Laboratoire De Physique Théorique Et Modélisation, Cergy-Pontoise, France, [4]Aix-Marseille Université, Institute For Systems Neuroscience, Marseille, France, [5]University of Strasbourg, Usias, Strasbourg, France

Theta and gamma oscillations are believed to organise hippocampal activity and function. The current dominant view posits the existence of two gamma frequency sub-bands, occurring at different theta phases in CA1, produced by different generators and sub-serving exclusive cognitive operations. However, this view relies on averaging over many oscillatory events, possibly overshadowing recently suggested manifold theta-nested gamma contents. We thus explored agnostically the diversity and informational capacity of individual theta-gamma bouts in LFPs recorded in the mouse dorsal hippocampus (n=5) during the learning of a spatial reference memory task. We found gamma bouts with nearly every combination of frequency, amplitude and theta-phase whichever the hippocampal layer. Importantly, although their average can resemble the two classic sub-bands pattern, they mainly reflect few strong power events. Furthermore, this diversity would not depend entirely on external generators: a spiking computational model of local recurrent circuitry involving one excitatory and one inhibitory (fast-spiking-like) populations can generate similarly complex oscillations fluctuating over the entire gamma spectrum without fine-tuning for most parameter combinations. Finally, gamma diversity is functional: a machine learning approach could accurately decode mice running speed and coarse maze position from individual theta-gamma oscillatory events, for all layers. The theta-gamma “code” nonetheless differed across layers and learning stages. Altogether, our findings suggest that hippocampal LFP oscillatory diversity is not mere noise but carries an actual encoding of context and behavior. These population codes are complex in nature and not reducible to simpler descriptions relying on few reference bands.

Memories of drug experience invigorate behavioural actions biased towards drug-paired stimuli. These maladaptive memories engage many brain regions; however, the patterns of inter-region coordination that relate to cocaine-paired memory retrieval remain elusive. Here, we uncover a brain-distributed motif of cooperative network oscillations that underlies dynamic retrieval of cocaine-paired memory. By simultaneously recording oscillatory activity in the prefrontal cortex, nucleus accumbens, amygdala, hippocampus and ventral tegmental area of the mouse brain, we show that a higher-order, cross-network pattern of beta-band (15–25 Hz) oscillatory activities reports initial recall of cocaine-paired memory, and its subsequent renewal following extinction. We further provide evidence that such beta-specific patterns of oscillatory coordination are organised by ventral tegmental area 4-Hz oscillations. Binding together a set of distributed brain networks in this manner may underlie the robustness of drug-paired memories, and hence the resilient nature of drug seeking behaviour.

What exactly is 'N' in cell culture and animal experiments?
Biologists determine experimental effects by perturbing biological entities or units. When done appropriately, independent replication of the entity-intervention pair contributes to the sample size (N) and forms the basis of statistical inference. If the wrong entity-intervention pair is chosen, an experiment cannot address the question of interest. We surveyed a random sample of published animal experiments from 2011 to 2016 where interventions were applied to parents and effects examined in the offspring, as regulatory authorities provide clear guidelines on replication with such designs. We found that only 22% of studies (95% CI = 17%-29%) replicated the correct entity-intervention pair and thus made valid statistical inferences. Nearly half of the studies (46%, 95% CI = 38%-53%) had pseudoreplication while 32% (95% CI = 26%-39%) provided insufficient information to make a judgement. Pseudoreplication artificially inflates the sample size, and thus the evidence for a scientific claim, resulting in false positives. We argue that distinguishing between biological units, experimental units, and observational units clarifies where replication should occur, describe the criteria for genuine replication, and provide concrete examples of in vitro, ex vivo, and in vivo experimental designs.

SLOW AND FAST OSCILLATORY DYNAMICS OF NEURAL NETWORKS DURING LEARNING OF AN OLFACTORY DISCRIMINATION TASK IN RAT

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Nicolas Fourcaud-Trocmé, Laura Lefèvre, Nathalie Buonviso
CNRS - Université Lyon 1, Center For Research In Neuroscience Of Lyon, BRON CEDEX, France

Neural oscillations are thought to provide a temporal structure facilitating information processing and inter-area communication. These oscillations coexist in different frequency bands involving neural networks at different spatial scales and are related to different aspects of behavior. We questioned the effect of learning on the dynamics of neural oscillations and the evolution of the associated neural networks. We tackled this question during an olfactory discrimination task in rats. Local field potentials were recorded in a large set of brain areas (including sensory, motor and limbic areas). We focused our analysis on the neural networks defined by rhythm synchronization in two frequency bands: (i) slow rhythms (1-10Hz), including animal respiration frequency and hippocampal theta rhythm, and (ii) beta band (15-30Hz), known to be modulated by odor learning. For the slow rhythms, preliminary analyses during odor sampling showed that hippocampal and respiratory rhythms were in a close frequency range only during a short window allowing for phase synchronization (1 or 2 cycles). Functional connectivity showed that these slow rhythms were supported by two distinct but overlapping networks which evolved during initial learning but stabilized as soon as the task rules were acquired. In the beta band, a large oscillation emerged at the end of odor sampling as the rat was learning the task. This oscillation was coherent across all recorded areas where it was expressed and when the context learning was acquired. In addition, rat behavior seemed no longer plastic when beta was strongly expressed.

UNSUPERVISED ANALYSIS OF A DIVERSITY OF SHARP-WAVE RIPPLES

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Enrique R. Sebastian[1], Teresa Jurado-Parras[1], Alberto Sanchez-Aguilera[2], Liset Menendez De La Prida[1]
[1]Cajal Institute - CSIC, Laboratorio De Circuitos Neuronales, Madrid, Spain, [2]Facultad de Medicina - UCM, Departamento De Fisiologia, Madrid, Spain

AIMS: Sharp-wave ripples (SWR) are high frequency hippocampal events, which presumably play different cognitive roles in memory consolidation and planning. Understanding how SWR waveform variability relates to the underlying microcircuits remains elusive but is essential to dissect cognitive function. METHODS: Here, we use topological data analysis to estimate the intrinsic structure of a wealth of SWR events recorded from awake head-fixed mice. We focus the analysis in the SWR waveform using filtered and unfiltered data centered on the SWR peak. We then apply dimensionality reduction and visualization methods to facilitate discovery of different SWR features. RESULTS: First, we show that a low number of intrinsic dimensions can explain waveform variability using a set of methods (Maximum Likelihood; Isomap; Expected Simplex Skewness; Principal Components Analysis) tested against a ground-truth. Next, we reduce dimensionality of SWR events to visualize how different potential features (e.g. frequency, amplitude, slopes, etc…) accounted for waveform variability. Using cluster measures, we evaluate the distribution of these different features over the low dimensional projection. We find different contribution of frequency, amplitude, slope and spectral entropy to the global variance of SWR, and confirmed some of these trends in synthetic datasets. CONCLUSIONS: Our study shows how topological analysis can be applied for unsupervised examination of SWR events. Moreover, by projecting physiologically relevant measures over the low dimensional SWR representation, we identify potential mechanisms associated to the expression of different features.

NMDA AND SIGMA-1 RECEPTOR MODULATION OF RODENT NETWORK OSCILLATIONS AND NEUROINFLAMMATION

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Bethany Dennis[1], Oliver Baddeley[1], Rowan Paxman[1], Gavin Clowry[2], Fiona Lebeau[2]
[1]Newcastle University, Biosciences Institute, Newcastle Upon Tyne, United Kingdom, [2]Newcastle University, Biosciences Institute, Newcastle upon Tyne, United Kingdom

Aims: Aberrant beta and gamma frequency oscillations are reported in patients with schizophrenia, alongside impaired working memory and attention. Additionally, increased neuroinflammation is reported in *post-mortem* tissue. Beta (20-30Hz) and gamma (30-80Hz) oscillations can be recorded from the rat anterior cingulate cortex (ACC) and hippocampus (HPC) in vitro. Cognitive and network dysfunction can be modelled in rodents using the NMDA receptor antagonist phencyclidine (PCP) and in vivo studies suggest sigma-1 receptor (σ1R) activation may reverse these deficits. However, the mechanism by which PCP causes disruption of oscillations, and the effects of PCP and σ1R modulation on network activation and neuroinflammation are unknown. **Methods:** Rat ACC/HPC slices were prepared by standard methods and transferred to an interface chamber for electrophysiological recording. Network oscillations were evoked using bath-applied kainate. PCP and/or σ1R agonist PRE-084, were bath applied with or without kainate. After recording, slices were re-sectioned and immunostained for reactive astrocyte marker GFAP. **Results:** PCP significantly increased the power of stable beta/gamma oscillations and slowed the oscillation frequency. However, the σ1R agonist PRE-084 had no effect on network oscillations. Exposing slices to PCP, versus kainate alone, showed a marked increase in reactive astrocytes. Our preliminary data suggests this PCP-evoked neuroinflammatory response was reduced by pre-application of PRE-084. **Conclusions:** Our data suggests that the NMDA-R antagonist PCP induces an abnormally large oscillation and increases neuroinflammation, whilst the σ1R agonist PRE-084 reduces PCP's neuroinflammatory effect. Further investigation is required to better understand the interplay between these two receptors and their effects on cognitive impairment.

HUMAN VISUAL GAMMA FOR COLOR STIMULI: WHEN LGN DRIVE IS EQUALIZED, RED IS NOT SPECIAL

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Benjamin J. Stauch[1], Alina Peter[2], Isabelle Ehrlich[3], Zora Nolte[1], Pascal Fries[1]
[1]The Ernst Strüngmann Institute (ESI) for Neuroscience in Cooperation with Max Planck Society, Fries Lab, Frankfurt am Main, Germany, [2]McGovern Institute for Brain Research, Dicarlo Lab, Cambridge, United States of America, [3]Goethe University Frankfurt, Department Of Psychology, Frankfurt am Main, Germany

Strong gamma-band oscillations in primate early visual cortex can be induced by homogeneous color surfaces. Compared to other hues, particularly strong gamma oscillations have been reported for red stimuli. However, precortical color processing and the resultant strength of input to V1 has often not been fully controlled for. Therefore, stronger responses to red might be due to differences in V1 input strength. We presented stimuli that had equal luminance and color contrast levels in a color coordinate system based on responses of the lateral geniculate nucleus, the main input source for area V1. With these stimuli, we recorded magnetoencephalography in 30 human participants. We found gamma oscillations in early visual cortex which, contrary to previous reports, did not differ between red and green stimuli of equal L-M cone contrast. Notably, blue stimuli with contrast exclusively on the S-cone axis induced very weak gamma responses, as well as smaller event-related fields and poorer change-detection performance. The strength of human color gamma responses could be well explained by the strength of thalamic input induced by each hue and does not show a clear red bias when this input strength is properly equalized.

[1]University of Manchester, Division Of Neuroscience And Experimental Psychology, Manchester, United Kingdom, [2]University of Manchester, Division Of Pharmacy And Optometry, Manchester, United Kingdom, [3]COMPASS Pathways plc, Preclinical R&d, London, United Kingdom

Background and Aims Psilocybin is a serotonergic psychedelic compound with great psychotherapeutic potential, however, its neural effects are not well understood. Psilocybin's profound cognition-, perception- and emotion-altering effects are associated with fMRI signal changes in human prefrontal cortex (PFC) and hippocampus, key structures in self-referential information processing. As these regions' functions rely on their orchestrated electrical oscillatory activity, our study aimed to evaluate psilocybin's effect on neural oscillations within and between these regions. **Methods** Multi-electrode arrays were inserted into the PFC (prelimbic cortex: PrL) and dorsal hippocampus (CA1) of urethane-anaesthetised adult male Lister Hooded rats. Local field potentials were recorded continuously during 20 min baseline, 60 min post-saline and 90 min post-dose with COMP360 (COMPASS Pathways' proprietary formulation of psilocybin; 3mg/kg i.p.) to evaluate power spectral and coherence changes. **Results** COMP360 induced a 10- and 32-fold increase in high frequency gamma (51-75 Hz) power in the PrL and CA1, respectively, and a 28-fold increase in PrL–CA1 high gamma coherence. These changes co-occurred with a decrease in low theta (3-5 Hz) and delta (0.5-3 Hz) power within each region. **Conclusion** COMP360 alters the activity within, and communication between, prelimbic cortex and hippocampal area CA1 in the rat, two brain regions whose functional equivalents in humans are strongly implicated in the pathophysiology of psychiatric disease. It remains to be seen to what extent these drug-induced changes in an anaesthetised rodent model can be related to COMP360's therapeutic mechanism of action in humans.

SHARP WAVE RIPPLES MODULATION BY THE RAPHE TO HIPPOCAMPUS GLUTAMATERGIC PATHWAY

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Justine Fortin-Houde[1,2], Guillaume Ducharme[2], Anne-Sophie Simard[1,2], Annie Durand-Marandi[1], Bénédicte Amilhon[1,2]
[1]Université de Montréal, Neurosciences, Montreal, Canada, [2]CHU Sainte-Justine Research Center, Neurosciences, Montreal, Canada

Aims: Sharp wave ripples (SWR), brief, high frequency oscillations (~50 ms, 100-250 Hz) in the hippocampus are essential for memory consolidation. The median raphe is known to modulate SWR activity, but the mechanism behind this modulation remains poorly understood. We are interested in the hippocampus-projecting glutamatergic neuronal population of the median raphe, characterized by the expression of the vesicular glutamate transporter type 3 (VGLUT3). We aim in this study to investigate more specifically their activity in relation to SWR and their contribution to SWR modulation. *Methods:* To target hippocampus-projecting VGLUT3-positive neurons we injected Cre-dependent retrograde viral vectors in VGLUT3-Cre mice allowing specific expression of our optogenetics tools in our population of interest. Optogenetic light stimulations are delivered through an optic fiber over the median raphe region while the hippocampal SWR are recorded in the dorsal hippocampus in the freely behaving animal. *Results:* During, non-rapid-eye-movement (non-REM) sleep, optogenetic activation of hippocampus-projecting glutamatergic neurons led to strong inhibition of SWR activity. Online detection of SWR followed by activation of the glutamatergic neurons led to reduction in length of the SWR. Control experiments in mice receiving a viral vector without an opsin showed no effect of light delivery in the median raphe on SWR activity. *Conclusion:* We reveal a powerful inhibitory control of SWR through median raphe glutamatergic neurons, suggesting a strong impact of this pathway on memory consolidation.

HIGHER COGNITION IN CROWS AND MONKEYS SHARES A NEURONAL FOUNDATION

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Lukas Hahn[1], Dmitry Balakhonov[1], Erica Fongaro[1], Mikael Lundqvist[2], Andreas Nieder[3], Jonas Rose[1]
[1]Ruhr University Bochum, Psychology Neural Basis Of Learning, Bochum, Germany, [2]Karolinska Institute, Department Of Clinical Neuroscience, Stockholm, Sweden, [3]University of Tuebingen, Animal Physiology-institute Of Neurobiology, Tuebingen, Germany

The mammalian neocortex produces coordinated neuronal dynamics that result in distinct local field potentials (LFP). Models of higher cognition often implicitly assume a layered neocortical organization. Higher associative regions of bird brains do not have cortical layering, yet these regions exhibit neuronal single-cell correlates of higher cognition that are very similar to those found in mammals.
We investigated the activity of single neurons, neuronal populations, and of LFP in the avian equivalent of prefrontal cortex, while crows performed a highly controlled and cognitively demanding working memory task, adapted from monkeys.
We found that neuronal encoding and maintenance of information were affected by item load, in a way that is virtually identical to results obtained from monkey prefrontal cortex. Further, the neuronal population of crows showed divisive normalization, a computational mechanism also observed in macaque monkeys. Moreover, signatures of LFP in a narrow gamma (30-59 Hz) and the beta frequency bands (13-19 Hz) contained information about the location of the target items on the screen and were modulated by working memory load. These LFP dynamics also included bursts in beta and gamma frequencies, similar to those observed in monkeys.
Our results demonstrate that computational principles underlying higher cognition have evolved convergently, originating from different neural organizations in birds and mammals. Furthermore, similar neural oscillations support the notion that oscillations are a key component of computations underlying cognition. Therefore, our ‘bird’s eye view’ on higher cognition lends support to many modern cognitive theories that so far are entirely based on mammalian data.

Working memory capacity of crows and monkeys arises from similar neuronal computations.
Complex cognition relies on flexible working memory, which is severely limited in its capacity. The neuronal computations underlying these capacity limits have been extensively studied in humans and in monkeys, resulting in competing theoretical models. We probed the working memory capacity of crows () in a change detection task, developed for monkeys (), while we performed extracellular recordings of the prefrontal-like area nidopallium caudolaterale. We found that neuronal encoding and maintenance of information were affected by item load, in a way that is virtually identical to results obtained from monkey prefrontal cortex. Contemporary neurophysiological models of working memory employ divisive normalization as an important mechanism that may result in the capacity limitation. As these models are usually conceptualized and tested in an exclusively mammalian context, it remains unclear if they fully capture a general concept of working memory or if they are restricted to the mammalian neocortex. Here, we report that carrion crows and macaque monkeys share divisive normalization as a neuronal computation that is in line with mammalian models. This indicates that computational models of working memory developed in the mammalian cortex can also apply to non-cortical associative brain regions of birds.

Working Memory as an Indicator for Comparative Cognition - Detecting Qualitative and Quantitative Differences.
Working memory (WM), the representation of information held accessible for manipulation over time, is an essential component of all higher cognitive abilities. It allows for complex behaviors that go beyond simple stimulus-response associations and inflexible behavioral patterns. WM capacity determines how many different pieces of information (items) can be used for these cognitive processes, and in humans, it correlates with fluid intelligence. As such, WM might be a useful tool for comparison of cognition across species. WM can be tested using comparatively simple behavioral protocols, based on operant conditioning, in a multitude of different species. Species-specific contextual variables that influence an animal's performance on a non-cognitive level are controlled by adapting the WM paradigm. The neuronal mechanisms by which WM

emerges in the brain, as sustained neuronal activity, are comparable between the different species studied (mammals and birds), as are the areas of the brain in which WM activity can be measured. Thus WM is comparable between vastly different species within their respective niches, accounting for specific contextual variables and unique adaptations. By approaching the question of "general cognitive abilities" or "intelligence" within the animal kingdom from the perspective of WM, the complexity of the core question at hand is reduced to a fundamental memory system required to allow for complex cognitive abilities. This article argues that measuring WM can be a suitable addition to the toolkit of comparative cognition. By measuring WM on a behavioral level and going beyond behavior to the underlying physiological processes, qualitative and quantitative differences in cognition between different animal species can be identified, free of contextual restraints.

NEURAL OSCILLATIONS IN STRIATUM-HIPPOCAMPUS-AMYGDALA NETWORK DURING A DOUBLE PAVLOVIAN CONDITIONING IN RATS

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Lisa Saleille[1], Lucille Tallot[1], Bruno Bozon[2], Sylvia Wirth[3], Valérie Doyère[1]
[1]Paris-Saclay Institute of Neurosciences, Cognitive & Network Neuroscience, Saclay, France, [2]Integrative Neuroscience and Cognition Center, Umr 8002, Paris, France, [3]ISC Marc Jeannerod, UMR5229, Cnrs, Bron, France

Pavlovian conditioning pairing a conditioned stimulus (CS) with an unconditioned stimulus (US) leads to a conditioned response. With training, a temporal pattern emerges, reflecting a timed expectancy of the US arrival. The literature suggests an anticipated expectancy (peak time) with an aversive US, but a better accuracy with an appetitive US. Different brain structures have been highlighted to be involved in temporal behavior. The difference in temporal response between appetitive and aversive conditions raises the question of whether the implication of these structures may differ between conditions. In the present study, we compared the temporal response of rats submitted to both appetitive and aversive Pavlovian conditioning, and we explored the implication of the striatum-hippocampus-amygdala network in this response through local field potentials (LFP) recording. Rats were trained to a double Pavlovian conditioning (sound1-shock and sound2-chocolate), with the US moment at 20 seconds in both conditions. After training, we recorded LFP in three structures (dorsal striatum, hippocampus, and basolateral amygdala) during unreinforced probe trials. Time-frequency analyses highlighted the engagement of the striatum and the hippocampus in both conditions around the moment of the expected reinforcement, but with opposite modulations in the power spectrum density of oscillatory activity at 8Hz. Concerning the engagement of the amygdala, the aversive, but not appetitive, CS triggered onset-evoked modulations. Whether the differential modulations reflect different behavior/motor-related correlates and/or some competition in neuronal mechanism between appetitive and aversive conditions is an open question to be addressed in future studies. SHIFT OF PREFERRED THETA PHASE OF SLOW GAMMA IN HIPPOCAMPAL CA1 IS DEPENDENT ON THE LEARNING PHASE

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Laura Dolon Vera[1,2], Abdelrahman Rayan[1,2], Jose Donoso[3], Marta Méndez-Couz[1], Sen Cheng[3], Denise Manahan-Vaughan[1]
[1]RUB, Medical Faculty, Department Of Neurophysiology, Bochum, Germany, [2]International Graduate School of Neuroscience, Department Of Neurophysiology, Bochum, Germany, [3]Ruhr-Universität Bochum, Faculty Of Computer Science, Institute For Neural Computation, Bochum, Germany

Aims Oscillatory brain activity reflects brain states associated with learning and memory. In the hippocampus, slow gamma (25-55 Hz) and fast gamma (60-100 Hz) oscillations are related to the encoding and retrieval of memories, respectively. Theta oscillations (4-12 Hz) are associated with information encoding. Interestingly, slow and fast gamma appear to be nested within different theta phases, and therefore, associated with its cycles. Although such interactions are likely to be related to mnemonic functions, the relationship between theta phase of gamma oscillations and memory demands remains unclear. **Methods** We recorded from the hippocampal CA1region while animals were learning an appetitive task in a T-maze over a three day period. We assessed the theta-phase preference of gamma oscillations in the starting zone, and the junction zone of the maze i.e. maze location where animals must choose a right or left turn. **Results** We found a ~180 degree shift in theta-phase preference of slow gamma when animals learned the task and evolved their performance from novice to skilled. This phase-shift occurred in the starting zone and not in the junction zone, suggesting that either a recall or a decision process took place at the starting zone. **Conclusions** Our findings support the idea of a double role of slow gamma oscillations in encoding and retrieval of memories which is dependent on the theta-phase at which it occurs. **Acknowledgements** This work was supported by the German Research Foundation (Deutsche Forschungsgemeinschaft, DFG) to D.M.-V. and S.C (SFB 1280/A04 & F01, project number: 316803389).

MMP-9 INHIBITION REDUCES SHARP WAVE RIPPLE ABUNDANCE AND WORKING MEMORY IN ZEBRAFISH

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Ismary Blanco, Katherine Conant, Samantha Deasy
Georgetown University, • department Of Neuroscience, Washington, United States of America

Major depressive disorder (MDD) affects over 300 million people worldwide. Currently 30-50% of patients are treatment resistant necessitating novel therapeutic targets. Previously, our lab showed that the antidepressant Venlafaxine rescues working memory in a stress mouse model combined with increased gamma power and sharp wave ripple (SWR) abundance, which are the neural correlates of learning and memory. The increase in gamma power and SWRs were dependent on Matrix Metalloproteinase-9 (MMP-9), altered in many psychiatric disorders including MDD, suggesting MMP-9 modulation as a novel mechanism for treating MDD. To investigate how modulation of MMP-9 impairs learning and memory, my research uses varied cellular and molecular techniques to answer the question: How does MMP-9 inhibition impair learning and memory in the zebrafish model? Behaviorally, we have corroborated our hypothesis that MMP-9 inhibition impairs working memory. At the cellular level MMP-9 inhibition changes the excitation to inhibition (E/I) balance in the brain as evidenced by a decrease in SWR abundance. Molecularly, the change in E/I can be partially explained by a decrease in GluA4 and Kv3.1 receptors, both of which are predominantly expressed by Parvalbumin positive (PV) neurons – a neuronal population critical for both gamma oscillations and SWR events. Though future studies will examine MMP-9 associated changes in pyramidal neurons, molecular changes in PV neurons could contribute to impaired gamma oscillations and working memory in this model organism. The implications of this research lie in the potential of MMP-9 to directly modulate E/I balance and learning and memory in zebrafish.

Cerebral ischemia induces the aggregation of proteins linked to neurodegenerative diseases.
Protein aggregation critically affects cell viability in neurodegenerative diseases, but whether this also occurs in ischemic brain injury remains elusive. Prior studies report the post-ischemic aggregation of ubiquitin, small ubiquitin-related modifier (SUMO) and ribosomes, however whether other proteins are also affected is unknown. Here we employed a proteomic approach to identify the insoluble, aggregated proteome after cerebral ischemia. Mice underwent transient middle cerebral artery occlusion or sham-surgery. After 1-hour reperfusion, prior to apparent brain injury, mice were sacrificed and detergent-insoluble proteins were obtained and identified by nanoLC-MS/MS. Naturally existing insoluble proteins were determined in sham controls and aggregated proteins after cerebral ischemia/reperfusion were identified. Selected aggregated proteins found by proteomics were biochemically verified and aggregation propensities were studied during ischemia with or without reperfusion. We found that ischemia/reperfusion induces the aggregation of RNA-binding and heat-shock proteins, ubiquitin, SUMO and other proteins involved in cell signalling. RNA-binding proteins constitute the largest group of aggregating proteins in ischemia. These include TDP43, FUS, hnRNPA1, PSF/SFPQ and p54/NONO, all of which have been linked to neurodegeneration associated with amyotrophic lateral sclerosis and frontotemporal dementia. The aggregation of neurodegeneration-related disease proteins in cerebral ischemia unveils a previously unappreciated molecular overlap between neurodegenerative diseases and ischemic stroke.

PULVINAR INACTIVATION INCREASES THE GAMMA BAND CONTRAST RESPONSE IN AREA 21A.

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Lamyae Ikan[1], Nelson Cortes[2], Christian Casanova[2]
[1]University of Montreal, Ecole D'optométrie, Montreal, Canada, [2]University of Montreal, École D'optométrie, Montreal, Canada

A recent study from our group has described the effect of pulvinar inactivation on the contrast response function (CRF) of neurons in areas 17 and 21a of the cat visual cortex (de Souza et al., 2019). It revealed that pulvinar signals modulate the activity of area 17 neurons, while modulatory and driver influences are observed in area 21a. These findings were based on the linear change of the CRF position (driver effect) and nonlinear variation in the CRF dynamic range (Rmax; modulatory effect). To study whether oscillatory cortical signals depend on the activity of the pulvinar, we investigated the contrast response of the gamma band in areas 17 and 21a during thalamic inactivation. Extracellular responses to full-field gratings of varying contrast were recorded in both cortical areas in anesthetized cats using linear probes before, during, and after the GABA inactivation of the pulvinar. Local field potentials (LFPs), from low-pass filtering of raw recordings, were analyzed with Wavelet to assess oscillatory gamma waves. The gamma-band contrast response was different across areas and cortical layers during inactivation. In area 17, the inactivation showed no significant changes across cortical layers. In area 21a, the inactivation yielded an increase in Rmax in most layers but mainly in layer IV. On average, for layer IV in area 21a, the coefficient of variation for Rmax increased by ~25%. These findings indicate that pulvinar signals modulate gamma rhythms in area 21a but not in the primary visual cortex. *Funding* : CIHR to CC

Sharp wave-ripples (SWRs) are high-frequency oscillatory events involved in the dialogue between the hippocampus and cortical regions to promote memory consolidation during sleep. Many studies aiming to investigate the role of SWRs in mnemonic processes employ closed-loop strategies to detect those events and manipulate different brain areas in real-time. However, the codes and schematics necessary to replicate the detection system are not always available, which contributes negatively to the reproducibility of experiments among different research groups. Furthermore, information about the performance is not usually reported. We present the development and validation of an open-source, real-time SWR detection plugin integrated to the Open Ephys acquisition system. It contains a built-in movement detector based on accelerometer or electromyogram data that prevents false ripple events (due to chewing, grooming or moving, for instance) from triggering the stimulation/manipulation device. To determine the accuracy of the detection algorithm we first carried out simulations in Matlab with synthetic and real ripple recordings. Using a specific combination of detection parameters, we obtained 97.9% of true positive rate and 2.29 false positives per minute on the real data. Next, an Open Ephys plugin based on the same detection algorithm was developed and a closed-loop system was set up to evaluate the round trip (ripple onset-to-stimulation) latency over synthetic data. The lowest latencies obtained were around 35 ms. Besides contributing to increased reproducibility, we anticipate that the developed SWR detector plugin will be useful for a number of closed-loop applications in the field of Systems Neuroscience.

MODULATION OF SHARP-WAVE RIPPLES BY DIFFERENT COGNITIVE DEMANDS

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Juan P. Quintanilla, Enrique R. Sebastian, Liset Menendez De La Prida
CSIC, Instituto Cajal, Madrid, Spain

AIMS: Hippocampal activity is crucial for navigation and memory abilities. However, understanding how hippocampal representations are influenced by different cognitive demands remains challenging. One example is sharp-wave ripple (SWR) events underlying memory retrieval and consolidation. Yet, whether changes in SWR follow specific trends in response to learning, novelty and memory remains unclear. METHODS: We recorded freely moving mice exposed to different types of tasks using either tetrodes or multi-site silicon probes. They explored familiar or novel open fields, and learnt running for water reward in an automatized maze that allows implementation of different navigational strategies. SWR were recorded before, during and after these several tasks, both in awake and sleep condition. SWR features were studied using standard spectral analysis and unsupervised classification algorithms. RESULTS: We identify specific trends of SWR features influenced by novelty, habituation and learning of different tasks. Novelty and learning had a significant impact in modulating SWR frequency, amplitude and spectral entropy during wake conditions. These changes however tended to habituate upon repeated expositions to the task. After the first learning session of a linear maze, SWR dynamic was strongly influenced by sleep and exhibited consistent segregation of frequency but neither of amplitude nor entropy. Unsupervised evaluation of SWR topological features suggests specific modulatory trends depending on task demands. CONCLUSION: SWR dynamics evolve distinctly under the influences of different cognitive demands.

Aims: Migraine is a complex disorder characterized by altered responsivity and abnormal processing of visual information. How the known synaptic alterations characterizing migraine reverberate into these network-level dysfunctions is however still unclear. **Methods**: We investigated the primary visual cortex (V1) extracellular potentials of wild-type (WT) and of a genetic rodent model of type-1-familial-hemiplegic-migraine (FHM1). **Results:** We found reduced multi-unit-activity in FHM1 mice in response to high visual contrasts. The local-field-potential γ narrow band (NB, peaking at ~60 Hz) induced by low contrasts was similar in WT and in FHM1 mice. High contrasts elicited activity in the low γ ([20-55] Hz) range for WT mice as previously observed. We observed instead that such activity induced by high visual contrasts was shifted towards higher frequencies (high γ, [70-90] Hz) in FHM1 mice. However, visual information transmission was preserved.
We investigated then with a computational model the relationship between migraine-driven synaptic alterations and the experimentally observed γ-band frequency shift. Embedding the pathological synaptic alterations characterizing the model in a spiking network model of mice V1, we replicated the aforementioned experimental results. Specifically, we found the γ band frequency shift to be linked to the increase of glutamatergic cortico-cortical signaling in FHM1. Interestingly, FHM1 alterations of thalamocortical afferents compensated for the increase in cortical recurrent excitation leading to an overall decrease of the excitation/inhibition ratio. **Conclusions:** These results shed light on the etiology of migraine-associated hypersensitivity to visual stimuli and might help properly tackling V1 circuitry to prevent this dysfunction.

[1]Instituto Cajal - CSIC, Systems Neuroscience, Madrid, Spain, [2]Grupo de Neurocomputación Biológica, Uam, Madrid, Spain

AIMS: Sharp-wave ripples (SWR) are high frequency events recorded in the local field potential (LFP) of the hippocampus of rodents and humans. During SWR, the sequential firing of ensembles of neurons acts to reactivate memory traces of previously encoded experience. SWR-related interventions can influence hippocampal-dependent cognitive function, making their real-time detection crucial to understand underlying mechanisms. Moreover, with the advent of ultra-dense recordings the need to automatic detection is pressing. METHODS: Here, we introduce a 1D convolutional neural network (CNN) operating over high-density LFP recordings to detect hippocampal SWR both offline and on-line. The adapted architecture included seven convolutional deep layers composed of different filters to process 8-channel LFP inputs in increasing hierarchical complexity and one output layer delivering the probability of an occurring SWR. RESULTS: We report offline performance on several types of recordings (e.g. linear arrays, high-density probes, ultradense Neuropixels) as well as on open databases that were not used for training. By saturating the operation of different filters, we examine and interpret their optimal behaviour associated to the ground truth versus a random selection. We then use dimensionality reduction techniques to visualize how the network evolve across learning. Finally, we show how by building a plug-in for a widely used open system such Open Ephys, our method detects SWRs in real time. CONCLUSIONS: We conclude this approach can be used as a discovery tool for better understanding the dynamics of SWR.

Multimodal determinants of phase-locked dynamics across deep-superficial hippocampal sublayers during theta oscillations.
Theta oscillations play a major role in temporarily defining the hippocampal rate code by translating behavioral sequences into neuronal representations. However, mechanisms constraining phase timing and cell-type-specific phase preference are unknown. Here, we employ computational models tuned with evolutionary algorithms to evaluate phase preference of individual CA1 pyramidal cells recorded in mice and rats not engaged in any particular memory task. We applied unbiased and hypothesis-free approaches to identify effects of intrinsic and synaptic factors, as well as cell morphology, in determining phase preference. We found that perisomatic inhibition delivered by complementary populations of basket cells interacts with input pathways to shape phase-locked specificity of deep and superficial pyramidal cells. Somatodendritic integration of fluctuating glutamatergic inputs defined cycle-by-cycle by unsupervised methods demonstrated that firing selection is tuneable across sublayers. Our data identify different mechanisms of phase-locking selectivity that are instrumental for flexible dynamical representations of theta sequences.

PROGRESSIVE ELECTROPHYSIOLOGICAL CHANGES IN A MOUSE PRION MODEL OF TERMINAL NEURODEGENERATIVE DISEASE

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Jessica Bowden[1], John Riddell[2], Keith Phillips[3], Andrew Tobin[1], Sophie Bradley[1]
[1]University of Glasgow, Centre For Translational Pharmacology, Glasgow, United Kingdom, [2]University of Glasgow, Centre For Neuroscience, Glasgow, United Kingdom, [3]Eli Lilly and Company, Neuroscience Next Generation Therapeutics, Cambridge, United States of America

Injection of prion brain homogenate into mice induces memory deficits, progressive neuronal loss and terminal disease. Pharmacological interventions can extend survival and preserve species-specific behaviour, but it is unclear whether neural activity is preserved. Here, we define oscillatory changes in the murine prion model in order to inform future studies of the effects of interventions on neural activity. Prion and control-inoculated mice implanted with seven surface electrodes underwent weekly wireless recording from 4 weeks post-inoculation. Recordings were made until prion mice exhibited clinical signs of disease, 9–12 weeks post-inoculation. At this point, mice were humanely killed and brains retained for histological analysis. Decibel power spectra were generated from recordings using a 2.5 s sliding window with 50% overlap. Peak theta frequency and area under the curve measures were extracted (Figure 1). Effects of prion and week post-inoculation were determined using mixed effects analyses. Prion mice exhibited a progressive reduction in peak theta frequency, which differed from control mice at 8- and 9-weeks post-inoculation (Figure 1). Prion mice with peak theta frequency >7.0 Hz at 9 weeks post-inoculation survived 10–25 days longer than mice <6.5 Hz. Area under the curve measures were similar between groups except for delta power, which showed a week by inoculation interaction. The murine prion model exhibits a slowing of theta oscillatory activity and altered delta power, which are common to human neurodegenerative diseases including Alzheimer's disease. This validates the use of the prion model to investigate potential disease modifying effects of interventions aimed at treating Alzheimer's disease and related

dementias.

Figure 1. Reduced peak theta frequency in prion mice at 9 weeks post-inoculation.

ALTERED MARKERS OF NEURAL OSCILLATORY ACTIVITY ARE LINKED TO IMPAIRED TACTILE TEMPORAL PERCEPTION IN HEPATIC ENCEPHALOPATHY

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Thomas Baumgarten[1], Moritz Lazar[1], Nur-Deniz Fuellenbach[2], Markus Joerdens[2], Dieter Haeussinger[2], Alfons Schnitzler[1], Joachim Lange[1]

The perceptual separation of tactile stimuli presented in quick succession into temporally distinct sensations is linked to low-frequency prestimulus neural oscillations. Hepatic encephalopathy (HE) is a clinical complication in patients with liver cirrhosis, featuring prominent visual and tactile perceptual deficits. Here, we investigated if the relationship between tactile temporal resolution and low-frequency prestimulus neural oscillations is likewise present in HE patients demonstrating tactile perceptual impairments. 17 controls (12 male, 63 ± 2.8 y) and 17 HE patients (13 male, 59 ± 2.3 y) performed a tactile temporal discrimination task. Two suprathreshold electrical stimuli with varying stimulus-onset-asynchrony (SOA; 0-400 ms) were presented to the left index finger. Participants reported if they perceived the stimulation as one single or two temporally separate sensations, yielding an individual measure of tactile temporal resolution. Whole-head neuromagnetic activity recorded during the task was used to compute source-level peak frequency estimates in the low frequency range (5-30 Hz), which were compared across groups and correlated with metrics of tactile temporal resolution. HE patients perceived a single stimulus more often than controls for SOAs between 125-400 ms, indicating impaired tactile temporal resolution. Patients demonstrated lower alpha- and beta- band peak frequencies in posterior and frontal cortex areas, respectively. Across groups, peak frequencies were negatively correlated with metrics of individual tactile temporal resolution. Perceptual impairments in HE extend to the tactile domain. Established oscillatory parameters known to underlie temporal perception in healthy subjects are decreased in HE patients and remain connected to metrics of impaired tactile temporal sampling.

Neural integration underlying naturalistic prediction flexibly adapts to varying sensory input rate.
Prediction of future sensory input based on past sensory information is essential for organisms to effectively adapt their behavior in dynamic environments. Humans successfully predict future stimuli in various natural settings. Yet, it remains elusive how the brain achieves effective prediction despite enormous variations in sensory input rate, which directly affect how fast sensory information can accumulate. We presented participants with acoustic sequences capturing temporal statistical regularities prevalent in nature and investigated neural mechanisms underlying predictive computation using MEG. By parametrically manipulating sequence presentation speed, we tested two hypotheses: neural prediction relies on integrating past sensory information over fixed time periods or fixed amounts of information. We demonstrate that across halved and doubled presentation speeds, predictive information in neural activity stems from integration over fixed amounts of information. Our findings reveal the neural mechanisms enabling humans to robustly predict dynamic stimuli in natural environments despite large sensory input rate variations.

Impaired Tactile Temporal Discrimination in Patients With Hepatic Encephalopathy.
The sensory system constantly receives stimuli from the external world. To discriminate two stimuli correctly as two temporally distinct events, the temporal distance or stimulus onset asynchrony (SOA) between the two stimuli has to exceed a specific threshold. If the SOA between two stimuli is shorter than this specific threshold, the two stimuli will be perceptually fused and perceived as one single stimulus. Patients with hepatic encephalopathy (HE) are known to show manifold perceptual impairments, including slowed visual temporal discrimination abilities as measured by the critical flicker frequency (CFF). Here, we hypothesized that HE patients are also impaired in their tactile temporal discrimination abilities and, thus, require a longer SOA between two tactile stimuli to perceive the stimuli as two temporally distinct events. To test this hypothesis, patients with varying grades of HE and age-matched healthy individuals performed a tactile temporal discrimination task. All participants received two tactile stimuli with varying SOA applied to their left index finger and reported how many distinct stimuli they perceived ("1" vs. "2"). HE patients needed a significantly longer SOA (138.0 ± 11.3 ms) between two tactile stimuli to perceive the stimuli as two temporally distinct events than healthy controls (78.6 ± 13.1 ms; < 0.01). In addition, we found that the temporal discrimination ability in the tactile modality correlated positively with the temporal discrimination ability in the visual domain across all participants (i.e., negative correlation between tactile SOA and visual CFF: = -0.37, = 0.033). Our findings provide evidence that temporal tactile perception is substantially impaired in HE patients. In addition, the results suggest that tactile and visual discrimination abilities are affected in HE in parallel. This finding might argue for a common underlying pathophysiological mechanism. We argue that the known global slowing of neuronal oscillations in HE might represent such a common mechanism.

Connecting occipital alpha band peak frequency, visual temporal resolution, and occipital GABA levels in healthy participants and hepatic encephalopathy patients.
Recent studies have proposed a connection between the individual alpha band peak frequency and the temporal resolution of visual perception in healthy human participants. This connection rests on animal studies describing oscillations in the alpha band as a mode of phasic thalamocortical information transfer for low-level visual stimuli, which critically relies on GABAergic interneurons. Here, we investigated the interplay of these parameters by measuring occipital alpha band peak frequency by means of magnetoencephalography, visual temporal resolution by means of behavioral testing, and occipital GABA levels by means of magnetic resonance spectroscopy. Importantly, we investigated a sample of healthy participants and patients with varying grades of hepatic encephalopathy, which are known to exhibit decreases in the investigated parameters, thus providing an increased parameter space. We found that occipital alpha band peak frequency and visual temporal resolution were positively correlated, i.e., higher occipital alpha band peak frequencies were on average related to a higher temporal resolution. Likewise, occipital alpha band peak frequency correlated positively with occipital GABA levels. However, correlations were significant only when both healthy participants and patients were included in the analysis, thereby indicating a connection of the measures on group level (instead of the individual level). These findings provide new insights into neurophysiological and neurochemical underpinnings of visual perception.

Beyond the Peak - Tactile Temporal Discrimination Does Not Correlate with Individual Peak Frequencies in Somatosensory Cortex.
The human sensory systems constantly receive input from different stimuli. Whether these stimuli are integrated into a coherent percept or segregated and perceived as separate events, is critically determined by the temporal distance of the stimuli. This temporal distance has prompted the concept of temporal integration windows or perceptual cycles. Although this concept has gained considerable support, the neuronal correlates are still discussed. Studies suggested that neuronal oscillations might provide a neuronal basis for such perceptual cycles, i.e., the cycle lengths of alpha oscillations in visual cortex and beta oscillations in somatosensory cortex might determine the length of perceptual cycles. Specifically, recent studies reported that the peak frequency (the frequency with the highest spectral power) of alpha oscillations in visual cortex correlates with subjects' ability to discriminate two visual stimuli. In the present study, we investigated whether peak frequencies in somatosensory cortex might serve as the correlate of perceptual cycles in tactile discrimination. Despite several different approaches, we were unable to find a significant correlation between individual peak frequencies in the alpha- and beta-band and individual discrimination abilities. In addition, analysis of Bayes factor provided evidence that peak frequencies and discrimination thresholds are unrelated. The results suggest that perceptual cycles in the somatosensory domain are not necessarily to be found in the peak frequency, but in other frequencies. We argue that studies based solely on analysis of peak frequencies might thus miss relevant information.

Subliminal stimuli modulate somatosensory perception rhythmically and provide evidence for discrete perception.
Despite being experienced as continuous, there is an ongoing debate if perception is an intrinsically discrete process, with incoming sensory information treated as a succession of single perceptual cycles. Here, we provide causal evidence that somatosensory perception is composed of discrete perceptual cycles. We used in humans an electrotactile temporal discrimination task preceded by a subliminal (i.e., below perceptual threshold) stimulus. Although not consciously perceived, subliminal stimuli are known to elicit neuronal activity in early sensory areas and modulate the phase of ongoing neuronal oscillations. We hypothesized that the subliminal stimulus indirectly, but systematically modulates the ongoing oscillatory phase in S1, thereby rhythmically shaping perception. The present results confirm that, without being consciously perceived, the subliminal stimulus critically influenced perception in the discrimination task. Importantly, perception was modulated rhythmically, in cycles corresponding to the beta-band (13-18 Hz). This can be compellingly explained by a model of discrete perceptual cycles.

Beta oscillations define discrete perceptual cycles in the somatosensory domain.
Whether seeing a movie, listening to a song, or feeling a breeze on the skin, we coherently experience these stimuli as continuous, seamless percepts. However, there are rare perceptual phenomena that argue against continuous perception but, instead, suggest discrete processing of sensory input. Empirical evidence supporting such a discrete mechanism, however, remains scarce and comes entirely from the visual domain. Here, we demonstrate compelling evidence for discrete perceptual sampling in the somatosensory domain. Using magnetoencephalography (MEG) and a tactile temporal discrimination task in humans, we find that oscillatory alpha- and low beta-band (8-20 Hz) cycles in primary somatosensory cortex represent neurophysiological correlates of discrete perceptual cycles. Our results agree with several theoretical concepts of discrete perceptual sampling and empirical evidence of perceptual cycles in the visual domain. Critically, these results show that discrete perceptual cycles are not domain-specific, and thus restricted to the visual domain, but extend to the somatosensory domain.

Prestimulus Alpha Power Influences Tactile Temporal Perceptual Discrimination and Confidence in Decisions.
Recent studies have demonstrated that prestimulus alpha-band activity substantially influences perception of near-threshold stimuli. Here, we studied the influence of prestimulus alpha power fluctuations on temporal perceptual discrimination of suprathreshold tactile stimuli and subjects' confidence regarding their perceptual decisions. We investigated how prestimulus alpha-band power influences poststimulus decision-making variables. We presented electrical stimuli with different stimulus onset asynchronies (SOAs) to human subjects, and determined the SOA for which temporal perceptual discrimination varied on a trial-by-trial basis between perceiving 1 or 2 stimuli, prior to recording brain activity with magnetoencephalography. We found that low prestimulus alpha power in contralateral somatosensory and occipital areas predicts the veridical temporal perceptual discrimination of 2 stimuli. Additionally, prestimulus alpha power was negatively correlated with confidence ratings in correctly perceived trials, but positively correlated for incorrectly perceived trials. Finally, poststimulus event-related fields (ERFs) were modulated by prestimulus alpha power and reflect the result of a decisional process rather than physical stimulus parameters around ~150 ms. These findings provide new insights into the link between spontaneous prestimulus alpha power fluctuations, temporal perceptual discrimination, decision making, and decisional confidence. The results suggest that prestimulus alpha power modulates perception and decisions on a continuous scale, as reflected in confidence ratings.

NEURAL NETWORK DYNAMICS OF ADULT MICE IN AFFILIATIVE SOCIAL CONTEXTS

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Alok Nath Mohapatra, Shai Netser, Shlomo Wagner
University of Haifa, Sagol Department Of Neurobiology, Haifa, Israel

Social interactions between mammalian conspecifics involve the dynamic coupling of multiple brain regions to modulate and control behavioral decisions (Chen & Hong, 2018). Oscillatory neural activity in the theta (4-12 Hz) and gamma (30-80 Hz) bands, coordinates communication within neuronal ensembles dispersed over multiple brain regions (Buzsáki & Draguhn, 2004). These coordinated processes underlie the demanding cognitive function of social behavior (Tendler & Wagner, 2015; Uhlhaas & Singer, 2006). Further, modified theta (Geschwind & Levitt, 2007; Rippon et al., 2007; Wass, 2011) and gamma rhythms (Lazaro et al., 2019) have been reported in autism spectrum disorders. We recorded extracellular neural activity from 19 brain regions of behaving CD-1 male mice in two social contexts to reveal the neural dynamics governing affiliative social interactions. The mice displayed similar social preferences but variable theta power between the contexts. Further, the various brain regions displayed altered coherence of theta rhythmicity during the investigation of the same stimuli while encountering them in distinct contexts, indicating the role of theta coherence in the neural representation of social context. Overall, our results suggest that a specific sub-network of brain regions exhibits synchronous activity in a given context.

Altering Opioid Neuromodulation in the Songbird Basal Ganglia Modulates Vocalizations.
Although the interplay between endogenous opioids and dopamine (DA) in the basal ganglia (BG) is known to underlie diverse motor functions, few studies exist on their role in modulating speech and vocalization. Vocal impairment is a common symptom of Parkinson's disease (PD), wherein DA depletion affects striosomes rich in μ-opioid receptors (μ-ORs). Symptoms of opioid addiction also include deficiencies in verbal functions and speech. To understand the interplay between the opioid system and BG in vocalization, we used adult male songbirds wherein high levels of μ-ORs are expressed in Area X, a BG region which is part of a circuit similar to the mammalian thalamocortical-basal ganglia loop. Changes in DA, glutamate and GABA levels were analyzed during the infusion of different doses of the μ-OR antagonist naloxone (50 and 100 ng/ml) specifically in Area X. Blocking μ-ORs in Area X with 100 ng/ml naloxone led to increased levels of DA in this region without altering the number of songs directed toward females (FD). Interestingly, this manipulation also led to changes in the spectro-temporal properties of FD songs, suggesting that altered opioid modulation in the thalamocortical-basal ganglia circuit can affect vocalization. Our study suggests that songbirds are excellent model systems to explore how the interplay between μ-ORs and DA modulation in the BG affects speech/vocalization.

A community-based transcriptomics classification and nomenclature of neocortical cell types.
To understand the function of cortical circuits, it is necessary to catalog their cellular diversity. Past attempts to do so using anatomical, physiological or molecular features of cortical cells have not resulted in a unified taxonomy of neuronal or glial cell types, partly due to limited data. Single-cell transcriptomics is enabling, for the first time, systematic high-throughput measurements of cortical cells and generation of datasets that hold the promise of being complete, accurate and permanent. Statistical analyses of these data reveal clusters that often correspond to cell types previously defined by morphological or physiological criteria and that appear conserved across cortical areas and species. To capitalize on these new methods, we

propose the adoption of a transcriptome-based taxonomy of cell types for mammalian neocortex. This classification should be hierarchical and use a standardized nomenclature. It should be based on a probabilistic definition of a cell type and incorporate data from different approaches, developmental stages and species. A community-based classification and data aggregation model, such as a knowledge graph, could provide a common foundation for the study of cortical circuits. This community-based classification, nomenclature and data aggregation could serve as an example for cell type atlases in other parts of the body.

Contusive spinal cord injury up regulates mu-opioid receptor (mor) gene expression in the brain and down regulates its expression in the spinal cord: possible implications in spinal cord injury research.
Traumatic spinal cord injury (SCI) is one of the dreaded neurological conditions and finding a cure for it has been a hot area of research. Naloxone - a mu-opiate receptor (mor) antagonist was considered for SCI treatment based on its positive effects under shock conditions. In contrary to animal studies based reports about the potential benefits of naloxone in treating SCI, a large scale clinical trial [National Acute Spinal Cord Injury Study II (NASCIS II)] conducted in USA failed to witness any effectiveness. The inconsistency noticed was intriguing. Therefore, the objective of the present study was to re-examine the role of naloxone in treating SCI using a highly standardised Multicenter Animal Spinal Cord Injury Study (MASCIS) animal model of contusive SCI. Results indicated that naloxone produced negligible and insignificant neuroprotection. In an attempt to understand the cause for the failure, it was found that mu-opioid receptor (mor) gene expression was upregulated in the brain but was down regulated in the spinal cord after contusive SCI. Given that the beneficial effects of naloxone are through its action on the mor, the results indicate that unlike the brain, spinal cord might not be bracing to utilise the opiate system in the repair process. This could possibly explain the failure of naloxone treatment in NASCIS II. To conclude, opiate antagonists like naloxone may be neuroprotective for treating traumatic brain injuries, but not for traumatic/contusive spinal cord injuries.

Blocking Opioid Receptors in a Songbird Cortical Region Modulates the Acoustic Features and Levels of Female-Directed Singing.
The organization of the anterior forebrain pathway (AFP) of songbirds important for context-dependent singing is similar to that of cortical basal ganglia loops (CBG) in mammals, which underlie motor behaviors including vocalization. Since different components of the AFP express high levels of μ-opioid receptors (μ-ORs) as do CBG loops, songbirds act as model systems to study the role of opioid modulation on vocalization and the motivation to sing. The AFP in songbirds includes the cortical/pallial region LMAN (lateral magnocellular nucleus of the anterior nidopallium) which projects to Area X, a nucleus of the avian basal ganglia. In the present study, microdialysis was used to infuse different doses of the opioid antagonist naloxone in LMAN of adult male zebra finches. Whereas all doses of naloxone led to significant decreases in the number of FD (female-directed) songs, only 100 and 200 ng/ml of naloxone affected their acoustic properties. The decrease in FD song was not accompanied by changes in levels of attention toward females or those of neurotransmitters (dopamine, glutamate, and GABA) in LMAN. An earlier study had shown that similar manipulations in Area X did not lead to alterations in the number of FD songs but had significantly greater effects on their acoustic properties. Taken together, our results suggest that there are reciprocal effects of OR modulation on cortical and basal ganglia components of the AFP in songbirds.

Investigating Behavioral Responses to Mirrors and the Mark Test in Adult Male Zebra Finches and House Crows.
Earlier evidence suggests that besides humans, some species of mammals and birds demonstrate visual self-recognition, assessed by the controversial "mark" test. Whereas, there are high levels of inter-individual differences amongst a single species, some species such as macaques and pigeons which do not spontaneously demonstrate mirror self-recognition (MSR) can be trained to do so. We were surprised to discover that despite being widely used as a model system for avian research, the performance of zebra finches () on the mark test had not been studied earlier. Additionally, we studied the behavioral responses of another species of passerine songbirds (Indian house crows;) to a mirror and the MSR mark test. Although a small number of adult male zebra finches appeared to display heightened responses toward the mark while observing their reflections, we could not rule out the possibility that these were a part of general grooming rather than specific to the mark. Furthermore, none of the house crows demonstrated mark-directed behavior or increased self-exploratory behaviors when facing mirrors. Our study suggests that self-directed behaviors need to be tested more rigorously in adult male zebra finches while facing their reflections and these findings need to be replicated in a larger population, given the high degree of variability in mirror-directed behaviors.

EVOLUTION OF HIPPOCAMPAL AND NEOCORTICAL SLEEP OSCILLATIONS DURING GRADUAL LEARNING OF A Y-MAZE ALLOCENTRIC TASK IN MICE.

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Audrey Hay[1,2], Yuqi Li[1], Gaëlle Mailhos[1], Urtė Baublytė[1], Ole Paulsen[1]
[1]University of Cambridge, Department Of Physiology, Development, And Neuroscience, Cambridge, United Kingdom, [2]Centre Recherche en Neurosciences de Lyon, Umr5292, Bron, France

Learning to navigate in space toward a goal (escape plateforme, reward, etc) is a gradual process. Some behavioural tasks for mice are designed so that gradual learning spans over few days. Here, we hypothesise that during sleep in between training sessions, coordination of sleep oscillations evolve with the learning stages. We ask whether some sleep oscillation parameters could predict mice performance on the following training session. To do so, we use an allocentric Y-maze spatial navigation task in which mice have to use visual clues to navigate toward a reward. Mice were allowed to run 10 sessions a day and took 3-4 days to learn to find reliably the reward. After each training session, we recorded hippocampal and neocortical local field potentials during sleep for 1-2 hours. We observe in our preliminary data that hippocampal sharp wave ripple density increases throughout learning, while thalamocortical spindle density increases in the initial phases of learning but decreases after mice reach learning plateau. Thus spindle density might predict next day task performance.

The variability of cortical single unit responses to external stimuli is well investigated. However, variability of the collective activity of large ensembles of cortical neurons is not understood. During the slow wave sleep (SWS) or immobility, large blocks of cortical tissue show synchronous slow oscillations. Here we show that the amplitude and duration of the slow oscillations are highly variable. Further, a minimal mean-field, deterministic model, with only two free parameters, without any noise, can capture this in vivo dynamics. In fact, we were able to obtain a quantitative match between the model and about ten independent experimental measurements, such as the duration and amplitude of the individual cycles and their fluctuations from cycle to cycle. The quantitative, theory-experiment match was accurate across several sessions and rats. Although this was a minimal, mean field theory model, we were able to explain several spiking characteristics of individual neurons. This close match between theory and experiment is unprecedented. It allowed us to interrogate the model to determine the mechanisms of collective variability of neural ensemble. The model revealed that the cortical ensemble cycles between a more active states that is near a dynamical critical point and a less active states that is subcritical. These predictions too match in a quantitative fashion between theory and experiment. In sum, the collective dynamics of large cortical ensembles is highly variable and it rapidly fluctuates between critical and subcritical states. These features are the emergent phenomena of a simple deterministic network without any noise.

The essential role of hippocampo-cortical connections in temporal coordination of spindles and ripples.
The predominant activity of slow wave sleep is cortical slow oscillations (SOs), thalamic spindles and hippocampal sharp wave ripples. While the precise temporal nesting of these rhythms was shown to be essential for memory consolidation, the coordination mechanism is poorly understood. Here we develop a minimal hippocampo-cortico-thalamic network that can explain the mechanism underlying the SO-spindle-ripple coupling indicating of the succession of regional neuronal interactions. Further we verify the model predictions experimentally in naturally sleeping rodents showing our simple model provides a quantitative match to several experimental observations including the nesting of ripples in the spindle troughs and larger duration but lower amplitude of the ripples co-occurring with spindles or SOs compared to the isolated ripples. The model also predicts that the coupling of ripples to SOs and spindles monotonically enhances by increasing the strength of hippocampo-cortical connections while it is stronger at intermediate values of the cortico-hippocampal projections.

Spontaneous slow oscillation-slow spindle features predict induced overnight memory retention.
Synchronization of neural activity within local networks and between brain regions is a major contributor to rhythmic field potentials such as the EEG. On the other hand, dynamic changes in microstructure and activity are reflected in the EEG, for instance slow oscillation (SO) slope can reflect synaptic strength. SO-spindle coupling is a measure for neural communication. It was previously associated with memory consolidation, but also shown to reveal strong interindividual differences. In studies, weak electric current stimulation has modulated brain rhythms and memory retention. Here, we investigate whether SO-spindle coupling and SO slope during baseline sleep are associated with (predictive of) stimulation efficacy on retention performance.

The intimate relationship between coalescent generators in very premature human newborn brains: Quantifying the coupling of nested endogenous oscillations.
Temporal theta slow-wave activity (TTA-SW) in premature infants is a specific neurobiomarker of the early neurodevelopment of perisylvian networks observed as early as 24 weeks of gestational age (wGA). It is present at the turning point between non-sensory driven spontaneous networks and cortical network functioning. Despite its clinical importance, the underlying mechanisms responsible for this spontaneous nested activity and its functional role have not yet been determined. The coupling between neural oscillations at different timescales is a key feature of ongoing neural activity, the characteristics of which are determined by the network structure and dynamics. The underlying mechanisms of cross-frequency coupling (CFC) are associated with several putative functions in adults. In order to show that this generic mechanism is already in place early in the course of development, we analyzed electroencephalography recordings from sleeping preterm newborns (24-27 wGA). Employing cross-frequency phase-amplitude coupling analyses, we found that TTAs were orchestrated by the SWs defined by a precise temporal relationship. Notably, TTAs were synchronized to the SW trough, and were suppressed during the SW peak. Spontaneous endogenous TTA-SWs constitute one of the very early signatures of the developing temporal neural networks with key functions, such as language and communication. The presence of a fine-tuned relationship between the slow activity and the TTA in premature neonates emphasizes the complexity and relative maturity of the intimate mechanisms that shape the CFC, the disruption of which can have severe neurodevelopmental consequences.

Motivated forgetting increases the recall time of learnt items: Behavioral and event related potential evidence.
We investigated modulation of the recall time in a motivated forgetting (MF) paradigm and the neural manifestation of it through event related potential (ERP) analysis. We studied whether compared to failed attempts in suppression, partial success can potentiate control mechanisms and this might manifest, neurally as modulation of ERP components related to conscious recollection, and behaviorally as delayed recall of learnt items. We employed a modified version of the Think\No-Think paradigm with dominant number of No-Think words (cued to forget). We defined a forgetting index as FI = Final Recall Time-Initial Recall Time. The MF trials were separated into three conditions according to their corresponding FI; Forget, Delayed Recall, and Recall conditions. The findings revealed significant late ERP effects in terms of a late parietal positivity (LPP), modulated by the item condition, that appeared to reflect the consequence of conscious suppression on actual retrieval of stored memory. Over the same topographic location, FI was negatively correlated with the LPP amplitude, demonstrating the consequence of inhibition processing during MF in modulating the recall time. The negative correlation between LPP and FI provides evidence that increased recall time due to MF is also related to reduced activity, probably in the hippocampal-parietal network, corresponding to recollection of suppressed memories.

Opposite effect of motivated forgetting on sleep spindles during stage 2 and slow wave sleep.
Memories selectively benefit from sleep. In addition to the importance of the consolidation of relevant memories, the capacity to forget unwanted memories is also crucial. We investigated the effect of suppressing unwanted memories on electroencephalography activity of subsequent sleep using a motivated forgetting (MF) paradigm as compared with a control non-forgetting task. Subjects were randomly assigned to nap or no-nap groups. We used a modified version of the think/no-think paradigm with dominant number of no-think words cued to be forgotten and included only subjects capable of suppressing unwanted memories by performing an initial subject inclusion experiment. In both groups and conditions, the performance of the subjects in recalling the word pairs learned in the beginning of the day was evaluated in a final recall test. We found that both nap and no-nap groups recalled significantly less no-think words in the MF condition compared to the control condition. Moreover, for the nap group, in the MF compared to the control condition, spindle power and density increased during stage 2 (S2) whereas they decreased during slow wave sleep (SWS). Interestingly, recall performance of no-think words was negatively correlated with spindle power during S2 whereas it was positively correlated with spindle power during SWS. These results indicate that sleep spindles are sensitive to the previous MF experiences and suggest a differential role of sleep spindles during S2 and SWS in memory processing during sleep.

Slow spindles are associated with cortical high frequency activity.
Thalamocortical network shows self-sustained oscillations in a broad frequency range especially during slow wave sleep when cortical neurons show synchronized transitions between a quiescent down state and an active up state with beta and gamma oscillations. Inconsistent with previous models, thalamocortical spindles are separated into slow spindles (8_12 Hz) and fast spindles (13_17 Hz) with differential properties. We proposed that cortical high frequency (~ 25 Hz) activity during up states is the key ingredient for the generation of slow spindles. In fact, the nonlinear interaction between cortical high

frequency and thalamic oscillations at fast spindle frequency reproduces oscillations in the range of the difference between the two frequencies that lies into the range of slow spindle. The developed simple deterministic thalamocortical model is able to reproduce up and down states with stochastic high-frequency up-state activity as well as both fast and slow spindles. In agreement with the previous experimental observations, the fast and slow spindles are generated at opposing phases of the up state. To further confirm the causal relationship between slow spindles and cortical high frequency oscillations, we next showed that externally applied high frequency stimulation enhanced the slow spindle activity. Moreover, the prediction of the model was validated experimentally by recording EEG from subjects during nap. Both model and experimental results show increase in high frequency activity before slow spindles. Our findings suggest the important role of cortical high frequency activity in the generation of slow spindles.

Nonlinear-dynamics theory of up-down transitions in neocortical neural networks.
The neurons of the neocortex show ~1-Hz synchronized transitions between an active up state and a quiescent down state. The up-down state transitions are highly coherent over large sections of the cortex, yet they are accompanied by pronounced, incoherent noise. We propose a simple model for the up-down state oscillations that allows analysis by straightforward dynamical systems theory. An essential feature is a nonuniform network geometry composed of groups of excitatory and inhibitory neurons with strong coupling inside a group and weak coupling between groups. The enhanced deterministic noise of the up state appears as the natural result of the proximity of a partial synchronization transition. The synchronization transition takes place as a function of the long-range synaptic strength linking different groups of neurons.

Geometrical correlations in the nucleosomal DNA conformation and the role of the covalent bonds rigidity.
We develop a simple elastic model to study the conformation of DNA in the nucleosome core particle. In this model, the changes in the energy of the covalent bonds that connect the base pairs of each strand of the DNA double helix, as well as the lateral displacements and the rotation of adjacent base pairs are considered. We show that because of the rigidity of the covalent bonds in the sugar-phosphate backbones, the base pair parameters are highly correlated, especially, strong twist-roll-slide correlation in the conformation of the nucleosomal DNA is vividly observed in the calculated results. This simple model succeeds to account for the detailed features of the structure of the nucleosomal DNA, particularly, its more important base pair parameters, roll and slide, in good agreement with the experimental results.

Twist-stretch correlation of DNA.
We present an elastic model for B-form DNA with variable radius to study the elastic twist-stretch coupling of stretched DNA. In this model, only two strain variables as well as the changes in the energy of the hydrogen and covalent bonds of DNA during the deformation are considered. It is found that, depending on the elastic constants, the correlation between twisting and stretching of a helical molecule can be positive or negative. It is shown that for the suitable elastic constants in the model, the twist-stretch coupling of DNA behaves nonmonotonically, and contrary to intuition, the DNA twisting and stretching are positively correlated for small distortions. This result is entirely consistent with recent experimental results.

LOW FREQUENCY FLUCTUATIONS OF BRAIN ACTIVITY DURING PROLONGED COGNITIVE PERFORMANCE: TOWARDS A PROACTIVE MODEL OF RESSOURCE CONTROL OF ATTENTION

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Souhir Dali, Célia Loriette, Camilla Ziane, Simon Clavagnier, Suliann Ben Hamed, Julian Amengual
UMR5229 Institut des sciences cognitives Marc Jeannerod, Neural Bases Of Spatial Cognition And Action, BRON CEDEX, France

Sustained attention refers to the capacity to focus on a particular task for a long period of time. Sustaining such cognitive activity at an optimal regime comes at a cost, and a consequent decrease of cognitive resources accompanied by a decrement in performance during long-lasting cognitive effort has been largely theorized. However, recent evidence from monkey research show that, during the execution of an attentional task for one hour and more, behavioural performance consistently fluctuates between phases of optimal and suboptimal performance at a very slow rhythm of circa 5 cycles per second, concomitant with fluctuations in the prefrontal spatial attention information, challenging the classical view that cognitive effort wanes executive control. Here, we provide evidence that this is also at play in humans and we describe the underlying neural markers. Specifically, we recorded EEG activity and pupil size diameter from 19 human participants while they performed a vigilance task for 90 minutes. We found that both detection times and pupil size fluctuated in the frequency rage around 5 cycles per hour. In addition, frequency analysis on the EEG signal along the whole recording session revealed significant low-frequency fluctuations in the same frequency range as detection time and pupil size, that were independent from response times. A topographical analysis highlights the involvement of prefrontal and parietal regions. These results suggest a proactive resource control mechanism, in which the system copes with resource depletion by imposing a fluctuation in cognitive resources, possibly mediated by the noradrenergic system and the locus coeruleus.

The brain is a place of intense rhythmic activity, each brain area can express one or more rhythms. A central question in neuroscience is to understand how these rhythmic activities can coordinate very distant brain areas. In recent years, several studies have showed the respiratory rhythm can drive the LFP from numerous brain areas. Hence, beyond its primary vital function, the respiratory rhythm could be used by the brain as a master clock promoting communication between distant brain areas. However, outside the olfactory system it is not known if respiration-related oscillation (RRo) could exist in the membrane potential (MP) of neurons neither if it can structure spiking discharge. To fill this gap, we co-recorded MP and LFP activities in different non-olfactory brain areas: median prefrontal cortex (mPFC), primary somatosensory cortex (S1), primary visual cortex (V1), and hippocampus (HPC), in urethane-anesthetized rats. Using respiratory cycle by respiratory cycle analysis, we observed that respiration could modulate both MP oscillations and spiking discharges in all recorded areas. Further quantifications revealed RRo episodes were transient in most neurons (5 consecutive cycles in average). RRo development in MP was largely influenced by the presence of respiratory modulation in the LFP. By showing the respiratory rhythm influenced brain activity deep to the MP of non-olfactory neurons, our data support the idea that respiratory rhythm could mediate long-range communication. As a conclusion, these findings reinforce the idea that the respiratory rhythm is a fundamental component of the neuronal network dynamics, and should not be underestimated.

The use of *in vitro* brain slices from animal models has largely been the one studied in both physiological and pathological research. However, from a translational perspective many fundamental neurobiological issues remain open. Here we undertake research on human brain tissue obtained from surgery for the treatment of epilepsy and brain tumors. We studied the dynamics of the human cerebral cortex network in vitro under spontaneous slow-wave activity and modulation of the excitation/inhibition balance. We recorded extracellular local field potentials using 16 and 32 multielectrode arrays and performed histology for an anatomical and physiological correlation. The average frequency of spontaneous slow oscillations was 0.36±0.31Hz (equivalent to that reported for other mammals). Interestingly, we found differences between slices from peritumoral tissue (0.38±0.31Hz) and those from epilepsy surgery (0.13±0.16Hz) that were characterized by shorter Up states (0.19±0.39sec) with higher firing and longer Down states (25±29.18sec). These findings are coherent with those reported before for $GABA_A$ blockade (Barbero-Castillo et al, 2021), suggesting a mechanistic base for the hyperexcitability in epileptic tissue. Indeed, applying $GABA_A$-Rs blockers, these changes were still enhanced, making peritumoral tissue fire similarly to the epileptic one. Finally, we found a layer-specific dynamics consistent with the one described for other species, showing higher firing rate and longer Up states in infragranular layers (infra: 0.17±0.07s, supra: 0.12±0.08s). This dynamical characterization broadens our understanding of the mechanistic organization of the human cortical network at the microscale.

Neuromodulation techniques aim to precisely control neural activity, and their development is relevant for both basic neuroscience and functional repair in neurological disorders. A promising neuromodulation tool is photopharmacology, the control by light of drug activation in the tissue following chemical drug manipulation to be photoswitchable. Here, we investigated the effects of two such novel drugs, a photoswitchable type-1 muscarinic agonist, Benzylquinolone-carboxylic acid–Azo-Iperoxo (BAI, Agnetta et al, 2017), and a photoswitchable type-1 muscarinic antagonist, Cryptozepine-2 (Riefolo et al, 2021), to determine their effects over synchronized network activity in the cerebral cortex. We first studied *in vitro* photoresponses in HEK cells and demonstrated that light-controlled BAI and Cryptozepine-2 were M1 specific. Next, evaluated them over a complex neuronal network, the cerebral cortex. Slow oscillatory activity in slices was transformed into a significantly faster oscillation following white light illumination of the BAI-containing tissue. The modulation of activity *in vivo* with BAI was consistent with *in vitro* results. In the case of M_1-antagonist Cryptozepine-2, not only slow oscillatory activity was modulated into a slower rhythm, but also seizure activity evoked by the muscarinic super-agonist, Iperoxo, was transformed into an oscillatory-like activity after ultra-violet light illumination of Cryptozepine-2. These results shed light on the contribution of the M1-acetylcholine receptor to cortical dynamics and validate the use of photoswitchable drugs for spatiotemporal modulation of brain networks by light. Control of Brain State Transitions with a Photoswitchable Muscarinic Agonist.
The ability to control neural activity is essential for research not only in basic neuroscience, as spatiotemporal control of activity is a fundamental experimental tool, but also in clinical neurology for therapeutic brain interventions. Transcranial-magnetic, ultrasound, and alternating/direct current (AC/DC) stimulation are some available means of spatiotemporal controlled neuromodulation. There is also light-mediated control, such as optogenetics, which has revolutionized neuroscience research, yet its clinical translation is hampered by the need for gene manipulation. As a drug-based light-mediated control, the effect of a photoswitchable muscarinic agonist (Phthalimide-Azo-Iper (PAI)) on a brain network is evaluated in this study. First, the conditions to manipulate M2 muscarinic receptors with light in the experimental setup are determined. Next, physiological synchronous emergent cortical activity consisting of slow oscillations-as in slow wave sleep-is transformed into a higher frequency pattern in the cerebral cortex, both in vitro and in vivo, as a consequence of PAI activation with light. These results open the way to study cholinergic neuromodulation and to control spatiotemporal patterns of activity in different brain states, their transitions, and their links to cognition and behavior. The approach can be applied to different organisms and does not require genetic manipulation, which would make it translational to humans.

QUANTIFICATION OF INFRA-SLOW BRAIN SIGNALS USING GRAPHENE MICROTRANSISTORS (GSGFETS)

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Nathalia Cancino Fuentes[1], Ana Pascual Segura[1], Anton Guimera-Brunet[2,3], Maria V. Sanchez-Vives[1,4]
[1]IDIBAPS, Systems Neurosciences, Barcelona, Spain, [2]Institut de Microelectrònica de Barcelona, Imb-cnm (csic), Bellaterra, Spain, [3]Centro de Investigación Biomédica en Red en Bioingeniería, Biomateriales y Nanomedicina, (ciber-bbn), Madrid, Spain, [4]ICREA, Catalan Institution For Research And Advanced Studies, Barcelona, Spain

Conventional methods for the acquisition and recording of cortical signals are limited by their filtering out of infra-slow signals (<0.1 hz). Traditional AC amplifiers filter out frequencies below 0.1-0.2Hz to avoid voltage drifts and signal attenuation due to electrode vs amplifier impedance. Graphene microtransistors (gSGFETs) allow the quantification of the brain's full band signal, hence they can record with high fidelity the infra-slow activity (DC potentials) simultaneously with the rest of higher (>0.1 Hz) frequencies (AC). Here, we used this capability of gSGFETs to measure full band activity, including infra-slow one, during spontaneous and evoked cerebral cortex activity in vitro. To address this objective, we recorded from slices of the cerebral cortex in animal models as well as in human cortical slices with arrays of 16 gSGFETs. The excitability levels as well as the emergent activity patterns were systematically controlled by varying potassium levels, electric fields, excitatory / inhibitory balance, $GABA_B$-Rs activation or cholinergic agonists. The DC components of the slow oscillations (Up and Down states), pre-epileptic activity and epileptiform discharges, was quantified. The use of graphene transistors allows the detailed investigation of the physiological properties of the infra-slow component of brain signals in space and time. This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No 881603 (Graphene Flagship).

PERTURBATIONAL CORTICAL COMPLEXITY ACROSS CORTICAL AREAS, BRAIN STATES AND STIMULUS LOCATION

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Martina Cortada[1], D Casas-Torremocha[1], Alessandra Camassa[1], N Tort-Colet[2], Alain Destexhe[2], Maria V. Sanchez-Vives[1,3]

Perturbational complexity index (PCI) is a measure of evoked cortical complexity used in the clinic to quantify awareness levels in patients with disorders of consciousness. Following stimulation, the causal interactions between cortical areas determine the spatiotemporal profile of the response and the evoked cortical complexity. In Dasilva et al 2021, we adapted this measure to micro-ECoG recordings in the mouse brain. There, we determined that PCI varied with anaesthesia levels, being lower for deeper versus lighter anaesthesia. Here, we explored the recently introduced PCI state-transition (PCI^{st}, Comolatti et al 2019) evoked by stimulation in two different areas: frontal versus occipital. We found that frontal-evoked PCI^{st} was larger than the one evoked by stimulation of the occipital cortex. This difference was consistent at all levels of anaesthesia. Interestingly, occipital-evoked PCI^{st} showed larger sensitivity to anaesthesia levels, while frontal-evoked PCI^{st} maintained higher values across all of them. We also evaluated PCI^{st} evoked by either cortical or thalamic stimulation. No differences were detected between both stimulus under isoflurane anaesthesia. Instead, under light ketamine, thalamic stimulation evoked significantly lower complexity than cortical stimulation. We include a computational model of PCI in the rodent's brain consisting of mean field models from different cortical areas integrated through a full brain connectome. We investigate the properties of complexity depending on brain states and stimulation location, providing some potential mechanisms underlying the observed features. DESCRIBING THE GRADUAL TRANSFORMATION OF PHYSIOLOGICAL CORTICAL NETWORK ACTIVITY (UP/DOWN STATES) INTO PAROXYSMAL DISCHARGES (INTERICTAL EVENTS, SWDS, SLES)

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Irini Skaliora[1], Michael Vinos[1], Georgia Skrempou[2], Eirini Papadaki[1]

AIMS: Epilepsy is a neurological disorder affecting millions worldwide. Up to 30% of the patients remain refractive to medications and many more experience severe side effects. It is therefore important to determine the factors that either promote, or prevent the emergence, propagation and maintenance of the paroxysmal discharges that characterize the epileptic brain. In the present study we explore the transition from normal/physiological network activity (in the form of spontaneously occurring Up/Down states), through recurrent interictal spikes to the establishment of full blown seizure-like events (SLEs).
METHODS: We performed LFP recordings from young and adult mouse brain slices, with up to 4 electrodes in cortical layers II/III and V, or in hippocampal CA3 area. Epileptiform activity was induced with the zero-Mg2+ model.
RESULTS: Upstate duration exhibits a bimodal distribution in layer V, but not in layers II/III. Under epileptogenic conditions, Upstate activity is accelerated until eventually eliminated and replaced by epileptiform events, beginning (interictal spikes) and stabilizing (SLEs) simultaneously in the different layers and columns. Compared to the hippocampus, the neocortex exhibits a reduced threshold for epileptiform activity, which is strongly dependent on the presence or absence of Upstate activity.
CONCLUSIONS: Our data reveal age-dependent, as well as region and layer-specific differences both in the pattern of endogenous activity and in the progression to epileptiform discharges. Ongoing analysis aims to characterize the patterns of synchronized activity in the different states, through dynamical systems analysis and data-driven comparative analysis of various network features evolution, both in time and in time-frequency domains.

TRAVELING UP STATES IN THE POST-SUBICULUM REVEAL AN ANATOMICAL GRADIENT OF INTRINSIC PROPERTIES

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Daniel Levenstein[1], Dhruv Mehrotra[1], Adrian Duszkiewicz[2], Guillaume Viejo[1], Adrien Peyrache[3]
[1]McGill University, Mni, Montreal, Canada, [2]The University of Edinburgh, Centre For Cognitive And Neural Systems, Edinburgh, United Kingdom, [3]McGill University, Montreal Neurological Institute – The Neuro, Montreal, Canada

The post-subiculum (PoSub) is the primary cortical stage of the head-direction (HD) system. PoSub's main downstream target, the medial entorhinal cortex (MEC), is organized along its dorsoventral (DV) axis with increasing scale of spatial tuning from dorsal to ventral regions accompanied by a decrease in rectifying currents. To investigate if a similar organization exists in PoSub, we recorded populations of PoSub neurons with linear silicon probes. In contrast to MEC, HD tuning was uniform across the PoSub DV axis. However, we found that a gradient of spiking properties emerged during non-Rapid Eye Movement (NREM) sleep. Neuronal firing rates decreased along the DV axis, corresponding to a gradient in the duration of population-wide periods of inactivity (DOWN states). Interestingly, DOWN-to-UP but not UP-to-DOWN transitions traveled from dorsal to ventral PoSub, resulting in the sequential activation of neurons along the DV axis. Because DOWN-to-UP sequences are thought to be important for the functional properties of NREM sleep, we sought to understand the mechanism underlying this gradient. We built a computational model with a linear array of recurrently connected units and compared the spatiotemporal properties of DOWN states generated by various biophysical gradients. The model uniquely matched experimental observations with a gradient in the strength of a rectifying current, suggesting that the sleep-related gradient in PoSub has a common anatomical origin to the functional gradient in MEC. These results reveal that MEC receives spatiotemporally structured input along the DV axis during NREM sleep, and shed light on the mechanisms of DOWN-to-UP spike sequences.

CHARACTERIZATION OF CONSCIOUS AND UNCONSCIOUS BRAIN PATTERNS IN RATS

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Arnau Manasanch[1], Melody Torao-Angosto[1], Alessandra Camassa[1], Maria V. Sanchez-Vives[1,2]
[1]IDIBAPS, System Neuroscience, Barcelona, Spain, [2]ICREA, Catalan Institution For Research And Advanced Studies, Barcelona, Spain

When going from unconscious to awake states, a wide range of spatio-temporal brain patterns are observed. The description and analysis of these dynamics is critical to assess the subject's level of consciousness. Here, we quantify the dynamics and properties of brain patterns occurring in the transition from unconsciousness towards wakefulness in rats. Local Field Potentials were recorded from six different cortical areas in freely moving rats under anesthesia and natural sleep conditions. Brain patterns were first manually classified as deep anesthesia (DEEP), light anesthesia (LIGHT), slow wave sleep (SWS), microarousals (MA), REM and awake (AW). We applied a set of computational metrics to find a unique identification of these patterns: spectral power, synchronization between different areas and the characteristics of the slow oscillations in DEEP, LIGHT and SWS (Torao-Angosto et al, 2021) were studied. A separation of the different brain patterns was obtained by analyzing and clustering their spectral properties, with the best separation being in the delta (1-4 Hz)-gamma (30-100 Hz) plane. Further, we identified sub-states within the bistable regime of unconsciousness (DEEP, LIGHT and SWS) by including the duration of Up/Down states in the feature space. The synchronicity between different brain areas was found to be higher in unconscious than in aroused states. The characterization of brain dynamics allowed us to identify and describe the different paths the brain takes to recover consciousness. Funded by the EU 2020 Framework Programme for Research and Innovation No. 945539 (Human Brain Project SGA3).

SOUND-EVOKED MULTIAREA CORTICAL RESPONSES IN DIFFERENT BRAIN STATES IN RATS

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Melody Torao-Angosto[1], Arnau Manasanch[1], Alejandro Suarez[1], Maria V. Sanchez-Vives[1,2]
[1]IDIBAPS, System Neuroscience, Barcelona, Spain, [2]ICREA, Catalan Institution For Research And Advanced Studies, Barcelona, Spain

Not only the properties of stimulation, but also the functional state of the cortical network determine the amplitude, gain, or spatiotemporal patterns of cortical responses to stimuli. In a previous study we described that during a brain state dominated by slow waves, the gain of the system varied between Up/Down states in a relationship that depended on stimulus intensity (Reig et al., 2015). Here, we explored different brain states exhibiting distinct activity patterns, including both physiological (slow wave sleep, rapid-eye movement sleep and wakefulness) and pharmacologically induced (deep, medium and light anesthesia levels), characterized as in (Manasanch et al., FENS-2022). Sound-evoked responses had maximum amplitude in those states of higher network synchronization, namely SWS and deep anesthesia. Such responses propagated to auditory related (A1, A2) and non-related primary cortices (M1, V1), associative (PtA) and higher-order cortical areas (OFC) in all stages of the sleep-wake cycle. Responses to identical stimuli, though, had smaller amplitude during REM and awake states than in SWS or deep anesthesia. Interestingly, such modulation of amplitude followed similar patterns as to those during Up (for awake or even REM) and Down states (as in SWS), suggesting that Up states share features with wakefulness. Instead, under different levels of anesthesia, sound-evoked responses were rather circumscribed to A1 and A2 but hardly propagated to other non-auditory cortical areas. We quantify the dialogue across areas to capture brain state dynamics and how incoming information flows across the network in different states. Funded by EU 2020 No 945539 (Human Brain Project, SGA3).

SPATIOTEMPORAL DYNAMICS OF ANOXIC DEPOLARIZATION IN THE RAT SOMATOSENSORY CORTICES

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Antoine Carton[1], Sofia Carrion-Falgarona[2], Paul Baudin[1], Sarah Lecas[2], Stéphane Charpier[2], Séverine Mahon[2]
[1]Institut du Cerveau et de la Moëlle Epinière, Pr. Charpier's Team, Paris, France, [2]Institut du Cerveau et de la Moëlle Epinière, Pr Charpier Team, Paris, France

To investigate the neocortical spatiotemporal dynamics induced by brain anoxia, we recorded electrocorticographic activities, multi-layer local field potential (LFP) using linear silicon probes and intracellular activities of single pyramidal neurons from the primary somatosensory cortex (S1) in an asphyxia rodent model. Oxygen deprivation resulted first in an increase in high-frequency activity (> 10 Hz), simultaneously present at all recording sites. This was followed by a short period of gradually fading slow oscillations that ended, about one minute after anoxia onset, in a continuous isoelectric profile. The isoelectric state was then transiently interrupted by a large amplitude tri-phasic wave - named ‘Wave of Anoxic Depolarization’ (WAD) -, which correlated with an anoxic-dependent large membrane depolarization of cortical neurons. LFP recordings showed that the anoxic depolarization was initiated in the deep layers of S1, from two potential cortical sites, and then propagated bidirectionally through the cortical column. Reinstating oxygen supply to the brain interrupted the depolarization-block and engaged a slow membrane repolarization in cortical neurons, captured extracellularly as a ‘Wave of post-Anoxic Repolarization’ (WpAR). Neuronal repolarization also started in the deep layers, although from a less circumscribed region than the onset depolarization process. The WpAR was systematically followed by a progressive return of cellular and network activities, suggesting that it could represent a valuable marker of brain functions recovery and may serve clinical research on interventional strategies to optimize resuscitation procedures.

STRUCTURE OR DYNAMICS? ON THE ROLE OF THE CANONIC CIRCUIT IN THE EMERGENCE OF CORTICAL MULTI-FREQUENCY OSCILLATIONS

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Samy Castro[1,2,3], Battaglia Demian[2,3]
[1]Université de Strasbourg, Laboratoire De Neurosciences Cognitives Et Adaptatives, Strasbourg, France, [2]University of Strasbourg, Usias, Strasbourg, France, [3]Université de Strasbourg, CNRS, Laboratoire De Neurosciences Cognitives Et Adaptatives, Umr 7364, Strasbourg, France

Bottom-up and top-down functional connectivity (FC) *between* cortical regions are mediated by faster and slower frequency oscillations. Eventually, different cortical layers also oscillate at different frequencies. Therefore, it has been proposed that FC in different directions operates at different frequencies because of the distinct resonance frequencies of the source and target layers. Based on a systematic modelling analysis, we propose here on the contrary that the frequency specialization of directed FC stems as an emergent by-product of self-organized collective dynamics rather than of hardwired anatomy and interneuronal diversity. Specifically, we analyze rate models of coupled cortical regions embedding a realistic multi-layer anatomical organization. Every layer includes an excitatory and a unique inhibitory population of the fast-spiking type, resonating at a fast gamma-range frequency. Despite this intrinsic resonance, we can obtain a great diversity of possible dynamical states as a function of contextual inputs and the relative strength of excitation and inhibition. Regimes in which faster and slower frequency oscillations predominate respectively in superficial or deeper layers arise spontaneously and robustly due to non-linear inter-layer interactions. However, we also find that the strength and the dominant frequencies of directed FC can be flexibly adjusted by modulating the dynamical regime of the network, without the need of structural changes. We furthermore show that dynamical regimes allowing such a multi-frequency adaptivity of directed functional interactions are extremely unlikely to arise in randomized networks. We thus speculate that the canonic circuit wiring may be optimized to favour the frequency multiplexing of inter-regional information routing.

NON-NECESSARY NEURAL ACTIVITY IN THE PRIMATE CORTEX

POSTER SESSION 01 - SECTION: EMERGENT DYNAMICS IN NEURAL NETWORKS

Sebastien Tremblay, Camille Testard, Jeanne Inchauspé, Michael Petrides
University of Pennsylvania, Neuroscience, Philadelphia, United States of America

When neurophysiologists record neural activity from the brain, they often conclude that neural tuning to task variables suggests a functional role of the brain area studied in task performance. However, it remains unknown how reliably such correlations indicate a functional role. To answer this question, we chronically recorded neural activity in the prefrontal cortex of monkeys during the performance of four cognitive tasks. Previous studies had demonstrated that only one of those tasks causally depends on the recorded area; the other three tasks are not impaired by lesions in the relevant area. Surprisingly, we found that the prevalence and strength of single neuron and ensemble tuning were equivalent across all four tasks. This suggests that non-necessary cognitive signals are prevalent in the cerebral cortex of primates, challenging one of the fundamental assumptions of cognitive neurophysiology.

3D POSE ESTIMATION ENABLES VIRTUAL HEAD-FIXATION IN FREELY MOVING RATS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Artur Schneider[1,2], Christian Zimmermann[3], Mansour Alyahyay[1,2], Florian Steenbergen[1,2], Thomas Brox[3], Ilka Diester[1,2,4]
[1]Albert-Ludwigs-Universität, Optophysiology - Optogenetics And Neurophysiology, Freiburg, Germany, [2]Albert-Ludwigs-Universität, Freiburg, Germany, Faculty Of Biology, Institute Of Biology Iii, Freiburg, Germany, [3]University of Freiburg, Department Of Computer Science, Freiburg, Germany, [4]Albert-Ludwigs-Universität, Bernstein Center For Computational Neuroscience, Freiburg, Germany

When studying movement control, questions are often tackled in a task designed to cover specific aspects of movement e.g., initiation or direction. However, such constrained behaviors might impact our ability to understand the continuous movement control in a natural setting. Additionally, spontaneous movements outside the task-related movements impact the ongoing neural activity. While movements of interest can be controlled, a wide range of out-of-context movements are still executed by the animal. This complicates the analysis, since neural activity is “contaminated” with out-of-context movements. We employed FreiPose, a versatile framework to capture 3D motion during freely moving behavior. FreiPose enabled us to reconstruct body poses and individual paw movements, detect behavioral classes, and optogenetic stimulation effects. Using GAMs we were able to describe the ongoing activity of recorded neurons in rat's motor cortex as a combination of simultaneous, multiplexed coding of body posture and paw movement parameters. Thus, the activity in the motor cortex was strongly influenced by movements of not just individual body parts, but the whole rat's body. To separate the individual influences, we developed “virtual head-fixation” approach which enabled us to remove the contribution of body posture-related neuronal activity. This revealed a much clearer representation of paw-related activity. We unveiled a large fraction of neurons with tuning to the paw movements, which was previously masked by body posture tuning. Together, measuring behavior using FreiPose and applying virtual head-fixation will enable a much better understanding of the single-trial neural activity in freely moving as well as constrained behavioral tasks.

The subjective experience of causing an action is known as the sense of agency (SoA). It has been suggested that an auditory hallucination results from dysfunction in the SoA over speech. However, the SoA over speech has not been well investigated so far. The current study sought to characterize the SoA over speech using implicit and explicit measures. We first examined temporal compression of a perceived interval between an action and its outcome, termed intentional binding, in a speech paradigm. We distorted the pitch of feedback voice to manipulate self-voice identity. As a result, a perceived interval was more compressed when participants heard their natural voice than the distorted voice, suggesting that the SoA over speech is enhanced by hearing one's own voice. Next, we switched the action for intentional binding from vocalization to button press to investigate the significance of hearing one's voice in the SoA. In consequence, we did not find a significant difference in perceived intervals between the different pitch conditions. This result suggests that the retrospective effect of hearing one's voice is less important for the SoA over speech than the prospective effect of predicting an outcome caused by one's speech act. Finally, we examined agency judgment as an explicit measure. We found a top-down effect of self-voice identity, causing the agency judgment to be resistant regarding low-level sensorimotor inconsistency. Our findings highlight the mechanism of how one experiences the SoA in speech and contribute to understanding aberrant experience in auditory hallucinations.

THE RELATIONSHIP BETWEEN THE VISUAL PREDICTION ERROR AND THE AUTOMATIC ONLINE CONTROL

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Kosuke Numasawa[1], Tomohiro Kizuka[2], Seiji Ono[2]
[1]University of Tsukuba, Graduate School Of Comprehensive Human Sciences, Tsukuba, Japan, [2]University of Tsukuba, Faculty Of Health And Sport Sciences, Tsukuba, Japan

The online control system allows for rapid corrective response to unexpected perturbation. The mechanism of the automatic motor correction is thought to be based on the sensory prediction error between the efference copy and the actual sensory feedback signals. However, it is still uncertain whether the amount of the prediction error affects the corrective response. Therefore, the purpose of the current study was to clarify the relationship between the prediction error and the automatic corrective response. Participants wore an electrode cap for EEG measurement and were required to control a cursor on a monitor synchronized with a stylus. They were asked to reach the center of a Gaussian blob target as accurate as possible for small and large Gaussian blob conditions. In addition, the cursor was displaced 1 cm to the left or right from the actual cursor position in half of the trials as a perturbation. The automatic corrective response was detected by the arm acceleration in the lateral direction, and the amount of prediction error was estimated by the N1 event-related potential (ERP). Our results showed that the amplitude of the automatic response and the N1 ERP to the cursor displacement was larger in the small Gaussian blob conditions than in the large one. In addition, the amplitude of the automatic response was correlated with the N1 ERP. Therefore, we suggested that the automatic corrective response is dependent on the prediction error manipulated by the size of the Gaussian blob.

THE COMMON DESCENDING NEURAL DRIVE TO AGONIST AND ANTAGONIST MUSCLES IS HIGHER IN STROKE PATIENTS COMPARED TO CONTROLS.

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Célia Delcamp[1], Camille Cormier[2], Alexandre Chalard[3], David Amarantini[1], David Gasq[2]
[1]Université de Toulouse, Inserm, UPS, Tonic, Toulouse Neuroimaging Center, Toulouse, France, [2]University Hospital of Toulouse, Department Of Functional Physiological Explorations, Hopital de Rangueil, TOULOUSE, France, [3]University of California Los Angeles, Department Of Neurology, Los Angeles, United States of America

Aims: The mechanisms underlying the disruption of motor control after stroke are still misunderstood. The study of the oscillatory link between electromyographic activity of synergistic muscles, i.e. intermuscular coherence (IMC), can provide information on the alteration of the neural control mechanisms underpinning muscular activation. To date, no study has investigated the effects of stroke on IMC in muscle pairs whose muscles have either similar or opposite functional roles, especially during an ecologic task with clinical implications. ***Methods***: Twenty-five chronic post-stroke subjects and twenty-four controls were included. Kinematic and electromyographic data were recorded during twenty active elbow extensions at spontaneous speed. IMC was quantified in the beta band between the biceps brachii and the brachioradialis (BB-BR) as antagonist muscle pair and between the triceps brachii and the brachioradialis (TB-BR) as agonist-antagonist muscle pair. ***Results***: A two-factor ANOVA revealed an overall Group effect, where patients had higher IMC than controls for both muscle pairs ($F(1,47)=5.23$, $p=0.02$, $\eta^2_p=0.05$ [0.003:0.13]) (**Fig. 1**).

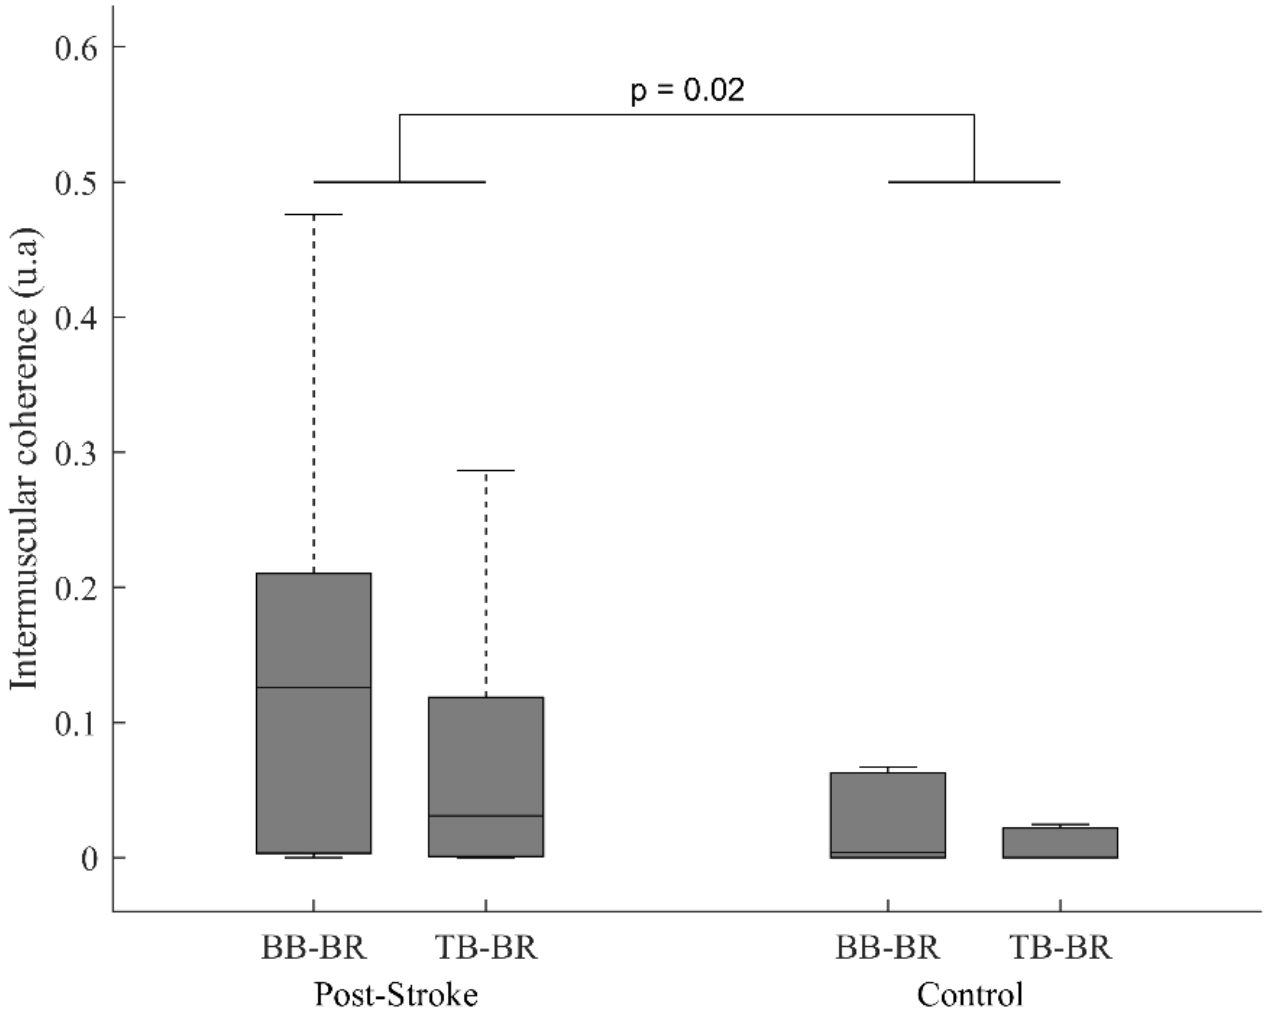

Figure 1: Intermuscular coherence of post-stroke patients and control subjects for the antagonist-antagonist (BB-BR) and agonist-antagonist (TB-BR) muscle pairs. ***Conclusions***: This work revealed higher IMC in post-stroke subjects compared to controls during active elbow extension. Whether the muscle pairs are composed of muscles with similar or opposite functional roles, there is no interaction effect that would allow to further specify this main result. We propose that these findings could reflect a simplification of the motor control mechanisms in post-stroke subjects, through a more common descending neural drive to the paretic upper-limb muscles.

MOLECULAR DELINEATION OF CORTICO-BRAINSTEM VERSUS CORTICO-SPINAL PROJECTION NEURONS DURING DEVELOPMENT

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Julia Kaiser, Payal Patel, Vibhu Sahni
Weill Cornell Medicine, Burke Neurological Institute, White Plains, United States of America

Skilled motor control requires precise connections between subcerebral projection neurons (SCPN) in the cerebral cortex with their appropriate targets, e.g., in brainstem or spinal cord. Corticospinal neurons (CSN) extend axons under tight molecular control to distinct spinal levels; however, the molecular mechanisms that limit axons of cortico-brainstem neurons (CBN) to supra-spinal levels are yet unknown. Here, we show that the brainstem-cervical transition zone distinguishes CBN from CSN from the earliest times of axon extension, and that CBN preferentially reside in lateral cortex. Using high throughput single cell RNA sequencing of retrogradely labeled, FACS purified CBN and CSN at critical times of white matter axon extension, we identified molecularly defined subpopulations within the broader SCPN population. SCPN can be further delineated based on their axonal projection specificity (brainstem vs. spinal) as well as their location in lateral vs. medial cortex. We establish that *Neuropeptide Y* (*Npy*) is specifically enriched in CBN in the lateral cortex. Our results highlight a molecular delineation of SCPN axon targeting at developmental times well before their axons reach their appropriate segmental target. This work will have direct impact on investigations into the development of circuitry required for skilled motor control and can potentially inform treatment options to enhance functional recovery after adult CNS injury.

Extracellular Vesicles: Multimodal Envoys in Neural Maintenance and Repair.
The physiology of the central nervous system (CNS) is built on a foundation of connection, integration, and the exchange of complex information among brain cells. Emerging evidence indicates that extracellular vesicles (EVs) are key players in the intercellular communication that underlies physiological processes such as synaptic plasticity and the maintenance of myelination. Furthermore, upon injury to the CNS, EVs may propagate inflammation across the blood-brain barrier and beyond, and also appear to mediate neuroprotection and modulate regenerative processes. In neurodegenerative diseases, EVs may play roles in the formation, spreading, and clearance of toxic protein aggregates. Here, we discuss the physiological roles of EVs in the healthy and the diseased CNS, with a focus on recent findings and emerging concepts.

TGFβ1 Induces Axonal Outgrowth via ALK5/PKA/SMURF1-Mediated Degradation of RhoA and Stabilization of PAR6.
Transforming growth factor (TGF)β1 has repeatedly been associated with axonal regeneration and recovery after injury to the CNS. We found TGFβ1 upregulated in the stroke-denervated mouse spinal cord after ischemic injury to the motor cortex as early as 4 d postinjury (dpi) and persisting up to 28 dpi. Given the potential role of TGFβ1 in structural plasticity and functional recovery after stroke highlighted in several published studies, we investigated its downstream signaling in an model of neurite outgrowth. We found that in this model, TGFβ1 rescues neurite outgrowth under growth inhibitory conditions via the canonical TGFβR2/ALK5 signaling axis. Thereby, protein kinase A (PKA)-mediated phosphorylation of the E3 ubiquitin ligase SMURF1 induces a switch of its substrate preference from PAR6 to the Ras homolog A (RhoA), in this way enhancing outgrowth on the level of the cytoskeleton. This proposed mechanism of TGFβ1 signaling could underly the observed increase in structural plasticity after stroke as suggested by the temporal and spatial expression of TGFβ1. In accordance with previous publications, this study corroborates the potential of TGFβ1 and associated signaling cascades as a target for future therapeutic interventions to enhance structural plasticity and functional recovery for stroke patients.

Early reduced behavioral activity induced by large strokes affects the efficiency of enriched environment in rats.
The majority of stroke patients develop post-stroke fatigue, a symptom which impairs motivation and diminishes the success

of rehabilitative interventions. We show that large cortical strokes acutely reduce activity levels in rats for 1-2 weeks as a physiological response paralleled by signs of systemic inflammation. Rats were exposed early (1-2 weeks) or late (3-4 weeks after stroke) to an individually monitored enriched environment to stimulate self-controlled high-intensity sensorimotor training. A group of animals received Anti-Nogo antibodies for the first two weeks after stroke, a neuronal growth promoting immunotherapy already in clinical trials. Early exposure to the enriched environment resulted in poor outcome: Training intensity was correlated to enhanced systemic inflammation and functional impairment. In contrast, animals starting intense sensorimotor training two weeks after stroke preceded by the immunotherapy revealed better recovery with functional outcome positively correlated to the training intensity and the extent of re-innervation of the stroke denervated cervical hemi-cord. Our results suggest stroke-induced fatigue as a biological purposeful reaction of the organism during neuronal remodeling, enabling new circuit formation which will then be stabilized or pruned in the subsequent rehabilitative training phase. However, intense training too early may lead to wrong connections and is thus less effective.

Direct, long-term intrathecal application of therapeutics to the rodent CNS.
Systemic application of therapeutics to the CNS tissue often results in subtherapeutic drug levels, because of restricted and selective penetration through the blood-brain barrier (BBB). Here, we give a detailed description of a standardized technique for intrathecal drug delivery in rodents, analogous to the technique used in humans. The intrathecal drug delivery method bypasses the BBB and thereby offers key advantages over oral or intravenous administration, such as maximized local drug doses with minimal systemic side effects. We describe how to deliver antibodies or drugs over several days or weeks from a s.c. minipump and a fine catheter inserted into the subdural space over the spinal cord (20 min operative time) or into the cisterna magna (10 min operative time). Drug levels can be sampled by quick and minimally invasive cerebrospinal fluid (CSF) collection from the cisterna magna (5 min procedure time). These techniques enable targeted application of any compound to the CNS for therapeutic studies in a wide range of CNS disease rodent models. Basic surgery skills are helpful for carrying out the procedures described in this protocol.

Targeting Therapeutic Antibodies to the CNS: a Comparative Study of Intrathecal, Intravenous, and Subcutaneous Anti-Nogo A Antibody Treatment after Stroke in Rats.
Antibody-based therapeutics targeting CNS antigens emerge as promising treatments in neurology. However, access to the CNS is limited by the blood-brain barrier. We examined the effects of a neurite growth-enhancing anti-Nogo A antibody therapy following 3 routes of administration-intrathecal (i.t.), intravenous (i.v.), and subcutaneous (s.c.)-after large photothrombotic strokes in adult rats. Intrathecal treatment of full-length IgG anti-Nogo A antibodies enhanced recovery of the grasping function, but intravenous or subcutaneous administration had no detectable effect in spite of large amounts of antibodies in the peripheral circulation. Thus, in contrast to intravenous and subcutaneous delivery, intrathecal administration is an effective and reliable way to target CNS antigens. Our data reveal that antibody delivery to the CNS is far from trivial. While intrathecal application is feasible and guarantees defined antibody doses in the effective range for a biological function, the identification and establishment of easier routes of administration remains an important task to facilitate antibody-based future therapies of CNS disorders.

The Spinal Transcriptome after Cortical Stroke: In Search of Molecular Factors Regulating Spontaneous Recovery in the Spinal Cord.
In response to cortical stroke and unilateral corticospinal tract degeneration, compensatory sprouting of spared corticospinal fibers is associated with recovery of skilled movement in rodents. To date, little is known about the molecular mechanisms orchestrating this spontaneous rewiring. In this study, we provide insights into the molecular changes in the spinal cord tissue after large ischemic cortical injury in adult female mice, with a focus on factors that might influence the reinnervation process by contralesional corticospinal neurons. We mapped the area of cervical gray matter reinnervation by sprouting contralesional corticospinal axons after unilateral photothrombotic stroke of the motor cortex in mice using anterograde tracing. The mRNA profile of this reinnervation area was analyzed using whole-genome sequencing to identify differentially expressed genes at selected time points during the recovery process. Bioinformatic analysis revealed two phases of processes: early after stroke (4-7 d post-injury), the spinal transcriptome is characterized by inflammatory processes, including phagocytic processes as well as complement cascade activation. Microglia are specifically activated in the denervated corticospinal projection fields in this early phase. In a later phase (28-42 d post-injury), biological processes include tissue repair pathways with upregulated genes related to neurite outgrowth. Thus, the stroke-denervated spinal gray matter, in particular its intermediate laminae, represents a growth-promoting environment for sprouting corticospinal fibers originating from the contralesional motor cortex.

This dataset provides a solid starting point for future studies addressing key elements of the post-stroke recovery process, with the goal to improve neuroregenerative treatment options for stroke patients. We show that the molecular changes in the spinal cord target tissue of the stroke-affected corticospinal tract are mainly defined by two phases: an early inflammatory phase during which microglia are specifically activated in the target area of reinnervating corticospinal motor neurons; and a late phase during which growth-promoting factors are upregulated which can influence the sprouting response, arborization, and synapse formation. By defining for the first time the endogenous molecular machinery in the stroke-denervated cervical spinal gray matter with a focus on promotors of axon growth through the growth-inhibitory adult CNS, this study will serve as a basis to address novel neuroregenerative treatment options for chronic stroke patients.

Nogo-A antibodies enhance axonal repair and remyelination in neuro-inflammatory and demyelinating pathology.
Two hallmarks of chronic multiple sclerosis lesions are the absence of significant spontaneous remyelination and primary as well as secondary neurodegeneration. Both characteristics may be influenced by the presence of inhibitory factors preventing myelin and neuronal repair. We investigated the potential of antibodies against Nogo-A, a well-known inhibitory protein for neuronal growth and plasticity, to enhance neuronal regeneration and remyelination in two animal models of multiple sclerosis. We induced a targeted experimental autoimmune encephalomyelitis (EAE) lesion in the dorsal funiculus of the cervical spinal cord of adult rats resulting in a large drop of skilled forelimb motor functions. We subsequently observed improved recovery of forelimb function after anti-Nogo-A treatment. Anterograde tracing of the corticospinal tract revealed enhanced axonal sprouting and arborisation within the spinal cord gray matter preferentially targeting pre-motor and motor spinal cord laminae on lesion level and above in the anti-Nogo-A-treated animals. An important additional effect of Nogo-A-neutralization was enhanced remyelination observed after lysolecithin-induced demyelination of spinal tracts. Whereas remyelinated fiber numbers in the lesion site were increased several fold, no effect of Nogo-A-inhibition was observed on oligodendrocyte precursor proliferation, migration, or differentiation. Enhancing remyelination and promoting axonal regeneration and plasticity represent important unmet medical needs in multiple sclerosis. Anti-Nogo-A antibodies hold promise as a potential new therapy for multiple sclerosis, in particular during the chronic phase of the disease when neurodegeneration and remyelination failure determine disability evolution.

HIP NEUROMUSCULAR CONTROL IN ATHLETES WITH ADDUCTOR-RELATED GROIN PAIN

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Teng-Kuan Cheng, Li-Wei Chou, Yi-Fen Shih, Min-Wei Lu
National Yang-Ming Chiao-Tung University, Physical Therapy And Assistive Technology, Taipei city, Taiwan

Background: Injury and pain have significant influence on athlete's neuromuscular control and performance. Hip adductor-related groin pain (ARGP) is a common injury in athletes requiring excessive hip mobility during sports. Functional movement test is commonly used clinically to determine functional performance. Here we investigated how ARGP affects functional performance, muscle activation, as well as functional connectivity between motor cortex and muscles during a functional movement screening test. **Method:** 15 for each healthy and ARGP athletes were recruited. Subjects were asked to perform Y-balance test (YBT), while electromyography (EMG) of the hip and trunk muscles and electroencephalography (EEG) were collected. Y-balance test scores, EMG amplitude, and corticomuscular coherence were calculated. We used independent t-test to determine if there were differences between healthy adults and ARGP athletes with α level at 0.05. **Results:** We have collected data on 10 healthy athletes so far. The reaching distance of the YBT were normalized with leg length, which results were 65.7±8.8% anteriorly, 106.4±12.8% posterolaterally, and 100.5±13.2% posteromedially[LC1] . The averaged muscles activation ratio of hip abductor/ adductor were 145.04±68.28%, 296.96±261.70%, and 159.43±129.95% in these three directions of YBT respectively. We observed dominant β and γ band CMC between the cortex and each of 3 muscles during the YBT. **Conclusion:** We plan to complete the whole data collection and present the overall results at the FENS 2022 conference.

MOTOR ADAPTATION AND ANTICIPATORY POSTURAL ADJUSTMENTS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Holly Morley, Andrew Murray
UCL, Sainsbury Wellcome Centre, London, United Kingdom

Transitioning between different voluntary movements has the potential to destabilise balance and posture through disturbance of the body's centre of mass. To prevent this, the nervous system makes pre-emptive adjustments to body posture prior to limb movements, termed anticipatory postural adjustments (APAs). These APAs are a form of motor adaptation. Through experience, the nervous system learns and updates how destabilising upcoming movements will disrupt postural equilibrium and adjusts the body posture accordingly. However, it is not clear how APAs are adapted during dynamic movements and we have little understanding of the neural circuitry that underlies these adjustments. Inspired by visuomotor transformation experiments in humans, we have developed a novel dual-belt travellator paradigm to induce adaptive APAs in freely moving mice. This behavioural assay allows a mismatch to be created between the expected (visual cue) and actual (belt) speeds of two moving belts as mice locomote between them, giving us the ability to flexibly manipulate the postural requirements of the task within the same experimental context. This provides an exciting avenue to probe the neural circuits involved in performing APAs.

Aims: There is experimental evidence that abdominal breathing is able to improve mental function and reduce exercise-induced oxidative stress. Visuomotor reaction time (VMRT) represents both mental and physical performance. Do people with more abdominal motion during spontaneous breathing have shorter VMRT? The present study aimed to make a preliminary investigation to answer this question. **Methods:** 434 healthy women (age: 20-59) living in the urban area in Beijing were enrolled by convenience sampling, received VMRT test on a simple visual reaction time tester (Xindonghuateng, Beijing, China) and respiration test using two respiration belts (Vernier, Beaverton, OR, USA). Two belts were tied at the height of the xiphoid and navel separately and ten continuous stable breathing cycles were selected for calculating the abdominal motion (AM), thoracic motion (TM), and thoracoabdominal ratio (TA ratio, the ratio of thoracic motion to abdominal motion). 393 subjects, whose data met the inclusion criteria, were divided into four age groups for analysis (20-29 years, n=40; 30-39 years, n=108; 40-49 years, n=146; 50-59 years, n=99). Both linear and non-linear correlation tests were conducted on SPSS and R-language. **Results:** The VMRT increased gradually from 550ms to 620ms with aging. The variability of TM was consistently higher compared to AM through all age groups. No correlation was found between VMRT and AM, TM, TA ratio. **Conclusions:** Women's visuomotor reaction time is not associated with the respiratory motion from the chest and abdomen recorded during spontaneous breathing.

DIRECTIONAL ACCURACY OF POINT-TO-POINT ARM MOVEMENTS IN DIFFERENT BODY ORIENTATIONS WITH RESPECT TO GRAVITY

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Simon Vandergooten[1], Laurent Opsomer[1], Jean-Louis Thonnard[1], Joseph Mcintyre[2,3], Philippe Lefèvre[4,5]
[1]UCLouvain, Icteam - Inma, Louvain-la-Neuve, Belgium, [2]Tecnalia, Basque Research And Technology Alliance, San Sebastian, Spain, [3]Centre National de la Recherche Scientifique, Cnrs, Paris, France, [4]UCLouvain, Icteam, Louvain-la-Neuve, Belgium, [5]UCLouvain, Institute Of Neuroscience, Brussels, Belgium

Aims: On Earth, gravity plays a primordial role during motor planning and control, both as a reference axis for proprioception and as a driving force for motor optimization. Previous studies have reported a progressive re-optimization of arm kinematics during exposure to microgravity, while discrete movements directed towards a target position get less accurate in the absence of visual feedback in microgravity compared to normal gravity. Here, we study the influence of body posture relative to gravity on the accuracy and kinematics trajectory of discrete point-to-point arm movements. Methods: Twelve participants performed discrete point-to-point arm movements parallel to the longitudinal body axis, with eyes open or with eyes closed, in three positions relative to gravity (0° Upright, 45° Intermediate and 90° Supine). A motion-tracking system was used to measure hand kinematics and a manipulandum was held between the thumb and the index finger during the tasks. Results: Body position had a significant impact on movement accuracy, and in particular on movement direction, when eyes were closed. More precisely, in the Intermediate and Supine positions movement direction drifted across trials in the absence of visual feedback and this drift was larger in the Supine position. Conclusion: Our results show that, in the absence of visual feedback, the direction of discrete point-to-point arm movements drifts across trials when the body axis is not aligned with the upright position.

CELL TYPE-SPECIFIC VISUAL INFORMATION ROUTING VIA THE SUPERIOR COLLICULUS IS INDISPENSABLE FOR GOAL-DIRECTED FORELIMB REACHING MOVEMENTS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Guillem Vicente-Ortiz[1,2,3], Pierre-Arthur Suray[1,3], Aya Takeoka[1,2,3]
[1]IMEC, Neuro Electronic Research Flanders, Leuven, Belgium, [2]KULeuven, Neuro-electronics Research Flanders (nerf), Leuven, Belgium, [3]Vlaams Instituut Voor Biotechnologie, Neuro Electronic Research Flanders, Leuven, Belgium

Integration of visual information providing an object's location, shape, and size is essential for executing forelimb reaching and grasping. However, the primary visual cortex is not required to learn or execute the behavior. Using an intersectional approach of mouse genetics, virus-mediated circuit manipulation and high-resolution kinematic analysis, we uncover that the ablation of narrow field neurons residing in the superficial layer of the superior colliculus (SC) deteriorates the refinement and execution of forelimb reaching. Optical tagging of narrow field neurons reveals activity tuning to a specific kinematic phase during reaching. They preferentially form synaptic connections to glutamatergic neurons in the intermediate SC (iSC) projecting to the pontine reticular nuclei (PRN) in the rostral brainstem. Selective ablation of the iSC-PRN projection neurons impairs the consistency of reaching kinematics, but not digit movements for grasping, indicating that the superior colliculi encode visual information necessary for the end-point refinement during the reaching phase. Moreover, the projection neurons receive input from diverse motor and sensory processing-related structures. Together, our study reveals cell type-specific dissemination of visual information provides essential input to the superior colliculus to act as a sensorimotor integration node to regulate forelimb reaching behavior.

MULTIVARIATE PATTERN ANALYSIS FOR CHARACTERIZATION OF CORTICAL NETWORKS OF BIMANUAL CONTROL

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Keenie Ayla Andersen[1,2], Hartwig Roman Siebner[1,3], Örjan De Manzano[4,5], Kristoffer Hougaard Madsen[1,6], Anke Karabanov[1,2]
[1]Copenhagen University Hospital Amager and Hvidovre, Danish Research Centre For Magnetic Resonance, Hvidovre, Denmark, [2]University of Copenhagen, Department Of Nutrition, Exercise And Sports, Copenhagen N, Denmark, [3]Copenhagen University Hospital Bispebjerg and Frederiksberg, Department Of Neurology, Copenhagen NV, Denmark, [4]Karolinska Institutet, Department Of Neuroscience, Solna, Sweden, [5]Max Planck Institute for Empirical Aesthetics, Max Planck Institute For Empirical Aesthetics, Frankfurt, Germany, [6]Technical University of Denmark, Department Of Applied Mathematics And Computer Science, Kongens Lyngby, Denmark

Background and Aim: Bimanual coordination is central to many manual skills but our knowledge on how sensorimotor networks represent different bimanual movement contexts is fragmented. The aim of this study was to use multi-voxel pattern analysis (MVPA) to explore how unimanual as well as symmetric and asymmetric bimanual movements are represented in cortical motor areas. **Methods:** 27 young (mean age 26 y/o) healthy participants (12 females) performed a visually guided pinch-force task that required quick shifts between movement contexts, i.e. experimental conditions varying in force direction (increase/decrease) and in bimanual context (symmetric/asymmetric/unimanual). We estimated task-related brain responses and trained a multivariate logistic regression classification algorithm, to discriminate response patterns based on BOLD signal within regions-of-interest (ROI). Based on the task nature (visually guided pinch force) one ROI covered cortical sensory-motor areas (M1, S1, SMA, PMd) while a second ROI covered visual areas (V1,V2, cuneus). **Results:** In the visual ROI, classification robustly discriminated all visual cues. In the motor ROI, bimanual tasks could be discriminated based on movement context but not force direction, e.g. symmetry vs. asymmetry, left hand stronger vs. right hand stronger. Voxels in the right dorsal premotor cortex contributed most to discrimination based on bimanual context. **Discussion:** Our results indicate that bimanual movements are represented in the motor cortices by unique activation patterns based on the bimanual coordination context and not as a simple summation of two unimanual movements – consistent with the notion that bimanual coordination requires complex and nonlinear interactions between representations in the motor cortex.

BEHAVIOURAL STRATEGIES AND BRAIN-WIDE NEURAL CIRCUITS DRIVING POSTURAL CONTROL IN LARVAL ZEBRAFISH

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Sharbatanu Chatterjee[1], Natalia Beiza[1], Muntasir Callachand[2], Hippolyte Moulle[1], Mattéo Dommanget-Kott[1], Georges Debrégeas[1], Volker Bormuth[1]
[1]Sorbonne Université, Laboratoire Jean Perrin, Paris, France, [2]Sorbonne Université, Paris Brain Institute–institut Du Cerveau, Paris, France

Loss of balance requires motor actions to stabilise posture. However, the behavioural strategies used and neural circuits involved in stabilisation are not well-characterised. We rolled head-mounted larval zebrafish around the rostrocaudal axis at various angles away from their preferred dorsal-up posture and characterised the tail response as a function of angle. We found different behavioural strategies at small and large angles respectively. At *small angles*, the fish responded by bending its tail to the contraversive side in a continuous manner proportional to the stimulus. The response saturated at a roll angle of about 12º. At *larger angles*, the fish executed, with increasing probability, additional discrete tail bouts of three types - swims, flips and flicks. The roll angle did not have any effect on the proportion of each type of motor response, tail-flip amplitude, or tail-frequency. However, at larger roll amplitudes, tail-flips became increasingly biased toward the contraversal side. This suggests that contraversal tail-flips are central discrete motor movements executed to regain stable posture. To identify the neuronal circuits involved in implementing these behavioural strategies, we recorded brain-wide neuronal activity during the responses using a rotating light-sheet microscope. A regression analysis identified neurons whose activity correlated with these different motor behaviours. We also found neuronal assemblies that displayed decreased activity during the triggering of discrete motor responses, suggesting that these assemblies are involved in motor output selection. Further studies will reveal whether these assemblies are part of a general circuit for motion selection or are specific to the vestibular response.

Planning and execution of voluntary movement depend on the contribution of distinct classes of neurons in primary motor and premotor areas. However, the specific functional role of GABAergic cells remains only partly understood. Here, electrophysiological and computational analyses are employed to compare directly the response properties of putative pyramidal (PNs) and fast-spiking, GABAergic neurons (FSNs) during licking and forelimb retraction in mice. Recordings from anterolateral motor cortex and rostral forelimb area, reveal that FSNs fire earlier and for a longer duration than PNs, with the exception of a subset of early-modulated PNs in deep layers. Computational analysis reveals that FSNs carry vastly more information than PNs about the onset of movement. While PNs differently modulate their discharge during distinct motor acts, most FSNs respond with a stereotyped increase in firing rate. Accordingly, the informational redundancy was greater among FSNs than PNs. These data suggest that a global rise of inhibition contributes to action initiation.

Chronic lithium administration in a mouse model for Krabbe disease.
Krabbe disease (KD; or globoid cell leukodystrophy) is an autosomal recessive lysosomal storage disorder caused by deficiency of the galactosylceramidase (GALC) enzyme. No cure is currently available for KD. Clinical applied treatments are supportive only. Recently, we demonstrated that two differently acting autophagy inducers (lithium and rapamycin) can improve some KD hallmarks in-vitro, laying the foundation for their in-vivo pre-clinical testing. Here, we test lithium carbonate in-vivo, in the spontaneous mouse model for KD, the Twitcher (TWI) mouse. The drug is administered ad libitum via drinking water (600 mg/L) starting from post natal day 20. We longitudinally monitor the mouse motor performance through the grip strength, the hanging wire and the rotarod tests, and a set of biochemical parameters related to the KD pathogenesis [i.e., GALC enzymatic activity, psychosine (PSY) accumulation and astrogliosis]. Additionally, we investigate the expression of some crucial markers related to the two pathways that could be altered by lithium: the autophagy and the β-catenin-dependent pathways. Results demonstrate that lithium has not a significant rescue effect on the TWI phenotype, although it can slightly and transiently improves muscle strength. We also show that lithium, with this administration protocol, is unable to stimulate autophagy in the TWI mice central nervous system, whereas results suggest that it can restore the β-catenin activation status in the TWI sciatic nerve. Overall, these data provide intriguing inputs for further evaluations of lithium treatment in TWI mice.

Pathogenic variants cause a developmental ocular phenotype recapitulated in a mutant mouse model.
Pathogenic variants cause a rare autosomal dominant neurodevelopmental disorder referred to as the Bosch-Boonstra-Schaaf Optic Atrophy Syndrome. Although visual loss is a prominent feature seen in affected individuals, the molecular and cellular mechanisms contributing to visual impairment are still poorly characterized. We conducted a deep phenotyping study on a cohort of 22 individuals carrying pathogenic variants to document the neurodevelopmental and ophthalmological manifestations, in particular the structural and functional changes within the retina and the optic nerve, which have not been detailed previously. The visual impairment became apparent in early childhood with small and/or tilted hypoplastic optic

nerves observed in 10 cases. High-resolution optical coherence tomography imaging confirmed significant loss of retinal ganglion cells with thinning of the ganglion cell layer, consistent with electrophysiological evidence of retinal ganglion cells dysfunction. Interestingly, for those individuals with available longitudinal ophthalmological data, there was no significant deterioration in visual function during the period of follow-up. Diffusion tensor imaging tractography studies showed defective connections and disorganization of the extracortical visual pathways. To further investigate how pathogenic variants impact on retinal and optic nerve development, we took advantage of an mutant mouse disease model. Abnormal retinogenesis in early stages of development was observed in mutant mice with decreased retinal ganglion cell density and disruption of retinal ganglion cell axonal guidance from the neural retina into the optic stalk, accounting for the development of optic nerve hypoplasia. The mutant mice showed significantly reduced visual acuity based on electrophysiological parameters with marked conduction delay and decreased amplitude of the recordings in the superficial layers of the visual cortex. The clinical observations in our study cohort, supported by the mouse data, suggest an early neurodevelopmental origin for the retinal and optic nerve head defects caused by pathogenic variants, resulting in congenital vision loss that seems to be non-progressive. We propose as a major gene that orchestrates early retinal and optic nerve head development, playing a key role in the maturation of the visual system.

Dysregulated autophagy as a new aspect of the molecular pathogenesis of Krabbe disease.
Krabbe disease (KD) is a childhood leukodystrophy with no cure currently available. KD is due to a deficiency of a lysosomal enzyme called galactosyl-ceramidase (GALC) and is characterized by the accumulation in the nervous system of the sphingolipid psychosine (PSY), whose cytotoxic molecular mechanism is not fully known yet. Here, we study the expression of some fundamental autophagy markers (LC3, p62, and Beclin-1) in a KD murine model [the twitcher (TWI) mouse] by immunohistochemistry and Western blot. Moreover, the autophagy molecular process is also shown in primary fibroblasts from TWI and WT mice, with and without PSY treatment. Data demonstrate that large p62 cytoplasmic aggregates are present in the brain of both early and late symptomatic TWI mice. p62 expression is also upregulated in TWI sciatic nerves compared to that measured for WT nerves. In vitro data suggest that this effect might not be fully PSY-driven. Finally, we investigate in vitro the capability of autophagy inducers (Rapamycin, RAP and Resveratrol, RESV) to reinstate the WT phenotype in TWI cells. We show that RAP administration can partially restore the autophagy markers levels, while RESV cannot, indicating a line along which new therapeutic approaches can be developed.

Quantitative Microproteomics Based Characterization of the Central and Peripheral Nervous System of a Mouse Model of Krabbe Disease.
Krabbe disease is a rare, childhood lysosomal storage disorder caused by a deficiency of galactosylceramide beta-galactosidase (GALC). The major effect of GALC deficiency is the accumulation of psychosine in the nervous system and widespread degeneration of oligodendrocytes and Schwann cells, causing rapid demyelination. The molecular mechanisms of Krabbe disease are not yet fully elucidated and a definite cure is still missing. Here we report the first in-depth characterization of the proteome of the Twitcher mouse, a spontaneous mouse model of Krabbe disease, to investigate the proteome changes in the Central and Peripheral Nervous System. We applied a TMT-based workflow to compare the proteomes of the corpus callosum, motor cortex and sciatic nerves of littermate homozygous Twitcher and wild-type mice. More than 400 protein groups exhibited differences in expression and included proteins involved in pathways that can be linked to Krabbe disease, such as inflammatory and defense response, lysosomal proteins accumulation, demyelination, reduced nervous system development and cell adhesion. These findings provide new insights on the molecular mechanisms of Krabbe disease, representing a starting point for future functional experiments to study the molecular pathogenesis of Krabbe disease. Data are available via ProteomeXchange with identifier PXD010594.

Motor learning and metaplasticity in striatal neurons: relevance for Parkinson's disease.
Nigro-striatal dopamine transmission is central to a wide range of neuronal functions, including skill learning, which is disrupted in several pathologies such as Parkinson's disease. The synaptic plasticity mechanisms, by which initial motor learning is stored for long time periods in striatal neurons, to then be gradually optimized upon subsequent training, remain unexplored. Addressing this issue is crucial to identify the synaptic and molecular mechanisms involved in striatal-dependent learning impairment in Parkinson's disease. In this study, we took advantage of interindividual differences between outbred rodents in reaching plateau performance in the rotarod incremental motor learning protocol, to study striatal synaptic plasticity ex vivo. We then assessed how this process is modulated by dopamine receptors and the dopamine active transporter, and

whether it is impaired by overexpression of human α-synuclein in the mesencephalon; the latter is a progressive animal model of Parkinson's disease. We found that the initial acquisition of motor learning induced a dopamine active transporter and D1 receptors mediated long-term potentiation, under a protocol of long-term depression in striatal medium spiny neurons. This effect disappeared in animals reaching performance plateau. Overexpression of human α-synuclein reduced striatal dopamine active transporter levels, impaired motor learning, and prevented the learning-induced long-term potentiation, before the appearance of dopamine neuronal loss. Our findings provide evidence of a reorganization of cellular plasticity within the dorsolateral striatum that is mediated by dopamine receptors and dopamine active transporter during the acquisition of a skill. This newly identified mechanism of cellular memory is a form of metaplasticity that is disrupted in the early stage of synucleinopathies, such as Parkinson's disease, and that might be relevant for other striatal pathologies, such as drug abuse.

Intravenous infusion of human bone marrow mesenchymal stromal cells promotes functional recovery and neuroplasticity after ischemic stroke in mice.
Transplantation of human bone marrow mesenchymal stromal cells (hBM-MSC) promotes functional recovery after stroke in animal models, but the mechanisms underlying these effects remain incompletely understood. We tested the efficacy of Good Manufacturing Practices (GMP) compliant hBM-MSC, injected intravenously 3.5 hours after injury in mice subjected to transient middle cerebral artery occlusion (tMCAo). We addressed whether hBM-MSC are efficacious and if this efficacy is associated with cortical circuit reorganization using neuroanatomical analysis of GABAergic neurons (parvalbumin; PV-positive cells) and perineuronal nets (PNN), a specialized extracellular matrix structure which acts as an inhibitor of neural plasticity. tMCAo mice receiving hBM-MSC, showed early and lasting improvement of sensorimotor and cognitive functions compared to control tMCAo mice. Furthermore, 5 weeks post-tMCAo, hBM-MSC induced a significant rescue of ipsilateral cortical neurons; an increased proportion of PV-positive neurons in the perilesional cortex, suggesting GABAergic interneurons preservation; and a lower percentage of PV-positive cells surrounded by PNN, indicating an enhanced plastic potential of the perilesional cortex. These results show that hBM-MSC improve functional recovery and stimulate neuroprotection after stroke. Moreover, the downregulation of "plasticity brakes" such as PNN suggests that hBM-MSC treatment stimulates plasticity and formation of new connections in the perilesional cortex.

Combining robotics with enhanced serotonin-driven cortical plasticity improves post-stroke motor recovery.
Despite recent progresses in robotic rehabilitation technologies, their efficacy for post-stroke motor recovery is still limited. Such limitations might stem from the insufficient enhancement of plasticity mechanisms, crucial for functional recovery. Here, we designed a clinically relevant strategy that combines robotic rehabilitation with chemogenetic stimulation of serotonin release to boost plasticity. These two approaches acted synergistically to enhance post-stroke motor performance. Indeed, mice treated with our combined therapy showed substantial functional gains that persisted beyond the treatment period and generalized to non-trained tasks. Motor recovery was associated with a reduction in electrophysiological and neuroanatomical markers of GABAergic neurotransmission, suggesting disinhibition in perilesional areas. To unveil the translational potentialities of our approach, we specifically targeted the serotonin 1A receptor by delivering Buspirone, a clinically approved drug, in stroke mice undergoing robotic rehabilitation. Administration of Buspirone restored motor impairments similarly to what observed with chemogenetic stimulation, showing the immediate translational potential of this combined approach to significantly improve motor recovery after stroke.

MOTOR CORTEX POPULATION DYNAMICS ASSOCIATED TO FACIAL MOVEMENT DIVERSITY IN THE MOUSE

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Marina Sabbadini[1], Juan Carlos Boffi[1], Tristan Wiessalla[2], Robert Prevedel[1,2,3]

Voluntary face movements are key behavioral features across animal species. These movements can be directly linked to survival, for example in nutrition, or have other relevant roles, such as communication through face expressions or the generation of sounds. Yet, to date, the relationship between neuronal activity in the primary motor cortex (M1) and face movement is not fully understood. The aim of this project is to characterize the link between M1 population dynamics and the generation of a diversity of facial movements. To this end we record the simultaneous neuronal population activity from a facial area of M1 while monitoring the associated face motor behavior in head-fixed awake mice.
By using a cutting-edge fast-volumetric calcium imaging method based on scanned temporal focusing two-photon microscopy, we recorded the simultaneous activity of thousands of neurons across a facial area of M1 and captured the associated face movements through videography. We implemented an unsupervised algorithm to classify the diversity of the captured behaviors, i.e. different whisking and sniffing movements, which allowed to compare the dynamics of the simultaneously recorded M1 population activity during the execution of these movements, and in comparison to resting states. The established approach opens new possibilities for the study of the integration of sensory feedback to M1 population dynamics in mice performing spontaneous or evoked voluntary face movements.

NEURAL CORRELATES OF SYMMETRIC AND ASYMMETRIC BIMANUAL CONTROL OF PINCH FORCE IN HUMANS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Anke Karabanov[1,2], Gaetana Chillemi[3], Kristoffer Hougaard Madsen[2], Hartwig Siebner[2,4]
[1]University of Copenhagen, Department Of Nutrition, Exercise And Sports, Copenhagen N, Denmark, [2]Copenhagen University Hospital Amager and Hvidovre, Danish Research Centre For Magnetic Resonance, Hvidovre, Denmark, [3]I.R.C.C.S., Centro Neurolesi Bonino Pulejo, MEssina, Italy, [4]Copenhagen University Hospital Bispebjerg and Frederiksberg, Department Of Neurology, Copenhagen NV, Denmark

Background: Although bimanual activities require quick shifts between symmetric and asymmetric coordination, previous functional neuroimaging research has mainly focused on the continuous performance of symmetric or asymmetric bimanual movements. Here we used functional magnetic resonance imaging (fMRI) to probe the bimanual motor network in a task context with rapid shifts between symmetric and asymmetric control . **Methods:** 25 healthy, right-handed volunteers performed a novel, visually guided pinch-force task that required quick shifts between bimanual symmetric, bimanual asymmetric and unimanual changes in pinch force. Task related changes in brain activity and functional coupling were analyzed with General Linear Models (GLM) and Dynamic Causal Modelling (DCM). **Results:** During asymmetric bimanual modulation of pinch force, the dorsal premotor cortex showed a bilateral increase in activity and effective coupling with the ipsilateral supplementary motor area (SMA). Coupling from the SMA to the ipsilateral M was high during all bimanual pinch force conditions. In left SMA, task related activity scaled positively with the degree of synchronous movement initiation, irrespectively of the bimanual context. Additionally, activity in a left-dominant network including the insula, cerebellum and M1 showed a linear increase with overall task accuracy. **Discussion:** Together, the results indicate an increasing engagement of the dorsal premotor cortex with the complexity of bimanual coordination. The relationship between left-hemispheric task-related activity and task measures of bimanual synchronicity and accuracy suggests some degree of hemispheric dominance during bimanual motor control.

MAPPING BRAINSTEM AND SPINAL CIRCUITS FOR LOCOMOTION AND ORIENTATION: DIVERSITY AND SPECIALIZATION OF V2A RETICULAR NEURONS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Giovanni Usseglio[1], Edwin Gatier[1], Alexis D'Humières[1], Elisa Toscano[2], Niccolò Zampieri[2], Julien Bouvier[1]
[1]Université Paris Saclay, Neuropsi, Cnrs, Saclay, France, [2]Max-Delbrück-Centrum für Molekulare Medizin (MDC), Development And Function Of Neural Circuits, Berlin, Germany

The brainstem reticular formation (RF) is key for controlling motor actions. Indeed, reticular neurons interface multiple sensory and cognitive modalities upstream, with executory motor circuits downstream. However, how the RF selects, initiates and combines multiple motor actions is largely unknown. We previously showed that the glutamatergic V2a neurons in the gigantocellular reticular nucleus (Gi) encompass a cervical-projecting subset inducing a head rotation and a change of locomotor trajectory, and a lumbar-projecting subset that, surprisingly, arrests locomotion (*Usseglio et al., 2020*). Here, we reveal that V2a reticular neurons also control other motor components of orienting whose executive circuits are located in the brainstem, including snout and eye. Importantly, these functions are supported by brainstem-projecting V2a subsets rather than by collaterals of spinally-projecting ones. Secondly, we question the possibility that the divergent outcomes across muscular groups (e.g., ipsilateral excitation for the head and snout, bilateral inhibition for the hindlimbs) might reflect differences in V2a efferent connectivity at each executory module. Hence, using a rabies-based transsynaptic strategy on newborn mice, we document the identity of the postsynaptic cells of the V2a neurons at different brainstem and spinal cord levels. Our work highlights that V2a Gi neurons orchestrate orienting motor actions and can be subdivided in at least two macro-categories, i) one controlling ocular and orofacial movements through supra-spinal projections, and ii) one controlling trunk and limb movements through spinal projections. Within each, a further specialization by projection site and postsynaptic target supports the control of individual motor components of a coherent multi-faceted behavior.

MULTIPLE BETA OSCILLATIONS BANDS UNDERLIE COMPLEMENTARY COGNITIVE AND SENSORIMOTOR ROLES IN THE MACAQUE FRONTAL MOTOR AREAS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Simon Nougaret[1], Émile Caytan[2], Julien Poitreau[3], Frédéric Barthélemy[4], Bjørg Kilavik[1]
[1]Aix-Marseille Université, CNRS, Institut De Neurosciences De La Timone, Marseille, France, [2]Faculty of Medicine, University of Crete, Foundation for Research and Technology - Hellas, Institute Of Applied And Computational Mathematics, Heraklion, Greece, [3]Laboratoire de Neurosciences Cognitives UMR 7291, Bases Neurales De La Navigation Spatiale, Marseille, France, [4]Research Centre Jülich, Institute Of Neuroscience And Medicine (inm-6), Computational And Systems Neuroscience & Institute For Advanced Simulation (ias-6), Theoretical Neuroscience & Jara-institut Brain Structure-function Relationships (inm-10), Jülich, Germany

Oscillations at specific frequencies might facilitate neuronal interactions. Particularly, sensorimotor beta oscillations were linked to postural control, movement preparation, but also sensorimotor anticipation and integration. Here, we investigated the relation of local field potential (LFP) beta amplitude in primary motor (M1) and dorsal premotor cortex (PMd) with these processes, while macaque monkeys were engaged in a rule-based cue-selection task requiring reaching movements. The timing of the valid spatial cue varied and was pre-cued in each trial. Therefore, temporal attention and movement preparation epochs depended on the task condition. Two spectral peaks in the beta range were visible in the LFPs. A high band centered on 26Hz was dominant in PMd. It decreased temporarily in trial-averaged amplitude slightly in anticipation of, and during the presentation of each visual stimulus, but somewhat more for the valid spatial cue. A low band centered on 16Hz was dominant in M1. It decreased in amplitude after the valid cue, when movement preparation started, remaining lower until the GO signal. Single-trial analysis revealed that both bands were modulated by small ‘fixational’ hand movements and exploratory eye movements. Whereas eye velocity was mainly negatively correlated with amplitude of both bands, hand velocity was mainly negatively correlated with low beta and positively correlated with high beta amplitude. These results might reconcile the somewhat disparate roles proposed for sensorimotor beta, with distinct, co-existing bands related differently to movement preparation and postural control on the one hand, but also anticipation and sensorimotor integration on the other hand.

TWO BRAINS IN ACTION: JOINT-ACTION CODING IN PARIETAL CORTEX OF MACAQUES

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Alexandra Battaglia-Mayer[1], Eros Quarta[2], Stefano Grasso[2], Roberto Caminiti[3]

Often our goals cannot be accomplished by acting alone but for a successful outcome rather require motor interaction among individuals. The neural mechanisms subtending inter-individual coordination remain largely unknown. In a previous study of the dorsal premotor cortex (PMd) in macaques engaged in a joint-action (JA) task, we found a class of JA-neurons discharging preferentially when a given action was performed jointly with another partner, relative to when the identical action was performed in a solo fashion (Solo task). Here, we report the results obtained in posterior parietal cortex (PPC), where single cell activity was recorded simultaneously from areas PFG of two interacting monkeys. The animals of the dyad were each trained to guide a visual cursor on a screen, in a Solo or in JA context, by exerting isometric hand force on a joystick. As in PMd, in PPC, beyond the canonical action-related cells, whose activity did not change depending on task conditions, we found a population of JA-neurons modulated by the dyadic context, despite the fact that identical actions were performed in the two conditions (Solo vs JA). However, JA parietal cells differed from PMd ones in their onset of activation, since the latter lead the former in time. Furthermore, parietal JA-neurons discriminate task conditions during action execution time only, contrary to PMd cells which showed high discrimination power mostly during action planning. Our findings provide evidence for a fronto-parietal shared representation of joint behavior, that might constitute a neural substrate for successful visuo-motor coordination between individuals.

POSTACTIVATION POTENTIATION EFFECTS ON SQUAT PERFORMANCE AND EMG IN RESISTANCE TRAINED MEN OF DIFFERENT LEVELS OF EXPERTISE

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Samuele Cravanzola[1], Matteo Romanazzi[2], Michela Giacosa[3], Giulia Panconi[1], Vincenzo Sorgente[1], Sara Guarducci[1], Diego Minciacchi[1], Riccardo Bravi[1]
[1]University of Florence, Department Of Experimental And Clinical Medicine, Florence, Italy, [2]University of Turin, School Of Exercise And Sport Sciences (suism), Turin, Italy, [3]University of Chester, Department Of Sport And Exercise Sciences, Chester, United Kingdom

Postactivation potentiation (PAP) is defined as an increased muscle contractile response following a stimulation called conditioning activity (CA) characterized by intense voluntary contraction. The generation of PAP has been speculated to be caused by the enhancement of the neuromuscular structure following CA. Indeed CA is shown to affect the peak and rate of a muscle contraction. This study aims to evaluate the effectiveness of PAP following CA in squat performance in experienced (EXP) and intermediate (INT) resistance trained men, by measuring the correlation between the increase in strength performance on the total tonnage lifted in the test and the electrical activity of the specific involved muscles. Following an initial evaluation of their one repetition maximum (1RM) of squat, after 4 days subjects were instructed to performed a protocol with CA, which involved performing 1 set of 2 repetitions at 90% of 1RM, after 7 minutes of rest 4 sets at 70% were proposed until concentric exhaustion with 3 minutes rest between sets. The EMG analysis used root mean square amplitude parameter normalized with maximum voluntary contraction and was evaluated on the vastus medialis, vastus lateralis, gluteus maximus and hamstring muscles. From the data analysis we can hypothesize that the subjects could show greater EMG activity in both groups, but the EXP group may present greater EMG activity than the INT group. We also assume that the total volume of work in the EXP group will be greater than the INT group.

SHARED NEURAL POPULATION DYNAMICS ACROSS ANIMALS PERFORMING THE SAME BEHAVIOUR

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Mostafa Safaie[1], Junchol Park[2], Joanna Chang[1], Lee Miller[3], Joshua Dudman[2], Matthew Perich[4], Juan Gallego[1]
[1]Imperial College London, Bioengineering, Sir Michael Uren Hub, London, United Kingdom, [2]Janelia Research Campus, Howard Hughes Medical Institute, Ashburn, United States of America, [3]Northwestern University, Department Of Physiology, Chicago, United States of America, [4]Université de Montréal, Département De Neurosciences, Montréal, Canada

Animals of the same species share a characteristic set of behaviours. This species-typical behavioural repertoire is shaped under selection pressures over evolutionary timescales. However, it is unclear how individual animals produce these similar behaviours despite the large differences in their brain circuitry. Here, we hypothesised that preserved neural population dynamics are the basis of species-specific behaviours: animals from the same species possess unique brains that are constrained so they can generate the 'appropriate' latent dynamics needed to produce their typical behaviours. Using motor cortical population recordings from monkeys and mice, we show that individuals from the same species share remarkably similar neural population latent dynamics when they perform the same behaviour. Furthermore, shared latent dynamics extend beyond cortical regions to the dorsal striatum, an evolutionarily older structure, and are also present during a cognitive task in which animals covertly plan future movements. These shared dynamics capture a large fraction of the variance of single-neuron activity and have behavioural relevance: they can be used to predict both ongoing movements and future actions. While neural population dynamics have been proposed as the first-level explainers of behavioural and cognitive phenomena, here we extend recent works to show that they are shared across different individuals engaged in the same behaviour, thus providing a novel framework for the implementation of behavioural adaptations in the brain. Our results also have strong implications for the development of brain-controlled devices, such as neuroprosthetics, that can better generalise across individuals to restore motor, affective, or even cognitive functions.

MOVEMENT-RELATED ELECTROPHYSIOLOGICAL ALTERATIONS AS BIOMARKERS TO PREDICT SPONTANEOUS RECOVERY AFTER MCAO IN MICE

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Claudia Alia[1], Verediana Massa[1], Irene Busti[1,2], Alessio Ricci[3], Maria Pasquini[4], Silvestro Micera[4], Matteo Caleo[5,6]
[1]National Research Council, Neuroscience Institute, Pisa, Italy, [2]School of Psychology, Department Of Neurosciences, Psychology, Drugs And Child Health Area (neurofarba), Florence, Italy, [3]Institute for Stroke and Dementia Research, University Hospital, Lmu Munich, Munich, Germany, [4]Scuola Superiore Sant'Anna, The Biorobotics Institute, Pontedera PI, Italy, [5]University of Padua, Department Of Biomedical Sciences, Padova, Italy, [6]Consiglio Nazionale delle Ricerche, Neuroscience Institute, Pisa, Italy

Stroke is a devastating pathology and the main cause of long-term disability, allowing currently less than 15% of the stroke survivors to fully recover and get back to normal life. Many cognitive domains result affected by strokes and motor functions are impaired in 80-85% of subjects. Efforts in improving rehabilitative therapy remain unsatisfactory, leaving many stroke survivors significantly impaired and with a need of continuous assistance from health care providers. Therefore, nowadays it is not possible to predict the final degree of recovery, making difficult to stratify stroke survivors and address them towards their optimal therapeutic protocol in order to maximize its own restoration potentiality. Here, we longitudinally collected Local Field Potentials (LFP) from stroke and healthy mice to define acute post-stroke alterations to be used as biomarkers to predict the final degree of recovery for each subject. Mice were implanted in their left and right Caudal Forelimb Areas (CFA) and electrophysiological signals were acquired during a forelimb retraction movement, before and after Middle Cerebral Artery Occlusion (MCAO). In particular, we analysed post-stroke alterations in the Event Related Potential (ERP), in the Perievent Spectograms and in the Event Related Synchronization/Desynchronization (ERS/ERD). These measures were also correlated with the individual degree of spontaneous recovery. Findings from this study will contribute to the Neurorehabilitation quest in identifying early, reliable neurophysiological biomarkers of recovery, which would allow a better tailoring of rehabilitation pathways and allocation of resources in an ageing world destined to a sharp increase in stroke disability.

Stroke is a disabling condition, despite many patients show a spontaneous recovery, due to a reorganization of spared areas and connections. Currently, there are no ways to determine either the extent or time-course of recovery in stroke patients, thus its prediction represents an urgent need for personalization of treatments. In our study we used a mouse model of middle cerebral artery occlusion (MCAO) to investigate novel prognostic tools in preclinical models. To determine spontaneous recovery, we conducted a battery of sensori-motor tests and a forelimb retraction task at different time points. To mimic clinical scales used in stroke patients, we implemented a novel "Global Motor Score" (GMS) comprehensive of the sensorimotor performance assessed in all single tests. GMS was able to detect a global deficit after MCAO but showing a partial overall recovery 4 weeks post-stroke. However, going deeper in individual performances, we found a large variability among stroke mice, allowing a distinction between poor and good recoverers. We found that chronic deficit can be explained by acute performance (as in humans) and by the structural integrity of the descending motor system. In particular, the CFA involvement and the anterior extension of the lesion, together with the Internal Capsule integrity showed to play a role in the extent of spotaneous recovery. These results confirm the MCAO model as a good animal model for studying stroke recovery and could be important to find reliable biomarkers with high translational potential to human stroke patients.

NEUROPHYSIOLOGICAL CORRELATES OF PERIPERSONAL SPACE REPRESENTATION IN HUMAN AND NON-HUMAN PRIMATES

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Aoife Fitzpatrick[1], Rory Bufacchi[1], Francesca Lanzarini[2], Davide Albertini[2], Monica Maranesi[2], Giacomo Novembre[1,3], Luca Bonini[2], Giandomenico Iannetti[1,4]
[1]Istituto Italiano di Tecnologia, Neuroscience And Behaviour Laboratory, Clns, Rome, Italy, [2]University of Parma, Department Of Medicine And Surgery, Parma, Italy, [3]Italian Institute of Technology, Neuroscience Of Perception And Action, Rome, Italy, [4]University College London, Department Of Neuroscience, Physiology And Pharmacology, London, United Kingdom

Sensory events occurring close to the body have particular behavioural relevance. Perhaps unsurprisingly, these events elicit enhanced behavioural or neurophysiological responses. Such “peripersonal space” (PPS) responses, traditionally interpreted as reflecting the position of the stimulus in egocentric coordinates, may in fact play a role in creating or avoiding contact with objects near the body. Here we provide a comprehensive characterisation of PPS responses across humans and non-human primates (NHP), with the aim of facilitating the assessment of their role in contact-related actions. We recorded high-density EEG in humans and intracranial neuronal signals in NHPs during the same task. Visual and tactile stimuli were presented along a mediolateral axis centred on the right hand (distance from the hand: ±24, ±12, 0cm [visual]; 0cm [tactile]). Crucially, eye and hand positions were manipulated to disentangle eye- versus hand-centered encoding. Both scalp and intracortical local field potentials were analysed in the frequency domain by computing power spectral densities. Preliminary results (24 humans, 1 NHP) revealed gaze-independent coding of stimulus position across species. In humans, alpha, beta, and gamma band power in posterior, predominantly lateralized regions was modulated by stimulus position. A qualitatively comparable positional coding was observed in NHP ventral premotor cortex. Further, hand position affected alpha and beta power in left-lateralised frontal and posterior electrodes, though this effect was rather independent of stimulus distance. These results provide the foundation for testing whether PPS responses reflect the value of contact-related actions. Additional computational modelling analyses will assess whether these responses represent action intention.

The neural basis of hand choice: An fMRI investigation of the Posterior Parietal Interhemispheric Competition model.
The current study investigates a new neurobiological model of human hand choice: The Posterior Parietal Interhemispheric Competition (PPIC) model. The model specifies that neural populations in bilateral posterior intraparietal and superior parietal cortex (pIP-SPC) encode actions in hand-specific terms, and compete for selection across and within hemispheres. Actions with both hands are encoded bilaterally, but the contralateral hand is overrepresented. We use a novel fMRI paradigm to test the PPIC model. Participants reach to visible targets while in the scanner, and conditions involving free choice of which hand to use (Choice) are compared with when hand-use is instructed. Consistent with the PPIC model, bilateral pIP-SPC is preferentially responsive for the Choice condition, and for actions made with the contralateral hand. In the right pIP-SPC, these effects include anterior intraparietal and superior parieto-occipital cortex. Left dorsal premotor cortex, and an area in the right lateral occipitotemporal cortex show the same response pattern, while the left inferior parietal lobule is preferentially responsive for the Choice condition and when using the ipsilateral hand. Behaviourally, hand choice is biased by target location - for targets near the left/right edges of the display, the hand in ipsilateral hemispace is favoured. Moreover, consistent with a competitive process, response times are prolonged for choices to more ambiguous targets, where hand choice is relatively unbiased, and fMRI responses in bilateral pIP-SPC parallel this pattern. Our data provide support for the PPIC model, and reveal a selective network of brain areas involved in free hand choice, including bilateral posterior parietal cortex, left-lateralized inferior parietal and dorsal premotor cortices, and the right lateral occipitotemporal cortex.

Now and then: Hand choice is influenced by recent action history.
Action choices are influenced by recent past and predicted future action states. Here, we demonstrate that recent hand-choice history affects both current hand choices and response times to initiate actions. Participants reach to contact visible

targets using one hand. Hand choice is biased in favour of which hand was used recently, in particular, when the biomechanical costs of responding with either hand are similar, and repeated choices lead to reduced response times. These effects are also found to positively correlate. Participants who show strong effects of recent history on hand choice also tend to show strong effects of recent history on response times. The data are consistent with a computational efficiency interpretation whereby repeated action choices confer computational gains in the efficiency of underpinning processes. We discuss our results within the framework of this model, and with respect to balancing predicted gains and losses, and speculate about the possible underlying mechanisms in neural terms.

A CASE-REPORT OF AN ALIEN HAND SYNDROME

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Kseniia Manysheva[1], Burliyat Abusueva[2]
[1]Dagestan State Medical University, Department Of Nervous Diseases, Medical Genetics And Neurosurgery, Makhachkala, Russian Federation, [2]Daghestan State Medical University, Department Of Nervous Diseases, Medical Genetics And Neurosurgery, Makhachkala, Russian Federation

Alien hand syndrome (AHS) is a rare movement disorder. We describe a case-report. A 46-years-old male patient was admitted to the clinic with complaints of weakness and impaired movement in his left hand, slowing down of the rate of speech and fuzziness. Describing the symptoms, the patient used the formulations "the hand does not obey", "the hand has its own head." Anamnesis morbi: the patient felt ill 5 weeks before the admission: on the stress background his left leg “failed”, speech became slurred. An urgently performed MRI of the brain revealed areas of cytotoxic edema in the frontal, parietal and occipital lobes and an extensive areas of paraventricular edema in the right hemisphere and in the structure of the corpus callosum. On neurological examination: Apraxia in the left hand: kinesthetic according to the visual and kinesthetic pattern, including transferring poses, kinetic, apraxia tests trying to perform only on the verbal model.
Clinical diagnosis: ischemic stroke in the right MCA circulation. Left-sided upper monoparesis, monohypalgesia, AHS, central prosoparesis, glossoparesis. Dysarthria.
To control the “alien” hand the patient put on a cloth glove at home, held a cane in this hand or held his wife by the elbow outside. Also he was prescripted clonazepam 0.25 mg/day. Completed a course of rehabilitation: mirror therapy, techniques of fine motor skills and interhemispheric interaction, classes with a speech therapist. After 2 months the patient fully controls the function of hand. This is a case-report of rare syndrome that inspires fear to patients and confuses doctors.

[Formation of neurology in the Daghestan (to the 85th anniversary of the Department of Nervous Diseases, Medical Genetics and Neurosurgery, Daghestan State Medical University)].
The article describes the history of the Department of Nervous Diseases, Medical Genetics and Neurosurgery of the Daghestan State Medical University on the basis of literature data and archival sources introduced into scientific circulation for the first time. The department, created in 1936, has gone through a difficult path in its formation and development. The authors reconstruct the history of the formation of this department of the university, dwelling on the problems faced by its first employees. Special attention is paid to the work of the department during the Great Patriotic War, when its staff was reduced to a minimum. The authors describe the appearance, stages of development and successful functioning of the scientific school for the study of thermoregulation under the guidance of Associate Professor V.A. Liechtenstein. The formation of the teaching of neurosurgery, as well as the work of the department in recent years, is described.

PHYSIOLOGY AND PHYSIOPATHOLOGY OF CEREBELLO-THALAMIC PATHWAYS IN MOTOR SKILL LEARNING

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Romain Sala[1], Hind Baba Aissa[1], Andres Varani[1], Elena Margarint[1], Caroline Mailhes-Hamon[1], Alexandre Tolboom[1], Denis Herve[2], Clement Lena[1], Daniela Popa[1]

Cerebellum is known to exert a key role in regulating fine locomotion. However, its broad connectivity with various cortical and subcortical structures supports its involvement in higher brain functions, such as executive functions, cognitive functions, and motor skill learning. A murine paradigm of motor skill learning, the accelerating rotarod, was shown to sequentially involve the primary motor cortex and the different compartments of the striatum, but little was known about an involvement of the cerebellum in this learning. Previous work from the team (Varani et al 2020, bioRxiv) demonstrated that the cerebellar output pathways differentially contribute to phases of accelerating rotarod learning. Indeed, cerebellar projections to motor thalamus (VAL) were involved in the offline consolidation of the motor skill, while its projection to striatal-projecting thalamus (CL) contributed to the expression of previously-consolidated motor skill. These cerebello-thalamic pathways can be altered in the context of brain disorders such as primary dystonia. Notably, primary forms of dystonia are associated to incomplete penetrance and endophenotypes in non-manifesting individuals, suggesting the presence of network alterations in both presymptomatic and symptomatic state. We used a combination of extracellular recordings and optogenetic stimulations to reveal an abnormal plasticity in a cerebello-thalamic tract (DN-CL) in a mouse model of DYT25, a genetic form of primary dystonia. We also observed an altered expression of accelerating rotarod learning in presymptomatic mice, consistent with the abnormalities in DN-CL pathway. All together, our results indicate that alteration of cerebello-thalamic tracts may explain the presence of endophenotypes in dystonia.

ACTING ALONE OR TOGETHER? EVALUATING THE COST OF INTER-INDIVIDUAL MOTOR COORDINATION IN MACAQUES

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Irene Lacal, Eros Quarta, Andrea Schito, Stefano Grasso, Ludovica Caratelli, Alexandra Battaglia-Mayer
Sapienza University of Rome, Department Of Physiology And Pharmacology, Rome, Italy

Acting with others can be advantageous to achieve goals unattainable by a single agent, however joint action (JA) requires costly inter-individual motor coordination. In macaque monkeys, we studied the decision-making processes subtending the free choice to act in a SOLO or joint fashion (JA), under different payoff contexts. Our aim was to quantitatively evaluate in lab settings the cost of dyadic motor coordination. Two animals, each guiding a visual cursor through an isometric joystick, were trained to choose between two alternative targets to gain a cued amount of reward to be obtained through individual or joint behaviour. In the JA option, animals had to coordinate their force to jointly bring their cursors to the final target location. The results indicate that for low Δ differences in reward amount associated to the two action types, both animals preferred the SOLO action regardless of the offer. By increasing the differences (Δ) in reward amounts, monkeys opted always in favour of JA. The indifference points of psychometric curves linking choice probability for JA vs SOLO found at Δ≠0 provided an estimate of the perceived cost of their collective behaviour. In conclusion, in macaques the economic evaluation of acting alone or together is not merely dictated by the payoff value but is subdued to the cost of their reciprocal motor coordination. The animals can accurately estimate this cost and use it to decide whether to act alone or with others. The neural mechanisms underlying these cognitive processes are under investigation in prefrontal cortex.

Distributed and Localized Dynamics Emerge in the Mouse Neocortex during Reach-to-Grasp Behavior.
A long-standing question in systems neuroscience is to what extent task-relevant features of neocortical processing are localized or distributed. Coordinated activity across the neocortex has been recently shown to drive complex behavior in the mouse, while activity in selected areas is canonically associated with specific functions (e.g., movements in the case of the motor cortex). Reach-to-grasp (RtG) movements are known to be dependent on motor circuits of the neocortex; however, the global activity of the neocortex during these movements has been largely unexplored in the mouse. Here, we characterized, using wide-field calcium imaging, these neocortex-wide dynamics in mice of either sex engaging in an RtG task. We demonstrate that, beyond motor regions, several areas, such as the visual and the retrosplenial cortices, also increase their activity levels during successful RtGs, and homologous regions across the ipsilateral hemisphere are also involved. Functional connectivity among neocortical areas increases transiently around movement onset and decreases during movement. Despite this global phenomenon, neural activity levels correlate with kinematics measures of successful RtGs in sensorimotor areas only. Our findings establish that distributed and localized neocortical dynamics co-orchestrate efficient control of complex movements. Mammals rely on reaching and grasping movements for fine-scale interactions with the physical world. In the mouse, the motor cortex is critical for the execution of such behavior, yet little is known about the activity patterns across neocortical areas. Using the mesoscale-level networks as a model of cortical processing, we investigated the hypothesis that areas beyond the motor regions could participate in RtG planning and execution, and indeed a large network of areas is involved while performing RtGs. Movement kinematics correlates mostly with neural activity in sensorimotor areas. By demonstrating that distributed and localized neocortical dynamics for the execution of fine movements coexist in the mouse neocortex during RtG, we offer an unprecedented view on the neocortical correlates of mammalian motor control.

Circle drawing and tracing dataset for evaluation of fine motor control.
We introduce a motion dataset from healthy human subjects (= 125) performing two fine motor control tasks on a graphic tablet, namely circle drawing and circle tracing. The article reports the methods and materials used to capture the motion data. The method for data acquisition is the same as the one used to investigate some aspects of fine motor control in

healthy subjects in the paper by Cohen et al. (2018) "Precision in drawing and tracing tasks: Different measures for different aspects of fine motor control" (https://doi.org/10.1016/j.humov.2018.08.004) [1]. The dataset shared here contains new raw files of the two-dimensional motion data, as well information on the participants (gender, age, laterality index). These data could be instrumental for assessing other aspects of fine motor control, such as speed-accuracy tradeoff, speed-curvature power law, etc., and/or test machine learning algorithms for e.g., task classification.

Future Portrait of the Athletic Brain: Mechanistic Understanding of Human Sport Performance Animal Neurophysiology of Motor Behavior.
Sport performances are often showcases of skilled motor control. Efforts to understand the neural processes subserving such movements may teach us about general principles of behavior, similarly to how studies on neurological patients have guided early work in cognitive neuroscience. While investigations on non-human animal models offer valuable information on the neural dynamics of skilled motor control that is still difficult to obtain from humans, sport sciences have paid relatively little attention to these mechanisms. Similarly, knowledge emerging from the study of sport performance could inspire innovative experiments in animal neurophysiology, but the latter has been only partially applied. Here, we advocate that fostering interactions between these two seemingly distant fields, i.e., animal neurophysiology and sport sciences, may lead to mutual benefits. For instance, recording and manipulating the activity from neurons of behaving animals offer a unique viewpoint on the computations for motor control, with potentially untapped relevance for motor skills development in athletes. To stimulate such transdisciplinary dialog, in the present article, we also discuss steps for the reverse translation of sport sciences findings to animal models and the evaluation of comparability between animal models of a given sport and athletes. In the final section of the article, we envision that some approaches developed for animal neurophysiology could translate to sport sciences anytime soon (e.g., advanced tracking methods) or in the future (e.g., novel brain stimulation techniques) and could be used to monitor and manipulate motor skills, with implications for human performance extending well beyond sport.

Deletion of the endogenous TrkB.T1 receptor isoform restores the number of hippocampal CA1 parvalbumin-positive neurons and rescues long-term potentiation in pre-symptomatic mSOD1(G93A) ALS mice.
Amyotrophic lateral sclerosis (ALS) causes rapidly progressive paralysis and death within 5 years from diagnosis due to degeneration of the motor circuits. However, a significant population of ALS patients also shows cognitive impairments and progressive hippocampal pathology. Likewise, the mutant SOD1(G93A) mouse model of ALS (mSOD1), in addition to loss of spinal motor neurons, displays altered spatial behavior and hippocampal abnormalities including loss of parvalbumin-positive interneurons (PVi) and enhanced long-term potentiation (LTP). However, the cellular and molecular mechanisms underlying these morpho-functional features are not well understood. Since removal of TrkB.T1, a receptor isoform of the brain-derived neurotrophic factor, can partially rescue the phenotype of the mSOD1 mice, here we tested whether removal of TrkB.T1 can normalize the number of PVi and the LTP in this model. Stereological analysis of hippocampal PVi in control, TrkB.T1, mSOD1, and mSOD1 mice deficient for TrkB.T1 (mSOD1/T1) showed that deletion of TrkB.T1 restored the number of PVi to physiological level in the mSOD1 hippocampus. The rescue of PVi neuron number is paralleled by a normalization of high-frequency stimulation-induced LTP in the pre-symptomatic mSOD1/T1 mice. Our experiments identified TrkB.T1 as a cellular player involved in the homeostasis of parvalbumin expressing interneurons and, in the context of murine ALS, show that TrkB.T1 is involved in the mechanism underlying structural and functional hippocampal degeneration. These findings have potential implications for hippocampal degeneration and cognitive impairments reported in ALS patients at early stages of the disease.

Neural plasticity and network remodeling: From concepts to pathology.
Neuroplasticity has been subject to a great deal of research in the last century. Recently, significant emphasis has been placed on the global effect of localized plastic changes throughout the central nervous system, and on how these changes integrate in a pathological context. Specifically, alterations of network functionality have been described in various pathological contexts to which corresponding structural alterations have been proposed. However, considering the amount of literature and the different pathological contexts, an integration of this information is still lacking. In this paper we will review the concepts of neural plasticity as well as their repercussions on network remodeling and provide a possible explanation to how these two concepts relate to each other. We will further examine how alterations in different pathological contexts may relate to each other and will discuss the concept of plasticity diseases, its models and implications.

Nedd4-2 haploinsufficiency causes hyperactivity and increased sensitivity to inflammatory stimuli.
Nedd4-2 (NEDD4L in humans) is a ubiquitin protein ligase best known for its role in regulating ion channel internalization and turnover. Nedd4-2 deletion in mice causes perinatal lethality associated with increased epithelial sodium channel (ENaC) expression in lung and kidney. Abundant data suggest that Nedd4-2 plays a role in neuronal functions and may be linked to epilepsy and dyslexia in humans. We used a mouse model of Nedd4-2 haploinsufficiency to investigate whether an alteration in Nedd4-2 levels of expression affects general nervous system functions. We found that Nedd4-2 heterozygous mice are hyperactive, have increased basal synaptic transmission and have enhanced sensitivity to inflammatory pain. Thus, Nedd4-2 heterozygous mice provide a new genetic model to study inflammatory pain. These data also suggest that in human, SNPs affecting NEDD4L levels may be involved in the development of neuropsychological deficits and peripheral neuropathies and may help unveil the genetic basis of comorbidities.

Music, clicks, and their imaginations favor differently the event-based timing component for rhythmic movements.
The involvement or noninvolvement of a clock-like neural process, an effector-independent representation of the time intervals to produce, is described as the essential difference between event-based and emergent timing. In a previous work (Bravi et al. in Exp Brain Res 232:1663-1675, 2014a. doi: 10.1007/

BOARD NUMBER: S00221-014-3845-9), we studied repetitive isochronous wrist's flexion-extensions (IWFEs), performed while minimizing visual and tactile information, to clarify whether non-temporal and temporal characteristics of paced auditory stimuli affect the precision and accuracy of the rhythmic motor performance. Here, with the inclusion of new recordings, we expand the examination of the dataset described in our previous study to investigate whether simple and complex paced auditory stimuli (clicks and music) and their imaginations influence in a different way the timing mechanisms for repetitive IWFEs. Sets of IWFEs were analyzed by the windowed (lag one) autocorrelation-wγ(1), a statistical method recently introduced for the distinction between event-based and emergent timing. Our findings provide evidence that paced auditory information and its imagination favor the engagement of a clock-like neural process, and specifically that music, unlike clicks, lacks the power to elicit event-based timing, not counteracting the natural shift of wγ(1) toward positive values as frequency of movements increase.

Increased anxiety-like behavior and selective learning impairments are concomitant to loss of hippocampal interneurons in the presymptomatic SOD1(G93A) ALS mouse model.
Amyotrophic lateral sclerosis (ALS), a fatal neurodegenerative disease primarily characterized by motor neuron death, causes damages beyond motor-related areas. In particular, cognitive impairments and hippocampal damage have been reported in ALS patients. We investigated spatial navigation learning and hippocampal interneurons in a mutant SOD1(G93A) mouse (mSOD1) model of ALS. Behavioral tests were performed by using presymptomatic mSOD1 mice. General motor activity was comparable to that of wild-type mice in the open-field test, in which, however mSOD1 exhibited increased anxiety-like behavior. In the Barnes maze test, mSOD1 mice displayed a delay in learning, outperformed wild-type mice during the first probe trial, and exhibited impaired long-term memory. Stereological counts of parvalbumin-positive interneurons, which are crucial for hippocampal physiology and known to be altered in other central nervous system regions of mSOD1 mice, were also performed. At postnatal day (P) 56, the population of parvalbumin-positive interneurons in mSOD1 mice was already reduced in CA1 and in CA3, and at P90 the reduction extended to the dentate gyrus. Loss of parvalbumin-positive hippocampal interneurons occurred mostly during the presymptomatic stage. Western blot analysis showed that hippocampal parvalbumin expression levels were already reduced in mSOD1 mice at P56. The hippocampal alterations in mSOD1 mice could at least partly account for the increased anxiety-like behavior and deficits in spatial navigation learning. Our study provides evidence for cognitive alterations and damage to the γ-aminobutyric acid (GABA)ergic system in the hippocampus of murine ALS, thereby revealing selective deficits antecedent to the onset of motor symptoms.

Acetylcholine, GABA and neuronal networks: a working hypothesis for compensations in the dystrophic brain.
Duchenne muscular dystrophy (DMD), a genetic disease arising from a mutation in the dystrophin gene, is characterized by muscle failure and is often associated with cognitive deficits. Studies of the dystrophic brain on the murine mdx model of DMD provide evidence of morphological and functional alterations in the central nervous system (CNS) possibly compatible

with the cognitive impairment seen in DMD. However, while some of the alterations reported are a direct consequence of the absence of dystrophin, others seem to be associated only indirectly. In this review we reevaluate the literature in order to formulate a possible explanation for the cognitive impairments associated with DMD. We present a working hypothesis, demonstrated as an integrated neuronal network model, according to which within the cascade of events leading to cognitive impairments there are compensatory mechanisms aimed to maintain functional stability via perpetual adjustments of excitatory and inhibitory components. Such ongoing compensatory response creates continuous perturbations that disrupt neuronal functionality in terms of network efficiency. We have theorized that in this process acetylcholine and network oscillations play a central role. A better understating of these mechanisms could provide a useful diagnostic index of the disease's progression and, perhaps, the correct counterbalance of this process might help to prevent deterioration of the CNS in DMD. Furthermore, the involvement of compensatory mechanisms in the CNS could be extended beyond DMD and possibly help to clarify other physio-pathological processes of the CNS.

A little elastic for a better performance: kinesiotaping of the motor effector modulates neural mechanisms for rhythmic movements.

A rhythmic motor performance is brought about by an integration of timing information with movements. Investigations on the millisecond time scale distinguish two forms of time control, event-based timing and emergent timing. While event-based timing asserts the existence of a central internal timekeeper for the control of repetitive movements, the emergent timing perspective claims that timing emerges from dynamic control of nontemporal movements parameters. We have recently demonstrated that the precision of an isochronous performance, defined as performance of repeated movements having a uniform duration, was insensible to auditory stimuli of various characteristics (Bravi et al., 2014). Such finding has led us to investigate whether the application of an elastic therapeutic tape (Kinesio® Tex taping; KTT) used for treating athletic injuries and a variety of physical disorders, is able to reduce the timing variability of repetitive rhythmic movement. Young healthy subjects, tested with and without KTT, have participated in sessions in which sets of repeated isochronous wrist's flexion-extensions (IWFEs) were performed under various auditory conditions and during their recall. Kinematics was recorded and temporal parameters were extracted and analyzed. Our results show that the application of KTT decreases the variability of rhythmic movements by a 2-fold effect: on the one hand KTT provides extra proprioceptive information activating cutaneous mechanoreceptors, on the other KTT biases toward the emergent timing thus modulating the processes for rhythmic movements. Therefore, KTT appears able to render movements less audio dependent by relieving, at least partially, the central structures from time control and making available more resources for an augmented performance.

EFFECTS OF REPETITIVE VIBRATION ON FORCE CONTROL, PROPRIOCEPTION, AND NEURAL ACTIVITIES IN THE CNS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Li-Wei Chou[1], Ting Hsien Chan[1], Chueh-Ho Lin[2], Shun-Hwa Wei[1]
[1]National Yang Ming Chiao Tung University, Physical Therapy And Assistive Technology, Taipei city, Taiwan, [2]Taipei Medical University, Master Program In Long-term Care, Taipei, Taiwan

Background: Sensory afferent inputs play an important role in sensorimotor control and plasticity in the neuromuscular system. Here we investigate how repetitive vibration input affects sensorimotor control and neural activities in the CNS. **Methods:** Healthy adults received sensory level vibration (frequency range = 125 – 300 Hz) applied on the muscle belly of right wrist/finger flexors. We recorded and analyzed grip force control and proprioception, EEG and EMG in the following 6 time points: before vibration, during vibration, 10-min vibration, 20-min vibration, 10-post vibration, and 20-min post vibration. Principle Component Analysis was used to identify major EEG signals in alpha, beta and gamma frequency bands. **Results:** Our preliminary results indicated that the accuracy and stability of force control were significantly improved after 20-min vibration ($p < 0.05$). During vibration, moderate correlation was observed between grip force steadiness and alpha band EEG power ($r=0.71$, $p < 0.05$). Also, grip force steadiness was highly correlated with alpha band EEG power with 10-min of vibration ($r=0.85$, $p < 0.05$), and 20 minutes post vibration ($r=0.70$, $p < 0.05$). On the other hand, improvement in force accuracy was highly correlated with changes in EEG beta band power during vibration ($r=0.69$, $p < 0.05$). **Conclusion:** 20-min of repetitive vibration improves grip force accuracy and stability. Improvement in force control performance was associated with changes in brain activity, suggesting central mechanisms for vibration induced improvement in sensorimotor performance.

PRE-MOVEMENT SPINAL CORD ACTIVITY IN HUMANS: A SIMULTANEOUS BRAIN-SPINAL CORD FMRI STUDY

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Sho Sugawara[1], Noboru Usuda[1], Hiroyuki Fukuyama[2], Kiyomi Amemiya[2], Yukio Nishimura[1]
[1]Tokyo Metropolitan Institute of Medical Science, Neural Prosthetics Project, Tokyo, Japan, [2]Tokyo Metropolitan Matsuzawa Hospital, Department Of Radiology, Tokyo, Japan

A corticospinal circuit is an important role in the voluntary control of limb movements. Previous non-human primate studies demonstrated that spinal interneurons show pre-movement preparatory activity. However, it remains unknown pre-movement preparatory activity in the human spinal cord. Here, we aimed to illustrate pre-movement preparatory activity in the human corticospinal circuit by using simultaneous brain-spinal cord fMRI. Seventeen healthy volunteers were scanned with simultaneous brain-spinal cord fMRI while they performed the ready-set-go task in a 3T-MRI scanner. In this behavioral task, participants were asked to prepare to respond at the display of ready cue and to grip the force device as quickly as possible at the display of go cue. The averaged pre-movement activity was observed in the contralateral primary motor cortex (M1) and supplementary motor area (SMA) at the ready phase, but not in the spinal cord. On the other hand, the degree of preparatory activity at the C6-C7 segments, where the motor nuclei for forearm muscles are located, was positively correlated with subsequent reaction time and peak-grip force measured at the following go phase. In addition, the activity at C4 segment, where the propriospinal neurons which relay the signal to forearm motoneurons are located, was positively correlated only with subsequent peak force. Taken together, the present findings firstly reveal pre-movement preparatory activity in the human spinal cord, and that this pre-movement activity of cervical enlargement encodes future motor outputs of the handgrip.

IMPACT OF VISUOSPATIAL ATTENTION ON MOTOR CONTROL AND HAND FUNCTION AFTER STROKE

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Elisa Dziezuk[1], Quentin Le Boterff[1], Macarena Cuenca[2], Guillaume Turc[3], Sonia Hamdoun[4], Pålvel Lindberg[1]
[1]INSERM Psychiatry and Neuroscience Institute, U1266, Paris, France, [2]GHU paris Psychiatrie et neurosciences, Centre De Recherche Clinique, Paris, France, [3]GHU Paris Psychiatrie et Neurosciences, Neurologie, Paris, France, [4]GHU Paris Psychiatrie et Neurosciences, Médecine Physique Et Réadaptation, Paris, France

Introduction: Impaired manual dexterity is common after stroke, reducing autonomy and quality of life. Dexterity, defined as the fine control of finger movements, requires interplay between sensorimotor and cognitive functions. Impairments in divided attention, involved in allocating resources during dual-task exercises, may contribute to dexterity impairment and impact rehabilitation. However, studies relating visuospatial and dexterity impairments after stroke are lacking. **Aim**: To compare visuospatial attention in chronic stroke patients and controls and to establish the relationship between visuospatial attention and manual dexterity. **Methods**: A visuomotor grip-force tracking task is combined with oculomotor recordings to quantify sensorimotor precision during (i) simple force tracking, (ii) dual-task condition with visual distractors where the subject is instructed to inhibit ocular saccades and (iii) dual-task condition with addition of numbers displayed on the screen (subject is instructed to perform saccades). Two measures inform on visuospatial divided attention capacity: the % of saccades inhibited in the distractor task and the dual-task cost on precision of grip force tracking. Chronic stroke patients with mild-moderate hemiparesis are compared to age-comparable healthy controls. Visuospatial attention will be correlated with clinical motor and cognitive assessments and with dexterity data obtained using novel force sensor technology and tablet-based applications. **Results**: Data collection is ongoing and results will be presented. **Conclusion**: The data will provide insights on visuospatial attention in stroke and its impact on manual dexterity.

STUDY OF THE CORTICOSPINAL ACTIVITY IN SENSORIMOTOR INTEGRATION

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Gilles Delbecq[1], Philippe Isope[2], Matilde Cordero-Erausquin[2]
[1]CNRS - Université de Strasbourg, Institut Des Neurosciences Cellulaires Et Intégratives Upr 3212, Strasbourg, France, [2]CNRS, Institut Des Neurosciences Cellulaires Et Intégratives Upr 3212, Strasbourg, France

Motion is an essential function for animals. The motor command is generated in the motor cortex and relayed to different targets involved in muscle contraction and its fine control. One of them is the spinal cord, receiving direct cortical input through the corticospinal tract (CST). The cortex is also involved in the modulation of sensory information, which is essential for the performance of adapted and coordinated movements. We have recently demonstrated that the CST projecting to the lumbar cord is mainly involved in sensory modulation while the muscle contraction command is relayed more indirectly. Yet the exact functional role of the lumbar CST during behavior is still imperfectly described. Since motor cortex involvement in locomotion is debated, our aim is to elucidate the importance of the lumbar CST in different locomotor behaviors, and to characterize the function of the corticospinal (CS) neurons during these behaviors. To do so, we first set out to identify behavioral paradigms in which the lumbar CST is critically involved. This is performed by selectively perturbing the lumbar CS neurons through optogenetics, while precisely recording hindlimb movements using a motion capture apparatus during 'skilled locomotion tasks' such as crossing obstacles, a round beam, and a ladder. We are also setting up extracellular in vivo recordings in the cortex on behaving animals, with optotagging used to identify CS neurons. The activity of this population will inform us about the dynamics of the information targeting the spinal sensorimotor circuits during the different phases of the movement.

PLANNING OF MULTIPLE ACTIONS IN MOTOR CORTEX

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Nicolas Meirhaeghe, Alexa Riehle, Thomas Brochier
Institut de Neurosciences de la Timone (INT), Umr 7289, Cnrs-aix Marseille Université, Marseille, France

It has been argued that the motor system has the capacity to plan multiple movements simultaneously. The leading model based on neurophysiological data proposes that parallel motor plans are formed and compete for movement execution. Here we provide experimental evidence for an alternative model grounded in the dynamical system's theory of motor cortex. We recorded motor cortical activity in non-human primates performing an instructed two-grip grasping task. We found that, contrary to what the existing model predicts, motor plans associated with the two possible movements were not simultaneously formed. Rather, a single motor plan emerged reflecting a tradeoff between the two possible motor plans, consistent with a model where movement preparation is optimized for both movements. This model predicts a direct relationship between the optimization process and behavioral performance, which holds true empirically. Together, our results challenge current views on multiple-movement preparation and further point to motor planning as a controlled dynamical process.

A precise and adaptive neural mechanism for predictive temporal processing in the frontal cortex.
The theory of predictive processing posits that the brain computes expectations to process information predictively. Empirical evidence in support of this theory, however, is scarce and largely limited to sensory areas. Here, we report a precise and adaptive mechanism in the frontal cortex of non-human primates consistent with predictive processing of temporal events. We found that the speed of neural dynamics is precisely adjusted according to the average time of an expected stimulus. This speed adjustment, in turn, enables neurons to encode stimuli in terms of deviations from expectation. This lawful relationship was evident across multiple experiments and held true during learning: when temporal statistics underwent covert changes, neural responses underwent predictable changes that reflected the new mean. Together, these results highlight a precise mathematical relationship between temporal statistics in the environment and neural activity in the frontal cortex that may serve as a mechanism for predictive temporal processing.

Bayesian Computation through Cortical Latent Dynamics.
Statistical regularities in the environment create prior beliefs that we rely on to optimize our behavior when sensory information is uncertain. Bayesian theory formalizes how prior beliefs can be leveraged and has had a major impact on models of perception, sensorimotor function, and cognition. However, it is not known how recurrent interactions among neurons mediate Bayesian integration. By using a time-interval reproduction task in monkeys, we found that prior statistics warp neural representations in the frontal cortex, allowing the mapping of sensory inputs to motor outputs to incorporate prior statistics in accordance with Bayesian inference. Analysis of recurrent neural network models performing the task revealed that this warping was enabled by a low-dimensional curved manifold and allowed us to further probe the potential causal underpinnings of this computational strategy. These results uncover a simple and general principle whereby prior beliefs exert their influence on behavior by sculpting cortical latent dynamics.

Reinforcement regulates timing variability in thalamus.
Learning reduces variability but variability can facilitate learning. This paradoxical relationship has made it challenging to tease apart sources of variability that degrade performance from those that improve it. We tackled this question in a context-dependent timing task requiring humans and monkeys to flexibly produce different time intervals with different effectors. We identified two opposing factors contributing to timing variability: slow memory fluctuation that degrades performance and reward-dependent exploratory behavior that improves performance. Signatures of these opposing factors were evident

across populations of neurons in the dorsomedial frontal cortex (DMFC), DMFC-projecting neurons in the ventrolateral thalamus, and putative target of DMFC in the caudate. However, only in the thalamus were the performance-optimizing regulation of variability aligned to the slow performance-degrading memory fluctuations. These findings reveal how variability caused by exploratory behavior might help to mitigate other undesirable sources of variability and highlight a potential role for thalamocortical projections in this process.

A Network Perspective on Sensorimotor Learning.
What happens in the brain when we learn? Ever since the foundational work of Cajal, the field has made numerous discoveries as to how experience could change the structure and function of individual synapses. However, more recent advances have highlighted the need for understanding learning in terms of complex interactions between populations of neurons and synapses. How should one think about learning at such a macroscopic level? Here, we develop a conceptual framework to bridge the gap between the different scales at which learning operates, from synapses to neurons to behavior. Using this framework, we explore the principles that guide sensorimotor learning across these scales, and set the stage for future experimental and theoretical work in the field.

CHARACTERIZATION OF IMPAIRED MOTOR MOVEMENTS IN A MOUSE MODEL OF FREEZING OF GAIT

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Evelyn Dylda[1,2], Matthias Deliano[3], Lars Büntjen[4], Janelle Pakan[1,2,5]
[1]Otto-von-Guericke-University Magdeburg, Center For Behavioral Brain Sciences, Magdeburg, Germany, [2]Otto-von-Guericke-University Magdeburg, Institute Of Cognitive Neurology And Dementia Research, Magdeburg, Germany, [3]Leibniz Institute for Neurobiology, Translational Behavioral Physiology, Magdeburg, Germany, [4]Otto-von-Guericke-University Magdeburg, Department Of Stereotactic Neurosurgery, Magdeburg, Germany, [5]German Center for Neurodegenerative Diseases, Neural Circuits & Network Dynamics, Magdeburg, Germany

The ability to voluntarily initiate goal-directed motor movements is crucial for all animals. When suffering from movement disorders such as Parkinson's disease, fluent, continuous movements are often impaired. A common motor deficit experienced by Parkinson patients is freezing of gait (FoG), a form of akinesia described as sudden short periods of inability to start walking or failure to continue movement. FoG symptoms have been shown to be particularly difficult to treat with traditional methods, therefore, more dedicated models to investigate the underlying dynamics of FoG are necessary. Here we use open-source software packages to characterize motor movements in head-fixed mice with and without haloperidol-induced cataleptic periods to establish if this is an effective model to recapitulate FoG. Using DeepLabCut (Mathis et al. 2018) we track individual body parts and further utilize VAME (Luxem et al. bioRxiv), a probabilistic machine learning framework, to define motor repertoires in healthy motor states and haloperidol induced 'FoG' periods. We found dose-dependent changes in movement repertoires, with haloperidol injected mice showing less movement. The ability to map body movements reliably across individuals, with emphasis on deciphering specific motor states such as freezing, and then further linking these behavioral states to neuronal activity is vital to facilitate the dissection of neuronal mechanisms involved in these movement disorders.

A BAYESIAN HIDDEN MARKOV MODEL FOR TRACKING LONG-TERM DYNAMIC CHANGES IN NEURONAL POPULATION ACTIVITY OF THE MOTOR CORTEX OF MONKEYS CHRONIC MULTI-ELECTRODE ARRAYS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Kirchherr[1], Sebastián Mildiner Moraga[2], Coudé[1], Emmeke Aarts[2], Pier Francesco Ferrari[1], Bonaiuto[1]
[1]CNRS, Institut Des Sciences Cognitives, Bron, France, [2]Utrecht University, Department Of Methodology And Statistics, Utrecht, Netherlands

Plasticity induced by long-term learning, for example in motor control, is challenging to analyze at the single cell level due to difficulty in tracking single units over long periods of time. We demonstrate the application of Bayesian hidden Markov models (HMMs) to analyze the dynamics of neural population collected from chronic multi-electrode arrays from the primary and premotor cortex of two macaque monkeys during a reach-and-grasp task. This approach uses a parametric HMMs, which includes time-varying condition covariates and can be extended to have a multi-level structure including continuously distributed random effects. Our preliminary results suggest stable population dynamics over several weeks of recording for a well-learned reach and grasp task. Although the model trained only on multi-unit spiking activity and had no information about task-related or behavioral events, the onset or offset of each state is associated with a particular behavioral event, and this remains unchanged throughout the recording duration. This HMM framework is therefore suitable for analysis of longitudinal electrophysiological data, and potentially of experimentally induced plasticity at the neural population level during motor learning.

Impact of drug consumption rooms on risk practices and access to care in people who inject drugs in France: the COSINUS prospective cohort study protocol.
The high prevalence of hepatitis C and the persistence of HIV and hepatitis C virus (HCV) risk practices in people who inject drugs (PWID) in France underlines the need for innovative prevention interventions. The main objective of this article is to describe the design of the COSINUS cohort study and outline the issues it will explore to evaluate the impact of drug consumption rooms (DCR) on PWID outcomes. Secondary objectives are to assess how DCR (a) influence other drug-related practices, such as the transition from intravenous to less risky modes of use, (b) reduce drug use frequency/quantity, (c) increase access to treatment for addiction and comorbidities (infectious, psychiatric and other), (d) improve social conditions and (e) reduce levels of violence experienced and drug-related offences. COSINUS will also give us the opportunity to investigate the impact of other harm reduction tools in France and their combined effect with DCR on reducing HIV-HCV risk practices. Furthermore, we will be better able to identify PWID needs.

Impaired contrast sensitivity at low spatial frequency in cannabis users with early onset.
The regular use of cannabis generates pronounced cognitive disorders, especially in users who begin before the age of 15-16. However, less is known about the impact of regular cannabis on visual function, especially in the case of early onset. Cannabinoid receptors (CB1) are expressed in areas of the visual system, like the thalamus and primary cortex, which might originate sensory disorders. Hence, we measured contrast sensitivity (CS) in three groups, i.e. cannabis users with late onset of cannabis use (after 16 years old), cannabis users with early onset". We used a constant method which allowed us to control for biased responses. Stimuli were presented at high and low spatial frequencies and in both static and dynamic conditions (8Hz). As contrast sensitivity is measured behaviorally based on an explicit response and could thus be impacted by attentional or vigilance disorders, participants' attention and vigilance were carefully monitored by means of the D2 test, CPT-AX for attention and pupillography for vigilance. Cannabis users with early onset were significantly impaired only at low spatial frequency. This effect was independent of response bias, vigilance and attention. These results show for the first time that early cannabis use impacts contrast sensitivity at low spatial frequency.

DISSECTING THE ROLE OF THE EXTERNAL GLOBUS PALLIDUS SUBPOPULATIONS IN AN INSTRUMENTAL, NON-LOCOMOTOR TASK

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Julien Carponcy
University of Oxford, Mrc Brain Network Dynamics Unit, Oxford, United Kingdom

The external globus pallidus (GPe) constitute the middle node of the basal ganglia's (BG) indirect pathway, receiving inputs mainly from D2R-expressing striatal neurons and projecting to BG outputs, finally regulating behaviour. Within it, two main and non-overlapping populations have been described as prototypic (Lhx6+, PV+/-) and arkypallidal (FoxP2+) neurons. They possess different projection patterns, developmental origins, and are differently affected by the loss of dopamine in Parkinson's. Despite early evidences pointing at different roles for these subpopulations in locomotor control in health and disease, little is known on how dopamine release dynamically tune the different GPe populations, and how these, in turn, influence non-locomotor movements and action selection. We developed a reaching-and-grasping instrumental version of a "Go-NoGo" paradigm were mice were instructed to initiate a ballistic movement in order to obtain a sucrose reward on a "Go" cue, whereas they should remain still for the whole duration of a "NoGo" cue, to avoid a mild air-puff. Dopamine concentration in the dorsal striatum was monitored using fiber photometry and prototypic or arkypallidal neurons where suppressed at specific epochs within the task by the delivery of light to the GPe of transgenic mice expressing a soma-targeted opsin. Our preliminary observations suggests that contralateral prototypic inhibition preferentially decreases reaching (Go) performance, especially when initiated before movement onset. These early results suggest that prototypic neurons could be particularly involved during motor preparation and/or initiation. They will be complemented by large-scale electrophysiological recordings to examine the physiological dynamics of these subpopulations during our task.

CEREBELLAR GRANULE CELL TEMPORAL REPRESENTATIONS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Franziska Bender, David Digregorio
Institut Pasteur, Department Of Neuroscience, Paris, France

The cerebellum processes contextual information with an internal model (Wolpert et al, 1998) and generates delayed temporal associations between conditioned sensory and unconditioned stimuli (Medina et al, 2000) to fine-tune motor and cognitive behaviors. Each granule cell (GC) receives diverse sensory information from mossy fibers (MFs) to represent rich contextual information within the population (Chabrol et al, 2015; Ishikawa et al, 2015). Information from multiple modalities is integrated, expanded and recoded to maximize the number of sensory patterns that can be detected and finally control body muscles (Marr, 1969; Albus, 1971). The GC layer is thought to generate a diverse temporal representation that enables learning temporally precise behaviors (Medina et al. 2000). A network model from the lab suggests that input specific diversity of MF-GC synaptic dynamics are sufficient to generate diverse GC firing patterns that act as a temporal basis for cerebellar learning. We expressed fast GCaMP8f in GCs and measured the diversity of sensory responses in vivo using two-photon laser-scanning microscopy. We observed a temporal distribution of calcium response times and durations across the population, which could not be accounted for by trial to trial variability and was consistent with a diverse temporal representation. By sparse expression of glutamate reporter SF-iGluSnfr (Marvin et al., 2017) we simultaneously recorded from all MF-GC synapses of a given GC. Specific MF-GC synapses responded to selective sensory stimuli or combinations and with differences in firing frequencies and delays. Hence it is possible to explore the synaptic basis of GC temporal representations in vivo.

ONGOING CLINICAL, ELECTROPHYSIOLOGICAL AND BIOPHYSICAL EVIDENCE OF HIGH-DENSITY FRONTO-CEREBELLAR TRANSCRANIAL DIRECT CURRENT STIMULATION IN MOTOR STROKE

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Xavier Corominas[1], Rosa Maria San Segundo[2], Montse Fibla[2], Antoni Valero-Cabre[3], Maria Teresa Colomina[4]
[1]University Rovira and Virgily, Psychology, Tarragona, Spain, [2]Hospital universitari Joan XXIII, Medicina Física Y Rehabilitación, Tarragona, Spain, [3]Sorbonne université, Icm, Paris, France, [4]Universitat Rovira i Virgili, Center Of Environmental, Food And Toxicological Technology (tecnatox), Reus, Spain

Transcranial direct current stimulation has shown promise to boost and guide neural activity towards a facilitatory state for the recovery of motor deficits after large-scale networks dysfunctions following storkes. However, large heterogenic results have been reported mainly influenced by stroke lesion features and the large variety of tDCS protocols highlighting the need to move towards the use of multi-site set-ups targeting networks rather than focusing on local isolated effects. A first step to address such ambitious goals is explore the accumulative potential of neuromodulation to face new paradigms such a “large-scale modulation”, guiding the hole brain towards a facilitatory state for motor recovery reversing a previously identified large-scale neural signature linking attentional with motor networks. We here designed a double-blind, sham-controlled, randomized pilot experimental study probing a new tDCS protocol targeting ipsilesional prefrontal and contralesional cerebellar areas aiming to recruit a cohort of 60 stroke chronic patients which will be randomized in 4 groups according to stimulation site: (I): Prefrontal ipsilesional (DLPFC) tDCS, (II): Contralesional cerebellar tDCS, (III): Combined prefrontal and cerebellar tDCS, (IIII): Sham tDCS, delivering respectively 1.7mA, 2.0mA, 3.7mA or 0mA in a 10 daily sessions intervention of 21 min. each. To date, we have designed the clinical trial and successfully employed a MRI based biophysical computational model tDCS optimization in a pilot cohort of n=8 stroke patients, allowing us to proof the feasibility and tolerability of this protocol and extract the electroencephalographic and behavioral response to this new intervention aiming to became a new tDCS treatment.

DYNAMIC MOTOR PRACTICE IMPROVES MOVEMENT ACCURACY, FORCE CONTROL AND LEADS TO INCREASED CORTICOSPINAL EXCITABILITY COMPARED TO ISOMETRIC MOTOR PRACTICE

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Malene Norup Stolpe, Jonas Rud Bjørndal, Patrick Wiegel, Jesper Lundbye-Jensen
University of Copenhagen, Department Of Nutrition, Exercise And Sports, Copenhagen N, Denmark

Different studies of human motor learning use behavioral models involving isometric contractions or dynamic motor practice (MP). To our knowledge, it has however not been investigated how dynamic motor practice influences force control and vice versa. Furthermore, it remains unexplored whether different types of MP are accompanied by differential effects on corticospinal excitability (CE). We tested effects of motor practice in a force or position control task involving discrete wrist flexions in the absence of online visual feedback. Motor performance quantified as errors (pixels) between the displayed target and the movement endpoint. In the main experiment, fourty-eight young adults were randomized to; position control (PC), force control (FC) motor practice or a resting control group (CON). Motor performance was assessed in both tasks before and after four blocks of motor practice with augmented visual feedback on performance. In the supplementary experiment, measures of CE was obtained in 20 additional participants by application of transcranial magnetic stimulation to the contralateral primary motor cortex prior to and following either PC or FC motor practice. The results demonstrate that performance in the force and position tasks improved from baseline to post tests, particularly for the task practiced. Additionally, position control practice also lead to improvements in force control. Motor practice with emphasis on position control was accompanied by increased CE compared to the changes observed following force control motor practice. In conclusion, dynamic motor practice improves movement accuracy, force control and leads to increased corticospinal excitability compared to isometric motor practice.

HEBBIAN PRIMING OF SPINAL MECHANISMS INVOLVED IN MOTOR LEARNING

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Jonas Rud Bjørndal[1], Mikkel Malling Beck[1,2], Lasse Jespersen[1], Lasse Christiansen[2], Jesper Lundbye-Jensen[1]
[1]University of Copenhagen, Department Of Nutrition, Exercise And Sports, Copenhagen N, Denmark, [2]Copenhagen University Hospital Amager and Hvidovre, Danish Research Centre For Magnetic Resonance, Centre For Functional And Diagnostic Imaging And Research, Hvidovre, Denmark

Improvements in motor control with practice rely on experience-dependent plasticity in sensorimotor networks involving spike-timing- and frequency-dependent changes in synaptic efficacy. Spike-timing-dependent bidirectional changes in corticospinal transmission can be induced by repeatedly pairing cortical transcranial magnetic stimulation (TMS) and motoneuronal electrical stimulation (i.e. paired corticomotoneuronal stimulation, PCMS) timed to arrive at the corticomotoneuronal synapses in close temporal proximity. It remains to be investigated if PCMS-induced Hebbian plasticity at the corticomotoneuronal level can prime subsequent motor learning. In a within-subject, cross-over design, eighteen neurologically intact participants practiced a ballistic finger flexion task following PCMS with inter-arrival intervals adjusted to promote ($PCMS_{-2}$) or inhibit ($PCMS_{+15}$) corticomotoneuronal transmission and following a control protocol ($PCMS_{+100}$). Superior learning was observed following $PCMS_{-2}$ compared to $PCMS_{+15}$ and the control protocol. As baseline performance did not differ between the three PCMS protocols, spinal mechanisms induced by $PCMS_{-2}$ likely interacted with training-induced effects to enhance learning. Follow-up experiments comparing $PCMS_{-2}$ to training alone confirmed the enhancing effect on learning. Amplitudes of motor evoked potentials (MEP) elicited in the resting FDI muscle by use of primary motor cortex TMS increased following PCMS. Only the $PCMS_{-2}$ protocol maintained increased corticospinal excitability after motor practice. Taken together, the results provide proof-of-principle that spinal plasticity accompanying motor learning can be primed by non-invasively induced plasticity governed by Hebbian learning rules. This offers a mechanistic rationale for priming of spinal mechanisms involved in sensorimotor training with individualized PCMS to enhance effects of motor practice e.g., in neurorehabilitation and sports.

Comprehension of Movement Variability is essential for exploring motor performance and motor skill learning. Even very trivial movements have considerable variability when repeated across trials. Earlier studies in humans have shown that movement variability is at the core of our rich motor repertoire and its adaptability. The current study aims at understanding the kinematic and neuronal sources of movement variability in monkeys. The kinematic data for this study has been recorded from two rhesus macaques during their performance of a visuo-motor (sequential landing) task using an exoskeleton robotic arm (Kinarm, Bkin). In parallel, extracellular multi-electrode recordings were obtained from multiple cortical areas along the visuo-motor pathway (motor areas M1/PMd, parietal areas DP, 7A and visual areas V1, V2). The monkeys were over-trained and performed the same task over months under the same protocols. We first found that the variability of hand trajectories is modulated by movement amplitude and direction, but for each given movement it is highly consistent across sessions and animals. Furthermore, movements with similar directions tend to show very similar trajectory variabilities. Trajectory variability show distinct levels of correlation with elbow and shoulder angular velocities and with their degrees of coordination that is specific to each monkey. The specific trends and patterns thus observed reveal the complex origin of hand movement variability. Cortical recordings will be further used to investigate the contribution of neuronal variability in different areas to hand movement variabilities.

Learning a motor task involves two distinct processes: the selection of a motor strategy that meets the objectives of the task and the optimisation of movement execution within that strategy. Previous studies have highlighted the key role of the basal ganglia, cerebellum and sensorimotor cortical areas in each of these two processes. However, the nature of the interactions between these processes during long-term learning and their neural correlates is not yet determined (*Penhune et al.,* 2011; *Diedrichsen et al.,* 2019). In order to address this issue, our work aims to characterise the behavioural correlates of long-term learning of a complex visual-motor task in macaque monkeys. In a second step, we will analyse the neural activity of several visual-motor cortical areas during this learning. In our task, six visual targets appear simultaneously on a screen, always at the same location. The monkey has to touch each target to obtain a reward. No instructions were given on the sequence in which the targets had to be reached. The performance of the two monkeys during the learning of this task was analysed over several months. Interestingly, both animals adopted the same evolution of the strategy used to reach the targets and of the motor performance to execute the movement. Our results demonstrate the close coupling between these two processes and clarifies the contribution of the visual-motor cortical network to their implementation.

USING EEG, EMG, AND OP-MEG TO STUDY FUNCTIONAL OSCILLATORY CONNECTIVITY DURING HUMAN STEPPING

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Meaghan Elizabeth Spedden[1], Beck[2], Tierney[3], O'Neill[3], Mellor[3], West[4], Farmer[5], Barnes[3], Nielsen[6], Jesper Lundbye-Jensen[1]
[1]University of Copenhagen, Nutrition, Exercise, And Sports, Copenhagen N, Denmark, [2]Danish Research Centre for Magnetic Resonance, Centre For Functional And Diagnostic Imaging And Research, Hvidovre, Denmark, [3]Wellcome Centre for Human Neuroimaging, Ucl Institute Of Neurology, London, United Kingdom, [4]University of Oxford, Nuffield Department Of Clinical Neurosciences, Oxford, United Kingdom, [5]The National Hospital for Neurology and Neurosurgery, Department Of Clinical Neurology, London, United Kingdom, [6]University of Copenhagen, Department Of Neuroscience, Copenhagen, Denmark

The brain and spinal mechanisms underlying the act of taking a step - including planning, execution, and modification - are not well understood. We hypothesized that oscillatory communication in a parieto-frontal and cortico-muscular network is involved in the neural control of visually guided steps. We addressed this hypothesis using source reconstruction and directed functional connectivity analysis of electroencephalographic (EEG) and electromyographic (EMG) recordings during visually guided stepping (n=24). We also report preliminary data from optically-pumped magnetometry-based magnetoencephalography (OP-MEG) during the same task (n=1). Steps were divided into planning, initiation, and execution phases. The EEG analysis demonstrated that taking a step was characterized by an up-regulation of beta/gamma coherence within the parieto-frontal network during planning followed by a down-regulation of alpha and beta/gamma coherence during initiation and execution. Step modification based on visual information involved bi-directional alpha and beta/gamma coherence modulations in the parieto-frontal network during the phases leading up to step execution. The OP-MEG analysis was able to replicate features of cortico-muscular coherence demonstrated previously with other modalities during walking. Results from an exploratory analysis also suggest that OP-MEG may be able to capture functional cerebellar-spinal and cerebello-cortical connectivity during human movement. The results suggest that the central nervous system modulates lagged synchronization of neural oscillations in the context of large-scale movements, suggesting a process of flexibly fine-tuning inter-regional communication by coherence to achieve precision control during human stepping. The OP-MEG results support the feasibility of applying this new technique to explore the spatio-temporal brain dynamics underlying natural movement.

CORTICOSPINAL NEURONS IN THE SELECTIVE EXECUTION OF LEARNED ACTIONS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Michelle Sanchez Rivera, Stephen Currie, Julian Ammer, Julia Schiemann, Joshua Dacre, Federico Claudi, Ian Duguid
University of Edinburgh, Centre For Discovery Brain Sciences, Edinburgh, United Kingdom

When interacting with their environment animals must select actions that result in favourable outcomes, whilst avoiding inappropriate actions. Primate and rodent studies have demonstrated strong correlations between the activity of corticospinal neurons (CSNs) and sensory-evoked motor responses, but how their spatiotemporal activity patterns relate to the selective execution of appropriate actions, remains unresolved. To address this, we used two-photon population calcium imaging of CSNs in head-restrained mice trained to execute a Go/NoGo forelimb lever push task. During Go trials, mice learned to execute highly stereotyped lever pushes; during NoGo trials mice responded with a rapid lever release-and-regrasp, followed by a long period of quiescence. From a population of 1051 CSNs, approximately half exhibited cue-evoked activity changes, the majority (91%) of which were trial-type specific. In upper layer 5B, we found that trial-type-specific responses and the direction of change (i.e., increase or decrease) were depth dependent, with superficial CSNs encoding either Go or NoGo trials via an increase in activity, while deeper CSNs almost exclusively encoded Go trials with a reduction in activity. To investigate whether dendritic activity patterns reflected somatic trial-type-specific output, we performed near-simultaneous imaging of the apical and distal dendrites of identified CSNs during task execution. We found that large-scale global changes in proximal and distal dendritic activity mirrored somatic trial-type specificity, suggesting a high degree of somato-dendritic coupling in motor cortical layer 5B neurons. Together, our data provide new insights into the spatiotemporal and depth-dependent organisation of movement-specific signalling in mouse CSNs.

NEURAL BASIS OF ANTICIPATION AND PREMATURE IMPULSIVE ACTION IN THE FRONTAL CORTEX

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Robertas Guzulaitis[1,2], Luca Godenzini[2], Lucy Palmer[2]
[1]Vilnius University, The Life Sciences Center, Vilnius, Lithuania, [2]University of Melbourne, Florey Institute Of Neuroscience And Mental Health, Melbourne, Australia

Planning and anticipating motor actions can increase behavioral performance[1], however, it can also lead to premature impulsive actions[2]. Although the anterior lateral motor cortex (ALM) is known to contribute to correct motor planning[3], it is currently unknown whether it is also involved in premature motor output. Here, this was addressed by using whole-cell patch clamp recordings from layer 2/3 (L2/3) pyramidal neurons within the ALM while mice were performing a cued-sensory association task. During both correct and premature performance in the task, a robust voltage response was evoked in L2/3 pyramidal neurons during the auditory cue. This cue-evoked voltage response was context dependent and greater during premature behavior. Optogenetically suppressing ALM during the cued-sensory association task lead to enhanced behavior, with fewer, and more delayed, premature responses and faster correct responses. Taken together, our findings suggest that ALM plays a critical role in anticipation by not only contributing to motor planning but by also driving premature actions. ACTIVITY IN MOUSE MOTOR CORTEX REFLECTS ACTION AND ITS LEARNED AUDITORY CONSEQUENCES

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Brooke Holey, David Schneider
New York University, Center For Neural Science, New York, United States of America

Movements make sounds. It is essential to retain sensitivity to environmental sounds during behavior, amidst all the sounds produced by one's own actions. Consistent with this perceptual need, neural responses to self-generated sounds are suppressed in the auditory cortex (A1), which is thought to involve motor cortical inputs that engage local A1 inhibitory circuits. However, it remains unknown what signals are sent from motor cortex to A1 during sound-generating behaviors, nor is it known whether motor-cortical activity reflects expectations regarding the acoustic outcome of an action. To answer these questions, we trained mice to push a lever that makes a highly predictable, experimenter-controlled sound. We then made extracellular recordings from the secondary motor cortex (M2), paired with optogenetic identification of A1-projecting M2 cells. A majority of M2 neurons are active during lever presses and a large fraction of cells have peak firing rates tightly aligned to the self-generated tone. Compared to the entire M2 population, A1-projecting M2 cells are more likely to be active just prior to the tone and a sub-population of M2 cells also respond to passively played tones. Interestingly, during sound-generating movements, the activity of many M2 cells are not well predicted as a linear sum of the same cell's activity during silent movements and in response to passive tones. These data indicate that M2 neurons integrate signals related to movement and sound, that specific movement-related information is selectively routed to A1, and that aspects of M2 timing are shaped by motor-auditory experience.

SEVEN YEARS OF BAD LUCK: CRACKS IN THE LONGSTANDING MIRROR NEURON HYPOTHESIS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

James Goodman[1], Stefan Schaffelhofer[2], Hansjörg Scherberger[1,3]
[1]Deutsches Primatenzentrum GmbH (German Primate Center), Neurobiology Laboratory, Goettingen, Germany, [2]cortEXplore GmbH, -, Linz, Austria, [3]University of Goettingen, Faculty Of Biology And Psychology, Goettingen, Germany

The primate parietofrontal grasping network, which comprises the anterior intraparietal area (AIP), rostroventral premotor cortex (F5), and primary motor cortex (M1), canonically performs visuomotor transformations necessary for the planning and execution of dexterous hand movements. Embedded in this circuit is also thought to be an action observation system wherein mirror neurons process observed movements as though they were executed. To address substantial controversy surrounding this putative mirror neuron system, we leveraged a large object set and population analyses enabled by multi-array neuronal recordings. We find substantial activity in F5 and AIP during action observation, but fail to find evidence for distinct clusters of mirror and nonmirror neurons. Nonetheless, we identify a latent subspace which processes visual features of objects even in the absence of the intention to move, and another orthogonal subspace which captures patterns of movement-related activity that are identical across action execution and observation contexts. However, within all cortical areas spanned by the grasping network, this latter subspace lacks grip-specific patterns of activity. Moreover, the observation context *per se* lacks grip-specific information interpretable by a linear grip classifier. We conclude that existing hypotheses about the neural processing of observed action are in need of revisions which dispense with a privileged subset of mirror neurons and which unequivocally identify the constraints on the action specificity of observation-related activity.

Neural population dynamics in motor cortex are different for reach and grasp.
Low-dimensional linear dynamics are observed in neuronal population activity in primary motor cortex (M1) when monkeys make reaching movements. This population-level behavior is consistent with a role for M1 as an autonomous pattern generator that drives muscles to give rise to movement. In the present study, we examine whether similar dynamics are also observed during grasping movements, which involve fundamentally different patterns of kinematics and muscle activations. Using a variety of analytical approaches, we show that M1 does not exhibit such dynamics during grasping movements. Rather, the grasp-related neuronal dynamics in M1 are similar to their counterparts in somatosensory cortex, whose activity is driven primarily by afferent inputs rather than by intrinsic dynamics. The basic structure of the neuronal activity underlying hand control is thus fundamentally different from that underlying arm control.

Postural Representations of the Hand in the Primate Sensorimotor Cortex.
Manual dexterity requires proprioceptive feedback about the state of the hand. To date, study of the neural basis of proprioception in the cortex has focused primarily on reaching movements to the exclusion of hand-specific behaviors such as grasping. To fill this gap, we record both time-varying hand kinematics and neural activity evoked in somatosensory and motor cortices as monkeys grasp a variety of objects. We find that neurons in the somatosensory cortex, as well as in the motor cortex, preferentially track time-varying postures of multi-joint combinations spanning the entire hand. This contrasts with neural responses during reaching movements, which preferentially track time-varying movement kinematics of the arm, such as velocity and speed of the limb, rather than its time-varying postural configuration. These results suggest different representations of arm and hand movements suited to the different functional roles of these two effectors.

28440308: Goodman JM, Bensmaia SJ
A Variation Code Accounts for the Perceived Roughness of Coarsely Textured Surfaces.
For decades, the dominant theory of roughness coding in the somatosensory nerves posited that perceived roughness was determined by the spatial pattern of activation in one population of tactile nerve fibers, namely slowly adapting type 1 (SA1) afferents. Indeed, the perceived roughness of coarsely textured surfaces tracks the spatial variation in SA1 responses - the

degree to which response strength varies across SA1 afferents. However, in a later study, the roughness of a different set of dot patterns was found to be a monotonic function of dot spacing, a result interpreted as evidence that roughness was determined by the strength of SA1 responses - the population firing rate - rather than their spatial layout. Then again, the spatial variation hypothesis was not tested directly as afferent responses to the conflicting patterns were not measured. To fill this gap, we simulated afferent responses to the dot patterns used in these roughness coding experiments using a model of skin mechanics. We then implemented the spatial variation and firing rate models of roughness based on these simulated responses to generate predictions of perceived roughness. We found that the spatial variation model accounts for perceived roughness under all tested conditions whereas the firing rate model does not.

Controlled unilateral isometric force generated by epidural spinal cord stimulation in the rat hindlimb.
Epidural electrical stimulation (EES) has often been used to restore stereotypic locomotor movements after spinal cord injury (SCI). However, restoring freeform movement requires specific force generation and independently controlled limbs for changing environments. Therefore, a second stimulus location would be advantageous, controlling force separately from locomotor movements. In normal and transected rats treated with mineral oil or saline, EES was performed at L1-L6 vertebral levels, caudal to spinal segments typical for locomotion, identifying secondary sites capable of activating hindlimb musculature, producing unilateral force at the paw. Threshold for generating force was identified and stimulation amplitude and duration varied to assess effects on evoked forces. Stimulation at L2 and L3 vertebral levels elicited negative vertical forces from extensor musculature while stimulation at L4 and L5 elicited positive vertical forces from flexion musculature. Thresholds were unchanged with transection or hydration method. Peak force magnitude was significantly correlated to stimulus amplitude, and response duration significantly correlated to stimulus duration in all animals. No differences were found in correlation coefficients or slopes of the regression for force or duration analyses with spinal condition or hydration method. This model demonstrates the ability to induce controlled forces with EES after SCI.

Decoding hand kinematics from population responses in sensorimotor cortex during grasping.
The hand-a complex effector comprising dozens of degrees of freedom of movement-endows us with the ability to flexibly, precisely, and effortlessly interact with objects. The neural signals associated with dexterous hand movements in primary motor cortex (M1) and somatosensory cortex (SC) have received comparatively less attention than have those associated with proximal upper limb control.

Unexpected complexity of everyday manual behaviors.
How does the brain control an effector as complex and versatile as the hand? One possibility is that neural control is simplified by limiting the space of hand movements. Indeed, hand kinematics can be largely described within 8 to 10 dimensions. This oft replicated finding has been construed as evidence that hand postures are confined to this subspace. A prediction from this hypothesis is that dimensions outside of this subspace reflect noise. To address this question, we track the hand of human participants as they perform two tasks-grasping and signing in American Sign Language. We apply multiple dimension reduction techniques and replicate the finding that most postural variance falls within a reduced subspace. However, we show that dimensions outside of this subspace are highly structured and task dependent, suggesting they too are under volitional control. We propose that hand control occupies a higher dimensional space than previously considered.

Finger Posture and Finger Load are Perceived Independently.
The ability to track the time-varying postures of our hands and the forces they exert plays a key role in our ability to dexterously interact with objects. However, how precisely and accurately we sense hand kinematics and kinetics has not been completely characterized. Furthermore, the dominant source of information about hand postures stems from muscle spindles, whose responses can also signal isometric force and are modulated by fusimotor input. As such, one might expect that changing the state of the muscles - for example, by applying a load - would influence perceived finger posture. To address these questions, we measure the acuity of human hand proprioception, investigate the interplay between kinematic and kinetic signals, and determine the extent to which actively and passively achieved postures are perceived differently. We find that angle and torque perception are highly precise; that loads imposed on the finger do not affect perceived joint angle; that joint angle does not affect perceived load; and that hand postures are perceived similarly whether they are achieved actively or passively. The independence of finger posture and load perception contrasts with their interdependence in the

upper arm, likely reflecting the special functional importance of the hand.

THE LIMIT OF CROSSING FINGERS: WHEN SPATIAL REPRESENTATION FAILS TO FOLLOW BODY POSTURE

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Lucile Dupin, Pável Lindberg
Institut de Psychiatrie et Neurosciences de Paris, Inserm/université De Paris, Paris, France

Aristotle's illusion, a well-known tactile illusion, corresponds to the perception of two objects when crossed index and middle fingers are in contact with only one object. In this case, perceiving two objects rather than one involves spatial coding of skin parts not updated by the posture of the crossed fingers. This failure to take the postural configuration into account, when processing the two tactile sensations arising from the contact with the object, has been supposed to be caused by the unusual finger posture or the unusual simultaneous contact area (external part of the two fingers). However, these two potential explanations suggest different mechanisms: the first relies on failed updating of spatial body representation and the second on the failure of the spatial association between two tactile sensations. The aim of this study is to identify if Aristotle's illusion originates from a failure of body representation or tactile object processing. To do so, we assessed the spatial representation of both the skin and fingers using tactile and verbal instructions, respectively. Participants with eyes closed had to indicate where he/she localizes different targets (knuckles and nails) in three different hand configuration conditions: fingers apart, fingers together, crossed fingers. As there is no object perception in the task, a failure to update body representation -and accordingly individual tactile stimuli- in the finger crossed condition, would mean that a spatial body representation mechanism is the origin of the illusion. Indeed, preliminary data indicate that the Aristotle's illusion has not a pure somatosensory origin.

MOTOR RESPONSES INDUCED BY INTRACORTICAL MICROSTIMULATION OF VENTRAL PREMOTOR MIRROR NEURONS

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Sofie De Schrijver[1,2], Thomas Decramer[3], Peter Janssen[1,2]
[1]KU Leuven, Research Group Neuro- And Psychophysiology, Leuven, Belgium, [2]KU Leuven, Leuven Brain Institute, Leuven, Belgium, [3]KU Leuven, Research Group Experimental Neurosurgery And Neuroanatomy, Leuven, Belgium

The premotor cortex is known to play a pivotal role in the processing of visuomotor actions. Previous studies have shown that it is possible to evoke mouth, hand and arm movements using intracortical microstimulation in premotor cortex. However, it is unknown to what extent motor responses can be evoked by microstimulation of mirror neurons in ventral premotor cortex (PMv). These neurons, which respond to both action execution and action observation, were discovered in area F5c of PMv. To investigate the causal role of PMv mirror neurons, we implanted 96-channel Utah arrays in area F5c in two macaque monkeys that were trained to perform a visually guided grasping task and to fixate videos of actions. We tested mirror activity during passive fixation of videos of a human or a monkey hand performing the same grasping task. In 33 sessions, we tested the motor responses when stimulating both mirror and non-mirror sites. Stimulation trains of biphasic pulses (duration 1 ms) were delivered at 100 Hz for 1000 ms at rest. We could evoke simple to complex movements of hand, arm and/or mouth with moderate currents, ranging from 60 to 130µA, in the large majority of both mirror and non-mirror sites. Furthermore, subthreshold microstimulation of F5c while the monkeys performed the visually guided delayed grasping task induced increased grasping times ($p < 0.05$), both in mirror (47%) and non-mirror (43%) sites. Together, these results have important implications for the interpretation of mirror neuron activity in PMv.

MOVEMENT EXECUTION ERROR AND TASK-PERFORMANCE FEEDBACK INDUCE OPPOSITE PATTERNS OF BETA BAND ACTIVITY

POSTER SESSION 01 - SECTION: VOLUNTARY CONTROL OF MOVEMENT

Antoine Schwey[1], Jyotika Bahuguna[2], Battaglia Demian[3], Nicole Malfait[1]
[1]CNRS/AMU, Institut De Neurosciences De La Timone (int), Umr 7289, Marseille, France, [2]Carnegie Mellon University, Department Of Psychology, Pittsburgh, United States of America, [3]Aix-Marseille Université, Institute For Systems Neuroscience, Marseille, France

Beta-band modulations following reward, task outcome feedback and error have been observed in cognitive and motor tasks. Observations from different studies are, however, difficult to conciliate. Among studies using cognitive response selection task, several reported an increase in beta-band activity following reward, whereas others on the contrary observed increased beta-power after negative outcome feedback (i.e., task error). On the other hand, in motor adaptation tasks, movement-execution errors are followed by an attenuation of the post-movement beta-rebound. Considering that, in motor tasks, kinematic error typically leads to and thus is associated with task error (e.g., target missed), one may wonder how opposite patterns (decrease for movement error vs increase for task error) may coexist. In the present study, with the same healthy participants and within the same task, we separate beta-activity in medial parietal (precuneus) and medial frontal (SMA) regions using independent component analysis. Consistent with our previous results, we find that medial-parietal low-beta power is significantly decreased by kinematic errors but is not sensitive to task error. Whereas medial-frontal high-beta activity is significantly modulated by task error, but not significantly altered by kinematic error. In addition, we find that medial-frontal high-beta band activity is significantly modulated during two trial epochs. Shortly after (~250ms) task performance feedback, high-beta is increased in successful trials, whereas at a longer latency (~800ms) high-beta power increase is associated with task failure. Our findings allow conciliating seemingly contradictory observations reported in separate studies. We discuss complementary hypotheses that may explain the functionally distinct observed beta-band activities.

EFFECTS OF EARLY LIFE STRESS IN AMYGDALA MICROCIRCUITRY AND SOCIO-AFFECTIVE BEHAVIOR: WHY SEX AND AGE MATTER

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Aroa Mañas-Ojeda, Clara García Mompó, José Francisco Hidalgo-Cortés, Mónica Navarro Sánchez, Isis Gil-Miravet, Esther Castillo-Gómez
Universitat Jaume I, Department Of Medicine, Castellón de la Plana, Spain

Neglect is the most common form of child abuse. It has been related to serious socio-affective disorders that can emerge either immediately or later in life. Although the underlying neural mechanisms remain poorly understood, it has been demonstrated that the amygdala has an important role in mediating these behavioral effects. Moreover, little attention has been paid to whether males and females respond differently to similar situations of child social neglect and whether these differences can be observed at the microcircuitry level (excitatory and inhibitory synapses). We hypothesize that early life stress in mice will affect socio-affective behavior and the balance between excitatory and inhibitory (E/I) synapses in MeA, BLA and/or CeA. These effects might be observed in the short and long term and also be dependent on sex. Therefore, our main objective will be to demonstrate our hypothesis in an animal model of child social neglect (maternal separation with early weaning, MSEW). Pups from the MSEW group were daily separated from their mothers for 4-8h from P2-P16 and were definitely weaned at P17. Socio-affective behavior was evaluated by the Open Field Test, Forced Swimming Test, Three Chamber (sociability and novelty), and Tube Dominance test. Then, E/I balance was measured by immunofluorescence of VGLUT1, VGLUT2 and VGAT markers. The long-term consequences of early life stress on socio-affective behavior are sex-dependent and are correlated with imbalances between excitatory and inhibitory synapses in different nuclei of the amygdala. However, in the short term, only behavioral alterations were observed in both males and females.

Becoming Stressed: Does the Age Matter? Reviewing the Neurobiological and Socio-Affective Effects of Stress throughout the Lifespan.
Social and affective relations occur at every stage of our lives. Impairments in the quality of this "social world" can be exceptionally detrimental and lead to psychopathology or pathological behavior, including schizophrenia, autism spectrum disorder, affective disorders, social phobia or violence, among other things. Exposure to highly stressful or traumatic events, depending on the stage of life in which stress exposure occurs, could severely affect limbic structures, including the amygdala, and lead to alterations in social and affective behaviors. This review summarizes recent findings from stress research and provides an overview of its age-dependent effects on the structure and function of the amygdala, which includes molecular and cellular changes, and how they can trigger deviant social and affective behaviors. It is important to highlight that discoveries in this field may represent a breakthrough both for medical science and for society, as they may help in the development of new therapeutic approaches and prevention strategies in neuropsychiatric disorders and pathological behaviors.

Relaxin-3 Innervation From the Nucleus Incertus to the Parahippocampal Cortex of the Rat.
Spatial learning and memory processes depend on anatomical and functional interactions between the hippocampus and the entorhinal cortex. A key neurophysiological component of these processes is hippocampal theta rhythm, which can be driven from subcortical areas including the pontine (NI). The NI contains the largest population of neurons that produce and presumably release the neuropeptide, relaxin-3, which acts via the G -protein-coupled receptor, relaxin-family peptide 3 receptor (RXFP3). NI activation induces general arousal including hippocampal theta, and inactivation induces impairment of spatial memory acquisition or retrieval. The primary aim of this study was to map the NI/relaxin-3 innervation of the parahippocampal cortex (PHC), including the medial and lateral entorhinal cortex, endopiriform cortex, perirhinal, postrhinal, and ectorhinal cortex, the amygdalohippocampal transition area and posteromedial cortical amygdala. Retrograde tracer

injections were placed in different parts of the medial and lateral entorhinal cortex, which produced prominent retrograde labeling in the ipsilateral NI and some labeling in the contralateral NI. Anterograde tracer injections into the NI and immunostaining for relaxin-3 produced fiber labeling in deep layers of all parahippocampal areas and some dispersed fibers in superficial layers. Double-labeling studies revealed that both hippocampal projecting and calcium-binding protein-positive (presumed GABAergic) neurons received a relaxin-3 NI innervation. Some of these fibers also displayed synaptophysin (Syn) immunoreactivity, consistent with the presence of the peptide at synapses; and relaxin-3-positive fibers containing Syn bouton-like staining were frequently observed in contact with hippocampal-projecting or calcium-binding protein-positive neuronal somata and more distal elements. Finally, hybridization studies revealed that entorhinal neurons in the superficial layers, and to a lesser extent in deep layers, contain RXFP3 mRNA. Together, our data support functional actions of the NI/relaxin-3-parahippocampal innervation on processes related to memory, spatial navigation and contextual analysis.

Involvement of the and Relaxin-3/RXFP3 Signaling System in Explicit and Implicit Memory.

Telencephalic cognitive and emotional circuits/functions are strongly modulated by subcortical inputs. The main focus of past research on the nature of this modulation has been on the widespread monoamine projections to the telencephalon. However, the (NI) of the pontine tegmentum provides a strong GABAergic and peptidergic innervation of the hippocampus, basal forebrain, amygdala, prefrontal cortex, and related regions; and represents a parallel source of ascending modulation of cognitive and emotional domains. NI GABAergic neurons express multiple peptides, including neuromedin-B, cholecystokinin, and relaxin-3, and receptors for stress and arousal transmitters, including corticotrophin-releasing factor and orexins/hypocretins. A functional relationship exists between NI neurons and their associated peptides, relaxin-3 and neuromedin-B, and hippocampal theta rhythm, which in turn, has a key role in the acquisition and extinction of declarative and emotional memories. Furthermore, RXFP3, the cognate receptor for relaxin-3, is a G protein-coupled receptor, and its activation inhibits the cellular accumulation of cAMP and induces phosphorylation of ERK, processes associated with memory formation in the hippocampus and amygdala. Therefore, this review summarizes the role of NI transmitter systems in relaying stress- and arousal-related signals to the higher neural circuits and processes associated with memory formation and retrieval.

COMPARING EFFICACY OF SSRIS TO AMELIORATE ANXIETY-LIKE BEHAVIOUR INDUCED EITHER BY VENTROMEDIAL PREFRONTAL OVERACTIVATION OR OCCURRING NATURALLY IN TRAIT-ANXIOUS MARMOSETS

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Kevin G. Mulvihill, Christian Wood, Angela Roberts
University of Cambridge, Physiology, Development And Neuroscience, Cambridge, United Kingdom

Extensive individual variability in pharmacological treatment efficacy remains a persistent obstacle in ameliorating clinical anxiety. The most common first-line treatments are selective serotonin reuptake inhibitors (SSRIs), but these typically show anxiolytic action only following weeks of treatment. More recently though, individual differences in the efficacy of acute SSRIs on aversive processing associated with anxiety has been demonstrated (Bhagwagar et al., 2004; Di Simplicio et al., 2014). Moreover, in marmoset monkeys (*Callithrix jacchus)* we have shown anxiolytic effects of an acute dose of the SSRI citalopram, that are genotype dependent (Santangelo et al., 2016). Here, we investigated further the contexts in which an acute SSRI may have anxiolytic effects, by comparing their efficacy in state-anxiety, induced by overactivation of area 14 in ventromedial (vm)PFC, and in naturally occurring high trait-anxiety. The human-intruder test measures the behavioural reactivity to an unfamiliar human; the human in this context being an uncertain stimulus provoking an anxiety-like response. Overactivation of area 14 via intracerebral infusion of dihydrokainic acid, a glutamate transporter (GLT-1) inhibitor has been shown to exacerbate anxiety within this paradigm (Stawicka et al., 2020). The efficacy of an acute, systemic dose of 10 mg/kg citalopram to reduce anxiety-like behaviour was compared in state and trait anxiety. Although the precise behavioural expression of anxiety differed between the two contexts, both were ameliorated by acute citalopram. Preliminary comparisons with alternative anxiolytics, including ketamine and a kappa-opioid antagonist, support the notion of a unique anxiolytic profile of citalopram on anxiety behaviour induced by uncertainty.

CHARACTERIZATION OF DISEASE-ASSOCIATED MICROGLIA IN SOCIAL DEFICITS LINKED TO EARLY LIFE ADVERSITY

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

A. Catarina Rodrigues-Neves[1], Rita Gaspar[1], Patrícia Patrício[2], Luísa Pinto[2], João Bessa[2], António F. Ambrósio[1], Catarina A. Gomes[1]
[1]iCBR - FMUC, Univ. Coimbra, Portugal, Coimbra, Portugal, [2]Life and Health Sciences Research Institute (ICVS), School of Medicine, University Of Minho, Braga, Portugal

Background: Synaptogenesis during brain development, which extends until adolescence, implicates microglia, innate immune cells able to screen and select newborn synapses to be kept or eliminated. The screening ability is mainly supported by dynamic morphologic alterations at the level of microglia cellular processes, that contact synapses, sense (via receptor activation) their functioning level and eventually phagocyte abnormal synaptic elements. A disturbance of microglia morphology during critical periods of development, as occurs in early life adversity (ELA) may compromise brain circuits and behavior (e.g. social impairment). Here, we hypothesize that social deficits associated with ELA are correlated with particular disease-associated microglia (DAM) phenotypes yet unidentified. **Methods:** Neurodevelopmental (infancy), social behavioral tests (adolescence) and microglia morphometry (in the *nucleus accumbens*, brain region involved in social behavior) were conducted in the offspring of pregnant rats administered with methylazoxymethanol acetate (MAM). **Results:** In postnatal period, MAM offspring presented alterations in neurodevelopmental milestones and, at adolescence, social deficits. DAM arise as early as postnatal phase, although following an age-dependent pattern of evolution characterized by a postnatal increase in complexity and a shift towards a microglia atrophy. **Conclusion:** Atrophic DAM observed at adolescence lead us to anticipate that a possible dysfunctional phagocytosis might contribute for the social deficits, a hypothesis that needs to be clarified. Treatment with A receptor antagonist KW6002 and caffeine intake regulate microglia reactivity and protect retina against transient ischemic damage.
Transient retinal ischemia is a major complication of retinal degenerative diseases and contributes to visual impairment and blindness. Evidences indicate that microglia-mediated neuroinflammation has a key role in the neurodegenerative process, prompting the hypothesis that the control of microglia reactivity may afford neuroprotection to the retina against the damage induced by ischemia-reperfusion (I-R). The available therapeutic strategies for retinal degenerative diseases have limited potential, but the blockade of adenosine A receptor (AR) emerges as candidate strategy. Therefore, we evaluated the therapeutic potential of a selective AR antagonist (KW6002) against the damage elicited by I-R. The administration of KW6002 after I-R injury reduced microglia reactivity and inflammatory response and afforded protection to the retina. Moreover, we tested the ability of caffeine, an adenosine receptor antagonist, in mediating protection to the retina in the I-R injury model. We demonstrated that caffeine administration dually regulated microglia reactivity and cell death in the transient retinal ischemic model, depending on the reperfusion time. At 24 h of reperfusion, caffeine increased microglial reactivity, inflammatory response and cell death elicited by I-R. However, at 7 days of reperfusion, caffeine administration decreased microglia reactivity and reduced the levels of proinflammatory cytokines and cell death. Together, these results provide a novel evidence for the use of adenosine AR antagonists as potential therapy for retinal ischemic diseases and demonstrate the effect of caffeine on the regulation of microglia-mediated neuroinflammation in the transient ischemic model.

Elevated Pressure Changes the Purinergic System of Microglial Cells.
Glaucoma is the second cause of blindness worldwide and is characterized by the degeneration of retinal ganglion cells (RGCs) and optic nerve atrophy. Increased microglia reactivity is an early event in glaucoma that may precede the loss of RGCs, suggesting that microglia and neuroinflammation are involved in the pathophysiology of this disease. Although global changes of the purinergic system have been reported in experimental and human glaucoma, it is not known if this is due to alterations of the purinergic system of microglial cells, the resident immune cells of the central nervous system. We now studied if elevated hydrostatic pressure (EHP), mimicking ocular hypertension, changed the extracellular levels of ATP and adenosine and the expression, density and activity of enzymes, transporters and receptors defining the purinergic system. The exposure of the murine microglial BV-2 cell line to EHP increased the extracellular levels of ATP and adenosine, increased the density of ecto-nucleoside triphosphate diphosphohydrolase 1 (E-NTPDase1, CD39) and decreased the density of the equilibrative nucleotide transporter 2 as well as the activity of adenosine deaminase. The expression of adenosine A receptor also decreased, but the adenosine A receptor was not affected. Notably, ATP and adenosine selectively control migration rather than phagocytosis, both bolstered by EHP. The results show that the purinergic system is altered in microglia in conditions of elevated pressure. Understanding the impact of elevated pressure on the purinergic system will help to unravel the mechanisms underlying inflammation and neurodegeneration associated with glaucoma.

The Retina as a Window or Mirror of the Brain Changes Detected in Alzheimer's Disease: Critical Aspects to Unravel.
Alzheimer's disease is the most frequent cause of dementia worldwide, representing a global health challenge, with a massive impact on the quality of life of Alzheimer's disease patients and their relatives. The diagnosis of Alzheimer's disease constitutes a real challenge, because the symptoms manifest years after the first degenerative changes occurring in the brain and the diagnosis is based on invasive and/or expensive techniques. Therefore, there is an urgent need to identify new reliable biomarkers to detect Alzheimer's disease at an early stage. Taking into account the evidence for visual deficits in Alzheimer's disease patients, sometimes even before the appearance of the first disease symptoms, and that the retina is an extension of the brain, the concept of the retina as a window to look into the brain or a mirror of the brain has received increasing interest in recent years. However, only a few studies have assessed the changes occurring in the retina and the brain at the same time points. Unlike previous reviews on this subject, which are mainly focused on brain changes, we organized this review by comprehensively summarizing findings related with structural, functional, cellular, and molecular parameters in the retina reported in both Alzheimer's disease patients and animal models. Moreover, we separated the studies that assessed only the retina, and those that assessed both the retina and brain, which are few but allow establishing correlations between the retina and brain. This review also highlights some inconsistent results in the literature as well as relevant missing gaps in this field.

Blockade of microglial adenosine A receptor suppresses elevated pressure-induced inflammation, oxidative stress, and cell death in retinal cells.
Glaucoma is a retinal degenerative disease characterized by the loss of retinal ganglion cells and damage of the optic nerve. Recently, we demonstrated that antagonists of adenosine A receptor (A R) control retinal inflammation and afford protection to rat retinal cells in glaucoma models. However, the precise contribution of microglia to retinal injury was not addressed, as well as the effect of A R blockade directly in microglia. Here we show that blocking microglial A R prevents microglial cell response to elevated pressure and it is sufficient to protect retinal cells from elevated pressure-induced death. The A R antagonist SCH 58261 or the knockdown of A R expression with siRNA in microglial cells prevented the increase in microglia response to elevated hydrostatic pressure. Furthermore, in retinal neural cell cultures, the A R antagonist decreased microglia proliferation, as well as the expression and release of pro-inflammatory mediators. Microglia ablation prevented neural cell death triggered by elevated pressure. The A R blockade recapitulated the effects of microglia depletion, suggesting that blocking A R in microglia is able to control neurodegeneration in glaucoma-like conditions. Importantly, in human organotypic retinal cultures, A R blockade prevented the increase in reactive oxygen species and the morphological alterations in microglia triggered by elevated pressure. These findings place microglia as the main contributors for retinal cell death during elevated pressure and identify microglial A R as a therapeutic target to control retinal neuroinflammation and prevent neural apoptosis elicited by elevated pressure.

A longitudinal multimodal in vivo molecular imaging study of the 3xTg-AD mouse model shows progressive early hippocampal and taurine loss.

The understanding of the natural history of Alzheimer's disease (AD) and temporal trajectories of in vivo molecular mechanisms requires longitudinal approaches. A behavioral and multimodal imaging study was performed at 4/8/12 and 16 months of age in a triple transgenic mouse model of AD (3xTg-AD). Behavioral assessment included the open field and novel object recognition tests. Molecular characterization evaluated hippocampal levels of amyloid β (Aβ) and hyperphosphorylated tau. Magnetic resonance imaging (MRI) included assessment of hippocampal structural integrity, blood-brain barrier (BBB) permeability and neurospectroscopy to determine levels of the endogenous neuroprotector taurine. Longitudinal brain amyloid accumulation was assessed using 11C Pittsburgh compound B positron emission tomography (PET), and neuroinflammation/microglia activation was investigated using 11C-PK1195. We found altered locomotor activity at months 4/8 and 16 months and recognition memory impairment at all time points. Substantial early reduction of hippocampal volume started at month 4 and progressed over 8/12 and 16 months. Hippocampal taurine levels were significantly decreased in the hippocampus at months 4/8 and 16. No differences were found for amyloid and neuroinflammation with PET, and BBB was disrupted only at month 16. In summary, 3xTg-AD mice showed exploratory and recognition memory impairments, early hippocampal structural loss, increased Aβ and hyperphosphorylated tau and decreased levels of taurine. In sum, the 3xTg-AD animal model mimics pathological and neurobehavioral features of AD, with early-onset recognition memory loss and MRI-documented hippocampal damage. The early-onset profile suggests temporal windows and opportunities for therapeutic intervention, targeting endogenous neuroprotectors such as taurine.

Intravitreal injection of adenosine A receptor antagonist reduces neuroinflammation, vascular leakage and cell death in the retina of diabetic mice.
Diabetic retinopathy is a major complication of diabetes mellitus and a leading cause of blindness. The pathogenesis of diabetic retinopathy is accompanied by chronic low-grade inflammation. Evidence shows that the blockade of adenosine A receptors (AR) affords protection to the retina through the control of microglia-mediated neuroinflammation. Herein, we investigated the therapeutic potential of an antagonist of AR in a model of diabetic retinopathy. Type 1 diabetes was induced in 4-5 months old C57BL/6 J mice with a single intraperitoneal injection streptozotocin. Animals were treated one month after the onset of diabetes. The AR antagonist was delivered by intravitreal injection once a week for 4 weeks. Microglia reactivity and inflammatory mediators were increased in the retinas of diabetic animals. The treatment with the AR antagonist was able to control microglial reactivity and halt neuroinflammation. Furthermore, the AR antagonist rescued retinal vascular leakage, attenuated alterations in retinal thickness, decreased retinal cell death and the loss of retinal ganglion cells induced by diabetes. These results demonstrate that intravitreal injection of the AR antagonist controls inflammation, affords protection against cell loss and reduces vascular leakage associated with diabetes, which could be envisaged as a therapeutic approach for the early complications of diabetes in the retina.

Microglial Activation in the Retina of a Triple-Transgenic Alzheimer's Disease Mouse Model (3xTg-AD).
Alzheimer's disease (AD) is the most common type of dementia in the world. The main biomarkers associated with AD are protein amyloid-β (Aβ) plaques and protein tau neurofibrillary tangles, which are responsible for brain neuroinflammation mediated by microglial cells. Increasing evidence has shown that the retina can also be affected in AD, presenting some molecular and cellular changes in the brain, such as microglia activation. However, there are only a few studies assessing such changes in the retinal microglia in animal models of AD. These studies use retinal sections, which have some limitations. In this study, we performed, for the first time in a triple-transgenic AD mouse model (3xTg-AD), a quantitative morphometric analysis of microglia activation (using the anti-Iba-1 antibody) in retinal whole-mounts, allowing visualization of the entire microglial cell, as well as its localization along the extension of the retina in different layers. Compared to age-matched animals, the retina of 3xTg-AD mice presents a higher number of microglial cells and a thicker microglial cell body area. Moreover, the microglia migrate, reorient, and retract their processes, changing their localization from a parallel to a perpendicular position relative to the retinal surface. These findings demonstrate clear microglia remodeling in the retina of 3xTg-AD mice.

Keep an eye on adenosine: Its role in retinal inflammation.
Adenosine is an endogenous purine nucleoside ubiquitously distributed throughout the body that interacts with G protein-coupled receptors, classified in four subtypes: AR, AR, AR and AR. Among the plethora of functions of adenosine, it has been increasingly recognized as a key mediator of the immune response. Neuroinflammation is a feature of chronic neurodegenerative diseases and contributes to the pathophysiology of several retinal degenerative diseases. Animal models

of retinal diseases are helping to elucidate the regulatory roles of adenosine receptors in the development and progression of those diseases. Mounting evidence demonstrates that the adenosinergic system is altered in the retina during pathological conditions, compromising retinal physiology. This review focuses on the roles played by adenosine and the elements of the adenosinergic system (receptors, enzymes, transporters) in the neuroinflammatory processes occurring in the retina. An improved understanding of the molecular and cellular mechanisms of the signalling pathways mediated by adenosine underlying the onset and progression of retinal diseases will pave the way towards the identification of new therapeutic approaches.

Retina and Brain Display Early and Differential Molecular and Cellular Changes in the 3xTg-AD Mouse Model of Alzheimer's Disease.
The concept 'the retina as a window to the brain' has been increasingly explored in Alzheimer´s disease (AD) in recent years, since some patients present visual alterations before the first symptoms of dementia. The retina is an extension of the brain and can be assessed by noninvasive methods. However, assessing the retina for AD diagnosis is still a matter of debate. Using the triple transgenic mouse model of AD (3xTg-AD; males), this study was undertaken to investigate whether the retina and brain (hippocampus and cortex) undergo similar molecular and cellular changes during the early stages (4 and 8 months) of the pathology, and if the retina can anticipate the alterations occurring in the brain. We assessed amyloid-beta (Aβ) and hyperphosphorylated tau (p-tau) levels, barrier integrity, cell death, neurotransmitter levels, and glial changes. Overall, the retina, hippocampus, and cortex of 3xTg-AD are not significantly affected at these early stages. However, we detected a few differential changes in the retina and brain regions, and particularly a different profile in microglia branching in the retina and hippocampus, only at 4 months, where the number and length of the processes decreased in the retina and increased in the hippocampus. In summary, at the early stages of pathology, the retina, hippocampus, and cortex are not significantly affected but already present some molecular and cellular alterations. The retina did not mirror the changes detected in the brain, and these observations should be taking into account when using the retina as a potential diagnostic tool for AD.

Sex-specific changes in peripheral metabolism in a model of chronic anxiety induced by prenatal stress.
Prenatal stress is associated with increased susceptibility to psychiatric and metabolic disorders later in life. Prenatal exposure to stress mediators may have sex-dependent effects on offspring brain and metabolic function, promoting a sex-specific vulnerability to psychopathology and metabolic alterations at adulthood. In this work, the impact of prenatal stress on glucose homeostasis and peripheral metabolism of male and female offspring was investigated in a chronic anxiety animal model.

Reduced responsiveness to rewarding stimuli is a common and major symptom in stress-related neuropsychiatric disorders such as depression and schizophrenia. The amygdala is a major region in neural circuitries of aversion and reward processing. The basal amygdala (BA) contains both reward- and aversion-responsive glutamate pyramidal neurons, some of which project to the nucleus accumbens. In young-adult male mice, chronic social stress (CSS) resulted in attenuated discriminative reward learning (DRLM) and reward-to-effort valuation (REV) compared to control mice (CON). Chronic tetanus toxin-mediated inhibition of BA-NAc glutamate pyramidal neurons led to similar deficits in DRLM and REV behaviour. Using fibre photometry of GCaMP6-expressing BA-NAc neurons, the CSS-induced deficits in the DRL and REV tests co-occurred with increased BA-NAc neuron activity at reward reinforcement. Using laser capture microdissection and RNA-Sequencing to assess CSS effects on the transcriptome of BA-NAc neuron samples, dysregulated genes were over-expressed in CSS compared to CON mice and a number of these were enriched in neurotransmitter signal transduction pathways. Based on the behavioural, fibre photometry and transcriptome evidence for CSS effects, mice underwent chronic chemogenetic activation of BA-NAc neurons and reward behaviour testing: chronic BA-NAc neuron activation recapitulated the effects of CSS in the DRLM and REV tests. These iterative findings identify the importance of the homeostatic functioning of BA-NAc glutamate pyramidal neurons for typical reward-directed behaviour and the restoration of such functioning as a therapeutic target for stress-induced deficits in reward responsiveness.

IDENTIFICATION OF A CORE IMMUNE SIGNALLING-ASSOCIATED DYSREGULATION IN AN ISOLATION REARING MODEL OF NEUROPSYCHIATRIC ILLNESS.

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Amie O'Neill, Bartlomiej Lukasz, Judith Ter Horst, Keith Murphy
Conway Institute, University College Dublin, Dublin, Ireland

Aims: Treatment and diagnosis of neuropsychiatric illnesses, such as schizophrenia, are complicated by the fact that each patient experiences a different combination of symptoms along with considerable differences in response to therapeutics. This creates a unique unmet need for novel treatment options beyond current strategies. This study aimed to identify potential targets for future therapeutic exploitation using an established model of neuropsychiatric disease. *Methods:* We utilised transcriptomic analysis of mRNA expression change in the isolation reared rodent model along with *in-vitro* investigation of identified gene clusters using a co-culture model of neurons and microglia. *Results:* We have correlated the emergence of behavioural, neurochemical and synapse ultrastructure deficits to transcriptional dysregulation in both the medial prefrontal cortex and dentate gyrus of the hippocampus of Wistar rats reared in isolation. A temporal map of sequential dysregulation across key life stages in both brain regions has been established, allowing a unique insight into the potential molecular cascade underlying disease emergence. The temporally altered genes were from a wide range of functional domains including transcriptional regulation, synaptic structure and function and, strikingly, immune-related signalling. Our *in-vitro* characterisation of members of this latter gene cluster suggests that altered expression of such immune-related genes may contribute to aberrant synaptic pruning, thought to be a key deficit underpinning the symptoms of schizophrenia. *Conclusions:* Further dissection of immune-related gene expression alterations, identified to be common to both brain regions, may reveal key insights into neuronal circuitry dysregulation and subsequent emergence of neurocognitive and psychotic symptoms of schizophrenia.

NICOTINIC RECEPTORS PROMOTE SUSCEPTIBILITY TO SOCIAL STRESS IN FEMALE MICE LINKED WITH NEUROADAPTATIONS WITHIN VTA DOPAMINE NEURONS

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Vanesa Ortiz, Renan Costa-Campos, Hugo Fofo, Sebastian Fernandez, Jacques Barik
Institut de Pharmacologie Moléculaire et Cellulaire, Université Côte D'azur, Valbonne, France

There are about twice as many women as men who experience depression during their lifetime. Although life circumstances and especially exposure to stressful situations constitute a major risk factor to develop depression, the underlying mechanisms have yet to be unraveled. We employed the chronic social defeat procedure to elicit depressive-like symptoms in females and ketamine to validate the model. We performed *ex-vivo* patch clamp recordings to assess cellular adaptations and used pharmacological agents to dissect these deregulations. Chronic social defeat exposure triggers a hyperactivity of VTA dopamine (DA) neurons, in females susceptible to stress but not resilient ones. This hyperactivity was fully reversed by a single administration of ketamine. In virally-identified brain circuits of both susceptible and resilient females, we found a hypercholinergic tone to the VTA arising from the laterodorsal tegmentum. Application of puffs of nicotine revealed a decreased sensitivity of DA neurons in resilient mice when compared to naive or susceptible ones. The *in vivo* acute administration of the positive allosteric modulator for a7 nicotinic acetylcholine receptors (nAChRs) not only increased susceptibility to stress by enhancing activity of VTA DA neurons, but also triggered a switch in phenotype from resilient to susceptible. Our data unravel dysregulation of VTA DA neurons activity exclusively in females exhibiting depressive-like symptoms and identify VTA nAChRs mediates susceptibility vs. resilience to social stress in female mice.

EFFECTS OF SOCIAL ISOLATION STRESS AND KETOGENIC DIET ON MICE BEHAVIOR AND METABOLISM

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Ilya Smolensky[1,2], Kilian Zajac-Bakri[1,2], Catherine Brégère[2], Raphael Guzman[2,3], Dragos Inta[1,2,4]
[1]University of Fribourg, Faculty Of Science And Medicine, Fribourg, Switzerland, [2]University of Basel, Department Of Biomedicine, Basel, Switzerland, [3]University Hospital Basel, Department Of Neurosurgery, Basel, Switzerland, [4]University of Heidelberg, Central Institute Of Mental Health, Manheim, Germany

While current antidepressants do not help up to 40% of patients with depression, other approaches are developing, including distinct diets. Here we estimated beneficial effect of ketogenic diet in a mice model of depression. Adult male and female mice were fed with one of the three diets during 8 weeks: normal diet (energy profile – 55% carbohydrates : 32% proteins : 13% fats), medium chain fatty acid-based ketogenic high-fat low-carb diet (KD, 3% C : 7% P : 90% F), non-ketogenic high-fat low-carb diet (LCD, 17% C : 23% P : 60% F). Half of each group underwent social isolation stress model of depression along with diet to explore effect of nutrition profile on stress-induced disturbances. During weeks 5-6 set of behavioral tests was performed to estimate depression-like behavior (sucrose preference test, tail suspension), anxiety (elevated plus maze, light-dark box), communication (social interaction test) and spatial memory (Barnes maze). After sacrifice blood, brain and fat tissue were extracted for histological and biochemical studies. KD decreased body weight only in males regardless of stress, while no changes were found for LCD and in all female groups. Behavioral tests showed that social isolation model is not severe enough to induce significant anxiety, depressive-like behavior and spatial memory disturbances in mice. However, in males but not in females, stress resulted in suppressed communication which in turn was restored by KD. Adult neurogenesis in hippocampus and metabolic factors in fat and blood samples and are planned to be analyzed further.

EFFECT OF EARLY-LIFE STRESS ON THE FUNCTIONAL DEVELOPMENT OF RAPHE-PREFRONTAL NETWORKS

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Heidi Teppola-Gürel, Henrike Hartung
University of Helsinki, Neuroscience Center, Helsinki, Finland

Exposure to early-life stress (ELS), such as inadequate maternal care, has been shown to increase anxiety and depression-like behavior in adult rodents. There are indications that these adverse experiences elicit developmental dysregulation of the dorsal raphe (DR) 5-HT system, resulting in elevated 5-HT levels in limbic projection areas, including the medial prefrontal cortex (mPFC). However, it is not yet known how ELS affects the activity of developing 5-HTergic neurons in the DR and the maturation of functional interactions within raphe-prefrontal networks. **Aims:** To investigate how ELS affects the firing activity of neonatal putative 5-HT neurons in the DR and the development of functional interactions between DR and mPFC. **Methods:** We induced stress between postnatal day (P) 4 and P9 in mice with a paradigm that limits the amount of bedding and nesting (LBN) and has been shown to cause fragmented and unpredictable maternal behavior. We performed multi-unit activity and local-field potential recordings simultaneously in DR and mPFC after LBN at P10/P11. We analyzed the firing activity in DR after ELS compared to controls as well as functional interactions within raphe-prefrontal networks. **Results:** Preliminary results indicate that LBN alters the firing activity of putative 5-HTergic neurons in DR and affects functional interactions between DR and mPFC. **Conclusions:** Our results highlight the importance of the 5-HT system in the functional development of networks underlying emotional behavior.

Unique Features of Network Bursts Emerge From the Complex Interplay of Excitatory and Inhibitory Receptors in Rat Neocortical Networks.
Spontaneous network activity plays a fundamental role in the formation of functional networks during early development. The landmark of this activity is the recurrent emergence of intensive time-limited network bursts (NBs) rapidly spreading across the entire dissociated culture . The main excitatory mediators of NBs are glutamatergic alpha-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptors (AMPARs) and -Methyl-D-aspartic-acid receptors (NMDARs) that express fast and slow ion channel kinetics, respectively. The fast inhibition of the activity is mediated through gamma-aminobutyric acid type A receptors (GABARs). Although the AMPAR, NMDAR and GABAR kinetics have been biophysically characterized in detail at the monosynaptic level in a variety of brain areas, the unique features of NBs emerging from the kinetics and the complex interplay of these receptors are not well understood. The goal of this study is to analyze the contribution of fast GABARs on AMPAR- and NMDAR- mediated spontaneous NB activity in dissociated neonatal rat cortical cultures at 3 weeks The networks were probed by both acute and gradual application of each excitatory receptor antagonist and combinations of acute excitatory and inhibitory receptor antagonists. At the same time, the extracellular network-wide activity was recorded with microelectrode arrays (MEAs). We analyzed the characteristic NB measures extracted from NB rate profiles and the distributions of interspike intervals, interburst intervals, and electrode recruitment time as well as the similarity of spatio-temporal patterns of network activity under different receptor antagonists. We show that NBs were rapidly initiated and recruited as well as diversely propagated by AMPARs and temporally and spatially maintained by NMDARs. GABARs reduced the spiking frequency in AMPAR-mediated networks and dampened the termination of NBs in NMDAR-mediated networks as well as slowed down the recruitment of activity in all networks. Finally, we show characteristic super bursts composed of slow NBs with highly repetitive spatio-temporal patterns in gradually AMPAR blocked networks. To the best of our knowledge, this study is the first to unravel in detail how the three main mediators of synaptic transmission uniquely shape the NB characteristics, such as the initiation, maintenance, recruitment and termination of NBs in cortical cell cultures .

Challenges in Reproducibility, Replicability, and Comparability of Computational Models and Tools for Neuronal and Glial Networks, Cells, and Subcellular Structures.
The possibility to replicate and reproduce published research results is one of the biggest challenges in all areas of science.

In computational neuroscience, there are thousands of models available. However, it is rarely possible to reimplement the models based on the information in the original publication, let alone rerun the models just because the model implementations have not been made publicly available. We evaluate and discuss the comparability of a versatile choice of simulation tools: tools for biochemical reactions and spiking neuronal networks, and relatively new tools for growth in cell cultures. The replicability and reproducibility issues are considered for computational models that are equally diverse, including the models for intracellular signal transduction of neurons and glial cells, in addition to single glial cells, neuron-glia interactions, and selected examples of spiking neuronal networks. We also address the comparability of the simulation results with one another to comprehend if the studied models can be used to answer similar research questions. In addition to presenting the challenges in reproducibility and replicability of published results in computational neuroscience, we highlight the need for developing recommendations and good practices for publishing simulation tools and computational models. Model validation and flexible model description must be an integral part of the tool used to simulate and develop computational models. Constant improvement on experimental techniques and recording protocols leads to increasing knowledge about the biophysical mechanisms in neural systems. This poses new challenges for computational neuroscience: extended or completely new computational methods and models may be required. Careful evaluation and categorization of the existing models and tools provide a foundation for these future needs, for constructing multiscale models or extending the models to incorporate additional or more detailed biophysical mechanisms. Improving the quality of publications in computational neuroscience, enabling progressive building of advanced computational models and tools, can be achieved only through adopting publishing standards which underline replicability and reproducibility of research results.

Morphological Differentiation Towards Neuronal Phenotype of SH-SY5Y Neuroblastoma Cells by Estradiol, Retinoic Acid and Cholesterol.
Human SH-SY5Y neuroblastoma cells maintain their potential for differentiation and regression in culture conditions. The induction of differentiation could serve as a strategy to inhibit cell proliferation and tumor growth. Previous studies have shown that differentiation of SH-SY5Y cells can be induced by all-trans-retinoic-acid (RA) and cholesterol (CHOL). However, signaling pathways that lead to terminal differentiation of SH-SY5Y cells are still largely unknown. The goal of this study was to examine in the RA and CHOL treated SH-SY5Y cells the additive impacts of estradiol (E2) and brain-derived neurotrophic factor (BDNF) on cell morphology, cell population growth, synaptic vesicle recycling and presence of neurofilaments. The above features indicate a higher level of neuronal differentiation. Our data show that treatment for 10 days in vitro (DIV) with RA alone or when combined with E2 (RE) or CHOL (RC), but not when combined with BDNF (RB), significantly ($p < 0.01$) inhibited the cell population growth. Synaptic vesicle recycling, induced by high-K(+) depolarization, was significantly increased in all treatments where RA was included (RE, RC, RB, RCB), and when all agents were added together (RCBE). Specifically, our results show for the first time that E2 treatment can alone increase synaptic vesicle recycling in SH-SY5Y cells. This work contributes to the understanding of the ways to improve suppression of neuroblastoma cells' population growth by inducing maturation and differentiation.

Modeling of Neuronal Growth In Vitro: Comparison of Simulation Tools NETMORPH and CX3D.
We simulate the growth of neuronal networks using the two recently published tools, NETMORPH and CX3D. The goals of the work are (1) to examine and compare the simulation tools, (2) to construct a model of growth of neocortical cultures, and (3) to characterize the changes in network connectivity during growth, using standard graph theoretic methods. Parameters for the neocortical culture are chosen after consulting both the experimental and the computational work presented in the literature. The first (three) weeks in culture are known to be a time of development of extensive dendritic and axonal arbors and establishment of synaptic connections between the neurons. We simulate the growth of networks from day 1 to day 21. It is shown that for the properly selected parameters, the simulators can reproduce the experimentally obtained connectivity. The selected graph theoretic methods can capture the structural changes during growth.

STRESSING BUT RELAXIN' THE BRAIN: HOW EARLY LIFE STRESS AFFECTS RLN-3 CIRCUITRY DEVELOPMENT AND AFFECTIVE BEHAVIOR

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Esther Castillo-Gómez, Aroa Mañas-Ojeda, Zineb Bouargane, Clara García-Mompó, José Francisco Hidalgo-Cortés, Isis Gil-Miravet, Mónica Navarro Sánchez, Francisco Ros-Bernal, Francisco Olucha-Bordonau

Early postnatal life is a critical period during which the brain undergo important changes to reach maturation. Indeed, the exposure to aversive experiences during this period influences brain development and leads to altered behaviour and impairment of neural structures that can persist through lifespan. The nucleus incertus (NI) has been described as a small cluster of neurons in the brainstem, containing predominately GABAergic neurons that express the neuropeptide Relaxin-3 (RLN-3). Those neurons participate into the modulation of brain circuits related to socio-affective behavior and, in fact, recent evidence suggests the role of NI in stress responsiveness. Here, we hypothetized that early postnatal stress is able to induce changes in the development of RLN3 networks that will result in higher emotional vulnerability, dependent on sex. To address this question, early life stress was induced by exposing both male and female mice mice pups to maternal separation from PND2-PND16. Our results show that maternal separation-induced stress generates depressive-like behavior in female but not male pups. However, the alterations in the number of RLN-3 positive neurons in the NI and the density of its projections to the Medial Septum (MS) are not dependent on sex, since they increased both in male and female mice. In sum, we demonstrated that early life stress alters the normal development of RLN-3 projections to the MS and the NI functioning and that in females, this neuroanatomical changes are correlated with disturbances in affective behavior.

UNDERSTANDING THE EMOTIONAL CONSEQUENCES OF CHRONIC PAIN: INSIGHT FROM ACC-LHB PATHWAY

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Sarah H. Journée[1], Robin Waegaert[1], Michel Barrot[1], Victor Mathis[2], Ipek Yalcin[1]

Depression and anxiety are some of the leading causes of disability worldwide, contributing to the global burden of diseases. Mood disorders often arise consequently to chronic pain. Indeed, the comorbidity between chronic pain and mood disorders is frequently observed with 50% of chronic pain patients developing mood or anxiety disorders during their lifespan. Compelling evidence from human studies and animal models suggest an important role of the anterior cingulate cortex (ACC) and the lateral habenula (LHb) in the development and maintenance of this comorbidity. In addition, track tracing analyses performed in our team showed a connection from the ACC towards the LHb and our fMRI study displayed altered ACC-LHb functional connectivity in our chronic pain induced depression (CPID) mice model. Our aim was then to decipher the functional role of the ACC-LHb pathway in CPID by combining optogenetic approaches with behavioural analysis. Our results showed that chronic activation of the ACC-LHb pathway induces anxiodepressive-like behaviours in naive animals while inhibiting this pathway in CPID mice alleviates chronic pain induced depressive-like behavior. We then also sought to understand whether this pathway is only implicated in CPID or also in other depression models, such as chronic variable stress (CVS). Our preliminary results suggest that inhibiting this pathway does not affect depressive-like behaviours induced by CVS. Altogether, these results highlight the importance of the ACC-LHb pathway specifically in chronic pain induced anxio-depressive like behaviours.

SOCIAL ISOLATION STRESS IN AGED MICE: WHAT ABOUT AFFECTIVE BEHAVIOR AND INHIBITORY CIRCUITS.

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

While healthy aging has been associated with a stable emotional state and weakened brain responses to negative stimuli, senescence has long been viewed as a period of decreased adaptiveness to stress, in part because depressive symptoms are very common in older people. However, despite the importance and high prevalence of socio-affective-related disorders among elderly people, and the apparent role of the basolateral amygdala (BLA) in these disorders, preclinical studies addressing these questions are still scarce. Moreover, little attention has been paid to whether males and females respond differently to similar stressful situations and whether these differences can be observed at the microcircuitry level. In the present study we investigated the impact of chronic isolation stress (CIS) and a subsequent resocialization period in aged (18-24 months) male and female mice. Interestingly CIS demonstrated sex-dependent effects in both behavior and inhibitory circuitry (parvalbumin expressing cells surrounded by perineuronal nets). At the behavioral level, CIS induced depressive-like behavior only in females that was effectively rescued by resocialization. Remarkably, these changes were correlated with modulatory effects on inhibitory circuitry. Therefore, the present study suggests that social isolation stress in aging induces high emotional response and modulates BLA inhibitory circuits.

Early Social Isolation Stress and Perinatal NMDA Receptor Antagonist Treatment Induce Changes in the Structure and Neurochemistry of Inhibitory Neurons of the Adult Amygdala and Prefrontal Cortex.
The exposure to aversive experiences during early life influences brain development and leads to altered behavior. Moreover, the combination of these experiences with subtle alterations in neurodevelopment may contribute to the emergence of psychiatric disorders, such as schizophrenia. Recent hypotheses suggest that imbalances between excitatory and inhibitory (E/I) neurotransmission, especially in the prefrontal cortex and the amygdala, may underlie their etiopathology. In order to understand better the neurobiological bases of these alterations, we studied the impact of altered neurodevelopment and chronic early-life stress on these two brain regions. Transgenic mice displaying fluorescent excitatory and inhibitory neurons, received a single injection of MK801 (NMDAR antagonist) or vehicle solution at postnatal day 7 and/or were socially isolated from the age of weaning until adulthood (3 months old). We found that anxiety-related behavior, brain volume, neuronal structure, and the expression of molecules related to plasticity and E/I neurotransmission in adult mice were importantly affected by early-life stress. Interestingly, many of these effects were potentiated when the stress paradigm was applied to mice perinatally injected with MK801 ("double-hit" model). These results clearly show the impact of early-life stress on the adult brain, especially on the structure and plasticity of inhibitory networks, and highlight the double-hit model as a valuable tool to study the contribution of early-life stress in the emergence of neurodevelopmental psychiatric disorders, such as schizophrenia.

Long-term behavioral programming induced by peripuberty stress in rats is accompanied by GABAergic-related alterations in the Amygdala.
Stress during childhood and adolescence is a risk factor for psychopathology. Alterations in γ-aminobutyric acid (GABA), the main inhibitory neurotransmitter in the brain, have been found following stress exposure and fear experiences and are often implicated in anxiety and mood disorders. Abnormal amygdala functioning has also been detected following stress exposure and is also implicated in anxiety and social disorders. However, the amygdala is not a unitary structure; it includes several nuclei with different functions and little is known on the potential differences the impact of early life stress may have on this system within different amygdaloid nuclei. We aimed here to evaluate potential regional differences in the expression of

GABAergic-related markers across several amygdaloid nuclei in adult rats subjected to a peripuberty stress protocol that leads to enhanced basal amygdala activity and psychopathological behaviors. More specifically, we investigated the protein expression levels of glutamic acid decarboxylase (GAD; the principal synthesizing enzyme of GABA) and of GABA-A receptor subunits α2 and α3. We found reduced GAD and GABA-A α3, but not α2, subunit protein levels throughout all the amygdala nuclei examined (lateral, basolateral, basomedial, medial and central) and increased anxiety-like behaviors and reduced sociability in peripubertally stressed animals. Our results identify an enduring inhibition of the GABAergic system across the amygdala following exposure to early adversity. They also highlight the suitability of the peripuberty stress model to investigate the link between treatments targeting the dysfunctional GABAergic system in specific amygdala nuclei and recovery of specific stress-induced behavioral dysfunctions.

The polysialylated form of the neural cell adhesion molecule (PSA-NCAM) is expressed in a subpopulation of mature cortical interneurons characterized by reduced structural features and connectivity.
Principal neurons in the adult cerebral cortex undergo synaptic, dendritic, and spine remodeling in response to different stimuli, and several reports have demonstrated that the polysialylated form of the neural cell adhesion molecule (PSA-NCAM) participates in these plastic processes. However, there is only limited information on the expression of this molecule on interneurons and on its role in the structural plasticity of these cells. We have found that PSA-NCAM is expressed in mature interneurons widely distributed in all the extension of the cerebral cortex and have excluded the expression of this molecule in most principal cells. Although PSA-NCAM expression is generally considered a marker of immature neurons, birth-dating analyses reveal that these interneurons do not have an adult or perinatal origin and that they are generated during embryonic development. PSA-NCAM expressing interneurons show reduced density of perisomatic and peridendritic puncta expressing different synaptic markers and receive less perisomatic synapses, when compared with interneurons lacking this molecule. Moreover, they have reduced dendritic arborization and spine density. These data indicate that PSA-NCAM expression is important for the connectivity of interneurons in the adult cerebral cortex and that its regulation may play an important role in the structural plasticity of inhibitory networks.

HIPPOCAMPUS PROTEOMICS PROFILING OF MAJOR DEPRESSION AND ANTIDEPRESSANT TREATMENT REVEALS PATHWAYS INVOLVED IN CELL PROLIFERATION, DIFFERENTIATION AND CONNECTIVITY

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Dhruv Limaye[1], Maura Boldrini[2], Lewis Brown[3]

Major Depressive Disorder (MDD) involves deficits in memory and emotion regulation that are dependent on hippocampus cell viability and connectivity, for which molecular regulators remain largely unknown. We performed shotgun proteomics and advanced data mining strategies, which revealed clusters of differentially expressed proteins (DEPs) in untreated MDD (uMDD) compared with non-psychiatric controls (CONT) and antidepressant-treated MDD subjects (MDDT, n=12/group). Some DEPs showed group-specific positive and negative correlations with numbers of cells at different stages of maturation in the dentate gyrus (DG). Our data indicates that DEPs with lower expression in uMDD *vs.* CONT are involved in cell cycle, mitosis, differentiation, and negative regulation of apoptosis; proteins with higher expression in uMDD control cell adhesion, neurite outgrowth, DNA damage repair and telomere maintenance, repress transcription, and inhibit cell cycle progression. DEPs with lower expression in uMDD *vs.*CONT and higher expression in MDDT *vs.* uMDD ("normalized") regulate Ca^{++}-dependent exocytosis, and supply choline to cells; proteins lower in MDDT *vs.* uMDD negatively regulate cell proliferation; a protein higher in uMDD and MDDT *vs.* CONT is a suppressor of mitosis. DEPs altered in uMDD and not "reversed" in MDDT may become new testable treatment targets. DEPs negatively correlated with number of NPCs and DCX+ cells in uMDD only are involved in cell cycle, adhesion, differentiation, neurite outgrowth and migration. DEPs positively correlated with NPC and DCX+ and GN cells number in CONT and/or MDDT and not uMDD regulate cell division and migration, differentiation, mitochondrial electron transport and negatively regulate apoptosis.

INVESTIGATION OF NMDA RECEPTOR FUNCTION IN A RODENT MODEL OF EARLY LIFE STRESS

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Matthew Wilkinson[1], Emma Robinson[2], Jack Mellor[1]
[1]University of Bristol, School Of Physiology, Pharmacology And Neuroscience, Bristol, United Kingdom, [2]Bristol University, Physiology, Pharmacology And Neuroscience, Bristol, United Kingdom

Aims: Early life stress (ELS) is an important risk factor in the aetiology of depression. Excess developmental glucocorticoid exposure impacts multiple brain regions, with the hippocampus being particularly vulnerable. Hippocampal-dependent behavioural adaptation, often impaired in depression, is dependent on NMDA receptor (NMDAR) mediated synaptic plasticity. In this study we investigated the effect of ELS upon hippocampal NMDAR function. **Methods:** Long-Evans rat pups (n=52) were either undisturbed or maternally separated for 180 minutes per day (MS180) between Post Natal Day 1 (PND1) and PND14. Animals were tested as adults for well-characterised markers of ELS: sucrose preference (n=18) and novelty supressed feeding (NSFT, n=34) alongside assessment of CORT and PVN cFos reactivity to stress and hippocampal neurogenesis (all n=18). To assess NMDAR function in CA1 pyramidal neurones, AMPA/NMDA ratios (n=19) were measured using whole-cell patch clamp alongside separate miniEPSC recordings (n=19). **Results:** MS180 animals showed increased feeding latency in the NSFT alongside increased overall CORT in the restraint stress experiment and increased PVN cFos expression in males but no changes in neurogenesis or sucrose preference. MS180 was associated with a lower AMPA/NMDA ratio with no change in miniEPSC amplitude but decreased frequency. There were no changes in input resistance or paired-pulse ratio between conditions. **Conclusions:** The MS180 model showed a behavioural phenotype consistent with previous work (Bonapersona et al.,2019,Neurosci-Biobehav-Rev,102,299–307). MS180 animals showed evidence supporting increased NMDAR function whereas changes in miniEPSC frequency may reflect decreased pre-synaptic release probability. Work is needed to confirm these findings and assess impact upon synaptic plasticity.

Investigation of reward learning and feedback sensitivity in non-clinical participants with a history of early life stress.
Early life stress (ELS) is an important risk factor for the development of depression. Impairments in reward learning and feedback sensitivity are suggested to be an intermediate phenotype in depression aetiology therefore we hypothesised that healthy adults with a history of ELS would exhibit reward processing deficits independent of any current depressive symptoms. We recruited 64 adults with high levels of ELS and no diagnosis of a current mental health disorder and 65 controls. Participants completed the probabilistic reversal learning task and probabilistic reward task followed by depression, anhedonia, social status, and stress scales. Participants with high levels of ELS showed decreased positive feedback sensitivity in the probabilistic reversal learning task compared to controls. High ELS participants also trended towards possessing a decreased model-free learning rate. This was coupled with a decreased learning ability in the acquisition phase of block 1 following the practice session. Neither group showed a reward induced response bias in the probabilistic reward task however high ELS participants exhibited decreased stimuli discrimination. Overall, these data suggest that healthy participants without a current mental health diagnosis but with high levels of ELS show deficits in positive feedback sensitivity and reward learning in the probabilistic reversal learning task that are distinct from depressed patients. These deficits may be relevant to increased depression vulnerability.

Comparison of conventional and rapid-acting antidepressants in a rodent probabilistic reversal learning task.
Deficits in reward processing are a central feature of major depressive disorder with patients exhibiting decreased reward learning and altered feedback sensitivity in probabilistic reversal learning tasks. Methods to quantify probabilistic learning in both rodents and humans have been developed, providing translational paradigms for depression research. We have utilised a probabilistic reversal learning task to investigate potential differences between conventional and rapid-acting antidepressants on reward learning and feedback sensitivity. We trained 12 rats in a touchscreen probabilistic reversal learning task before investigating the effect of acute administration of citalopram, venlafaxine, reboxetine, ketamine or

scopolamine. Data were also analysed using a Q-learning reinforcement learning model to understand the effects of antidepressant treatment on underlying reward processing parameters. Citalopram administration decreased trials taken to learn the first rule and increased win-stay probability. Reboxetine decreased win-stay behaviour while also decreasing the number of rule changes animals performed in a session. Venlafaxine had no effect. Ketamine and scopolamine both decreased win-stay probability, number of rule changes performed and motivation in the task. Insights from the reinforcement learning model suggested that reboxetine led animals to choose a less optimal strategy, while ketamine decreased the model-free learning rate. These results suggest that reward learning and feedback sensitivity are not differentially modulated by conventional and rapid-acting antidepressant treatment in the probabilistic reversal learning task.

NODES OF RANVIER ARE MODULATED BY CHRONIC PSYCHOSOCIAL STRESS IN MICE AND UNDERGO AXON-SPECIFIC STRUCTURAL REMODELING IN RESPONSE TO CHRONIC NEURONAL ACTIVATION

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Maija-Kreetta Koskinen[1], Mikaela Laine[1], Ali Abdollahzade[2], Adrien Gigliotta[1], Sarah Journée[1], Varpu Alenius[1], Kalevi Trontti[1], Jussi Tohka[2], Petri Hyytiä[3], Alejandra Sierra[2], Iiris Hovatta[1]

Differential expression of myelin-related genes and changes in myelin thickness have been demonstrated in mice after chronic psychosocial stress, a risk factor for anxiety disorders. Here, we developed a 3D reconstruction analysis to investigate whether and how chronic stress affects nodes of Ranvier structural remodeling, another form of myelin plasticity, in male mice from two genetic backgrounds, C57BL/6NCrl (B6) and DBA/2NCrl (D2). We report strain-dependent effects of chronic stress on nodes of Ranvier morphology, including elongation of paranodes in the medial prefrontal cortex (mPFC) gray matter in D2 mice. Furthermore, chronic chemogenetic activation of the ventral hippocampus (vHPC)-to-mPFC pathway resulted in increased risk assessment behavior and shortening of paranodes specifically in stimulated axons, providing a direct link between anxiety-like behavior and remodeling of the nodes of Ranvier. Overall, our data demonstrate the involvement of nodes of Ranvier remodeling in the stress response and suggest an activity-dependent regulation of paranodes in anxiety-related circuits. Nodal remodeling may thus contribute to aberrant circuit function associated with anxiety disorders.

From stress to depression: development of extracellular matrix-dependent cognitive impairment following social stress.
Stress can predispose to depressive episodes, yet the molecular mechanisms regulating the transition from the initial stress response to a persistent pathological depressive state remain poorly understood. We profiled the development of an enduring depressive-like state by assessing affective behavior and hippocampal function during the 2 months following social-defeat stress. We measured remodeling of hippocampal extracellular matrix (ECM) during this period, as we recently identified ECM changes to mediate cognitive impairment during the sustained depressive-like state. Affective disturbance and cognitive impairments develop disparately after social stress, with gradual appearance of affective deficits. In contrast, spatial memory was impaired both early after stress and during the late-emerging chronic depressive-like state, while intact in-between. Similarly, we observed a biphasic regulation of the hippocampal ECM coinciding with hippocampus-dependent memory deficits. Together our data (1) reveal a dichotomy between affective and cognitive impairments similar to that observed in patients, (2) indicate different molecular processes taking place during early stress and the chronic depressive-like state, and (3) support a role of the ECM in mediating long-lasting effects on memory. From a translational point of view, it is important to prioritize on temporal phenotypic aspects in animal models to elucidate the underlying mechanisms of depression.
Sci Rep, 2020; 10

Incubation of depression: ECM assembly and parvalbumin interneurons after stress.
The extracellular space is occupied by a complex network of proteins creating a mesh-like assembly known as the extracellular matrix (ECM). ECM assembles into dense net-like structures, perineuronal nets (PNNs), that envelope cell somas and proximal neurites of predominantly parvalbumin-(PV) interneurons. ECM regulates cell-to-cell communication, thereby modulating neuronal network function. Accumulating evidence points to the importance of network dysfunction in the pathophysiology of psychiatric diseases, in which stress acts as a major predisposing factor. Here we review stress-induced changes in ECM/PNNs and PV-interneurons in preclinical models of (or for) depression, with a special focus on social stress. We argue that the direction of these alterations largely depends on stress recency, as well as on stress timing and the brain region under investigation. A biphasic temporal regulation of ECM/PNNs and PV-interneuron function is typically observed after stress. Understanding the complex mechanisms underlying ECM organization in relation to stress-induced molecular,

cellular and network changes is crucial to further decipher the implications of ECM remodeling in the incubation of depressive symptoms.

Hippocampal extracellular matrix alterations contribute to cognitive impairment associated with a chronic depressive-like state in rats.
Patients with depression often suffer from cognitive impairments that contribute to disease burden. We used social defeat-induced persistent stress (SDPS) to induce a depressive-like state in rats and then studied long-lasting memory deficits in the absence of acute stressors in these animals. The SDPS rat model showed reduced short-term object location memory and maintenance of long-term potentiation (LTP) in CA1 pyramidal neurons of the dorsal hippocampus. SDPS animals displayed increased expression of synaptic chondroitin sulfate proteoglycans in the dorsal hippocampus. These effects were abrogated by a 3-week treatment with the antidepressant imipramine starting 8 weeks after the last defeat encounter. Next, we observed an increase in the number of perineuronal nets (PNNs) surrounding parvalbumin-expressing interneurons and a decrease in the frequency of inhibitory postsynaptic currents (IPSCs) in the hippocampal CA1 region in SDPS animals. In vivo breakdown of the hippocampus CA1 extracellular matrix by the enzyme chondroitinase ABC administered intracranially restored the number of PNNs, LTP maintenance, hippocampal inhibitory tone, and memory performance on the object place recognition test. Our data reveal a causal link between increased hippocampal extracellular matrix and the cognitive deficits associated with a chronic depressive-like state in rats exposed to SDPS.

EFFECTS OF EARLY LIFE STRESS ON THE EXCITABILITY OF PARVALBUMIN-EXPRESSING GABAERGIC INTERNEURONS IN THE HIPPOCAMPUS AND AMYGDALA

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Vasilii Shteinikov, Anton Lakstygal, Henrike Hartung, Sari Lauri
University of Helsinki, Neuroscience Center, Helsinki, Finland

Early life stress (ELS) is a known cause of numerous mental health disorders. Limited bedding and nesting (LBN) model of ELS in rodents has now been extensively described from the behavioral point of view, but the associated functional changes remain less well characterized. Aims: To elucidate the effects of the LBN on physiological functions of GABAergic parvalbumin-positive (PV+) interneurons in the amygdala and hippocampus. Methods: WT and PV-CrexAi14 reporter mouse line was used. LBN conditions were kept during P4-P14, with exposure to maternal separation (1h) at P8, P10 and P12. Behavior was assessed at P60-P80 via a battery of tests: elevated plus maze, open field, light-dark box, and fear conditioning. Electrophysiological recordings were performed in acute slices at P60-P80 with the whole-cell patch clamp method. Results: Male mice exposed to LBN displayed increased anxiety-like behavior and both males and females showed impaired fear learning. We found a significant reduction in sEPSC frequency in PV+ neurons in the basolateral amygdala of male but not female mice, and an increase in the intrinsic excitability of PV+ neurons in both sexes. In PV+ cells of ventral hippocampus CA3 we observed no changes in sEPSC characteristics, while the intrinsic excitability was upregulated in females and downregulated in males. Conclusions: ELS produces gender-specific functional changes in PV+ neurons in the hippocampus and amygdala in adult animals. Given the important role PV+ cells play in circuit regulation, observed alterations of their functional properties likely contribute to the behavioral changes induced by the ELS.

Downregulation of kainate receptors regulating GABAergic transmission in amygdala after early life stress is associated with anxiety-like behavior in rodents.
Early life stress (ELS) is a well-characterized risk factor for mood and anxiety disorders. GABAergic microcircuits in the amygdala are critically implicated in anxiety; however, whether their function is altered after ELS is not known. Here we identify a novel mechanism by which kainate receptors (KARs) modulate feedforward inhibition in the lateral amygdala (LA) and show that this mechanism is downregulated after ELS induced by maternal separation (MS). Specifically, we show that in control rats but not after MS, endogenous activity of GluK1 subunit containing KARs disinhibit LA principal neurons during activation of cortical afferents. GluK1 antagonism attenuated excitability of parvalbumin (PV)-expressing interneurons, resulting in loss of PV-dependent inhibitory control and an increase in firing of somatostatin-expressing interneurons. Inactivation of Grik1 expression locally in the adult amygdala reduced ongoing GABAergic transmission and was sufficient to produce a mild anxiety-like behavioral phenotype. Interestingly, MS and GluK1-dependent phenotypes showed similar gender specificity, being detectable in male but not female rodents. Our data identify a novel KAR-dependent mechanism for cell-type and projection-specific functional modulation of the LA GABAergic microcircuit and suggest that the loss of GluK1 KAR function contributes to anxiogenesis after ELS.

Kainate receptors regulate development of glutamatergic synaptic circuitry in the rodent amygdala.
Perturbed information processing in the amygdala has been implicated in developmentally originating neuropsychiatric disorders. However, little is known on the mechanisms that guide formation and refinement of intrinsic connections between amygdaloid nuclei. We demonstrate that in rodents the glutamatergic connection from basolateral to central amygdala (BLA-CeA) develops rapidly during the first 10 postnatal days, before external inputs underlying amygdala-dependent behaviors emerge. During this restricted period of synaptic development, kainate-type of ionotropic glutamate receptors (KARs) are highly expressed in the BLA and tonically activated to regulate glutamate release via a G-protein-dependent mechanism.

Genetic manipulation of this endogenous KAR activity locally in the newborn LA perturbed development of glutamatergic input to CeA, identifying KARs as a physiological mechanism regulating formation of the glutamatergic circuitry in the amygdala.

Hydrophobic Amines and Their Guanidine Analogues Modulate Activation and Desensitization of ASIC3.
Acid-sensing ion channel 3 (ASIC3) is an important member of the acid-sensing ion channels family, which is widely expressed in the peripheral nervous system and contributes to pain sensation. ASICs are targeted by various drugs and toxins. However, mechanisms and structural determinants of ligands' action on ASIC3 are not completely understood. In the present work we studied ASIC3 modulation by a series of "hydrophobic monoamines" and their guanidine analogs, which were previously characterized to affect other ASIC channels via multiple mechanisms. Electrophysiological analysis of action via whole-cell patch clamp method was performed using rat ASIC3 expressed in Chinese hamster ovary (CHO) cells. We found that the compounds studied inhibited ASIC3 activation by inducing acidic shift of proton sensitivity and slowed channel desensitization, which was accompanied by a decrease of the equilibrium desensitization level. The total effect of the drugs on the sustained ASIC3-mediated currents was the sum of these opposite effects. It is demonstrated that drugs' action on activation and desensitization differed in their structural requirements, kinetics of action, and concentration and state dependencies. Taken together, these findings suggest that effects on activation and desensitization are independent and are likely mediated by drugs binding to distinct sites in ASIC3.

30557561: Shteinikov VY, Barygin OI, Gmiro VE, Tikhonov DB
Multiple modes of action of hydrophobic amines and their guanidine analogues on ASIC1a.
Hydrophobic monoamines containing only a hydrophobic/aromatic moiety and protonated amino group are a recently described class of acid-sensing ion channel (ASIC) modulators. Intensive studies have revealed a number of active compounds including endogenous amines and pharmacological agents and shown that these compounds potentiate and inhibit ASICs depending on their specific structure and on subunit composition of the target channel. The action of monoamines also depends on the application protocol, membrane voltage, conditioning and activating pH, suggesting complex mechanism(s) of the ligand-receptor interaction. Without understanding of these mechanisms analysis of structure-function relationships and predictive search for new potent and selective drugs are hardly possible. To this end, we investigated the modes of action for a representative series of amine and guanidine derivatives of adamantane and phenylcyclohexyl. The study was performed on transfected Chinese hamster ovary (CHO) cells and rat hippocampal interneurons using whole-cell patch clamp recording. We found that complex picture of monoamine action can be rationalized assuming four modes of action: (1) voltage-dependent pore block, (2) acidic shift of activation, (3) alkaline shift of activation and (4) acidic shift of steady-state desensitization. Structure-activity relationships are discussed in the light of this framework. The experiments on native heteromeric ASICs have shown that some of these mechanisms are shared between them and recombinant ASIC1a, implying that our results could also be relevant for amine action in physiological and pathological conditions.

Potentiation and Block of ASIC1a by Memantine.
Acid-sensing ion channels (ASICs) are modulated by various classes of ligands, including the recently described hydrophobic monoamines, which inhibit and potentiate ASICs in a subunit-specific manner. In particular, memantine inhibits ASIC1a and potentiates ASIC2a homomers. The aim of the present work was to characterize action mechanism of memantine on recombinant ASIC1a expressed in CHO (Chinese hamster ovary) cells. We have demonstrated that effect of memantine on ASIC1a strongly depends on membrane voltage, conditioning pH value and application protocol. When applied simultaneously with activating acidification at hyperpolarized voltages, memantine caused the strongest inhibition. Surprisingly, application of memantine between ASIC1a activations at zero voltage caused significant potentiation. Analysis of the data suggests that memantine produces two separate effects, voltage-dependent open-channel block and shift of steady-state desensitization curve to more acidic values. Putative binding sites are discussed based on the computer docking of memantine to the acidic pocket and the pore region.

Ligands of histamine receptors modulate acid-sensing ion channels.
Recently we found that synthetic compounds containing amino group linked to hydrophobic or aromatic moiety are potent modulators of the proton-gated channels (ASICs). These structures have clear similarity with ligands of histamine receptors. We have also demonstrated that histamine potentiates homomeric ASIC1a by shifting its activation dependence to less acidic

conditions. In the present work the action of a series of histamine receptors ligands on recombinant ASIC1a and ASIC2a was characterized. Two types of action were found for ASIC1a. 1-methylhistamine, N-alpha-methylhistamine, dimaprit and thioperamide caused significant potentiation, which was pH-dependent and voltage-independent. The H4R antagonist A943931 caused inhibition, which is likely due to voltage-dependent pore block. ASIC2a were virtually insensitive to the drugs tested. We conclude that ligands of histamine receptors should also be considered as ASIC modulators.

THE PSYCHOTOMIMETIC KETAMINE DISRUPTS THE TRANSFER OF SENSORY INFORMATION IN THE CORTICOTHALAMIC NETWORK

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Didier Pinault[1], Yi Qin[1,2,3], Ali Mahdavi[1,4], Paul Anderson[5], Sofya Kulikova[6]
[1]Université de Strasbourg, Crbs, Inserm U1114, Strasbourg, France, [2]Universite de Strasbourg, Crbs, Inserm U1114, Strasbourg, France, [3]University of Amsterdam, Netherlands Institute For Neuroscience, Amsterdam, Netherlands, [4]University of Freiburg, Bernstein Center Freiburg, Freiburg im Breisgau, Germany, [5]Medical University of Vienna, Centre For Brain Research, Vienna, Austria, [6]National Research University, Higher School Of Economics, Perm, Russian Federation

In prodromal and early schizophrenia, disorders of attention and perception are associated with structural and chemical brain abnormalities, and with dysfunctional, highly distributed corticothalamic networks exhibiting disturbed brain rhythms. The underlying mechanisms are elusive. The non-competitive NMDA receptor antagonist ketamine simulates the symptoms of prodromal and early psychotic disorders, including the disturbances in ongoing and task/sensory-related broadband gamma frequency (30-80 Hz) oscillations in corticothalamic networks. In normal healthy subjects and rodents, complex integration processes, like sensory perception, induce transient, large-scale synchronized gamma oscillations in a time window of a few hundreds of ms (200-700 ms) after the presentation of the object of attention (e.g., sensory stimulation). AIM: Our goal was to investigate the effects of a single psychotomimetic low-dose (2.5 mg/kg, subcutaneous) of ketamine on sensory-induced gamma oscillations in the frontoparietal somatosensory system in an attempt to understand the effect of NMDA receptor antagonism on the functional interactions between the cortex and thalamus. METHODS: Electrophysiological multisite cortical and thalamic EEG and extracellular recordings were performed in lightly anesthetized rats. Induced gamma oscillations occurred 200-700 ms after electrical stimulation of the vibrissae teguments. Spectral analysis, multiscale entropy, and coherence connectivity were computed. RESULTS: Ketamine transiently increased the power of baseline gamma oscillations and decreased sensory-induced gamma oscillations. In addition, it disrupted information transferability in both the somatosensory thalamus and the related cortex and decreased the stimulus-induced gamma-frequency band thalamocortical connectivity. CONCLUSION: The present findings support the hypothesis that NMDA receptor antagonism disrupts the transfer of perception-related information in the cortico-thalamo-cortical system.

ROLE OF GHRELIN ISOFORMS ON FOOD ANTICIPATORY ACTIVITY AND NEURONAL ACTIVATION IN A MOUSE MODEL OF CHRONIC FOOD RESTRICTION

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Julia Mattioni, Nicolas Lebrun, Heloise Hamelin, Lauralee Robichon, Odile Viltart, Virginie Tolle
University of Paris, Ipnp - Inserm Umr-s1266, Paris, France

Aims. Anorexia nervosa is a psychiatric disorder characterized by food restriction, intense physical activity, and elevated plasma ghrelin concentrations. Ghrelin is a gastrointestinal signal of undernutrition and exists under an acylated peptide (AG) that targets GHS-R-expressing neurons in both the hypothalamus and mesolimbic structures, and a desacylated peptide (DAG), which exact function remains unknown. We hypothesized that during states of chronic undernutrition, elevated ghrelin participates in the rewarding effect of physical activity. We measured running wheel activity during food anticipation (FAA), a period of intense physical activity in food restricted animals. Furthermore, c-Fos activation was assessed in hypothalamic and mesolimbic neurons following peripheral injections of AG and/or DAG. **Methods.** WT or GHS-R KO female mice were placed in a cage containing a running wheel with access to food (ALW) then exposed to 50% food restriction (FRW). Physical activity was measured using automated running wheels. AG, DAG (10 nmol/10 g BW) or saline were injected subcutaneously in WT mice under FRW conditions. Physical activity and c-Fos immunoreactivity were evaluated in hypothalamic, VTA and nucleus accumbens neurons 2 hours following the injection. **Results.** In FRW conditions, FAA was reduced in GHS-R KO mice. In the absence of food, AG, but not DAG, induced c-Fos activation in hypothalamic AgRP neurons known to convey negative valence to reward neurons. We also explored the rewarding effect of activity in a conditioned place preference. **Conclusions.** These results suggest that, when food is not available, ghrelin signalling is important for food anticipatory activity by targeting hypothalamic-mesolimbic circuits.

EARLY-LIFE STRESS ALTERS THE DEVELOPMENT OF FUNCTIONAL INTERACTIONS WITHIN PREFRONTAL-AMYGDALA NETWORKS

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Francescangelo Vedele, Angelica Donati, Henrike Hartung
University of Helsinki, Neuroscience Center, Helsinki, Finland

Early-life stress (ELS) is known to affect the development of the brain, with its consequences extending into adult life. Although many effects of ELS have been described, its impact on the functional maturation of networks underlying emotional behavior is still poorly understood. **Aims:** To describe the effect of ELS onto the development of functional interactions between the prefrontal cortex (PFC) and basolateral amygdala (BLA) in male and female mice. **Methods:** ELS was induced in mice with the established model of limited bedding and nesting (LBN) implemented between P4-P14 and combined with maternal separation for one hour at P8, P10, and P12. *In vivo* multi-unit activity and local-field potential (LFP) recordings were performed simultaneously in the prelimbic subdivision of PFC and BLA of urethane anaesthetized pups at P18-P20. **Results:** We found that male mice exposed to ELS showed a markedly lower spectral power in the theta and low-gamma bands in both layers II/III of PFC and BLA. Functional interactions between the BLA and PFC, as measured with LFP-LFP coherence, showed a decrease between 1-10 Hz. Interestingly, this alteration did not extend to females, nor to the deep layers of PFC. **Conclusions:** These data highlight a previously unknown effect of ELS onto brain development, appearing both as an impairment within the BLA and the PFC but also indicating an altered functional connectivity between them. These changes in the functional development of prefrontal-amygdala networks may underlie the increased susceptibility to neuropsychiatric disorders caused by ELS.

Nilotinib restores memory function by preventing dopaminergic neuron degeneration in a mouse model of Alzheimer's Disease.
What happens precociously to the brain destined to develop Alzheimer's Disease (AD) still remains to be elucidated and this is one reason why effective AD treatments are missing. Recent experimental and clinical studies indicate that the degeneration of the dopaminergic (DA) neurons in the Ventral Tegmental Area (VTA) could be one of the first events occurring in AD. However, the causes of the increased vulnerability of DA neurons in AD are missing. Here, we deeply investigate the physiology of DA neurons in the VTA before, at the onset, and after onset of VTA neurodegeneration. We use the Tg2576 mouse model of AD, overexpressing a mutated form of the human APP, to identify molecular targets that can be manipulated pharmacologically. We show that in Tg2576 mice, DA neurons of the VTA at the onset of degeneration undergo slight but functionally relevant changes in their electrophysiological properties and cell morphology. Importantly, these changes are associated with accumulation of autophagosomes, suggestive of a dysfunctional autophagy, and with enhanced activation of c-Abl, a tyrosine kinase previously implicated in the pathogenesis of neurodegenerative diseases. Chronic treatment of Tg2576 mice with Nilotinib, a validated c-Abl inhibitor, reduces c-Abl phosphorylation, improves autophagy, reduces Aβ levels and - more importantly - prevents degeneration as well as functional and morphological alterations in DA neurons of the VTA. Interestingly, the drug prevents the reduction of DA outflow to the hippocampus and ameliorates hippocampal-related cognitive functions. Our results strive to identify early pathological brain changes in AD, to provide a rational basis for new therapeutic interventions able to slow down the disease progression.

Blunting neuroinflammation with resolvin D1 prevents early pathology in a rat model of Parkinson's disease.
Neuroinflammation is one of the hallmarks of Parkinson's disease (PD) and may contribute to midbrain dopamine (DA) neuron degeneration. Recent studies link chronic inflammation with failure to resolve early inflammation, a process operated by specialized pro-resolving mediators, including resolvins. However, the effects of stimulating the resolution of inflammation in PD - to modulate disease progression - still remain unexplored. Here we show that rats overexpressing human α-synuclein (Syn) display altered DA neuron properties, reduced striatal DA outflow and motor deficits prior to nigral degeneration. These early alterations are coupled with microglia activation and perturbations of inflammatory and pro-resolving mediators, namely IFN-γ and resolvin D1 (RvD1). Chronic and early RvD1 administration in Syn rats prevents central and peripheral inflammation, as well as neuronal dysfunction and motor deficits. We also show that endogenous RvD1 is decreased in human patients with early-PD. Our results suggest there is an imbalance between neuroinflammatory and pro-resolving processes in PD.

Neurodevelopmental Disorders: Functional Role of Ambra1 in Autism and Schizophrenia.
The activating molecule in Beclin-1-regulated autophagy (Ambra1) is a highly intrinsically disordered protein best known for its role as a mediator in autophagy, by favoring the formation of autophagosomes. Additional studies have revealed that Ambra1 is able to coordinate cell responses to stress conditions such as starvation, and it actively participates in cell proliferation, cytoskeletal modification, apoptosis, mitochondria removal, and cell cycle downregulation. All these functions highlight the importance of Ambra1 in crucial physiological events, including metabolism, cell death, and cell division. Importantly, Ambra1 is also crucial for proper embryonic development, and its complete absence in knock-out animal models leads to severe brain morphology defects. In line with this, it has recently been implicated in neurodevelopmental disorders affecting humans, particularly autism spectrum disorders and schizophrenia. Here, we discuss the recent links between Ambra1 and neurodevelopment, particularly focusing on its role during the maturation of hippocampal parvalbumin interneurons and its importance for maintaining a proper excitation/inhibition balance in the brain.

THE ROLE OF THE NUCLEUS ACCUMBENS SHELL IN ALCOHOL USE DESPITE NEGATIVE CONSEQUENCES

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Allison Mcdonald[1], Thijs Van 'T Hullenaar[2], Panthea Nemat[2], Yvar Van Mourik[1], Isis Alonso-Lozares[1], Dustin Schetters[1], Taco De Vries[1], Nathan Marchant[1]

Alcohol use is widespread across most societies. While most people can control their alcohol consumption, a vulnerable sub-population may develop alcohol use disorder (AUD), characterized by continued alcohol use despite negative consequences. We use a rodent model of alcohol use despite negative consequences, to identify neurobiological differences that may underlie addiction-like vulnerability. This model reliably identifies two sub-populations of rats: Some substantially decrease alcohol use in the face of punishment (punishment-sensitive, controlled use) while others continue alcohol use despite negative consequences (punishment-resistant, addictive-like behavior). Here, we trained Long-Evans outbred rats (n=92, m/f) to self-administer alcohol, and then introduced punishment of alcohol self-administration with response-contingent foot-shock. Interestingly, we found that more females developed punishment-resistant alcohol use compared to males. Using immunohistochemical detection of c-Fos (neural activity marker), we found that lower c-Fos expression in nucleus accumbens shell (NAcSh) was associated with punishment-resistant alcohol use, compared to punishment-sensitive use or unpunished consumption (n=24). To test for a causal role of NAcSh activity, in another group (n=68), we applied chemogenetic inhibition of NAcSh throughout each phase of the experiment. We found that chemogenetic NAcSh inhibition increased alcohol consumption during unpunished alcohol self-administration. In punished sessions, however, NAcSh inhibition did not alter alcohol consumption. These results imply that NAcSh may be involved in the drive to consume alcohol, but not when alcohol use involves the possibility of negative consequences. Identifying the contributions of NAcSh, and associated neural circuits, in alcohol use despite negative consequences will improve our understanding of the neurobiological underpinnings of AUD.

Alcohol Seeking Under Risk of Punishment Is Associated With Activation of Cortical and Subcortical Brain Regions.
In humans, stimuli associated with alcohol availability can provoke relapse during abstinence. In this study, we investigated the role of discriminative stimuli (DS) in the control of alcohol seeking in two types of behavioral tests. The first test examined the ability of an alcohol-associated DS to promote alcohol seeking (relapse) after punishment-imposed abstinence in the presence of a different DS. Following this, we tested whether the differentially associated DS can promote and suppress alcohol self-administration in a within-session discrimination task. During the within-session discrimination task, we also tested the rate of alcohol self-administration when two DS are presented in a compound. We first trained Long-Evans male rats (= 24) to self-administer alcohol in the presence of one DS (reward-associated discriminative stimulus, rewDS) and then punished that behavior in the presence of a different DS (punishment-associated discriminative stimulus, punDS). On the test, we found that rats tested with the rewDS showed higher alcohol seeking than rats tested with the punDS. This result shows that a single Cue DS can promote alcohol seeking in a manner comparable to contexts. Subsequently, we trained 16 of these rats in a within-session trial-based discrimination task, comprised of intervening 2-min trials of rewDS, punDS, or conflict with rewDS and punDS in compound and a reduced probability of punishment. We found that alcohol self-administration is bi-directionally regulated by the rewDS and punDS. In conflict trials, alcohol self-administration was at a rate that was intermediate between the rewDS and punDS trials. In a final test, rats were presented with one of the three trial conditions and perfused for Fos immunohistochemistry. We found Fos expression was higher in the rats tested in the conflict condition in three interconnected sub-cortical brain regions. This study demonstrated the important role that alcohol-associated DS plays an important role in promoting relapse to alcohol seeking after punishment-imposed abstinence. We also implemented a within-session discrimination task that allows for the study of alcohol seeking under motivational conflict, which may be relevant for alcohol use despite negative consequences. The results from the Fos data suggest that higher alcohol seeking in approach-avoidance motivational conflict is associated with activation of sub-cortical regions but not

cortical regions.

CONSISTENT METABOLIC AND MIRNA SIGNATURES OF CHILDHOOD TRAUMA ACROSS DIFFERENT BODY FLUIDS IN HUMAN

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Magdalena Gomółka[1], Weronika Tomaszewska[1], Adria-Jaume Roura Canalda[2], Bozena Kaminska[2], Anna Ziomkiewicz-Wichary[3], Ali Jawaid[1]

Aims: The main goal of this project is to systematically examine miRNA changes in different human body fluids, i.e., serum, sperm and milk that are relevant to long-term sequelae of childhood trauma including its intergenerational transmission. **Methods:** Small RNA sequencing followed by quantitative reverse transcriptase polymerase chain reaction assays were performed to identify and validate differentially regulated miRNAs in the serum of children with recent trauma in the form of paternal loss and maternal separation (PLMS), sperm of adult men with a history of complex trauma up to the age of 17 years, and milk from lactating mothers with prior history of childhood trauma. Pathway analysis for altered miRNAs was performed based on the Tarbase database. **Results:** Small RNA sequencing analysis revealed 48 miRNAs to be differentially expressed in the serum of PLMS children vs. control; whereas 29 miRNAs were differentially expressed in the sperm of adult men with a history of complex childhood trauma. Several differentially regulated miRNAs overlapped between the analyses. Furthermore, the pathway analysis and functional relevance of the altered miRNAs suggest a potential implication of lipids-associated miRNA carriers in the observed changes. **Conclusions:** This study found overlapping miRNA changes in a range of human body fluids after childhood trauma that seem to be conserved across diverse cohorts and age groups. The close relevance of these miRNAs to lipid-derived carriers is the premise of our current investigations.

Stem Cells as a Source of Pancreatic Cells for Production of 3D Bioprinted Bionic Pancreas in the Treatment of Type 1 Diabetes.
Type 1 diabetes (T1D) is the third most common autoimmune disease which develops due to genetic and environmental risk factors. Often, intensive insulin therapy is insufficient, and patients require a pancreas or pancreatic islets transplant. However, both solutions are associated with many possible complications, including graft rejection. The best approach seems to be a donor-independent T1D treatment strategy based on human stem cells cultured in vitro and differentiated into insulin and glucagon-producing cells (β and α cells, respectively). Both types of cells can then be incorporated into the bio-ink used for 3D printing of the bionic pancreas, which can be transplanted into T1D patients to restore glucose homeostasis. The aim of this review is to summarize current knowledge about stem cells sources and their transformation into key pancreatic cells. Last, but not least, we comment on possible solutions of post-transplant immune response triggered stem cell-derived pancreatic cells and their potential control mechanisms.

Novel Strategies in Artificial Organ Development: What Is the Future of Medicine?
The technology of tissue engineering is a rapidly evolving interdisciplinary field of science that elevates cell-based research from 2D cultures through organoids to whole bionic organs. 3D bioprinting and organ-on-a-chip approaches through generation of three-dimensional cultures at different scales, applied separately or combined, are widely used in basic studies, drug screening and regenerative medicine. They enable analyses of tissue-like conditions that yield much more reliable results than monolayer cell cultures. Annually, millions of animals worldwide are used for preclinical research. Therefore, the rapid assessment of drug efficacy and toxicity in the early stages of preclinical testing can significantly reduce the number of animals, bringing great ethical and financial benefits. In this review, we describe 3D bioprinting techniques and first examples of printed bionic organs. We also present the possibilities of microfluidic systems, based on the latest reports. We demonstrate the pros and cons of both technologies and indicate their use in the future of Medicine.

Irradiation with 365 nm and 405 nm wavelength shows differences in DNA damage of swine pancreatic islets.
3D printing is being used more extensively in modern biomedicine. One of the problems is selecting a proper crosslinking method of bioprinted material. Amongst currently used techniques we can distinguish: physical crosslinking (e.g. Ca2+ and Sr2+) and chemical crosslinking-the UV light crosslinking causing the biggest discussion. UV radiation is selectively absorbed by DNA, mainly in the UV-B region but also (to some extent) in UV-A and UV-C regions. DNA excitement results in typical photoproducts. The amount of strand breaks may vary depending on the period of exposition, it can also differ when cells undergo incubation after radiation.

Type 1 diabetes: genes associated with disease development.
Type 1 diabetes (T1D) is the third most common autoimmune disease which develops due to genetic and environmental risk factors. Based on the World Health Organization (WHO) report from 2014 the number of people suffering from all types of diabetes ascended to 422 million, compared to 108 million in 1980. It was calculated that this number will double by the end of 2030. In 2015 American Diabetes Association (ADA) announced that 30.3 million Americans (that is 9.4% of the overall population) had diabetes of which only approximately 1.25 million had T1D. Nowadays, T1D represents roughly 10% of adult diabetes cases total. Multiple genetic abnormalities at different loci have been found to contribute to type 1 diabetes development. The analysis of genome-wide association studies (GWAS) of T1D has identified over 50 susceptible regions (and genes within these regions). Many of these regions are defined by single nucleotide polymorphisms (SNPs) but molecular mechanisms through which they increase or lower the risk of diabetes remain unknown. Genetic factors (in existence since birth) can be detected long before the emergence of immunological or clinical markers. Therefore, a comprehensive understanding of the multiple genetic factors underlying T1D is extremely important for further clinical trials and development of personalized medicine for diabetic patients. We present an overview of current studies and information about regions in the human genome associated with T1D. Moreover, we also put forward information about epigenetic modifications, non-coding RNAs and environmental factors involved in T1D development and onset.

STUDIES ON HIPPOCAMPAL HISTOARCHITECTURE AND NEUROCHEMISTRY IN PSYCHOLOGICALLY STRESSED RATS GIVEN GUT MICROBIOME SUPPLEMENTATION

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Afoluwajuwonlo Obaoye, Witness Tebamifor, Jacob Medubi, Odunola Adekunle, Daisy Ochoma, Abraham Osinubi
University of Lagos, Anatomy, Lagos, Nigeria

Introduction: Life-threatening psychological stress (PS) disrupts the gut microbiome and accelerates decline in cognitive and memory functions and may predispose to certain neurodegenerative diseases. It is not known if the administration of probiotics (probio) can mitigate the detrimental effect of psychological stress on hippocampal histoarchitecture and neurochemistry. **Aim:** This study, was, therefore, designed to test the hypothesize that the administration of probiotics has beneficial effects on the neurohistology and neurochemistry of the hippocampus following exposure to psychological stress. **Methods**: Thirty-five adult male Wistar rats were assigned into seven groups (n=5) comprising the control, acute PS, acute probio, acute PS+probio, chronic PS, chronic probio, chronic PS+probio. Each animal in the probio groups was fed 10×10^6 colony-forming units of *lactobacillus acidophilus* every other day while the PS groups were exposed to predator stress for one hour between 7-10 am daily. The treatments lasted for 21days. Animals were sacrificed, the hippocampus was carefully harvested for histology and assay of dopamine, serotonin, malondialdehyde (MDA), catalase (CAT), superoxide dismutase (SOD) and reduced glutathione, (GHS). **Results**: Data analyses reveal that both acute and chronic PS significantly ($p< 0.05$) depress hippocampal serotonin and dopamine levels, cause increased lipid peroxidation, and impaired antioxidant parameters. The probiotics groups exhibited statistically significant better results on all parameters assessed and compared. There were no obvious histoarchitectural differences seen between any two groups. **Discussion**: Overall, data analyses suggest that the gut microbiome might play a significant role in hippocampal function because supplementing it mitigate stress-induced perturbations of hippocampal neurochemistry and redox status

EXPOSURE TO CHRONIC SOCIAL STRESS OF IMMATURE ANIMALS EXPERIENCED EARLY-LIFE SEIZURES: BEHAVIORAL PHENOTYPING

POSTER SESSION 01 - SECTION: STRESS, ANXIETY AND MENTAL HEALTH

Anna Mikulecka[1], Martin Kucera[2], Hana Kubova[2]
[1]Institute of Physiology The Czech Academy of Sciences, Developmental Epileptology, Praha , Czech Republic, [2]Institute of Physiology The Czech Academy of Sciences, Developmental Epileptology, Praha, Czech Republic

This study aimed to determine whether unpredictable chronic social stress induces long-lasting effects on the behavioral responsiveness of immature animals experienced status epilepticus We exposed Wistar rats with early-life seizures to chronic stress using a resident–intruder paradigm, starting at adolescence. The animals were transferred to PhenoTyper cages (Noldus Information Technology), where their behavior was automatically monitored for 24 hours. The animals were tested three times with one-, two-and three-month delays. Phenotypic markers of locomotor, emotional, and reward behavior were evaluated. PhenoTyper testing has revealed an increase in the distance moved during the day and a decrease in that moved during the night in both groups, suggesting that stress has affected chronobiologic rhythms in both controls and SE animals. In addition, SE animals exposed to stress had a higher sucrose preference than controls, indicating that social stress triggered a higher level of anxiety and not hedonic behavior as a marker of depressive-related behavior. In conclusion, our results have shown that chronic social stress leads to higher sensitivity to anxiety and emotive behavior in animals experiencing early status epilepticus. This study was supported by grant Czech Science Foundation (19-11931S), European Regional Development Fund project PHARMABRAIN, CZ.02.1.01/0.0/0.0/16_025/000744 (co-supported by EU).

Aims Identify differences in new VTA synapses on ACC pyramidal neurons formed during stress exposure in stress resilient and stress susceptible mice. **Methods** Pre-eGRASP and post-eGRASP expressing AAV's are used to label newly formed synapses formed by projections from ventral tegmental area (VTA), ventral hippocampus (VH), basolateral amygdala (BLA) onto anterior cingulate cortex (ACC) in cyan, green, yellow, respectively. TagRFP-T is used to label ACC dendritic tree. Three C57BL/6 male mice were exposed to chronic social defeat stress for 10 days and separated into stress susceptible and resilient groups by social interaction test. 60 µm-thick sections were imaged by acquiring 30 µm z-stacks under 405,488,552 and 635 nm excitation. Acquisition was done in multiple spectral emission channels with different bandwidths (445-800 nm) to differentiate between cyan, green, yellow-eGRASP, TagRFP-T and autofluorescence. Pixels were spectrally unmixed using LUMoS algorithm. Unmixed images were deconvolved and median-filtered to increase signal-to-noise ratio. Fluorescent signals corresponding to newly formed VTA-ACC synapses in layer 2/3 were manually counted in 3D Z-stacks. **Results** Number of new synapses formed between VTA projections and L2/3 ACC neurons was significantly higher in stress susceptible mice than in resilient mice (10.6±5.16 and 5.44±2.91, respectively, $p = 0.047$, 14 z-stacks, mean ± SD). Evaluation of newly formed synapses between VH-ACC and BLA -ACC is in progress. **Conclusions** Not only dopaminergic but also glutamatergic VTA neuronal projections onto ACC determine stress susceptibility. HYPOTHALAMIC UROCORTIN3 EXPRESSING NEURONS PROJECT TO THE PITUITARY GLAND AND SIGNAL TO THE PERIPHERY

POSTER SESSION 01 - SECTION: THERMOREGULATION, ENERGY HOMEOSTASIS AND HORMONES

Ilaria Carta
Albert Einstein College of Medicine, Neuroscience, Bronx, United States of America

Urocortin3 (Ucn3) expressing neurons located in the perifornical area of the hypothalamus (PeFA) are important for many functions, including social behavior and stress. Previous work from our lab revealed that these neurons send projections to the median eminence (ME), the fiber bundle that connects the brain and the pituitary gland, suggesting that Ucn3+ neurons might be implicated in neuroendocrine signaling. First, we sought to find out whether Ucn3+ axons terminate in the pituitary and to which subdivision/s. We found that Ucn3+ puncta can be observed in the posterior pituitary in close proximity to blood vessels, although they are not very abundant. We also observed a population of cells, not previously described, that expresses Ucn3 and densely populates the anterior pituitary. Optogenetic stimulation of $PeFA^{Ucn3}$ neurons results in increased plasma Ucn3, suggesting that Ucn3 is either released in the blood from hypothalamic axons, or from the anterior pituitary upon hypothalamic activation. Interestingly, acute stress also results in increased levels of plasma Ucn3, with peak levels 2 hours after stress and recovery to baseline levels at 6 hours. Taken together, our preliminary findings suggest that $PeFA^{Ucn3}$ neurons may regulate the stress response by signaling to peripheral organs, either by interacting with the HPA (hypothalamo-pituitary-adrenal) axis or via an independent neuroendocrine circuit. Our lab is currently trying to further dissect the contribution of $PeFA^{Ucn3}$ projections to regulating circulating Ucn3 levels, via the pituitary, using molecular and in vivo approaches.

Cerebellar modulation of the reward circuitry and social behavior.
The cerebellum has been implicated in a number of nonmotor mental disorders such as autism spectrum disorder, schizophrenia, and addiction. However, its contribution to these disorders is not well understood. In mice, we found that the cerebellum sends direct excitatory projections to the ventral tegmental area (VTA), one of the brain regions that processes and encodes reward. Optogenetic activation of the cerebello-VTA projections was rewarding and, in a three-chamber social task, these projections were more active when the animal explored the social chamber. Intriguingly, activity in the cerebello-VTA pathway was required for the mice to show social preference in this task. Our data delineate a major, previously unappreciated role for the cerebellum in controlling the reward circuitry and social behavior.

neurons in the mouse perifornical area promote infant-directed neglect and aggression.
While recent studies have uncovered dedicated neural pathways mediating the positive control of parenting, the regulation of infant-directed aggression and how it relates to adult-adult aggression is poorly understood. Here we show that ()-expressing neurons in the hypothalamic perifornical area (PeFA) are activated during infant-directed attacks in males and females, but not other behaviors. Functional manipulations of PeFA neurons demonstrate the role of this population in the negative control of parenting in both sexes. PeFA neurons receive input from areas associated with vomeronasal sensing, stress, and parenting, and send projections to hypothalamic and limbic areas. Optogenetic activation of PeFA axon terminals in these regions triggers various aspects of infant-directed agonistic responses, such as neglect, repulsion, and aggression. Thus, PeFA neurons emerge as a dedicated circuit component controlling infant-directed neglect and aggression, providing a new framework to understand the positive and negative regulation of parenting in health and disease.

PARADOXICAL ROLES OF TRPV1 AND TRPM2 IN WARM TEMPERATURE DETECTION

POSTER SESSION 01 - SECTION: THERMOREGULATION, ENERGY HOMEOSTASIS AND HORMONES

Muad Abd El Hay[1], Gretel Kamm[2], Jan Siemens[1]
[1]Heidelberg University Clinic, Pharmacology, Heidelberg, Germany, [2]European Molecular Biology Laboratory, Cell Biology And Biophysics, Heidelberg, Germany

TRPV1 and TRPM2 are temperature sensitive cation channels belonging to the family of transient receptor potential (TRP) channels. Recent findings implicate a role for both TRPV1 and TRPM2 in warm-temperature detection. Cellular data from animals lacking TRPV1 and TRPM2, as well as pharmacological inhibition experiments, support this idea. However, in-vivo assessment of TRPV1- and TRPM2-involvement in temperature detection yields seemingly contradictory results. In this study, the role of TRPV1 and TRPM2 in warmth detection was evaluated in-vivo and in-vitro under comparable conditions. We developed a behavioral paradigm that assesses the thermal preference of animals to ambient and floor temperature. Animals lacking TRPM2 showed deficits in warm-temperature detection. TRPV1-KO animals, however, did not present a marked phenotype. Calcium imaging of DRG neurons from TRPV1- or TRPM2-KO animals cultured for three days showed a significant reduction in the proportion of warmth-sensitive neurons (WSN) compared to wildtype cultures. These results confirm the involvement of TRPM2 in warm temperature detection, while presenting a disconnect between the in-vitro and in-vivo observations for TRPV1. Intriguingly, animals over-expressing TRPV1 in TRPV1-positive sensory neurons showed a faster aversion to warm temperatures compared to wildtype animals in the behavioral paradigm. This is reflected in DRG cultures as an increase in the proportion of WSN, compared to wildtype cultures. This suggests that TRPV1 is capable of modulating warm temperature responses, in-vitro and in-vivo. In summary, we show that both TRPV1 and TRPM2 participate in the detection of warmth in-vitro and in-vivo, albeit with different and seemingly paradoxical contributions.

In response to stress, catecholamines are the first hormones to be released into the blood. Catecholamine secretion is allowed by a tightly coordinated sequence of cellular and tissular mechanisms, in which the adrenal neuroendocrine chromaffin cells play a crucial role. A finely-tuned regulation of chromaffin cell electrical activity is required for appropriate hormone secretion in response to the whole-organism demand. While the repertoire of ion channels involved in generating the spiking activity is well known, how this spiking pattern is regulated by ion conductances operating nearby the resting membrane potential (RMP) is much less investigated. We show in mouse acute adrenal slices that at RMP chromaffin cells display a composite firing pattern, alternating between active periods composed of action potentials firing with a regular or a bursting mode, and silent periods. RMP is sensitive to changes in extracellular sodium (Na^+) concentration, as such a low Na^+-containing saline hyperpolarizes the membrane. This RMP drive reflects the contribution of a depolarizing conductance, which is i) not blocked by tetrodotoxin or cesium, ii) displays a linear I/V relationship between -110 to -40 mV and iii) is carried by cations with $g_{Na}>g_K>g_{Cs}$. These biophysical attributes, together with the expression of the sodium-leak channel *Nalcn* transcript in chromaffin cells, argue for a possible contribution of NALCN to chromaffin cell excitability. These results are the first description of a regulatory action of a background Na^+ conductance on chromaffin cell excitability. They also extend the inventory of tissues in which NALCN is expressed to neuroendocrine glands.

Astrocytes are glial cells proposed as the main Sonic Hedgehog (Shh)-responsive cells in the adult brain. In the hypothalamus, astrocytes support neuronal circuits implicated in the regulation of energy metabolism. We have identified the distribution of gene transcripts of the Shh pathway including the Shh-receptor Patched (Ptc) and Gli1-3 in astrocytes using single molecule fluorescence *in situ* hybridization in the adult mouse hypothalamus. Further phenotyping of Shh mRNA expressing cells in the hypothalamus revealed that almost 30% of neurons were positive for Shh transcripts in the dorsomedial hypothalamic nucleus (DMH), 40% in the Arcuate nucleus (ARC), and 70% in the ventromedial hypothalamic nucleus (VMH). We recently reported that the activation of Shh signaling in Glast^{+} astrocytes induced by Ptc deletion enhanced insulin responsiveness (Tirou et al, Mol Metab, 2021). We have further characterized Glast-Cre^{ERT2}-YFP-Ptc$^{-/-}$ (YFP-Ptc$^{-/-}$) mice and their controls (YFP-Ptc$^{+/+}$) to investigate the potential effects of conditional astrocytic deletion of Ptc on hypothalamic inflammation. Interestingly, we observed that the increase over time of Iba1^{+} microglial cells identified in the DMH, the ARC and the VMH, was not observed in YFP-Ptc$^{-/-}$ compared to controls. Furthermore, Iba1^{+} microglial cells displayed a reactive morphology 7 days post-tamoxifen in YFP-Ptc$^{-/-}$ compared to controls while inflammation related gene CD11b was downregulated 7 months post-tamoxifen in Ptc-deleted mice. Experiments are in progress to further characterize hypothalamic Shh action from neurons on glial cells during aging and obesity-related metabolic disorders.

ADAPTABILITY OF TUBEROINFUNDIBULAR DOPAMINE (TIDA) NEURON ELECTRICAL ACTIVITY IN FEMALE MICE: THE ROLE OF ESTRADIOL IN THE NEUROENDOCRINE CONTROL OF PROLACTIN.

POSTER SESSION 01 - SECTION: THERMOREGULATION, ENERGY HOMEOSTASIS AND HORMONES

Aim: Hypothalamic tuberoinfundibular dopamine neurons (TIDA) control prolactin secretion. Male mouse TIDA neurons exhibit asynchronous membrane potential oscillations associated with tonic low serum prolactin, but prolactin levels in females fluctuate along the oestrous cycle in an oestradiol-dependent manner. As sex-hormone sensitive tissues change daily over the oestrous cycle, we aimed to determine if direct oestradiol-mediated effects on TIDA membrane properties could explain this rapid adaptive control. Methods: Whole-cell patch-clamp recordings in acute hypothalamic slices from postpubertal female mice expressing tdTomato under control of the dopamine transporter promoter. Recordings were performed during a) natural sex hormone variations (oestrous cycle), b) chronic changes in hormone levels (ovariectomy) and c) local acute application of oestradiol and progesterone. Results: TIDA neurons in female mice exhibited either oscillatory or non-oscillatory firing patterns, which could not be interconverted by current injection or synaptic blockade. The oscillatory:non-oscillatory ratio was cycle phase-dependent, and significantly altered after ovariectomy. Oestradiol powerfully converted TIDA electrical state in a phenotype-dependent pattern, inducing hyperpolarization of non-oscillatory, and depolarization of oscillatory, TIDA cells. Both of these opposite effects – mediated by different membrane conductances - appeared, however, to both yield silencing of TIDA neurons, as the hormone-induced depolarization block of oscillatory cells. Application of progesterone did not affect the firing of TIDA neurons. Conclusions: The membrane properties of TIDA neurons may be subject to both acute and long-term regulation by gonadal steroids. This modulation may be involved in shaping the prolactin serum profile, by contributing to oestradiol-mediated stimulation of prolactin release.

Anterior pituitary gland synthesises dopamine from l-3,4-dihydroxyphenylalanine (l-dopa).
Prolactin (PRL) is a hormone principally secreted by lactotrophs of the anterior pituitary gland. Although the synthesis and exocytosis of this hormone are mainly under the regulation of hypothalamic dopamine (DA), the possibility that the anterior pituitary synthesises this catecholamine remains unclear. The present study aimed to determine if the anterior pituitary produces DA from the precursor l-3,4-dihydroxyphenylalanine (l-dopa). Accordingly, we investigated the expression of aromatic l-amino acid decarboxylase (AADC) enzyme and the transporter vesicular monoamine transporter 2 (VMAT2) in the anterior pituitary, AtT20 and GH3 cells by immunofluorescence and western blotting. Moreover, we investigated the production of DA from l-dopa and its release in vitro. Then, we explored the effects of l-dopa with respect to the secretion of PRL from anterior pituitary fragments. We observed that the anterior pituitary, AtT20 and GH3 cells express both AADC and VMAT2. Next, we detected an increase in DA content after anterior pituitary fragments were incubated with l-dopa. Also, the presence of l-dopa increased DA levels in incubation media and reduced PRL secretion. Likewise, the content of cellular DA increased after AtT20 cells were incubated with l-dopa. In addition, l-dopa reduced corticotrophin-releasing hormone-stimulated adrenocorticotrophic hormone release from these cells after AADC activity was inhibited by NSD-1015. Moreover, DA formation from l-dopa increased apoptosis and decreased proliferation. However, in the presence of NSD-1015, l-dopa decreased apoptosis and increased proliferation rates. These results suggest that the anterior pituitary synthesises DA from l-dopa by AADC and this catecholamine can be released from this gland contributing to the control of PRL secretion. In addition, our results suggest that l-dopa exerts direct actions independently from its metabolisation to DA.

Adaptive Resetting of Tuberoinfundibular Dopamine (TIDA) Network Activity during Lactation in Mice.
Giving birth triggers a wide repertoire of physiological and behavioral changes in the mother to enable her to feed and care for her offspring. These changes require coordination and are often orchestrated from the CNS, through as of yet poorly

understood mechanisms. A neuronal population with a central role in puerperal changes is the tuberoinfundibular dopamine (TIDA) neurons that control release of the pituitary hormone, prolactin, which triggers key maternal adaptations, including lactation and maternal care. Here, we used Ca imaging on mice from both sexes and whole-cell recordings on female mouse TIDA neurons to examine whether they adapt their cellular and network activity according to reproductive state. In the high-prolactin state of lactation, TIDA neurons shift to faster membrane potential oscillations, a reconfiguration that reverses upon weaning. During the estrous cycle, however, which includes a brief, but pronounced, prolactin peak, oscillation frequency remains stable. An increase in the hyperpolarization-activated mixed cation current, I, possibly through unmasking as dopamine release drops during nursing, may partially explain the reconfiguration of TIDA rhythms. These findings identify a reversible plasticity in hypothalamic network activity that can serve to adapt the dam for motherhood. Motherhood requires profound behavioral and physiological adaptations to enable caring for offspring, but the underlying CNS changes are poorly understood. Here, we show that, during lactation, neuroendocrine dopamine neurons, the "TIDA" cells that control prolactin secretion, reorganize their trademark oscillations to discharge in faster frequencies. Unlike previous studies, which typically have focused on structural and transcriptional changes during pregnancy and lactation, we demonstrate a functional switch in activity and one that, distinct from previously described puerperal modifications, reverses fully on weaning. We further provide evidence that a specific conductance (I) contributes to the altered network rhythm. These findings identify a new facet of maternal brain plasticity at the level of membrane properties and consequent ensemble activity.

mPRs represent a novel target for PRL inhibition in experimental prolactinomas.

Membrane progesterone receptors are known to mediate rapid nongenomic progesterone effects in different cell types. Recent evidence revealed that mPRα is highly expressed in the rat pituitary, being primarily localized in lactotrophs, acting as an intermediary of P4-inhibitory actions on prolactin secretion. The role of mPRs in prolactinoma development remains unclear. We hypothesize that mPR agonists represent a novel tool for hyperprolactinemia treatment. To this end, pituitary expression of mPRs was studied in three animal models of prolactinoma. Expression of mPRs and nuclear receptor was significantly decreased in tumoral pituitaries compared to normal ones. However, the relative proportion of mPRα and mPRβ was highly increased in prolactinomas. Interestingly, the selective mPR agonist (Org OD 02-0) significantly inhibited PRL release in both normal and tumoral pituitary explants, displaying a more pronounced effect in tumoral tissues. As P4 also regulates PRL secretion indirectly, by acting on dopaminergic neurons, we studied mPR involvement in this effect. We found that the hypothalamus has a high expression of mPRs. Interestingly, both P4 and OrgOD 02-0 increased dopamine release in hypothalamus explants. Moreover, in an in vivo treatment, that allows both, pituitary and hypothalamus actions, the mPR agonist strongly reduced the hyperprolactinemia in transgenic females carrying prolactinoma. Finally, we also found and interesting gender difference: males express higher levels of pituitary mPRα/β, a sex that does not develop prolactinoma in these mice models. Taken together, these findings suggest mPRs activation could represent a novel tool for hyperprolactinemic patients, especially those that present resistance to dopaminergic drugs.

Role of GPER in the anterior pituitary gland focusing on lactotroph function.

Ovarian steroids control a variety of physiological functions. They exert actions through classical nuclear steroid receptors, but rapid non-genomic actions through specific membrane steroid receptors have been also described. In this study, we demonstrate that the G-protein-coupled estrogen receptor (GPER) is expressed in the rat pituitary gland and, at a high level, in the lactotroph population. Our results revealed that ~40% of the anterior pituitary cells are GPER positive and ~35% of the lactotrophs are GPER positive. By immunocytochemical and immuno-electron-microscopy studies, we demonstrated that GPER is localized in the plasmatic membrane but is also associated to the endoplasmic reticulum in rat lactotrophs. Moreover, we found that local Gper expression is regulated negatively by 17β-estradiol (E2) and progesterone (P4) and fluctuates during the estrus cycle, being minimal in proestrus. Interestingly, lack of ovarian steroids after an ovariectomy (OVX) significantly increased pituitary GPER expression specifically in the three morphologically different subtypes of lactotrophs. We found a rapid estradiol stimulatory effect on PRL secretion mediated by GPER, both in vitro and ex vivo, using a GPER agonist G1, and this effect was prevented by the GPER antagonist G36, demonstrating a novel role for this receptor. Then, the increased pituitary GPER expression after OVX could lead to alterations in the pituitary function as all three lactotroph subtypes are target of GPER ligand and could be involved in the PRL secretion mediated by GPER. Therefore, it should be taken into consideration in the response of the gland to an eventual hormone replacement therapy.

JAK2/STAT5 Pathway Mediates Prolactin-Induced Apoptosis of Lactotropes.

Prolactinomas are increasingly viewed as a "problem of signal transduction." Consequently, the identification of factors and signaling pathways that control lactotrope cell turnover is needed in order to encourage new therapeutic developments. We have previously shown that prolactin (PRL) acts as a proapoptotic and antiproliferative factor on lactotropes, maintaining anterior pituitary cell homeostasis, which contrasts with the classical antiapoptotic and/or proliferative actions exerted by PRL in most other target tissues. We aimed to investigate the PRLR-triggered signaling pathways mediating these nonclassical effects of PRL in the pituitary. Our results suggest that (i) the PRLR/Jak2/STAT5 pathway is constitutively active in GH3 cells and contributes to PRL-induced apoptosis by increasing the Bax/Bcl-2 ratio, (ii) PRL inhibits ERK1/2 and Akt phosphorylation, thereby contributing to its proapoptotic effect, and (iii) the PI3K/Akt pathway participates in the PRL-mediated control of lactotrope proliferation. We hypothesize that the alteration of PRL actions in lactotrope homeostasis due to the dysregulation of any of the mechanisms of actions described above may contribute to the pathogenesis of prolactinomas.

Participation of membrane progesterone receptor α in the inhibitory effect of progesterone on prolactin secretion.
The membrane progesterone receptors (mPRα, mPRβ, mPRγ, mPRδ and mPRε) are known to mediate rapid nongenomic progesterone functions in different cell types. However, the functions of these receptors in the pituitary have not been reported to date. In the present study, we show that the expression of mPRα was the highest among the mPRs in the rat anterior pituitary gland. Immunostaining of mPRα was detected in somatotrophs, gonadotrophs and lactotrophs. Interestingly, 63% of mPRα-positive cells within the pituitary were lactotrophs, suggesting that mPRα is involved in controlling prolactin (PRL) secretion in the pituitary. To test this hypothesis, rat pituitaries were incubated (1 hour) with either progesterone (P4) or the mPRα-specific agonist Org OD 02-0. PRL secretion was then measured by radioimmunoassay. The results of this experiment revealed that both P4 and Org OD 02-0 decreased PRL secretion. Moreover, the results from the GH3 cell line (CCL-82.1) showed that P4 and Org OD 02-0 inhibited PRL release, although the nuclear PR agonist R5020 was ineffective. Our investigation of the cellular mechanisms behind mPRα activity indicated that both P4 and Org OD 02-0 decreased cAMP accumulation, whereas R5020 was ineffective. In addition, the Org OD 02-0-effect on PRL release was blocked by pretreatment with pertussis toxin, an inhibitor of Go/Gi proteins. Because transforming growth factor (TGF)β1 is a potent inhibitor of PRL secretion in lactotrophs, we lastly evaluated whether TGFβ1 was activated by progesterone and whether this effect was mediated by mPRα. Our results showed that P4 and Org OD 02-0, but not R5020, increased active TGFβ1 levels. This effect was not observed when cells were transfected with mPRα-small interfering RNA. Taken together, these data provide new evidence suggesting that mPRα mediates the progesterone inhibitory effect on PRL secretion through both decreases in cAMP levels and activation of TGFβ1 in the lactotroph population.

Prolactin induces apoptosis of lactotropes in female rodents.
Anterior pituitary cell turnover occurring during female sexual cycle is a poorly understood process that involves complex regulation of cell proliferation and apoptosis by multiple hormones. In rats, the prolactin (PRL) surge that occurs at proestrus coincides with the highest apoptotic rate. Since anterior pituitary cells express the prolactin receptor (PRLR), we aimed to address the actual role of PRL in the regulation of pituitary cell turnover in cycling females. We showed that acute hyperprolactinemia induced in ovariectomized rats using PRL injection or dopamine antagonist treatment rapidly increased apoptosis and decreased proliferation specifically of PRL producing cells (lactotropes), suggesting a direct regulation of these cell responses by PRL. To demonstrate that apoptosis naturally occurring at proestrus was regulated by transient elevation of endogenous PRL levels, we used PRLR-deficient female mice (PRLRKO) in which PRL signaling is totally abolished. According to our hypothesis, no increase in lactotrope apoptotic rate was observed at proestrus, which likely contributes to pituitary tumorigenesis observed in these animals. To decipher the molecular mechanisms underlying PRL effects, we explored the isoform-specific pattern of PRLR expression in cycling wild type females. This analysis revealed dramatic changes of long versus short PRLR ratio during the estrous cycle, which is particularly relevant since these isoforms exhibit distinct signaling properties. This pattern was markedly altered in a model of chronic PRLR signaling blockade involving transgenic mice expressing a pure PRLR antagonist (TGΔ1-9-G129R-hPRL), providing evidence that PRL regulates the expression of its own receptor in an isoform-specific manner. Taken together, these results demonstrate that i) the PRL surge occurring during proestrus is a major proapoptotic signal for lactotropes, and ii) partial or total deficiencies in PRLR signaling in the anterior pituitary may result in pituitary hyperplasia and eventual prolactinoma development, as observed in TGΔ1-9-G129R-hPRL and PRLRKO mice, respectively.

Use of prolactin receptor antagonist to better understand prolactin regulation of pituitary homeostasis.

The anterior pituitary is permanently regulated by processes of apoptosis and proliferation in order to maintain tissue homeostasis. Several factors have been implicated in this regulation and lately, prolactin (PRL) has been included into that list. However, since PRL is secreted by anterior pituitary lactotropes, the actual outcome of its autocrine/paracrine actions on pituitary cells has remained difficult to assess. The availability of the pure PRL receptor antagonist Del1-9-G129R-hPRL has been helpful to circumvent this problem. While PRL has been traditionally associated with increased cell proliferation, recent studies revealed that this hormone actually induces apoptosis and decreases proliferation of anterior pituitary cells, by mechanisms involving the PRL receptor. The aim of this short review is to overview our current understanding of the regulation of pituitary homeostasis by PRL. Moreover, studies involving Del1-9-G129R-hPRL have helped anticipate to what extent future treatments involving PRL receptor inhibitors may interfere with processes regulated by PRL at the central level.

Prolactin receptor antagonism in mouse anterior pituitary: effects on cell turnover and prolactin receptor expression.
Since anterior pituitary expresses prolactin receptors, prolactin secreted by lactotropes could exert autocrine or paracrine actions on anterior pituitary cells. In fact, it has been observed that prolactin inhibits its own expression by lactotropes. Our hypothesis is that prolactin participates in the control of anterior pituitary cell turnover. In the present study, we explored the action of prolactin on proliferation and apoptosis of anterior pituitary cells and its effect on the expression of the prolactin receptor. To determine the activity of endogenous prolactin, we evaluated the effect of the competitive prolactin receptor antagonist Δ1-9-G129R-hPRL in vivo, using transgenic mice that constitutively and systemically express this antagonist. The weight of the pituitary gland and the anterior pituitary proliferation index, determined by BrdU incorporation, were higher in transgenic mice expressing the antagonist than in wild-type littermates. In addition, blockade of prolactin receptor in vitro by Δ1-9-G129R-hPRL increased proliferation and inhibited apoptosis of somatolactotrope GH3 cells and of primary cultures of male rat anterior pituitary cells, including lactotropes. These results suggest that prolactin acts as an autocrine/paracrine antiproliferative and proapoptotic factor in the anterior pituitary gland. In addition, anterior pituitary expression of the long isoform of the prolactin receptor, measured by real-time PCR, increased about 10-fold in transgenic mice expressing the prolactin receptor antagonist, whereas only a modest increase in the S3 short-isoform expression was observed. These results suggest that endogenous prolactin may regulate its own biological actions in the anterior pituitary by inhibiting the expression of the long isoform of the prolactin receptor. In conclusion, our observations suggest that prolactin is involved in the maintenance of physiological cell renewal in the anterior pituitary. Alterations in this physiological role of prolactin could contribute to pituitary tumor development.

N-terminal prolactin-derived fragments, vasoinhibins, are proapoptoptic and antiproliferative in the anterior pituitary.
The anterior pituitary is under a constant cell turnover modulated by gonadal steroids. In the rat, an increase in the rate of apoptosis occurs at proestrus whereas a peak of proliferation takes place at estrus. At proestrus, concomitant with the maximum rate of apoptosis, a peak in circulating levels of prolactin is observed. Prolactin can be cleaved to different N-terminal fragments, vasoinhibins, which are proapoptotic and antiproliferative factors for endothelial cells. It was reported that a 16 kDa vasoinhibin is produced in the rat anterior pituitary by cathepsin D. In the present study we investigated the anterior pituitary production of N-terminal prolactin-derived fragments along the estrous cycle and the involvement of estrogens in this process. In addition, we studied the effects of a recombinant vasoinhibin, 16 kDa prolactin, on anterior pituitary apoptosis and proliferation. We observed by Western Blot that N-terminal prolactin-derived fragments production in the anterior pituitary was higher at proestrus with respect to diestrus and that the content and release of these prolactin forms from anterior pituitary cells in culture were increased by estradiol. A recombinant preparation of 16 kDa prolactin induced apoptosis (determined by TUNEL assay and flow cytometry) of cultured anterior pituitary cells and lactotropes from ovariectomized rats only in the presence of estradiol, as previously reported for other proapoptotic factors in the anterior pituitary. In addition, 16 kDa prolactin decreased forskolin-induced proliferation (evaluated by BrdU incorporation) of rat total anterior pituitary cells and lactotropes in culture and decreased the proportion of cells in S-phase of the cell cycle (determined by flow cytometry). In conclusion, our study indicates that the anterior pituitary production of 16 kDa prolactin is variable along the estrous cycle and increased by estrogens. The antiproliferative and estradiol-dependent proapoptotic actions of this vasoinhibin may be involved in the control of anterior pituitary cell renewal.

RNA-SEQUENCING REVEALS TREATMENT AND SEX DIFFERENCES IN THE BRAINS OF LETROZOLE-TREATED COMMON MARMOSETS (C. JACCHUS)

POSTER SESSION 01 - SECTION: THERMOREGULATION, ENERGY HOMEOSTASIS AND HORMONES

Melise Edwards[1], Sam Lam[2], Ravi Ranjan[3], Mariana Pereira[1], Courtney Babbitt[2], Agnes Lacreuse[1]
[1]University of Massachusetts Amherst, Psychological And Brain Sciences, Amherst, United States of America, [2]University of Massachusetts Amherst, Biology Department, Amherst, United States of America, [3]University of Massachusetts Amherst, Genome Resource Laboratory, Amherst, United States of America

Aromatase inhibitors (AIs) are drugs commonly given to patients with estrogen receptor (ER)-dependent breast cancers to reduce estrogenic stimulation. However, AIs like Letrozole are associated with negative side effects such as cognitive deficits, sleep disturbances and hot flashes. We have previously shown that these negative effects can be recapitulated in common marmosets (*Callithrix jacchus*) treated with Letrozole (20 µg daily) for 4 weeks and that Letrozole-treated marmosets show increased levels of estradiol in the hippocampus (Gervais et al., 2019). In order to better understand the mechanisms through which AIs affect cognitive function and increase steroid levels in the hippocampus, we used bulk, paired-end RNA-sequencing to examine gene expression differences between Letrozole-treated (LET; n=8) and vehicle-treated (VEH; n=8) male and female animals. Gene ontology results show significant reduction in LET animals across hundreds of categories ($P < 0.05$), some of the most significant being inflammatory response, stress response, MHC Class II protein complex binding, T-cell activation, carbohydrate binding and signaling receptor binding ($P < 5.0E-5$). GSEA results indicate only LET females show enrichment for hormonal gene sets (FDR = 0.1), an effect not observed in LET males (FDR = 0.67). Based on the transcriptional changes observed, we conclude that AIs may differentially affect the sexes in part due to processes mediated by the CYP-450 superfamily. Ongoing studies will further investigate the longitudinal effects of AIs on behavior and whether AIs increase the risk of stress-induced neurodegeneration.

The marmoset as an important primate model for longitudinal studies of neurocognitive aging.
Age-related cognitive decline has been extensively studied in humans, but the majority of research designs are cross-sectional and compare across younger and older adults. Longitudinal studies are necessary to capture variability in cognitive aging trajectories but are difficult to carry out in humans and long-lived nonhuman primates. Marmosets are an ideal primate model for neurocognitive aging as their naturally short lifespan facilitates longitudinal designs. In a longitudinal study of marmosets tested on reversal learning starting in middle-age, we found that, on average, the group of marmosets declined in cognitive performance around 8 years of age. However, we found highly variable patterns of cognitive aging trajectories across individuals. Preliminary analyses of brain tissues from this cohort also show highly variable degrees of neuropathology. Future work will tie together behavioral trajectories with brain pathology and provide a window into the factors that predict age-related cognitive decline.

Hindbrain Administration of Oxytocin Reduces Food Intake, Weight Gain and Activates Catecholamine Neurons in the Hindbrain Nucleus of the Solitary Tract in Rats.
Existing studies show that CNS oxytocin (OT) signaling is important in the control of energy balance, but it is unclear which neurons may contribute to these effects. Our goals were to examine (1) the dose-response effects of acute OT administration into the third (3V; forebrain) and fourth (4V; hindbrain) ventricles to assess sensitivity to OT in forebrain and hindbrain sites, (2) the extent to which chronic 4V administration of OT reduces weight gain associated with the progression of diet-induced obesity, and (3) whether nucleus tractus solitarius (NTS) catecholamine neurons are downstream targets of 4V OT. Initially, we examined the dose-response effects of 3V and 4V OT (0.04, 0.2, 1, or 5 µg). 3V and 4V OT (5 µg) suppressed 0.5-h food intake by 71.7 ± 6.0% and 60 ± 12.9%, respectively. 4V OT (0.04, 0.2, 1 µg) reduced food intake by 30.9 ± 12.9, 42.1 ± 9.4, and 56.4 ± 9.0%, respectively, whereas 3V administration of OT (1 µg) was only effective at reducing 0.5-h food intake by

38.3 ± 10.9%. We subsequently found that chronic 4V OT infusion, as with chronic 3V infusion, reduced body weight gain (specific to fat mass) and tended to reduce plasma leptin in high-fat diet (HFD)-fed rats, in part, through a reduction in energy intake. Lastly, we determined that 4V OT increased the number of hindbrain caudal NTS Fos (+) neurons (156 ± 25) relative to vehicle (12 ± 3). The 4V OT also induced Fos in tyrosine hydroxylase (TH; marker of catecholamine neurons) (+) neurons (25 ± 7%) relative to vehicle (0.8 ± 0.3%). Collectively, these findings support the hypothesis that OT within the hindbrain is effective at reducing food intake, weight gain, and adiposity and that NTS catecholamine neurons in addition to non-catecholaminergic neurons are downstream targets of CNS OT.

Effects of Combined Oxytocin and Beta-3 Receptor Agonist (CL 316243) Treatment on Body Weight and Adiposity in Male Diet-Induced Obese Rats.
Previous studies have indicated that oxytocin (OT) reduces body weight in diet-induced obese (DIO) rodents through reductions in energy intake and increases in energy expenditure. We recently demonstrated that hindbrain [fourth ventricular (4V)] administration of OT evokes weight loss and elevates interscapular brown adipose tissue temperature (T) in DIO rats. What remains unclear is whether OT can be used as an adjunct with other drugs that directly target beta-3 receptors in IBAT to promote BAT thermogenesis and reduce body weight in DIO rats. We hypothesized that the combined treatment of OT and the beta-3 agonist, CL 316243, would produce an additive effect to decrease body weight and adiposity in DIO rats by reducing energy intake and increasing BAT thermogenesis. We assessed the effects of 4V infusions of OT (16 nmol/day) or vehicle (VEH) in combination with daily intraperitoneal injections of CL 316243 (0.5 mg/kg) or VEH on food intake, T , body weight and body composition. OT and CL 316243 alone reduced body weight by 7.8 ± 1.3% (< 0.05) and 9.1 ± 2.1% (< 0.05), respectively, but the combined treatment produced more pronounced weight loss (15.5 ± 1.2%; < 0.05) than either treatment alone. These effects were associated with decreased adiposity, adipocyte size, energy intake and increased uncoupling protein 1 (UCP-1) content in epididymal white adipose tissue (EWAT) (< 0.05). In addition, CL 316243 alone (< 0.05) and in combination with OT (< 0.05) elevated T and IBAT UCP-1 content and IBAT thermogenic gene expression. These findings are consistent with the hypothesis that the combined treatment of OT and the beta-3 agonist, CL 316243, produces an additive effect to decrease body weight. The findings from the current study suggest that the effects of the combined treatment on energy intake, fat mass, adipocyte size and browning of EWAT were not additive and appear to be driven, in part, by transient changes in energy intake in response to OT or CL 316243 alone as well as CL 316243-elicited reduction of fat mass and adipocyte size and induction of browning of EWAT.

Chronic hindbrain administration of oxytocin elicits weight loss in male diet-induced obese mice.
Previous studies indicate that oxytocin (OT) administration reduces body weight in high-fat diet (HFD)-induced obese (DIO) rodents through both reductions in food intake and increases in energy expenditure. We recently demonstrated that chronic hindbrain [fourth ventricular (4V)] infusions of OT evoke weight loss in DIO rats. Based on these findings, we hypothesized that chronic 4V OT would elicit weight loss in DIO mice. We assessed the effects of 4V infusions of OT (16 nmol/day) or vehicle over 28 days on body weight, food intake, and body composition. OT reduced body weight by approximately 4.5% ± 1.4% in DIO mice relative to OT pretreatment body weight (< 0.05). These effects were associated with reduced adiposity and adipocyte size [inguinal white adipose tissue (IWAT)] (< 0.05) and attributed, in part, to reduced energy intake (< 0.05) at a dose that did not increase kaolin intake (= NS). OT tended to increase uncoupling protein-1 expression in IWAT (0.05 < < 0.1) suggesting that OT stimulates browning of WAT. To assess OT-elicited changes in brown adipose tissue (BAT) thermogenesis, we examined the effects of 4V OT on interscapular BAT temperature (). 4V OT (1 µg) elevated at 0.75 (= 0.08), 1, and 1.25 h (< 0.05) postinjection; a higher dose (5 µg) elevated at 0.75-, 1-, 1.25-, 1.5-, 1.75- (< 0.05), and 2-h (0.05 < < 0.1) postinjection. Together, these findings support the hypothesis that chronic hindbrain OT treatment evokes sustained weight loss in DIO mice by reducing energy intake and increasing BAT thermogenesis at a dose that is not associated with evidence of visceral illness.

A large-scale standardized physiological survey reveals functional organization of the mouse visual cortex.

To understand how the brain processes sensory information to guide behavior, we must know how stimulus representations are transformed throughout the visual cortex. Here we report an open, large-scale physiological survey of activity in the awake mouse visual cortex: the Allen Brain Observatory Visual Coding dataset. This publicly available dataset includes the cortical activity of nearly 60,000 neurons from six visual areas, four layers, and 12 transgenic mouse lines in a total of 243 adult mice, in response to a systematic set of visual stimuli. We classify neurons on the basis of joint reliabilities to multiple stimuli and validate this functional classification with models of visual responses. While most classes are characterized by responses to specific subsets of the stimuli, the largest class is not reliably responsive to any of the stimuli and becomes progressively larger in higher visual areas. These classes reveal a functional organization wherein putative dorsal areas show specialization for visual motion signals.

Background and aims How sex chromosomes and steroids interact to shape the sexually dimorphic brain during development has, to date, only been studied in a few brain areas. We have shown that high-field MRI can map the development of sex dimorphisms across the entire mouse brain (*Qiu et al., 2018*). We have also investigated sex differences in adult brain structure with MRI using the Four Core Genotype (FCG) model, separating out the effects of base XX vs XY chromosomes from gonadal factors (*Corre et al., 2016*). Here we propose to establish the impact of gonadal hormones and sex chromosome dosage on brain development from early postnatal days (P) using anatomical imaging. To this end we will image the Sex Chromosome Trisomy (SCT) mouse model, which allows for the investigation of the effects of sex chromosome dosage, comparing gonadal male and female mice with different combinations of sex chromosomes (XX, XY, XXY, XYY). **Methods** The 8 genotypes of the SCT mice (n=10 mice/genotype) will be imaged in 7 developmental timepoints (P4, P7, P10, P17, P23, P33 and P65) with high-resolution MRI at 7T (MGE, 6 echoes, 60μm isotropic). To optimise contrast, Mn^{2+}will be administered to pups 24h prior imaging. **Results/Conclusions** To date, a scanning protocol has been successfully optimised, while the experimental setup for neonatal studies has been established. By the end of the study and following the longitudinal MRI analysis, structural changes in the basis of the age, gonadal sex and sex chromosome dosage will be
established.

Prolactin (PRL) secretion is involved in the regulation of numerous functions depending on the target it reaches. A number of physiological functions involve feedback of the hormone in the brain. We investigate the impact of PRL on the best-known central target of PRL, the arcuate nucleus. This hypothalamic nucleus contains several populations of PRL-sensitive neurons and in particular the dopaminergic neurons of the arcuate nucleus (TIDA) that are the major regulator of PRL secretion via inhibition of its release by lactotroph cells of the pituitary. By in vivo imaging, we showed that both TIDA cells display sexually dimorphic spontaneous and PRL-induced activities, with a robust spontaneous activity in males, significantly reduced in females. This sexual dimorphism is absent in acute slices. To investigate the sensitivity of TIDA to PRL, PRL was bath applied on slices. It induced reorganization of calcium activity with the recruitment of coactive cells displaying persisting rhythmic oscillations both in males and females. Single PRL i.p injections, in vivo, induced a similar reorganization of the functional network in males and a temporary increase in activity of female TIDA neurons. Long-term modifications of the levels of circulating PRL by pharmacology in vivo, suggest that the in vivo sexual dimorphism of PRL concentration in the blood orchestrates the TIDA network properties. Altogether our results show that TIDA neurons behave as a PRL sensitive network and that the origin of the sexual dimorphism of PRL secretion is probably not encoded by TIDA neurons of the arcuate themselves.

TWO ENDOPHENOTYPES OF ANOREXIA NERVOSA BASED ON CLINICAL FACTORS RELATED TO PHYSICAL ACTIVITY AND LEPTIN LEVELS.

POSTER SESSION 01 - SECTION: THERMOREGULATION, ENERGY HOMEOSTASIS AND HORMONES

Anna Yamamotova[1], Josef Bulant[2], Hana Papezova[2]
[1]Charles University, Third Faculty of Mediciner, Department Of Physiology, Prague, Czech Republic, [2]Charles University, First Faculty of Medicine, Department Of Psychiatry, Prague, Czech Republic

A frequent symptom of patients with anorexia nervosa (AN) is increased physical activity and excessive exercises. In recent years, this phenomenon has been investigated in rats in Activity Based Anorexia model. In this study we have focused on the relationship between activity, leptin, ghrelin, hunger and anxiety. In 30 patients with AN (age 23, BMI = 14.93 $kg.m^{-2}$), we measured the physical activity using Actiwatch Score, which the patients wore for non-dominant hand for three days. The patient's subjective intensity of hunger and anxiety was recorded in the watch at 2-hour intervals from 8 am to 8 pm. In the whole group, only leptin correlated with physical activity ($r = 0.52$, $p = 0.003$), but this relationship was rather parabolic, suggesting a negative correlation in patients with lower activity (LA) and positive correlation in patients with higher activity (HA). After dividing the group according to the median of physical activity, it has been shown that in the LA group the amount of activity correlated negatively with hunger and positively with anxiety. In the HA group, the amount of activity correlated with BMI. Activity in LA patients may be more biologically determined for reduction of emotion-driven anxiety contrary to the HA patients, whose positive association between activity and leptin and BMI may be more under cognitive control with the intention of deliberately limiting weight gain within the therapeutic program. OXYTOCIN AND LACTATIONALLY-TRIGGERED EMBRYONIC DIAPAUSE IN MICE

POSTER SESSION 01 - SECTION: THERMOREGULATION, ENERGY HOMEOSTASIS AND HORMONES

Jessica Minder[1,2,3,4], Moses Chao[2,3,4], Robert Froemke[2,3,4]
[1]NYU School of Medicine, Vilcek Institute, New York, United States of America, [2]Neuroscience Institute, Neuroscience And Physiology, New York, United States of America, [3]New York University, Center For Neural Science, New York, United States of America, [4]NYU School of Medicine, Skirball Institute, New York, United States of America

Embryonic diapause is a state in which the development of the pre-implantation embryo is paused under conditions of maternal duress, such as while nursing a previous litter. Embryonic development is halted at the blastocyst stage and implantation into the uterine endometrium is temporarily prevented, as the required estrogen surge for uterine receptivity is blocked due to an unknown mechanism. Development resumes as normal upon a return to maternal homeostasis (Renfree and Shaw, 2000). We aim to examine whether oxytocin initiates lactationally-triggered facultative diapause in mice. To model low estrogen levels and to test how this loss affects oxytocin neurons, we treated the hypothalamic cell line GT1-7 with the estrogen receptor antagonist 4-hydroxytamoxifen and saw that oxytocin mRNA levels were increased relative to saline treatment. This suggests that maternal oxytocin levels are raised in the diapause state, and that this maternally-sourced oxytocin may function as a direct cue for the embryo to halt its development. We have documented oxytocin receptor expression in mouse blastocysts using reporter mice and tested the effect of oxytocin directly on mouse blastocysts ex vivo. We found that embryo implantation in the presence of oxytocin is delayed in comparison to saline using an in vitro model of implantation (Bedzhov et al., 2014). Our findings suggest that if pregnancy occurs coincident with nursing, maternal oxytocin levels rise and may initiate the pausing of embryonic development. Understanding the role that the hypothalamic pituitary axis plays in altering the timing of embryo implantation has major implications for reproductive medicine.

Oxytocin neurons enable social transmission of maternal behaviour.
Maternal care, including by non-biological parents, is important for offspring survival. Oxytocin, which is released by the hypothalamic paraventricular nucleus (PVN), is a critical maternal hormone. In mice, oxytocin enables neuroplasticity in the auditory cortex for maternal recognition of pup distress. However, it is unclear how initial parental experience promotes hypothalamic signalling and cortical plasticity for reliable maternal care. Here we continuously monitored the behaviour of female virgin mice co-housed with an experienced mother and litter. This documentary approach was synchronized with neural recordings from the virgin PVN, including oxytocin neurons. These cells were activated as virgins were enlisted in maternal care by experienced mothers, who shepherded virgins into the nest and demonstrated pup retrieval. Virgins visually observed maternal retrieval, which activated PVN oxytocin neurons and promoted alloparenting. Thus rodents can acquire maternal behaviour by social transmission, providing a mechanism for adapting the brains of adult caregivers to infant needs via endogenous oxytocin.

HIT-COVID, a global database tracking public health interventions to COVID-19.
The COVID-19 pandemic has sparked unprecedented public health and social measures (PHSM) by national and local governments, including border restrictions, school closures, mandatory facemask use and stay at home orders. Quantifying the effectiveness of these interventions in reducing disease transmission is key to rational policy making in response to the current and future pandemics. In order to estimate the effectiveness of these interventions, detailed descriptions of their timelines, scale and scope are needed. The Health Intervention Tracking for COVID-19 (HIT-COVID) is a curated and standardized global database that catalogues the implementation and relaxation of COVID-19 related PHSM. With a team of over 200 volunteer contributors, we assembled policy timelines for a range of key PHSM aimed at reducing COVID-19 risk for the national and first administrative levels (e.g. provinces and states) globally, including details such as the degree of

implementation and targeted populations. We continue to maintain and adapt this database to the changing COVID-19 landscape so it can serve as a resource for researchers and policymakers alike.

Oxytocin Modulation of Neural Circuits.
Oxytocin is a hypothalamic neuropeptide first recognized as a regulator of parturition and lactation which has recently gained attention for its ability to modulate social behaviors. In this chapter, we review several aspects of the oxytocinergic system, focusing on evidence for release of oxytocin and its receptor distribution in the cortex as the foundation for important networks that control social behavior. We examine the developmental timeline of the cortical oxytocin system as demonstrated by RNA, autoradiographic binding, and protein immunohistochemical studies, and describe how that might shape brain development and behavior. Many recent studies have implicated oxytocin in cognitive processes such as processing of sensory stimuli, social recognition, social memory, and fear. We review these studies and discuss the function of oxytocin in the young and adult cortex as a neuromodulator of central synaptic transmission and mediator of plasticity.

Sensitivity and engineered resistance of myeloid leukemia cells to BRD9 inhibition.
Here we show that acute myeloid leukemia (AML) cells require the BRD9 subunit of the SWI-SNF chromatin-remodeling complex to sustain MYC transcription, rapid cell proliferation and a block in differentiation. Based on these observations, we derived small-molecule inhibitors of the BRD9 bromodomain that selectively suppress the proliferation of mouse and human AML cell lines. To establish these effects as on-target, we engineered a bromodomain-swap allele of BRD9 that retains functionality despite a radically altered bromodomain pocket. Expression of this allele in AML cells confers resistance to the antiproliferative effects of our compound series, thus establishing BRD9 as the relevant cellular target. Furthermore, we used an analogous domain-swap strategy to generate an inhibitor-resistant allele of EZH2. To our knowledge, our study provides the first evidence for a role of BRD9 in cancer and reveals a simple genetic strategy for constructing resistance alleles to demonstrate on-target activity of chemical probes in cells.

Role of SWI/SNF in acute leukemia maintenance and enhancer-mediated Myc regulation.
Cancer cells frequently depend on chromatin regulatory activities to maintain a malignant phenotype. Here, we show that leukemia cells require the mammalian SWI/SNF chromatin remodeling complex for their survival and aberrant self-renewal potential. While Brg1, an ATPase subunit of SWI/SNF, is known to suppress tumor formation in several cell types, we found that leukemia cells instead rely on Brg1 to support their oncogenic transcriptional program, which includes Myc as one of its key targets. To account for this context-specific function, we identify a cluster of lineage-specific enhancers located 1.7 Mb downstream from Myc that are occupied by SWI/SNF as well as the BET protein Brd4. Brg1 is required at these distal elements to maintain transcription factor occupancy and for long-range chromatin looping interactions with the Myc promoter. Notably, these distal Myc enhancers coincide with a region that is focally amplified in ~3% of acute myeloid leukemias. Together, these findings define a leukemia maintenance function for SWI/SNF that is linked to enhancer-mediated gene regulation, providing general insights into how cancer cells exploit transcriptional coactivators to maintain oncogenic gene expression programs.

Sex-Specific Differences in Oxytocin Receptor Expression and Function for Parental Behavior.
Parental care is among the most profound behavior expressed by humans and other animals. Despite intense interest in understanding the biological basis of parental behaviors, it remains unknown how much of parenting is encoded by the genome and which abilities instead are learned or can be refined by experience. One critical factor at the intersection between innate behaviors and experience-dependent learning is oxytocin, a neurohormone important for maternal physiology and neuroplasticity. Oxytocin acts throughout the body and brain to promote prosocial and maternal behaviors and modulates synaptic transmission to affect neural circuit dynamics. Recently we developed specific antibodies to mouse oxytocin receptors, found that oxytocin receptors are left lateralized in female auditory cortex, and examined how oxytocin enables maternal behavior by sensitizing the cortex to infant distress sounds. In this study we compare oxytocin receptor expression and function in male and female mice. Receptor expression is higher in adult female left auditory cortex than in right auditory

cortex or males. Developmental profiles and mRNA expression were comparable between males and females. Behaviorally, male and female mice began expressing parental behavior similarly after cohousing with experienced females; however, oxytocin enhanced parental behavior onset in females but not males. This suggests that left lateralization of oxytocin receptor expression in females provides a mechanism for accelerating maternal behavior onset, although male mice can also effectively co-parent after experience with infants. The sex-specific pattern of oxytocin receptor expression might genetically predispose female cortex to respond to infant cues, which both males and females can also rapidly learn.

MPGES-1 DEFICIENT RATS LACK LPS-INDUCIBLE SUPPRESSION OF PULSATILE SECRETION OF LUTEINIZING HORMONE

POSTER SESSION 01 - SECTION: THERMOREGULATION, ENERGY HOMEOSTASIS AND HORMONES

Takashi Matsuwaki, Keitaro Yamanouchi
The University of Tokyo, Department Of Veterinary Physiology, Tokyo, Japan

The function of the mammalian reproductive system is controlled by hypothalamus-pituitary-gonadal (HPG) axis, which is suppressed under infectious stress conditions. We have previously demonstrated the possible role of prostaglandin E_2 (PGE_2) in the CNS to mediate the suppressive effect of immune signals. On the other hand, PGE_2 is known to enhance the activity of the HPG axis, inducing the secretion of gonadotropin-releasing hormone (GnRH) from the hypothalamus and luteinizing hormone (LH) from the pituitary, when injected intracerebroventricularly. Accordingly, we have established a line of knockout (KO) rats lacking the inducible PGE_2 synthase, microsomal prostaglandin E synthase-1 (mPGES-1) for further investigation of the role of endogenous PGE_2 in the maintenance of the reproductive function. As an infectious stressor, lipopolysaccharide (LPS, 0.1 mg/kg) was injected into the animals. Three hours after LPS injection, PGE_2 concentration in the CSF has significantly increased in the wild-type (WT) rats but not in the KO rats. Subsequently, a blood sample was withdrawn every 5 minutes through the indwelling jugular cannula for 3 hours and LPS was administered 1 hour after starting sampling through the cannula. In the WT rats, LPS strongly suppressed the pulsatile secretion of LH, which is correspondent with the previous studies. In contrast, LPS did not affect the LH pulsatility of the KO rats. Those results suggest that PGE_2 is the key mediator of infectious stress to suppress reproductive function.

TRH NEURONS IN ENERGY HOMEOSTASIS AND REGULATION OF BROWN ADIPOSE TISSUE

POSTER SESSION 01 - SECTION: THERMOREGULATION, ENERGY HOMEOSTASIS AND HORMONES

Andreea Constantinescu
University of Lübeck, Institute Of Experimental And Clinical Pharmacology And Toxicology, Lübeck, Germany

Neurons containing thyrotropin releasing hormone (TRH) in the paraventricular hypothalamus (PVN) are a key component of the hypothalamic-pituitary-thyroid (HPT) axis and have been well characterized along with their projections to the median eminence (ME). Despite the existence of TRH neuron populations throughout the brain, these remain little described. We focus on the effect of TRH neurons in the dorsomedial hypothalamus (DMH) and medial preoptic area (MPA) on brown adipose tissue (BAT) thermogenesis, food intake, and energy expenditure, by using a strategy involving transgenic mice and AAV-based chemogenetic tools in combination with calorimetric measurements.
Stimulation of TRH neurons in the PVN, DMH, and MPA increased energy expenditure, respiratory exchange rate and feeding behavior. However, only stimulation of TRH neurons in the PVN led to increased T3 and T4 levels along with BAT activation, while DMH stimulation failed to increase T4 levels and MPA stimulation showed no effect on these parameters. BAT activation depended on beta-adrenergic signaling as shown by administering a β_3 adrenergic receptor (β_3-AR) blocker. We show functional differences of TRH neurons in the PVN, DMH and MPA regarding the stimulation of BAT thermogenesis, in a β_3-AR-dependent manner. We confirm that TRH signaling plays a pivotal role in the regulation of food intake and subsequent energy expenditure. Furthermore, our findings show that these effects are separable from the action of TRH on the HPT axis through projections to the median eminence.

HYPOTHALAMIC PACEMAKING MECHANISM THAT DRIVES ACCLIMATION-INDUCED HEAT RESILIENCE.

POSTER SESSION 01 - SECTION: THERMOREGULATION, ENERGY HOMEOSTASIS AND HORMONES

Wojciech Ambroziak, Sara Nencini, Joerg Pohle, Kristina Zuza, Jan Siemens
University of Heidelberg, Pharmacology, Heidelberg, Germany

Thermal acclimation is an important adaptive process allowing homeothermic organisms to adapt to long-lasting changes in ambient temperature. Due to increasing environmental temperatures world-wide, heat acclimation is an especially interesting aspect of such adaptation. While the biology of heat acclimation is not well understood, the present study aims to elucidate central neuronal components of adaptation to heat in a mouse model. We have recently identified a discreet population of hypothalamic preoptic area (POA) neurons, marked by the expression of the Leptin receptor, that fundamentally change their electrophysiological profile over the course of heat acclimation to eventually become intrinsically-driven “pacemaker”-like neurons. We found this phenotype shift to be vital for mice to become heat-resilient and therefore we refer to this neuronal population as acclimation-activated neurons (AANs). POA is known to contain the so-called warm-responsive neurons (WRNs) that express the immediate-early gene Fos upon acute warm stimuli. While we hypothesized that AANs could to a large extent comprise of WRNs, our results suggest that AAN and WRN populations do not overlap significantly, and AANs likely do not receive extensive direct synaptic input from the spinoparabrachial tract. We then used electrophysiology to disentangle the ionic mechanism behind the intrinsic tonic firing in AANs; we found that a combination of sodium “leak”-driven depolarization bias and enhanced subthreshold NaV currents largely passed by the NaV1.3 ion channel drive the pacemaker-like cellular phenotype. In conclusion, we identified a functionally novel neuronal population that plastically changes its electrophysiological properties upon long-lasting heat exposure to promote heat resilience**.**

ROLE OF TRPM8 IN THERMOREGULATION AND THERMOGENESIS IN NAKED MOLE-RAT

POSTER SESSION 01 - SECTION: THERMOREGULATION, ENERGY HOMEOSTASIS AND HORMONES

Lin Wang, Valérie Bégay, Ole Eigenbrod, Gary R. Lewin
Max Delbrück Center for Molecular Medicine, Department Of Neuroscience, Berlin, Germany

The subterranean dwelling naked mole-rat (*Heterocephalus glaber*, NM-R) has received much attention for their extreme and unique physiology. One unique feature of amongst mammals is the fact that NM-Rs fail to maintain their body temperature when exposed to temperatures outside their thermoneutral zone, and are therefore defined as poikilotherms. In mammals, temperature-sensitive primary sensory neurons detect environmental temperature and transmit thermal information from the skin and peripheral organs to the central nervous system. The transient receptor potential melastatin 8 (TRPM8) ion channel is a major sensor of environmental cold temperatures in mammals. So far little is known about TRPM8 functions in NM-Rs. To clarify whether TRPM8 plays a role in thermoreception and thermoregulation in NM-Rs, we applied RNAscope, high-resolution fluorescence imaging and molecular biology approaches. As predicted by protein sequence alignment we found that NM-R TRPM8 cDNA has an extended N-terminal part, not found in other rodents or mammals. RNA sequencing and RNAscope data showed a broad expression pattern of TrpM8 mRNA in NM-Rs in particular in the grey matter of the spinal cord. In contrast, TrpM8 expression in mice is largely restricted to sensory ganglia. This preliminary data suggests that TRPM8 channel might play a different role in thermoreception and thermoregulation in NM-Rs compared to other rodents.

Energy expenditure, glucose homeostasis, and thermogenesis has been strongly associated with circadian clock gene expression in mammals. Astrocytes autonomously function as a central pacemaker regulating molecular and behavioral circadian rhythms. Remarkably, the effects of deletion of astrocytic BMAL1 on circadian locomotor activity, cognition, and its metabolic disturbances including body weight and glucose homeostasis were just reported in male mice. Here we show that selective ablation of BMAL1 from astrocytes induces sexual dimorphic alterations in circadian behavior, energy homeostasis, glucose tolerance, and thermogenesis in mice. Specifically, while male mutants displayed altered glucose homeostasis and increased body weight with age, female mice showed decreased body weight despite increased food intake and normal spontaneous locomotor activity. Moreover, female mutants had increased energy expenditure and brown adipose tissue thermogenesis. Remarkably, in a high-fat diet, this metabolic phenotype of the females was reverted and showed increased body weight and respiratory quotient, altered glucose homeostasis, and normal thermogenesis. In sum, our results indicate that the astrocyte clock is required to optimize energetic resources and thermogenesis in a sex- and diet-specific manner in mice.

Direct bioenergetic effects of cannabinoids (via CB1 receptor present on mitochondrial membranes) play a central role on brain mitochondrial activity and memory. The activation of intra-mitochondrial Gαi proteins by exogenous agonists of CB1 leads to a decrease of brain mitochondrial activity, which is responsible for cannabinoids-induced amnesia. However, the direct evidence on how the modulation of mitochondrial G-protein signaling can affect the mitochondrial bioenergetic and cognitive processes is still missing. To this aim, we generated and characterized a novel chemogenetic tool (MLS-DREADD-Gs) which allow us to manipulate mitochondrial Gs activity in vitro an in vivo. This tool was able to increase mitochondrial activity and counteract the inhibitory effects of CB1 activation on mitochondrial respiration. Thus, given the relevance of mitochondrial G-protein signaling and bioenergetic processes in behavioral cognitive aspects, we evaluated how in vivo MLS-DREADD-Gs activation can interfere with the effects of cannabinoids on memory consolidation. This study extends our knowledge on direct link between the impact of cannabinoids on brain mitochondrial signaling and some of their most important intracellular and behavioral effects, such as cellular respiration and amnesia respectively. In particular, it introduces an innovative pharmaco-genetic tool which can be used to manipulate intra-mitochondrial GPCRs signaling with relevant impacts on mitochondrial bioenergetics processes and relevant brain functions as memory.

Background: Physical activity enhances brain plasticity and improves cognition. A complex exercise-induced adaptive response is coordinated by network of molecules, including metabolites, which represent both energy substrates and signaling molecules. **The aim** of our study was to identify changes in metabolome before & after 90-minute run in plasma and cerebrospinal fluid (CSF), and to explore relationships between CSF & plasma metabolome and cognitive functions. **Methods:** Study population: 19 healthy young adults (M/F 13/6; median age 25(IQR 22-31)yrs, BMI 23.2(IQR 21.7-24.5)kg/m^2 &VO_2max 47(IQR 38.1-51.2)mL/kg/min). Sampling was performed before (CSF/plasma), immediately after (plasma) and 1-hour after (CSF/plasma) 90-minute run. Targeted broad-spectrum metabolomics was performed (HPLC-TMS). Cognitive functions were assessed by (MemTrax, Cogstate) before & after run. **Results:** In CSF, purines & pyrimidines changes represented 32% and neurotransmiter changes 14% of the metabolic impact. Around 25% of top regulated metabolites in CSF decreased and 75% increased after run. In plasma, metabolites of fatty acids accounted for 46%-60% of the metabolic impact immediately & 1-hour after run, respectively. There was a limited number of associations between metabolites in CSF and plasma, indicating a narrow window of communication between brain and periphery. Specific CSF metabolites were correlated to cognitive functions and their running-induced change. **Conclusions:** An acute bout of physical exercise distinctly regulated metabolite profile in cerebrospinal fluid. Running-induced changes of specific metabolites and cognitive functions were related, indirectly indicating the role of metabolites & neurotransmitters in the adaptive response to endurance exercise. MIRNA-186-5P – A NEW CULPRIT OF CHRONIC STRESS-INDUCED SYNAPTIC DYSFUNCTION

POSTER SESSION 01 - SECTION: THERMOREGULATION, ENERGY HOMEOSTASIS AND HORMONES

Beatriz Rodrigues[1,2], Mariline Silva[1,2], Paulo Pinheiro[1,2], Ana Luisa Carvalho[1,3]
[1]Center for Neuroscience and Cell Biology, Cnc, Coimbra, Portugal, [2]University of Coimbra, Institute Of Interdisciplinary Research, Coimbra, Portugal, [3]University of Coimbra, Department Of Life Sciences, Coimbra, Portugal

Exposure to chronic stress (CS) represents a major risk for mental illnesses. In the prefrontal cortex (PFC), CS leads to synaptic alterations, which consequently disrupt PFC-dependent functions. However, the molecular targets of CS ensuing synaptic dysfunctions remain largely unknown. miRNAs are implicated in brain (dys)function, including the stress response, and are ideally suited to trigger the complex changes in gene expression underlying the synaptic and behavioural effects of CS. miR-186-5p is increased in the brain of stressed animals and our data show both a stress hormone-induced increase in miR-186-5p levels and miR-186-5p-dependent silencing of synaptic glutamate receptors and transmission in cultured neurons. Hence, we hypothesize that, by silencing critical transcripts for synaptic function, upregulated miR-186-5p orchestrates essential features of the synaptic and behavioural responses to CS. By assessing the effects of prolonged glucocorticoid receptor (GR) activation on cortical cultures, we found a reduction on excitatory synapse number, alongside with a decrease on GluA2-containing AMPAR clusters and AMPAR-mediated currents, which correlates with the miR-186-5p-induced switch on AMPAR composition. Furthermore, miR-186-5p inhibition during GR activation reverted the maladaptive response on AMPAR levels and synaptic transmission. Since functional alteration of excitatory transmission are closely related with anxiety and cognitive impairments, we are currently assessing, in chronically stressed mice, a relationship between anxious behaviours, PFC-dependent cognition and miR-186-5p levels and synaptic function. This work will provide new mechanistic insights into CS-induced changes in PFC neurotransmission and related behavioural outputs, identifying key molecular players in maladaptive brain response to CS, pointing to future therapeutic targets.

MicroRNA-186-5p controls GluA2 surface expression and synaptic scaling in hippocampal neurons.
Homeostatic synaptic scaling is a negative feedback response to fluctuations in synaptic strength induced by developmental or learning-related processes, which maintains neuronal activity stable. Although several components of the synaptic scaling apparatus have been characterized, the intrinsic regulatory mechanisms promoting scaling remain largely unknown. MicroRNAs may contribute to posttranscriptional control of mRNAs implicated in different stages of synaptic scaling, but their role in these mechanisms is still undervalued. Here, we report that chronic blockade of glutamate receptors of the AMPA and NMDA types in hippocampal neurons in culture induces changes in the neuronal mRNA and miRNA transcriptomes, leading to synaptic upscaling. Specifically, we show that synaptic activity blockade persistently down-regulates miR-186-5p. Moreover, we describe a conserved miR-186-5p-binding site within the 3'UTR of the mRNA encoding the AMPA receptor GluA2 subunit, and demonstrate that GluA2 is a direct target of miR-186-5p. Overexpression of miR-186 decreased GluA2 surface levels, increased synaptic expression of GluA2-lacking AMPA receptors, and blocked synaptic scaling, whereas inhibition of miR-186-5p increased GluA2 surface levels and the amplitude and frequency of AMPA receptor-mediated currents, and mimicked excitatory synaptic scaling induced by synaptic inactivity. Our findings elucidate an activity-dependent miRNA-mediated mechanism for regulation of AMPA receptor expression.

Despite our knowledge on diet-induced plasticity at the blood-hypothalamus barrier, much remains to be uncovered in terms of transcriptional activity and sexual-dimorphism, a critical but rarely studied parameter. In this light, we sought to determine how the brain integrates and responds to sexually-dimorphic metabolic signals at the cellular and molecular level,and understand marked sex-specific differences under metabolic perturbations such as obesity. Using single-cell RNA sequencing, we studied cell and gene regulatory networks in the median-eminence and the periventricular (ME-PV) zone of the tuberal hypothalamus, the key brain region influencing food-intake and energy homeostasis, in wild-type C57BL/6J adult male and female mice fed with high-fat diet (HFD,60%) and standard-diet for ten-weeks. The body-weight composition and glucose-tolerance were measured for both male and female mice, based on which HFD-sensitive and resistant mice were grouped. Estrous stage of female mice was recorded daily to determine their cyclicity. Single-cell RNA sequencing of microdissected ME-PV region (from chow and HFD-fed male and female mice including chow-fed female mice at different stages of estrous cyclicity) and subsequent analysis resulted in 35 cell clusters comprising of 46,161 cells that were annotated based on the top marker genes, with astrocytes, tanycytes, endothelial cells and oligodendrocytes forming major cell-populations, and revealing distinct and yet unidentified sexually-dimorphic and HFD-induced gene expression profiles. Together, these results represent a comprehensive resource demonstrating ME-PV cell types and sex-specific gene expression dynamics in response to ovarian cycle in standard-diet fed female mice as well as sex-specific long term HFD-fed male and female mice.

Normal reproductive function requires the precise temporal and quantitative regulation of gonadotropin-releasing hormone (GnRH) secretion at all levels of the hypothalamic–pituitary–gonadal (HPG) axis. GnRH control depends on a multidimensional cellular network involving among others, kisspeptin, the main GnRH stimulator, and NO, the only known negative regulator of GnRH. We hypothesize that kisspeptin and NO-releasing neurons (nNOS; NOS1) may form a neuronal microcircuit responsible for rhythmically shaping GnRH release. RNAscope is used to identify the expression pattern of *Kiss1*, Kiss1 receptor and *Nos1* mRNAs in female mouse hypothalamus. Chemogenetics are used to selectively manipulate kisspeptin and nNOS afferences *in vivo*. The concentration of NO being released is measured *in vivo* and *ex vivo* using a newly-designed cGMP biosensor. Patch-clamp approach is applied on $Nos1^{KO}$::$GnRH^{gfp}$ mouse model in order to decipher the dynamics of the KiNG network. nNOS and kisspeptin are distinct neuronal populations, found to anatomically associate and interact with GnRH neurons in the mediobasal hypothalamus (MBH) and preoptic area (POA). *Kiss1R* is found expressed by nNOS neurons and kisspeptin-induced nNOS activation is observed in both MBH and POA. Kisspeptin is able to stimulate the production of NO in a dose dependent manner, through nNOS functioning. Kisspeptin and nNOS interplay leads to the generation of GnRH pulses and surges, crucial for the proper function of reproduction. We postulate that kisspeptin and nNOS create a dynamic network, where kisspeptin provides the “ON” signal, promoting GnRH release, while NO mediates the “OFF” signal, acting as a tonic brake on GnRH secretion.

Aims: Polycystic Ovarian Syndrome (PCOS) is a complex endocrine disease and characterized with oligo/amenorrhea, hyperandrogenemia, hirsutism, chronic anovulation and cystic structures. We aimed to investigate effects of chemogenetic manipulations of kisspeptin neurons in the hypothalamic arcuate nucleus (ARC) on folliculogenesis in Kiss-Cre PCOS mouse model.
Methods: Female Kiss-Cre mice were used. For chemogenetic manipulations, hM3D receptor genes were injected intracranially into the ARC using adeno-associated virus. Pre-pubertal Kiss-cre mice were daily injected subcutaneous with DHEA (6mg/100g body weight for 20 consecutive days). Chronic stimulation was performed by administration of CNO (160µg/5ml) to the drinking water of the mice for four days. After chronic activation, ovaries were isolated. Hematoxylin-eosin staining was performed for morphological evaluation. Alterations in the electrical activity of neurons were measured by electrophysiology patch clamp technique. Data was analyzed by using Student's t-test.
Results: Follicular morphology was impaired in the ovaries of kisspeptin-activated mice. Atretic follicles increased and non-ovulated follicular cysts were detected, and corpus luteum (CL) structure was not observed in the PCOS group. In the chronic activation group, atretic follicles were also present in the ovaries, but follicular cysts were not observed. However, the CL structure was not determined in the activation group. The firing frequency of kisspeptin neurons did not significantly change between the groups.
Conclusions: Our results suggest that the cystic structures formed in the PCOS model regressed after chronic activation of ARC-kisspeptin neurons. However, it was determined that the absence of CL in the ARC-kisspeptin group was not sufficient to induce ovulation.
Acknowledgement: This study was supported by TUBITAK (Project # 219S554).

CELL PLASTICITY OF NEUROPEPTIDERGIC SYSTEMS IN THE MOUSE HYPOTHALAMUS

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

M. Pilar Madrigal, Nuria Viudes, Sandra Jurado
Institute of Neuroscience, Synaptic Neuromodulation, San Juan de Alicante Alicante, Spain

The neuropeptides oxytocin (OXT) and arginine vasopressin (AVP) regulate brain-body homeostasis and complex behaviors, such as maternal and social behavior. Both neuropeptides are synthetized at specific hypothalamic nuclei, mainly at paraventricular and supraoptic nucleus (PVN and SON). Our previous work (Madrigal & Jurado, 2021) revealed a significant number of neurons co-expressing OXT and AVP during early postnatal stages coinciding with a critical period for social interaction. This mixed population drastically declines in the adult brain suggesting that a switch in neuropeptide expression is required for neuronal maturation. Here, we have analyzed the plastic properties of OXT circuits in the adult brain using tissue clearing techniques (iDISCO$^+$) and 3D imaging. Our study has revealed region-specific cell plasticity in several hypothalamic nuclei in response to sexual experience, motherhood, and aging. Our data indicate higher OXT level in females, which seemed significantly increased after parturition in several hypothalamic nuclei, particularly the SON, with some regions exhibiting the expression of additional neuromodulators, suggesting changes in the internal program of a distinct population of OXT neurons. Furthermore, natural aging also induced plastic changes in the oxytocinergic system by reducing the number of OXT-expressing cells in rostral hypothalamic areas. Our findings revealed new information relevant to understand some of the key properties and temporal dynamics of neuropeptidergic circuits´ adaptations during development, motherhood, and aging.

EVALUATION OF THE CIRCADIAN EXPRESSION OF OREXIN RECEPTORS IN THE MOUSE BRAIN BY RNASCOPE®

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Gina Krause[1], Anne Albrecht[1,2]
[1]Otto-von-Guericke University, Institute Of Anatomy, Magdeburg, Germany, [2]Otto-von-Guericke University, Center For Behavioral Brain Sciences, Magdeburg, Germany

Orexin A and B are wake-promoting neuropeptides that originate from hypothalamic neurons and project to diverse brain areas widespread throughout the central nervous system. There, they modulate various physiological functions via their orexin 1 (OXR1) and 2 (OXR2) receptors, including sleep-wake rhythm but also cognitive function. The expression of orexins varies over the course of a day, peaking during the active awake phase. To investigate now whether orexin receptors show circadian and region-specific expression differences as well, RNAscope® as a novel multiplex *in situ* hybridization technique was used. OXR1 and OXR2 mRNA was analyzed in subareas of the dorsal hippocampus and medial prefrontal cortex at four different timepoints over the course of 24 hours. The percentage of orexin receptor mRNA expressing cells was constant over time within brain areas, but significant expression differences between brain regions and subareas were evident. The highest percentage of OXR1 mRNA-positive cells was observed in the hilus of the dentate gyrus and the stratum pyramidale of the CA3 region, while the highest percentage of OXR2 mRNA-positive cells was seen in the stratum pyramidale of the CA1 and CA3 regions of the dorsal hippocampus. In subareas of the PFC expression of both receptor subtypes was lower. Detecting orexin receptor mRNA expression with RNAscope® provides high selectivity and great spatial resolution. The distinct expression profiles of both receptor subtypes within hippocampal subareas provide an interesting basis for future interventional studies of orexin receptor function in spatial and emotional memory.

OPIOID-INDUCED SYNAPTIC PLASTICITY IN THE LATERAL PARABRACHIAL NUCLEUS

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Valeria Mussetto, Roni Hogri, Bernhard Heinke, Ruth Drdla-Schutting, Jürgen Sandkühler
Center for Brain Research, Medical University of Vienna, Department Of Neurophysiology, Vienna, Austria

Background Withdrawal from opioids can induce complex neuroadaptations that underlie severe side effects, including an aversive dysphoric state. A key site for aversive behaviour is the lateral parabrachial nucleus (LPBN). μ-Opioid receptors (MORs) activation has been shown to acutely modulate LPBN synaptic transmission; however, long lasting effects are still unexplored. In this study, we aim to understand whether the LPBN is a site of opioid-induced plasticity. **Methods** We performed patch-clamp recordings in acute slices containing the LPBN from rats and evoked excitatory post synaptic currents by electrical or optogenetic stimulation. Channelrhodopsin-2 was expressed in either spinal or periaqueductal grey neurons using a viral vector. The MOR agonist DAMGO was bath applied at a low or high dose for 15 minutes, followed by abrupt withdrawal via application of the MOR antagonist CTOP. **Results** Withdrawal from low dose DAMGO induced a long term depression (LTD), while withdrawal from high dose DAMGO induced a long term potentiation (LTP). Glia inhibitor fluoroacetate and NMDA receptor antagonist D-AP5 blocked the induction of high-dose LTP, but not low-dose LTD. Low-dose LTD was widely expressed at all synapses, while high-dose LTP was induced only at spino-parabrachial synapses. **Conclusion** Here, we demonstrate a bimodal effect of opioid withdrawal on excitatory transmission in the LPBN. Low-dose LTD involves a neuronal, NMDAR-independent mechanism; high-dose LTP requires glia and NMDAR activation. These synaptic adaptations are differentially expressed in a synapse-specific manner. These novel forms of opioid-induced plasticity in the LPBN possibly contribute to the development of aversive symptoms during opioid withdrawal.

DIFFERENTIAL REGULATION OF CREB AND AKT BY CYCLIC AMP IN THE DEVELOPING RETINA: THE ROLE OF A1 ADENOSINE RECEPTORS

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Roberto Paes-De-Carvalho, Lohan Ximenes, Millena Guimarães-Souza, Natalia Gomes-Da-Silva
Universidade Federal Fluminense, Neurobiologia, Niterói, Brazil

Aims Neurotransmitters activate distinct signaling pathways and regulate specific functions during development such as survival and differentiation of neurons. We are currently studying the development of important transcription factors and signaling pathways in the developing chick retina, where previous work showed that cyclic AMP levels are regulated by dopamine and adenosine. Here we studied the effects of activation or inhibition of adenylyl cyclase on CREB and AKT phosphorylation in diferent stages of retina development. **Methods** Retinas from 10-day-old chick embryos (E10), an early stage of development, and E16, a more developed stage, were dissected and stimulated for 30 minutes in Hanks saline with forskolin (10 µM) or the adenosine A1 receptor agonist cyclohexyladenosine (CHA, 100 nM) to respectively activate or inhibit adenylyl cyclase. After the incubation period, retinas were lysed and analysed by western blotting using antibodies against phosho-CREB or phospho AKT, or the respective total proteins. **Results** Forskolin strongly stimulates CREB phosphorylation in E10 retinas, but a much smaller stimulation was observed in E16 retinas. However, in an interesting way, forskolin promotes a decrease of AKT phosphorylation in E10 or even with a higher degree in E16 retinas. Moreover, although A1 adenosine receptors are negatively coupled to adenylyl cyclase, CHA stimulates CREB and to a smaller extent Akt in E10, but not in E16 retinas, in a Src kinase, PKC and Erk-dependent way. **Conclusions** Our results indicate that cyclic AMP and its regulation by A1 adenosine receptors differentially controls diferent signaling pathways during retinal development.

The orexinergic system of the lateral hypothalamus is classically considered to regulate arousal, sleep/wake cycle, and feeding behaviour. New evidence suggests that it may also play a role during the development of nervous system, with orexin concentration in the brain peaking in early infancy. The aim of our study was to therefore assess the role of orexins in the developing rodent visual system. Specifically, we focused on the mouse and rat dorsolateral geniculate nucleus (DLG), as its retinorecipient thalamocortical neurons are directly responsible for image-forming vision. Here, using RT-qPCR and fluorescent *in situ* hybridisation, we showed that orexin receptor 2 (*Hcrtr2*) is transiently expressed in the DLG during development. *Hcrtr2* expression was high at postnatal day 1 (P1) but linearly declined until P19. Patch-clamp and multi-electrode array recordings in DLG slices *ex vivo* revealed that orexin A robustly activate DLG neurons at P10-16 (few days prior to and following eye opening around P13). However, both the amplitude and frequency of this response were significantly reduced after P16. This early developmental period was also accompanied by dramatic changes in the basic electrophysiology of DLG neurons (e.g., membrane potential, resistance, capacitance, and excitability), stabilising at P14-20. Together, our results revealed a possible role for orexin in early visual system development. The confined developmental window of the orexinergic effects on DLG neurons suggests that this neuropeptide may play an important role in retinothalamic synaptic maturation, at a time when robust activation of thalamocortical cells is critical for appropriate visual function in adulthood.

NOAEL DOSE INTEREST ASSESSMENT AS AN OPTIMIZED DOSE OF OXIME IN THE TREATMENT OF ORGANOPHOSPHORUS COMPOUNDS EXPOSURE

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Institut de Recherche Biomédicale des Armées, Toxicologie Et Risques Chimiques, Brétigny-sur-Orge, France

Despite the international convention on the prohibition of chemical weapons signed in 1997, the threat of conflicts and terrorist attacks involving such weapons still exists. Among these, organophosphorus-nerve agents (NOPs) inhibit cholinesterases causing cholinergic syndrome. The reactivation of these enzymes is therefore essential to protect the intoxicated individual. However, these reactivating molecules called oximes have major drawbacks with an efficacy spectrum limited against some NOPs and a non-negligible cholinesterase inhibitor potential if administered to an inadequate dose, an effect which they are precisely supposed to mitigate. As a result, this project focused, in mice, on the assessment of HI-6 therapeutic efficacy to its NOAEL dose, the maximum dose of oxime which does not induce any observable toxic effect. After determining the HI-6 NOAEL dose by double-chamber plethysmography, the protective index against 2 NOPs were established using survival tests. A pharmacokinetic and pharmacodynamic study completed the evaluation of HI-6. The HI-6 NOAEL dose does not show any better protection compared to the dose of 100 µmol/kg conventionally used by the laboratory. On the contrary, increasing doses of HI-6 improved the protection correlated with more favorable pharmacokinetics, but by inducing a respiratory function impairment. This alteration was not explained by cholinesterase inhibition as expected.

DOWNSTREAM SIGNALING OF MUSCARINIC M4 RECEPTORS IS INFLUENCED BY RECEPTOR DENSITY AND CELLULAR ENVIRONMENT

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Madeleine Merz[1], Charlotte Playle[1], Pia Saegmueller[1], Monika Palchaudhuri[1], Ulrike Gross[2], Daniel Ursu[1]
[1]Boehringer Ingelheim Pharma GmbH & Co. KG, Cns Diseases Research, Biberach, Germany, [2]Boehringer Ingelheim Pharma GmbH & Co. KG, Medicinal Chemistry, Biberach, Germany

Multiple muscarinic M4 receptors modulators are currently advancing in clinical development for treatment of positive symptoms in schizophrenia: agonists (KarXT by Karuna-Ph3, Heptares/Neurocrine-Ph2) or positive allosteric modulators (Emraclidine by Cerevel-Ph2). The aim of this work was to investigate M_4 receptor signaling pathways (Gi/o, Gs and Gq coupling) upon activation by a structurally diverse set of muscarinic agonists. We looked into the role receptor expression levels and cellular environment have on downstream signaling. We have used HEK-293 cells and rat primary neurons expressing human M4 receptors and measured kinetics of cAMP levels and effects on neuronal network activity. Receptor expression levels were controlled by a TET-ON system and quantified by using a radioactive binding assay. Most agonists caused a concentration dependent reduction of cAMP levels (Gi/o) at low concentrations, while inducing increase of cAMP at higher concentrations (Gs). When receptor density in HEK-293 cells was reduced we observed a less prominent coupling via Gs. In the neuronal assay most compounds showed a consistent inhibition of neuronal activity, in line with the cAMP data. A distinct group of agonists showed a specific profile, with no Gs coupling at high receptor density, partial activation at low receptor density and low to no effects in the neuronal assay. This study provides a side-by-side comparison of activity of structurally diverse M4 agonists and points to compound specific activation of GPCR intracellular signaling pathways. The data bring new insights into M4 receptor pharmacology that might lead to development of novel therapies for treatment of psychiatric diseases.

DISTINCT ROLES OF DOPAMINE AND DIRECT- AND INDIRECT-PATHWAY NEURONS IN THE TAIL OF THE STRIATUM IN THREAT MANAGEMENT IN A SEMI-NATURALISTIC FORAGING TASK

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Iku Tsutsui-Kimura, Naoshige Uchida, Mitsuko Watabe-Uchida
Harvard University, Molecular And Cellular Biology, Cambridge, United States of America

In natural environments, it is critical to properly assess potential threats for appropriate behavioral choices. Here we used a semi-naturalistic foraging paradigm to model avoidance of potential threats. In this paradigm, a thirsty mouse freely goes out of a homing area and enters a foraging arena to obtain a water reward. In test sessions, a predator-like object ("monster") surges when a mouse approaches a reward. In the presence of the monster, mice failed to retrieve reward and fled into the homing area. Across trials, mice returned home earlier and earlier before the monster charged, indicating that mice learned to predict a potential threat. Over multiple monster sessions, mice gradually succeeded in acquiring reward. This task, thus, allows us to study various aspects of threat managements under threat-reward conflicts, such as threat avoidance, threat prediction and eventual overcoming. We found that ablation of dopamine neurons that project to the tail of the striatum impaired threat avoidance and prediction. Mice with ablation of direct-pathway medium spiny neurons (dMSNs) decreased avoidance of the monster, while mice with ablation of indirect-pathway medium spiny neurons (iMSNs) exhibited intact avoidance but failed to improve success rate. dMSNs were more activated in avoidance trials (failure of reward acquisition) while iMSNs were more activated in successful trials, especially in later sessions. These results indicate differential roles of dMSNs and iMSNs in threat management: avoidance and overcoming, respectively. These findings provide a basic principle of how MSNs dynamically regulate different aspects of behavior under the control of dopamine.

Distinct temporal difference error signals in dopamine axons in three regions of the striatum in a decision-making task.
Different regions of the striatum regulate different types of behavior. However, how dopamine signals differ across striatal regions and how dopamine regulates different behaviors remain unclear. Here, we compared dopamine axon activity in the ventral, dorsomedial, and dorsolateral striatum, while mice performed a perceptual and value-based decision task. Surprisingly, dopamine axon activity was similar across all three areas. At a glance, the activity multiplexed different variables such as stimulus-associated values, confidence, and reward feedback at different phases of the task. Our modeling demonstrates, however, that these modulations can be inclusively explained by moment-by-moment in the expected reward, that is the temporal difference error. A major difference between areas was the overall activity level of reward responses: reward responses in dorsolateral striatum were positively shifted, lacking inhibitory responses to negative prediction errors. The differences in dopamine signals put specific constraints on the properties of behaviors controlled by dopamine in these regions.

Distinct Roles of Ventromedial versus Ventrolateral Striatal Medium Spiny Neurons in Reward-Oriented Behavior.
The ventral striatum (VS) is a key brain center regulating reward-oriented behavior [1-4]. The VS can be anatomically divided into medial (VMS) and lateral (VLS) portions based on cortical input patterns. The VMS receives inputs from medial pallium-originated limbic structures (e.g., the medial prefrontal cortex [mPFC]), and the VLS receives inputs from the lateral pallium-originated areas (e.g., the insula) [5, 6]. This anatomical feature led us to hypothesize a functional segregation within the VS in terms of the regulation of reward-oriented behavior. Here, we engineered a fiber photometry system [4] and monitored population-level Ca activities of dopamine D2-receptor-expressing medium spiny neurons (D2-MSNs), one of the major cell types in the striatum, during a food-seeking discrimination task. We found that VLS D2-MSNs were activated at the time of cue presentation. In stark contrast, VMS D2-MSNs were inhibited at this time point. Optogenetic counteraction of those changes in the VLS and VMS impaired action initiation and increased responding toward non-rewarded cues, respectively. During lever-press reversal training, VMS inhibition at the time of cue presentation temporarily ceased and optogenetic activation of VMS D2-MSNs facilitated acquisition of the new contingency. These data indicate that the opposing inhibition

and excitation in VMS and VLS are important for selecting and initiating a proper action in a reward-oriented behavior. We propose distinct subregional roles within the VS in the execution of successful reward-oriented behavior.

Milnacipran affects mouse impulsive, aggressive, and depressive-like behaviors in a distinct dose-dependent manner.
Serotonin/noradrenaline reuptake inhibitors (SNRIs) are widely used for the treatment for major depressive disorder, but these drugs induce several side effects including increased aggression and impulsivity, which are risk factors for substance abuse, criminal involvement, and suicide. To address this issue, milnacipran (0, 3, 10, or 30 mg/kg), an SNRI and antidepressant, was intraperitoneally administered to mice prior to the 3-choice serial reaction time task, resident-intruder test, and forced swimming test to measure impulsive, aggressive, and depressive-like behaviors, respectively. A milnacipran dose of 10 mg/kg suppressed all behaviors, which was accompanied by increased dopamine and serotonin levels in the medial prefrontal cortex (mPFC) but not in the nucleus accumbens (NAc). Although the most effective dose for depressive-like behavior was 30 mg/kg, the highest dose increased aggressive behavior and unaffected impulsive behavior. Increased dopamine levels in the NAc could be responsible for the effects. In addition, the mice basal impulsivity was negatively correlated with the latency to the first agonistic behavior. Thus, the optimal dose range of milnacipran is narrower than previously thought. Finding drugs that increase serotonin and dopamine levels in the mPFC without affecting dopamine levels in the NAc is a potential strategy for developing novel antidepressants.

A New Paradigm for Evaluating Avoidance/Escape Motivation.
Organisms have evolved to approach pleasurable opportunities and to avoid or escape from aversive experiences. These 2 distinct motivations are referred to as approach and avoidance/escape motivations and are both considered vital for survival. Despite several recent advances in understanding the neurobiology of motivation, most studies addressed approach but not avoidance/escape motivation. Here we develop a new experimental paradigm to quantify avoidance/escape motivation and examine the pharmacological validity.

Ventrolateral Striatal Medium Spiny Neurons Positively Regulate Food-Incentive, Goal-Directed Behavior Independently of D1 and D2 Selectivity.
The ventral striatum is involved in motivated behavior. Akin to the dorsal striatum, the ventral striatum contains two parallel pathways: the striatomesencephalic pathway consisting of dopamine receptor Type 1-expressing medium spiny neurons (D1-MSNs) and the striatopallidal pathway consisting of D2-MSNs. These two genetically identified pathways are thought to encode opposing functions in motivated behavior. It has also been reported that D1/D2 genetic selectivity is not attributed to the anatomical discrimination of two pathways. We wanted to determine whether D1- and D2-MSNs in the ventral striatum functioned in an opposing manner as previous observations claimed, and whether D1/D2 selectivity corresponded to a functional segregation in motivated behavior of mice. To address this question, we focused on the lateral portion of ventral striatum as a region implicated in food-incentive, goal-directed behavior, and recorded D1 or D2-MSN activity by using a gene-encoded ratiometric Ca indicator and by constructing a fiberphotometry system, and manipulated their activities via optogenetic inhibition during ongoing behaviors. We observed concurrent event-related compound Ca elevations in ventrolateral D1- and D2-MSNs, especially at trial start cue-related and first lever press-related times. D1 or D2 selective optogenetic inhibition just after the trial start cue resulted in a reduction of goal-directed behavior, indicating a shared coding of motivated behavior by both populations at this time. Only D1-selective inhibition just after the first lever press resulted in the reduction of behavior, indicating D1-MSN-specific coding at that specific time. Our data did not support opposing encoding by both populations in food-incentive, goal-directed behavior. An opposing role of dopamine receptor Type 1 or Type 2-expressing medium spiny neurons (D1-MSNs or D2-MSNs) on striatum-mediated behaviors has been widely accepted. However, this idea has been questioned by recent reports. In the present study, we measured concurrent Ca activity patterns of D1- and D2-MSNs in the ventrolateral striatum during food-incentive, goal-directed behavior in mice. According to Ca activity patterns, we conducted timing-specific optogenetic inhibition of each type of MSN. We demonstrated that both D1- and D2-MSNs in the ventrolateral striatum commonly and positively encoded action initiation, whereas only D1-MSNs positively encoded sustained motivated behavior. These findings led us to reconsider the prevailing notion of a functional segregation of MSN activity in the ventral striatum.

28145402: Tsutsui-Kimura I, Takiue H, Yoshida K, Xu M, Yano R, Ohta H, Nishida H, Bouchekioua Y, Okano H, Uchigashima M, Watanabe M, Takata N, Drew MR, Sano H, Mimura M, Tanaka KF

Dysfunction of ventrolateral striatal dopamine receptor type 2-expressing medium spiny neurons impairs instrumental motivation.
Impaired motivation is present in a variety of neurological disorders, suggesting that decreased motivation is caused by broad dysfunction of the nervous system across a variety of circuits. Based on evidence that impaired motivation is a major symptom in the early stages of Huntington's disease, when dopamine receptor type 2-expressing striatal medium spiny neurons (D2-MSNs) are particularly affected, we hypothesize that degeneration of these neurons would be a key node regulating motivational status. Using a progressive, time-controllable, diphtheria toxin-mediated cell ablation/dysfunction technique, we find that loss-of-function of D2-MSNs within ventrolateral striatum (VLS) is sufficient to reduce goal-directed behaviours without impairing reward preference or spontaneous behaviour. Moreover, optogenetic inhibition and ablation of VLS D2-MSNs causes, respectively, transient and chronic reductions of goal-directed behaviours. Our data demonstrate that the circuitry containing VLS D2-MSNs control motivated behaviours and that VLS D2-MSN loss-of-function is a possible cause of motivation deficits in neurodegenerative diseases.

Neuronal codes for the inhibitory control of impulsive actions in the rat infralimbic cortex.
Poor impulse control is a debilitating condition observed in various psychiatric disorders and could be a risk factor for drug addiction, criminal involvement, and suicide. The rat infralimbic cortex (IL), located in the ventral portion of the medial prefrontal cortex, has been implicated in impulse control. To elucidate the neurophysiological basis of impulse control, we recorded single unit activity in the IL of a rat performing a 3-choiceserial reaction time task (3-CSRTT) and 2-choice task (2-CT), which are animal models for impulsivity. The inactivation of IL neuronal activity with an injection of muscimol (0.1 μg /side) disrupted impulse control in the 3-CSRTT. More than 60% (38/56) of isolated IL units were linked to impulse control, while approximately 30% of all units were linked to attentional function in the 3-CSRTT. To avoid confounding motor-related units with the impulse control-related units, we further conducted the 2-CT in which the animals' motor activities were restricted during recording window. More than 30% (14/44) of recorded IL units were linked to impulse control in the 2-CT. Several types of impulse control-related units were identified. Only 16% of all units were compatible with the results of the muscimol experiment, which showed a transient decline in the firing rate immediately before the release of behavioral inhibition. This is the first study to elucidate the neurophysiological basis of impulse control in the IL and to propose that IL neurons control impulsive actions in a more complex manner than previously considered.

Milnacipran remediates impulsive deficits in rats with lesions of the ventromedial prefrontal cortex.
Deficits in impulse control are often observed in psychiatric disorders in which abnormalities of the prefrontal cortex are observed, including attention-deficit/hyperactivity disorder and bipolar disorder. We recently found that milnacipran, a serotonin/noradrenaline reuptake inhibitor, could suppress impulsive action in normal rats. However, whether milnacipran could suppress elevated impulsive action in rats with lesions of the ventromedial prefrontal cortex, which is functionally comparable with the human prefrontal cortex, remains unknown.
Int J Neuropsychopharmacol, 2014; 18
22892727: Tsutsui-Kimura I, Ohmura Y, Izumi T, Kumamoto H, Yamaguchi T, Yoshida T, Yoshioka M
Milnacipran enhances the control of impulsive action by activating D_1-like receptors in the infralimbic cortex.
Elevated impulsivity is often observed in patients with depression. We recently found that milnacipran, an antidepressant and a serotonin/noradrenaline reuptake inhibitor, could enhance impulse control in rats. However, the neural mechanisms underlying the effects of milnacipran on impulsive action remain unclear. Milnacipran increases not only extracellular serotonin and noradrenaline but also dopamine specifically in the medial prefrontal cortex, which is one of the brain regions responsible for impulsive action.
Psychopharmacology (Berl), 2013; 225

The effects of serotonin and/or noradrenaline reuptake inhibitors on impulsive-like action assessed by the three-choice serial reaction time task: a simple and valid model of impulsive action using rats.
Impulsivity is a pathological symptom in several psychiatric disorders, underscoring the need for animal models of impulsive action to develop a brief screening method for novel therapeutic agents of impulsive action. The aims of this study were (i) to evaluate whether the three-choice serial reaction time task (3-CSRTT), a simple version of the five-choice serial reaction time task (5-CSRTT), is appropriate for brief assessment of impulsive-like action and (ii) to examine the effects of fluvoxamine, a selective serotonin reuptake inhibitor, and milnacipran, a serotonin/noradrenaline reuptake inhibitor, on impulsive-like action using the 3-CSRTT. After training in the 3-CSRTT, rats were administered nicotine (0, 0.1, 0.2, and 0.4 mg/kg, salt, subcutaneously), atomoxetine [0, 0.01, 0.1, and, 1.0 mg/kg, intraperitoneally (i.p.)], fluvoxamine (0, 2, 4, and 8 mg/kg, i.p.), or

milnacipran (0, 3, and 10 mg/kg, i.p.). The training time for the 3-CSRTT was significantly shorter than that for the 5-CSRTT. Nicotine increased, whereas atomoxetine decreased the number of premature responses, an index of impulsive-like action, which is consistent with earlier studies. Milnacipran, but not fluvoxamine, dose-dependently decreased premature responses. These results indicate that the 3-CSRTT could provide an appropriate and simpler rodent model of impulsive-like action and that milnacipran could have some beneficial effects on impulsivity-related disorders.

Serotonin (5-HT) is a major monoamine neurotransmitter, its dysfunction causes psychiatric disorders, such as depression. Selective serotonin reuptake inhibitors (SSRIs) are a class of antidepressants that block the serotonin reuptakes . Chronic SSRI administration leads first to a decrease in 5-HT levels by a negative feedback exerted by the 5-HT1A receptor on serotonin producing cells Further treatment induces a long-lasting 5-HT1A desensitization and increase of extracellular 5-HT levels. To uncover the molecular mechanisms involved in serotonin autoregulation and 5-HT1A desensitization, we used Tph2-KO mice which completely lack serotonin in the brain, and SERT-KO mice which have high extracellular serotonin levels, as models of two extreme states of extracellular serotonin. First, we collected the dorsal raphe area in which serotonergic neurons are enriched and run high-throughput proteomics and phosphoproteomics to investigate the effects of high and low serotonin. The results showed 11 proteins and 8 phosphorylated proteins (FDR=0.1) differentially expressed among different genotypes. Among the selected potential factors, the most interesting one is RAP1GAP2, which activates a GTPase for the regulatory protein RAP-1A, converting it into the inactive GDP-bound state. RAP1GAP2 and A0A17EBK8, an isoform of RAP1GAP2 with a longer alternative N-terminus, were down-regulated in the SERT-KO group. The phosphorylation site at serine 53 of A0A17EBK8 was also down-regulated in the SERT-KO group. RAP1 activity analysis showed that SERT-KO raphe cells with lower RAP1GAP2 level have a significantly higher RAP1 activity. These data provide evidence, that RAP1GAP2 and RAP1 are involved in 5-HT1A mediated autoregulation of serotonin in the brain.

Dopamine transmission exerts a central neuromodulatory control over neuronal networks involved in reward processing and motor control. Its impairment plays an important role in numerous neurological disorders. Despite its pathophysiological relevance, the molecular and structural organization of the dopaminergic synapse largely remains to be established. We used targeted labeling and fluorescence-activated sorting to purify striatal dopaminergic synaptosomes. This methodology, coupled with mass spectrometry, allowed us to explore the proteome of dopaminergic synapses. Beyond canonical markers of dopamine neurotransmission, we found 57 proteins specifically enriched and further validated 6 of them that were not previously identified at these synapses (Cpne7, Apba1/Mint1, Cadps2, Cadm2/SynCAM 2, Stx4, Mgll). Moreover, our data reveal a complex organization of the dopaminergic synapse with the adhesion of dopaminergic varicosities to glutamatergic, GABAergic, or cholinergic synapses in multipartite structures we named « hub synapses ». Indeed, our dopaminergic synaptosomes proteomic dataset exhibits different pre-and post-synaptic markers from glutamatergic, GABAergic, and cholinergic synapses that are maintained after purification. We confirmed these results by performing wide field and super-resolution immunofluorescence of sorted striatal dopaminergic synaptosomes. With those findings and methodology, we provide a new framework not only for the molecular exploration of dopaminergic transmission but also for the characterization of projection-specific synaptomes.

INFLUENCE OF GLYPHOSATE INTOXICATION ON GALANIN-LIKE IMMUNOREACTIVE ENTERIC NEURONS IN THE PORCINE SMALL INTESTINE

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Katarzyna Palus, Aleksandra Karpiesiuk
University of Warmia and Mazury in Olsztyn, Poland, Department Of Clinical Physiology, Faculty Of Veterinary Medicine, Olsztyn, Poland

Glyphosate is the main active component of Roundup, one of the most widely used herbicide in the world. The present study was created to establish the effect of glyphosate supplementation on population of galanin- like immunoreactive (GAL-LI) intramural neurons in the porcine small intestine. Fifteen sexually immature gilts divided into 3 groups were used: control - animals receiving empty gelatine capsules; G1 - animals receiving a low dose of glyphosate - corresponding to the theoretical maximum daily intake (TMDI) - 0.05 mg/kg bw/day; G2 - animals receiving a higher dose of glyphosate - corresponding to the acceptable daily intake (ADI) - 0.5 mg/kg/day) in gelatine capsules orally for 28 days. After this time, the animals were euthanized and small intestine samples were collected. Frozen sections were then subjected to the procedure of double immunofluorescent staining. Glyphosate supplementation increased the number of GAL-LI neurons. The most remarkable changes were observed in the ileum, where an increase was noted in both experimental groups and all types of intramural plexuses (myenteric plexus (MP), outer submucous plexus (OSP), inner submucous plexus (ISP)). In the jejunum, the greatest increase was recorded in the G2 group and the OSP. Similarly in the duodenum, the higher dose of glyphosate increased the number of GAL-LI neurons in all type of plexus, whereas in the G1 group changes was observed only in the ISP. The obtained results suggest that GAL may play an important role in the protection of enteric nervous system neurons against the harmful effects of glyphosate.

AUTOCRINE ACTION OF SOMATOSTATIN RELEASED BY O-LM INTERNEURONS

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Maria Laura Musella[1], Salvatore Incontro[2], Dominique Debanne[3]
[1]Inserm UMR_S 1072, Université Aix-marseille, MARSEILLE, France, [2]UMR1072, Universite Aix Marseille, MARSEILLE, France, [3]Inserm UMR1072, AMU, Faculté De Médecine, Marseille, France

Somatostatin (SST) is a neuropeptide whose expression characterises a subpopulation of GABAergic interneurons. SST is of great interest in the pathophysiological context as a deficit of SST is observed in many neurological and psychiatric diseases. SST exerts its physiological role through five G protein-coupled receptors. In the hippocampus, the effects of SST on the principal cells are well known. It inhibits excitatory synaptic transmission by decreasing glutamate release from pyramidal neurons and reduces their intrinsic excitability. This decrease in excitability is achieved by facilitating currents carried by Kv7 channels. Within the hippocampus, O-LM interneurons contain SST and express Kv7.2/3 channels. However, there is no data on the presence of SST auto-receptors on O-LM interneurons, on its mode of release and on the effect it might have on the intrinsic excitability of these interneurons as well as on the synaptic transmission they have with neighbouring pyramidal neurons. We therefore studied how SST is released by O-LM interneurons in the hippocampal CA1 and defined its potential inhibitory action by autocrine (on O-LM) pathway. The preliminary results obtained suggest that SST transiently decreases the excitability of O-LM interneurons as well as the synaptic transmission that takes place between the pyramidal cells and the latter and that there is indeed an autocrine effect of SST that the O-LM interneurons release only following stimulation at a frequency > 20 Hz. In conclusion, the SST neuropeptide similarly to the GABA neurotransmitter modulates neuronal activity by controlling synaptic excitation and excitability onto O-LM cells.

THE MODULATION OF THALAMIC RETICULAR NUCLEUS NEURONS BY CORTICOTROPIN-RELEASING HORMONE

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Loredana Cumpana, Carmen Sandi, Simone Astori
EPFL, Laboratory Of Behavioural Genetics, Brain Mind Institute, Lausanne, Switzerland

We aim to investigate the effect of the stress- and anxiety-related mediator corticotropin-releasing hormone (CRH) on the thalamic reticular nucleus (TRN), a main modulator of thalamic function that contributes to sleep rhythmogenesis. Previous literature and our data show that the CRH receptor 1 (CRHR1) is highly expressed in TRN neurons. However, how CRH affects TRN function, in particular for sleep regulation, has not been explored. Using *ex-vivo* electrophysiology with bath-application of CRH or photoactivation of CRH-releasing fibers, we found that CRHR1 activation decreases the propensity of TRN neurons to fire low-threshold calcium bursts through a negative modulation of the afterhyperpolarizing potentials. Furthermore, synaptic inputs of cortical origin were increased in amplitude upon CRHR1 activation. We mapped through viral tracing the endogenous sources of CRH to the TRN. Our data indicate diverse origins, such as the basolateral-amygdala, zona incerta, and other candidate regions, projecting to different subsectors of TRN. Overall, we found that CRH modulates TRN excitability, potentially impacting the generation and maintenance of thalamocortical rhythms. We are investigating the functional implications of these findings for sleep regulation by combining *in-vivo* polysomnographic recordings with optogenetic manipulations, along with monitoring of the endogenous CRH fluctuations using fiberphotometry. Revealing the mechanisms of interaction between the CRH system and sleep regulation at the TRN level may help advance our understanding of how stress affects sleep stability and sleep-related functions, such as memory consolidation, processes that are often impaired and exacerbated by stress in neuropsychiatric conditions.

Cell And Tissue Biology, School Of Medicine, Mexico City, Mexico, [3]National Institute of Mental Health, Section On Molecular Neuroscience, Bethesda, United States of America

The hindbrain parabrachial complex (PBc) is a sensory relay in the CNS. The forebrain extended amygdala (EA) orchestrates adaptive responses to emotional events. While PBc-EA connection has been extensively studied, cell type specificity and types of synapses remained unclear. Here, using systematic anatomical analysis (IHC and DISH) of neuropeptides PACAP, CGRP and neurotensin-NT distribution in rat and mouse brains, we observed perisomatic ring-like structures containing the three peptides as well as VGLUT1/VGLUT2 in the EA. The origin of those structures was studied using in vivo juxtacellular labeling and tracing study using Adcyap1-Cre for Cre-dependent expression of fluorescent marker fused with artificial channelrhodopsin. PACAP/CGRP/NT/VGLUT1/VGLUT2 expression was a molecular signature of the pre-synaptic neurons from the posterior-ventral division of PBc. This signature was found in the Calyx-of-Held synapse in brainstem' medial nucleus of the trapezoid body (MNTB), which receive globular bushy neurons in the ventral cochlear nucleus. Calyx-of-Held is a rare perisomatic large glutamatergic synapse in the MNTB. PKCdelta-GABAergic neurons in the EA, co-expressing Adcyap1r1 and Vipr1 mRNA were identified as the post-synaptic cells – the same molecular signature was found in the MNTB, except co-expressing PKCdelta. Using TEM and FIBSEM in combination with immunohistochemistry, we demonstrated that the ring-structures in EA are highly similar to the Calyx-of-Held observed in the MNTB. Taken together, our results suggest a common molecular basis for calyceal synaptogenesis both in hindbrain and forebrain. The PBc-->EA Calyx-of-Held synapse may represent a previously unappreciated morphological substrate for high fidelity sensory alert to the forebrain center for adaptive response.

Cannabinoid CB1 receptor (CB_1R) located at both excitatory and inhibitory synapses strongly influences the brain-transmission balance showing a complex and biphasic fine-tuning of several brain functions. This complexity can be sustained by the striking differences in the signaling events triggered by CB_1R among different cell types. Previous evidence had shown that CB_1R can be associated to certain intracellular proteins that modulate its action. By using a high-throughput proteomic approach, complemented with a wide array of *in vitro* and *in vivo* assays, we unveil that CB1R interacts with growth-associated protein 43 (GAP-43)/neuromodulin, a presynaptic cytoskeleton-associated protein, mostly in its S41-phosphorylated form. In brain tissue, we detected CB_1R-GAP43 complexes selectively in glutamatergic axon terminals of the MCs in the dentate gyrus (DG), as shown by in situ PLA in brain sections from conditional knockout and rescue mouse models. MCs establish an associative excitatory circuit with granular cells (GCs) in the DG involved in epileptic seizures. By adeno-associated virus (AAV)-mediated intracranial delivery of GAP43-S41D or GAP43-S41A, we could determine that the phosphorylated form of GAP43 decreases DSE and WIN-55,212-2-mediated suppression of neurotransmission at MC-GC synapses, strongly suggesting that GAP43 inhibits CB_1R at those synapses. In addition, we generated conditional GAP43-knockout mice, specifically in glutamatergic and GABAergic neurons. We tested kainate-induced epilepsy on these mouse lines and found that GAP43 deletion from glutamatergic neurons facilitates CB_1R anti-seizure activity. Taken together, these findings unveil a new protein that can interact with CB_1R in a synapse-specific manner, hampering CB_1R action on the MC-GC recurrent excitatory circuit.

Identification of BiP as a CB Receptor-Interacting Protein That Fine-Tunes Cannabinoid Signaling in the Mouse Brain.
Cannabinoids, the bioactive constituents of cannabis, exert a wide array of effects on the brain by engaging Type 1 cannabinoid receptor (CBR). Accruing evidence supports that cannabinoid action relies on context-dependent factors, such as the biological characteristics of the target cell, suggesting that cell population-intrinsic molecular cues modulate CBR-dependent signaling. Here, by using a yeast two-hybrid-based high-throughput screening, we identified BiP as a potential CBR-interacting protein. We next found that CBR and BiP interact specifically , and mapped the interaction site within the CBR -terminal (intracellular) domain and the BiP -terminal (substrate-binding) domain-α. BiP selectively shaped agonist-evoked CBR signaling by blocking an "alternative" G protein-dependent signaling module while leaving the "classical" G protein-dependent inhibition of the cAMP pathway unaffected. proximity ligation assays conducted on brain samples from various genetic mouse models of conditional loss or gain of CBR expression allowed to map CBR-BiP complexes selectively

on terminals of GABAergic neurons. Behavioral studies using cannabinoid-treated male BiP mice supported that CBR-BiP complexes modulate cannabinoid-evoked anxiety, one of the most frequent undesired effects of cannabis. Together, by identifying BiP as a CBR-interacting protein that controls receptor function in a signaling pathway- and neuron population-selective manner, our findings may help to understand the striking context-dependent actions of cannabis in the brain.
Cannabis use is increasing worldwide, so innovative studies aimed to understand its complex mechanism of neurobiological action are warranted. Here, we found that cannabinoid CB receptor (CBR), the primary molecular target of the bioactive constituents of cannabis, interacts specifically with an intracellular protein called BiP. The interaction between CBR and BiP occurs selectively on terminals of GABAergic (inhibitory) neurons, and induces a remarkable shift in the CBR-associated signaling profile. Behavioral studies conducted in mice support that CBR-BiP complexes act as fine-tuners of anxiety, one of the most frequent undesired effects of cannabis use. Our findings open a new conceptual framework to understand the striking context-dependent pharmacological actions of cannabis in the brain.

IGF-1 facilitates extinction of conditioned fear.
Insulin-like growth factor-1 (IGF-1) plays a key role in synaptic plasticity, spatial learning, and anxiety-like behavioral processes. While IGF-1 regulates neuronal firing and synaptic transmission in many areas of the central nervous system, its signaling and consequences on excitability, synaptic plasticity, and animal behavior dependent on the prefrontal cortex remain unexplored. Here, we show that IGF-1 induces a long-lasting depression of the medium and slow post-spike afterhyperpolarization (mAHP and sAHP), increasing the excitability of layer 5 pyramidal neurons of the rat infralimbic cortex. Besides, IGF-1 mediates a presynaptic long-term depression of both inhibitory and excitatory synaptic transmission in these neurons. The net effect of this IGF-1-mediated synaptic plasticity is a long-term potentiation of the postsynaptic potentials. Moreover, we demonstrate that IGF-1 favors the fear extinction memory. These results show novel functional consequences of IGF-1 signaling, revealing IGF-1 as a key element in the control of the fear extinction memory.

Astroglial monoacylglycerol lipase controls mutant huntingtin-induced damage of striatal neurons.
Cannabinoids exert neuroprotection in a wide array of preclinical models. A number of these studies has focused on cannabinoid CB receptors in striatal medium spiny neurons (MSNs) and the most characteristic MSN-degenerative disease, Huntington's disease (HD). Accruing evidence supports that astrocytes contribute to drive HD progression, and that they express CB receptors, degrade endocannabinoids, and modulate endocannabinergic transmission. However, the possible role of the astroglial endocannabinoid system in controlling MSN integrity remains unknown. Here, we show that JZL-184, a selective inhibitor of monoacylglycerol lipase (MGL), the key enzyme that deactivates the endocannabinoid 2-arachidonoylglycerol, prevented the mutant huntingtin-induced up-regulation of the pro-inflammatory cytokine tumor necrosis factor-α in primary mouse striatal astrocytes via CB receptors. To study the role of astroglial MGL in vivo, we injected stereotactically into the mouse dorsal striatum viral vectors that encode mutant or normal huntingtin under the control of the glial fibrillary acidic protein promoter. We observed that, in wild-type mice, pharmacological blockade of MGL with JZL-184 (8 mg/kg/day, i.p.) conferred neuroprotection against mutant huntingtin-induced striatal damage, as evidenced by the prevention of MSN loss, astrogliosis, and motor coordination impairment. We next found that conditional mutant mice bearing a genetic deletion of MGL selectively in astroglial cells (MGL mice) were resistant to mutant huntingtin-induced MSN loss, astrogliosis, and motor coordination impairment. Taken together, these data support that astroglial MGL controls the availability of a 2-arachidonoylglycerol pool that ensues protection of MSNs in the mouse striatum in vivo, thus providing a potential druggable target for reducing striatal neurodegeneration.

Pathway-Specific Control of Striatal Neuron Vulnerability by Corticostriatal Cannabinoid CB1 Receptors.
The vast majority of neurons within the striatum are GABAergic medium spiny neurons (MSNs), which receive glutamatergic input from the cortex and thalamus, and form two major efferent pathways: the direct pathway, expressing dopamine D1 receptor (D1R-MSNs), and the indirect pathway, expressing dopamine D2 receptor (D2R-MSNs). While molecular mechanisms of MSN degeneration have been identified in animal models of striatal damage, the molecular factors that dictate a selective vulnerability of D1R-MSNs or D2R-MSNs remain unknown. Here, we combined genetic, chemogenetic, and pharmacological strategies with behavioral and neurochemical analyses, and show that the pool of cannabinoid CB1 receptor (CB1R) located on corticostriatal terminals efficiently safeguards D1R-MSNs, but not D2R-MSNs, from different

insults. This cell-specific response relies on the regulation of glutamatergic signaling, and is independent from the CB1R-dependent control of astroglial activity in the striatum. These findings define cortical CB1R as a pivotal synaptic player in dictating a differential vulnerability of D1R-MSNs versus D2R-MSNs, and increase our understanding of the role of coordinated cannabinergic-glutamatergic signaling in establishing corticostriatal circuits and its dysregulation in neurodegenerative diseases.

Across life span, the brain learns to choose adaptively between different behavioral options to reach specific goals. This process requires behavioral flexibility, and is supported by frontostriatal circuits and their optimal modulation by ascending neuromodulatory systems (i.e. dopamine) and local neuromodulatory signals (i.e. endocannabinoids). In the striatum, the endocannabinoid (eCB) system, formed by synthetizing enzymes (i.e. DAG lipase alpha, DGL) and receptors (cannabinoid receptor type 1, CB_1R), acts as a highly-organized neuromodulatory signaling complex that controls the release of glutamate at cortical afferents to principal striatal projection neurons (SPNs). We investigated whether behavioral flexibility is supported by nanoscale adaptations in the eCB signaling complex. To this purpose, we subjected mice to different training regimes of instrumental conditioning of nose poke for food reward, which promote either flexible goal-directed (short-training) or inflexible behavior (over-training). Each training was followed by an omission procedure in which mice have to learn a new causal A-O association. By using ex-vivo brain slices electrophysiology and super resolution microscopy, we find that dynamic regulation of molecular components of striatal eCB signaling complex represents a key molecular substrate for behavioral flexibility.

Methamphetamine (METH) abuse increases the incidence of HIV-1 associated neurocognitive disorders. We have demonstrated that the HIV-1 regulatory protein, transactivator of transcription (Tat), decreases dopamine (DA) transport via the DA transporter (DAT) and vesicular monoamine transporter-2 (VMAT-2). This study examined the synergistic effects of Tat and METH on DA uptake through VMAT-2 and associated METH-induced conditioned place preference (CPP). *In vitro* incubation of isolated mouse whole brain vesicles with recombinant Tat_{1-86} or METH displayed a concentration-dependent inhibition of vesicular [^{3}H]DA uptake, in which a combination of Tat and METH induced an additive reduction of DA uptake via VMAT-2 compared to Tat or METH alone. 21-day doxycycline (Dox, 100 mg/kg/day, i.p.)-induced Tat expression caused a 57% decrease in the maximal velocity (V_{max}) value in inducible Tat transgenic (iTat-tg) mice, which was attenuated in control G-tg (Tat null) mice. 14-day administration of METH (3 mg/kg, i.p.) alone induced a 35% and 52% reduction of V_{max} in iTat-tg and G-tg mice, respectively, whereas a greater decrease (66%) in V_{max} was observed in iTat-tg mice of Dox-METH group. Following 14-day treatment of Dox, the iTat-tg mice potentiated METH-CPP 6-fold over saline-treated mice, suggesting that Tat expression potentiates the rewarding effect of METH. Considering that both Tat and METH interact with DAT and VMAT-2, these results provide evidence that Tat and METH could disrupt DA transmission by inhibiting both DAT and VMAT-2 function. This study raises the exciting possibility of a potential therapeutic strategy by targeting VMAT-2 for METH abuse in HIV infected individuals.

LATERAL AXO-AXONAL NEUROMODULATION IS REQUIRED FOR NOISE FREE AVERSIVE OLFACTORY CONDITIONING IN ADULT DROSOPHILA MELANOGASTER

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Julia Manoim[1], Moshe Parnas[1,2]
[1]Tel-Aviv University, Physiology And Pharmacology, Tel-Aviv, Israel, [2]Tel-Aviv University, Sagol School Of Neuroscience, Tel-Aviv, Israel

Objective: In order to survive animals must learn to modify their behavior according to environmental cues. Such learning often occurs by reinforcing signals that modulate connection strengths between neurons. Importantly, such neuromodulation can occur via direct synaptic release onto postsynaptic structures located at all target neurons or even by volume transmission. How then does the neuromodulatory signal affects only the relevant subset of target neurons? It is generally agreed that coupling between the release of the modulatory signal and activity of the target neurons is required. However, it was demonstrated that neuromodulation occurs even without coupling. Thus, a question arises whether learning and memory resides on a background of noisy neuromodulation or whether mechanisms exist which reduce this noisy background modulation. To address this question, we focused on the *Drosophila* cholinergic Kenyon cells (KCs) where olfactory learning and memory occurs following Dopaminergic neuromodulation. **Results:** We show using a combination of behavioral experiments, 2-photon functional imaging, genetics, and connectomics analysis, that KCs have numerous axo-axonal connections mediated by the muscarinic type B receptor (mAChR-B). These axo-axonal connections have a dual function: they reduce Ca^{2+} elevation in KCs presynaptic terminals that is required for dopaminergic neuromodulation, and they induce a neuromodulatory signal that counters the dopaminergic neuromodulation. As a result, this lateral neuromodulation limits dopaminergic neuromodulation only to relevant KCs and reduces unspecific learning. **Conclusion**: Cholinergic activation of mAChR-B contrasts the noisy background modulation that occurs during the learning process, resulting in sharpening and enhancement of the learning process.

Glial ER and GAP junction mediated Ca waves are crucial to maintain normal brain excitability.
Astrocytes play key roles in regulating multiple aspects of neuronal function from invertebrates to humans and display Ca fluctuations that are heterogeneously distributed throughout different cellular microdomains. Changes in Ca dynamics represent a key mechanism for how astrocytes modulate neuronal activity. An unresolved issue is the origin and contribution of specific glial Ca signaling components at distinct astrocytic domains to neuronal physiology and brain function. The Drosophila model system offers a simple nervous system that is highly amenable to cell-specific genetic manipulations to characterize the role of glial Ca signaling. Here we identify a role for ER store-operated Ca entry (SOCE) pathway in perineurial glia (PG), a glial population that contributes to the Drosophila blood-brain barrier. We show that PG cells display diverse Ca activity that varies based on their locale within the brain. Ca signaling in PG cells does not require extracellular Ca and is blocked by inhibition of SOCE, Ryanodine receptors, or gap junctions. Disruption of these components triggers stimuli-induced seizure-like episodes. These findings indicate that Ca release from internal stores and its propagation between neighboring glial cells via gap junctions are essential for maintaining normal nervous system function.

INTERACTION OF BDNF-TRKB AND CORTICOSTEROIDS SIGNALING PATHWAYS

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Cecilia Brunello
University of Helsinki, Neuroscience Center, Hilife, Helsinki, Finland

The rewiring of neuronal networks that allows brains to learn and to adapt to changing environments is called neuroplasticity, and impaired neuroplasticiy is involved in the pathophysiology of a wide range of brain disorders. This raises the need to understand the molecular pathways underneath in order to design effective treatments to restore physiological neuroplasticity. One of the central players maintaining it is the Brain derived neurotrophic factor (BDNF) signaling through its cognate Tropomyosin receptor kinase B (TRKB), ultimately responsible for synaptic development and maintenence. However, other molecules, such as corticosteroid hormones, physiologically promote neuroplasticity, suggesting an interplay between different pathways. In this study, we investigate in vitro the relationship between glucocorticoids, such as corticosterone and dexamethasone, and mineralocorticoids, such as aldosterone, on TRKB signaling. We developed a protein-fragment complementation assay (PCA) to monitor TRKB homodimerization and interaction with other cellular proteins to examine its activity. We found that corticosteroids affect TRKB signaling in a non-genomic way, indicating a possible synergistic effect of the two pathways.

REGULATION OF NMDA RECEPTOR DYNAMICS BY BRAIN-DERIVED NEUROTROPHIC FACTOR IN HIPPOCAMPAL NEURONS

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Pasqualino De Luca, Pedro Afonso, Miranda Mele, Carlos Duarte
University of Coimbra, Center For Neuroscience And Cell Biology, Coimbra, Portugal

The neurotrophin brain-derived neurotrophic factor (BDNF) is an important mediator of long-term synaptic potentiation (LTP) induced by high-frequency presynaptic stimulation, in the hippocampus and in other brain regions. The early effects of BDNF are mediated by posttranslational modification of synaptic components, while the delayed responses require transcription activity and de novo protein synthesis. However, the BDNF-induced alterations in the synaptic proteome coupled to synaptic strengthening are poorly understood. Studies performed in cultured hippocampal neurons showed that BDNF induces synaptic accumulation of NMDA receptors and increases the amplitude of NMDAR-mediated mEPSCs, by a mechanism dependent on the activation of the tyrosine kinase Pyk2 and dependent of protein synthesis. The BDNF-induced upregulation in synaptic NMDAR was correlated with an increase in their stability in this compartment, as determined by single particle quantum dot imaging. The effects of BDNF on local protein synthesis at the synapse depends on the delivery of transcripts along dendrites, within RNA granules. The RNA binding protein hnRNP K was found to play an important role in the delivery of Pyk2 mRNA to the synapse. Activation of BDNF-TrkB signaling at the synapse leads to the release of the latter transcripts from the RNA binding protein, allowing the synthesis of the kinase. Together, the results show a key role for Pyk2 synthesis at the synapse as a mediator of the effects of BDNF on the local distribution of NMDAR, which may have an impact on LTP.

The nucleus accumbens (NAc), a brain area that integrates diverse monoaminergic inputs to coordinate motivated behaviours, are innervated by histaminergic fibers originating in neurons located in the hypothalamic tuberomammillary nucleus.
Although the NAc expresses different subtypes of histamine receptors, the mechanisms by which histamine may affect NAc activity have not been identified yet. By performing whole-cell patch-clamp recordings, we found that activation of histamine 2 (H2) receptors elevates evoked firing of NAc medium spiny neurons (MSNs). The evoked firing of MSNs increased after seconds of local H2 agonist administration and remained elevated for minutes. H2 receptor (H2R) activation quickened subthreshold depolarization in response to current injection, increased the action potential half-width, diminished action potential afterhyperpolarization and reduced the latency to fire. The increased excitability was PKA-dependent and associated with decreased A-type K+ currents. Indeed, selective pharmacological inhibition of the Kv4.2 channel, the main molecular determinant of A-type K+ currents in MSNs, occluded the increased excitability induced by H2R activation. Overall, these findings indicate that histaminergic transmission in the NAc increases the excitability of MSN through H2R-dependent modulation of Kv4.2 channels and extend the current conceptual framework of HA signaling in the brain.

Aim: Spinocerebellar ataxia type 1 (SCA1) is caused by a polyQ expansion in the ataxin-1 protein. MED15, a key component of Mediator Complex interacts with ataxin-1 and strongly enhances its aggregation, suggesting that this interaction (PPI) may affect the progression of SCA1. The aim of our work is the identification of compounds that would inhibit ATXN1-MED15 protein interaction. **Methods:** Here, we present a computational and experimental workflow enabling the discovery of compounds that block ATXN1-MED15 PPI. We used I-TASSER software for prediction of ATXN1 and MED15 protein structures and simulation of their interaction. Protein docking results were validated using the LuTHy assay for ATXN1-MED15 PPI. Next, we employed an in-silico screening for inhibitors that bind to the PPI interaction site and hamper ATXN1-MED15 interaction. Selected compounds were tested in high-throughput ATXN1-MED15 LuTHy assays and a MED15-induced protein aggregation primary cell model. **Results:** First, we predicted the structures of target proteins using the I-TASSER software and computationally simulated their interaction. Predicted interaction sites between ATXN1 and MED15 were validated using LuTHy, a mammalian cell-based assay which enables the detection and quantification of PPIs. Next, we performed an *in-silico* screening and identified 30 compounds that bind to the ATXN1 interaction site. These compounds were tested whether they inhibit this interaction in high-throughput LuTHy assays. 7 hit compounds were further tested whether they reduce MED15-induced ataxin-1 protein aggregation in a novel inducible cell-based model. **Conclusions:** Our work may lead to the discovery of novel compounds that would suppress SCA1 disease progression.

BRAIN DIFFUSION PARAMETERS ARE CHANGED BY DISRUPTION OF EXTRACELLULAR MATRIX AFTER ORAL TREATMENT OF 4-METHYLUMBELLIFERONE.

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Eva Sykova[1], Ivan Vorisek[1], Zenon Starcuk[2], Jiri Kratochvila[2], Iveta Pavlova[2], Sarka Kubinova[3], Jana Svobodova Burianova[4], Jessica Kwok[5], Josef Syka[4], Tomas Smolek[1], Norbert Zilka[1]

Transient changes of extracellular matrix (ECM) and perineuronal nets (PNN) have been observed to change extracellular space (ECS) diffusion parameters during brain pathologies or in knock-out animals. We investigated the effect of oral treatment of rats with 4-methylumbelliferone (4-MU), inhibitor of hyaluronan synthesis, on ECM and brain diffusion parameters. We measured the level of hyaluronan (using hyaluronan binding protein) and chondroitin sulfates (using CS56 antibody) by densitometry measurement on brain sections. We found that 2 months of 4-MU diet have led to 42.3% ± 11.2% and 38.7% ± 9.1% reduction of hyaluronan and chondroitin sulfates, respectively. There was a significant down-regulation of PNN on neuronal surface, labelled by *Wisteria floribunda* agglutinin. We used *in vivo* diffusion-weighted magnetic resonance imaging (DW-MRI) and found that exposure to 4-MU diet resulted in cortex, thalamus, hippocampus and pallidum in a significant decrease of the apparent diffusion coefficient of water from 967 ± 8 to 903 ± 12 mm^2/s, the fractional anisotropy from 0.21 ± 0.02 to 0.16 ± 0.01 and perfusion detected by arterial spin labelling from 82 ± 9 to 52 ± 4 ml/100g/min (data from cortex). We have not found changes in brain metabolites as measured by MR proton spectroscopy. After the animals were fed again with a standard diet, the parameters returned to control values. We suggest that DW-MRI can be used for *in vivo* detection of the changes in ECM which can affect synaptic plasticity, extrasynaptic transmission and contribute to observed functional effects of 4-MU. Supported by LM2018129 and APVV-20-0331.

There is increasing evidence for influence of Alzheimer´s proteins and neuropathology on ischemic brain injury. Production and deposition of β-amyloid protein is an important key player involved in mechanism in Alzheimer´s disease as well as ischemic neurodegeneration. To date, efficient therapeutics drugs are still insuficient, making necessary to find relevant compounds amongst masses of potential candidates. A first cell-based screening model for secretase inhibitors using MCDK cells followed by a second assay in cortical neurons where cell parameters associated with membrane damage, cell viability and neurite outgrowth were measured using HCS analysis. In the primary screen we identified 57 inhibitors of β-secretase in the 1200 compounds of Prestwich library. These initial hits were further analyzed for their capacity to protect primary cortical neurons against the neurotoxicity induced by oxygen glucose deprivation (OGD). In this neuron-screen, just only 4 and of these 57 compound (metergoline, bepridil, carbetapentane and raloxifene), all antagonist of calcium channels and inhibitors of amyloid production, displayed as highly neuroprotective in a pre-treatment toxicity assay but only metergoline compound remained active when tested in a post-treatment protocol administered six hours post OGD damage. Our work stablishes the feasibility of identifying molecule inhibitors of neuronal damage using both screening models and provides novel insights into the mechanisms of neuroprotection by calcium channels antagonists.

EXPLORING P2X4 PURINERGIC RECEPTOR MODULATION BY ALLOPREGNANOLONE.

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Michele Barraco, Maria Angela Sortino, Mariangela Chisari
University of Catania, Biomedical And Biotechnological Sciences, Catania, Italy

Aim: allopregnanolone (alloP) positively modulates P2X4 receptor (P2X4R) current. We explored the possibility that alloP modulation might vary depending on ATP concentration. Also, we compared a naïve (BV2 microglia cells) and a heterologous model (HEK-293 cells transfected with rat P2X4R-YFP) to identify eventual differences. Methods: patch-clamp recordings were performed in both cell lines. Cells were stimulated for 5s with ATP for a stable current, exposed to alloP for 25s, followed by a co-stimulation with ATP for 5s. Pre-exposure to alloP is necessary to observe current potentiation, suggesting its distribution on the plasma membrane. Current obtained with alloP was normalized to corresponding basal ATP current. One-way ANOVA test was performed. Results: we determined the ATP concentration-response curves (HEK-293 cells, EC_{50} 13.3 μM, Hill slope 0.649; BV2 cells, EC_{50} 5 μM, Hill slope 0.172). We compared two different alloP concentrations (0.1 and 10 μM) on P2X4 current elicited by ATP 5 and 50 μM. In HEK-293, current potentiation was observed with alloP 0.1 μM using ATP 5 μM (1.95±0.06), while alloP 10 μM potentiated at both ATP concentrations (1.73±0.06; 1.18±0.03). In BV2 cells, alloP 0.1 and 10 μM potentiated current with ATP 5 μM (1.63±0.04; 1.19±0.03, respectively), while at ATP 50 μM, only alloP 10 μM showed potentiation (1.29±0.04). Conclusions: P2X4 current is potentiated by alloP but the effect is less pronounced at increasing ATP concentrations, in both cell lines. Such outcome suggests that alloP influences the pore opening features, because its plasma membrane redistribution is essential to observe P2X4 current potentiation.

ANALYSIS OF RAT DOPAMINERGIC NEURON NMDA RECEPTOR DOSE-RESPONSE RELATION AND POTENTIATION EFFECTS OF THE POSITIVE ALLOSTERIC MODULATOR, PTC-174.

POSTER SESSION 01 - SECTION: MOLECULAR NEUROPHARMACOLOGY

Alasdair Gibb, Bangyuan Liu
UCL, Pharmacology, London, United Kingdom

NMDA receptor (NMDAR) dysfunction is involved in a variety of neurological disorders including NMDA receptor hypofunction in schizophrenia and there is growing interest in NMDARs as therapeutic targets and in development of subtype-specific allosteric modulator drugs. NMDARs are tetrameric proteins mainly composed of two different types of subunits with two glycine-binding GluN1 and two glutamate-binding GluN2 subunits (4 types, A, B, C and D). Varying expression of each subunit type in different brain regions is the main determinant of functional diversity of NMDARs. NMDARs expressed by dopaminergic neurons of the substantia nigra pars compacta (SNc) are likely to be GluN1/2B/2D triheteromers, which have some characteristics of both diheteromeric GluN1/2B and GluN1/2D receptors. In our experiments, seven day old neonatal rats were humanely killed followed by rapid brain removal to obtain acute brain slices, and patch-clamp whole cell recordings from dopaminergic neurons in substantia nigra compacta (SNc) region were used as a model system to study drug effects on the electrophysiological properties of SNc NMDARs, as well as the pharmacological character of a recently-developed NMDAR positive allosteric modulator, PTC-174 (10.1016/j.neuropharm.2020.107971). NMDAR activation was potentiated 1.7-fold (n=20) by PTC-174 (10 μM), at near maximal NMDAR activation by 10 μM glycine and 200 μM NMDA which suggests the open probability of NMDARs might have been increased by PTC-174 providing insights into the mechanism of drug action. Modelling the NMDAR response suggests the action of PTC can be described by a combination of increased channel open probability combined with a moderate decrease in agonist affinity.

Altered synaptic functions have been associated with neurological disabilities and cognitive impairments. In particular, the normal synaptic function requires a tight organization of the postsynaptic density, including receptors and structural and signaling proteins. Here we analyze the role of the adaptor protein KIAA1217 (the human homolog of murine sickle tail gene, hSKT), in regulating synaptic plasticity. A total Skt-/- mouse was characterized for behavioral analysis, in vivo and in vitro dendritic spines (DDs) morphology, electrophysiological properties through Microelectrode Array (MEA), and biochemical interaction of SKT with different synaptic proteins. Finally, we generated the SKT interactomics profile by mass spectrometry (MS) analysis. Mouse brain slices and primary cultured neurons from Skt-/- mice showed a decreased number in total DSs, with a reduction of mushroom DSs and an increase in immature filopodia spine structures. The Puzzle Box Test revealed that Skt-/- mice show an impaired cortical function compared to WT controls. The MEA in primary hippocampal cultures exhibited a substantial delay in neuronal synchronization and maturation. Moreover, to assess the functional molecular interactions of hSKT with the principal PSD components, we found that hSKT interacts with PSD-95 and Shank 3. Finally, MS showed that SKT interacts with proteins involved in cytoskeleton regulation, vesicles cycle, and ionotropic glutamate receptor modulation. All together, these data pave the way to hSKT as a new relevant player in the structural and functional organization of the PSD, suggesting that its absence or alteration could lead to impairment of cognitive processes, memory establishment typical of neurological disorders

HILAR MOSSY CELLS REGULATE THE ACTIVITY OF HIPPOCAMPAL DENTATE GYRUS CIRCUITRY IN A FREQUENCY-DEPENDENT MANNER

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Yingxin Li[1], Zafar Bashir[2], Denize Atan[1]
[1]University of Bristol, Bristol Medical School, Translational Health Sciences, Bristol, United Kingdom, [2]University of Bristol, Faculty Of Life Science, School Of Physiology, Pharmacology And Neuroscience, Bristol, United Kingdom

Mossy cells (MCs) are glutamatergic neurons within the hippocampal dentate gyrus (hDG). They are implicated in key roles of the hDG, such as context discrimination and spatial memory. Our aim was to stimulate the hDG at physiological frequencies associated with spatial memory and determine how MCs regulate this circuitry. We recorded excitatory postsynaptic potentials (EPSPs) induced in dentate granule cells (GCs) by medial perforant pathway (MPP) stimulation in acute hippocampal slices from wildtype (WT) mice and genetically-modified mice that lack MCs. We found the absence of MCs increased the excitability of GCs to MPP stimulation at 20Hz and 50Hz but not at 5Hz. These results were recapitulated in WT slices by the application of type 1 cannabinoid receptor agonist WIN 55,212-2 that selectively blocks glutamate release at MC-GC synapses. These results suggest that MCs regulate GC responses to MPP stimulation at frequencies relevant to spatial memory processing in the hDG.

SYNAPTIC BASIS OF CEREBELLAR GRANULE CELL POPULATION DYNAMICS

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Berat Sermet, Franziska Bender, Giovanni Diana, Francisco Urra Quiroz, David Digregorio
Institut Pasteur, Department Of Neuroscience, Paris, France

As the input layer of the cerebellar cortex, the granule cell layer integrates information from multiple pathways to execute complex sensory-motor behaviors reliably. Sensations and motor actions are temporally extended events that require a representation of the passage of time. Temporal sequences of neural activity have been implicated for reading out time during behavior, but the neural mechanisms underlying such population dynamics are not known. Recently our lab has implemented a simple cerebellar cortex network model that predicts that heterogeneity in short-term synaptic plasticity generates the rich diversity of cerebellar granule cell firing patterns. Synaptic recordings in the lateral cerebellum (Crus I) where, when compared vestibular cerebellum, indicate that synaptic strength and plasticity can vary between regions responsible for different tasks. With the recent development of a fast calcium indicator (GCaMP8f), we reasoned that characterization of the diversity of temporal activity patterns in GCs *in situ* might indeed be possible for the first time. We therefore directly stimulated many MFs with extracellular stimulation and then imaged the activity responses in GCs using two-photon microscopy. Our initial results indicate the existence of a temporal basis generated by the diverse firing patterns of the granule cells. We are currently exploring differences in the population activity patterns between Lobe X and Crus I, as would be suggested by differences in synaptic strength and dynamics between the two regions. Our results begin to provide experimental evidence that short-term synaptic plasticity is a substrate for diverse activity patterns within neural circuits underlying temporal learning.

MOTOR SEQUENCE LEARNING INDUCES RAPID MICROSTRUCTURAL REORGANIZATION, A DWI-STUDY

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Whitney Stee[1,2], Michele Guerreri[3], Antoine Legouhy[3], Hui Zhang[3], Philippe Peigneux[1,2]
[1]Université Libre de Bruxelles, Ur2nf-neuropsychology And Functional Neuroimaging Research Unit Affiliated At Crcn – Centre For Research In Cognition And Neurosciences And Uni - Ulb Neuroscience Institute, Brussels, Belgium, [2]University of Liège (ULiège), Giga - Cyclotron Research Centre - In Vivo Imaging, Liège, Belgium, [3]University College London, Department Of Computer Science & Centre For Medical Image Computing, London, United Kingdom

Aims: Diffusion-weighted imaging (DWI) allows observing rapid (micro)structural brain remodeling in cortical and subcortical regions after restricted motor learning time. Even if sensitive, diffusion tensor imaging (DTI) is inherently non-specific, limiting information about underlying cellular processes. Multicompartment diffusion imaging (Neurite Orientation Dispersion and Density Imaging – NODDI) that estimates the microstructural complexity of dendrites and axons would allow tracking neural density changes that dynamically develop. **Methods:** Sixty young (18-30y), healthy adults underwent two DWI MRI sessions before and after 1h-Serial Reaction Time Task learning (30blocks – 96 trials/block) followed by 30min break. DTI and NODDI analyses were conducted on subcortical regions of interest (ROIs). **Results:** A multivariate analysis on DTI/NODDI parameters revealed microstructural modulation in the left thalamus ($p = 0.006$) and putamen ($p = 0.005$), right caudate ($p = 0.006$), and bilateral hippocampus ($ps < 0.007$) and cerebellum ($ps < 0.001$). Univariate post-hoc tests disclosed (a) decreased mean diffusivity (MD) in left putamen, right caudate, bilateral hippocampus and cerebellum; (b) decreased free water fraction (FWF) in bilateral cerebellum and right caudate; (c) increased neurite dispersion index (NDI) in left putamen. Fractional anisotropy (FA) and orientation dispersion index (ODI) were unaltered. **Conclusions:** MD reductions in subcortical regions confirm previously reported motor learning-related microstructural changes. Reduced FWF suggests tissue proportion increased following learning whereas enhanced left putamen NDI suggests a motor learning-related reorganization in brain tissue microstructure and neurite density, potentially reflecting structural brain plasticity changes.

[1]Mount Sinai Hospital, Lunenfeld-tanenbaum Research Institute, Toronto, Canada, [2]University of Toronto, Department Of Physiology, Toronto, Canada, [3]The Hospital for Sick Children, The Centre For Phenogenomics, Ontario, Canada, [4]The Hospital for Sick Children, The Centre For Applied Genomics, Toronto, Canada, [5]Toronto Western Hospital, Tanz Centre For Research In Neurodegenerative Diseases, Toronto, Canada

Dysfunction of the tau protein is the main driver in a group of sex-dependent learning and memory disorders called tauopathies (PMID:33632820). A major factor underlying the low efficacy of past tauopathy therapeutics in humans is the lack of consideration for sex and species differences. Tauopathies impact males and females at different severities and *mice* do not develop tauopathy signs as observed in humans. In comparison to *mice* models, *rat* models better resemble human tau isoform composition (PMID:19141083), tauopathy signs, and overall physiological, genetic and morphologic traits and behaviors of humans (PMID:24161192). For these reasons, we developed a novel CRISPR-Cas9 microtubule-associated protein tau homozygous knock-out (*Mapt*$^{-/-}$) rat model to study sex-specific functions of tau that may be lost in tauopathies. We began by investigating differences in synaptic plasticity in both sexes of P14 – 17 *Mapt*$^{-/-}$ rats by performing electrophysiological recordings of hippocampal Schaffer-collateral to CA1 synapses. Unlike findings in male *Mapt*$^{-/-}$ *mice,* which exhibit no long-term depression (LTD) (PMID:24298146), our findings inversely show that male and female *Mapt*$^{-/-}$*rats*, exhibit increased and no change in LTD, respectively. This is while synaptic transmission, probability-of-neurotransmitter release, and long-term potentiation are unchanged in both sexes of *Mapt*$^{-/-}$ rats. We have further established that this increased LTD in male but not female *Mapt*$^{-/-}$ rats occurs independently of *N*-methyl-$_D$-aspartate receptors (NMDARs). Taken together, our results suggest that sex, and species differences in rodent models may be critical for informing the development of efficacious therapeutics for tauopathies.

The three sisters of fate: Genetics, pathophysiology and outcomes of animal models of neurodegenerative diseases. Alzheimer's disease (AD), Parkinson's disease (PD), and Huntington's disease (HD) are neurodegenerative disorders characterized by progressive structural and functional loss of specific neuronal populations, protein aggregation, an insidious adult onset, and chronic progression. Modeling AD, PD, and HD in animal models is useful for studying the relationship between neuronal dysfunction and abnormal behaviours. Animal models are also excellent tools to test therapeutic approaches. Numerous genetic and toxin-induced models have been generated to replicate these neurodegenerative disorders. These differ in the genetic manipulation employed or the toxin used and the brain region lesioned, and in the extent to which they mimic the neuropathological and behavioral deficits seen in the corresponding human condition. Each model exhibits unique advantages and drawbacks. Here we present a comprehensive overview of the numerous AD, PD, and HD animal models currently available, with a focus on their utilities and limitations. Differences among models might underlie some of the discrepancies encountered in the literature and should be taken into consideration when designing new studies and testing putative therapies.

ACTIVITY-INDUCED POLYADENYLATION OF MRNAS IN THE BRAIN

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Bozena Kuzniewska[1], Pawel Krawczyk[2], Francois Pauzin[3], Jacek Milek[1], Clive Bramham[3,4], Andrzej Dziembowski[2], Magdalena Dziembowska[1]
[1]University of Warsaw, Centre Of New Technologies, Warsaw, Poland, [2]International Institute of Molecular and Cell Biology, Laboratory Of Rna Biology, Warsaw, Poland, [3]University of Bergen, Mohn Center For Research On The Brain, Bergen, Norway, [4]University of Bergen, Biomedicine, Bergen, Norway

Local translation of numerous synaptic proteins is essential to the maintenance and plasticity of neuronal synapses. One of the major determinants of mRNA stability and translation is the poly(A) tail. Poly(A) tail is deposited during mRNA maturation in the nucleus, still for some RNAs, its extension may occur in the cytoplasm, allowing for a context-specific regulation of translation. It has been proposed that some dendritically localized mRNAs may undergo activity-induced polyadenylation. However, the mechanism and functional impact of neuronal cytoplasmic mRNA polyadenylation are largely unknown. We applied Oxford Nanopore direct RNA sequencing to measure the genome-wide mRNA poly(A) tail dynamics upon neuronal activity. We analyzed mRNA poly(A) tail length in synaptoneurosomes stimulated *in vitro* for 3, 6 and 12 minutes. Our preliminary data show that indeed some mRNAs display lengthening of poly(A) tails in response to *in vitro* stimulation. Furthermore, we used a model of LTP (long-term synaptic plasticity) induced *in vivo* in rats. LTP was induced by high-frequency stimulation of the medial perforant path input to the dentate gyrus on one side of the rat brain (contralateral non-stimulated side served as control). As a result of these experiments we obtained a dataset of genome-wide poly(A) tail dynamics induced by LTP in the dentate gyrus. We will show and discuss the population of mRNAs that dynamically change their poy(A) tail lengths upon the stimulation.

Mitochondrial protein biogenesis in the synapse is supported by local translation.
Synapses are the regions of the neuron that enable the transmission and propagation of action potentials on the cost of high energy consumption and elevated demand for mitochondrial ATP production. The rapid changes in local energetic requirements at dendritic spines imply the role of mitochondria in the maintenance of their homeostasis. Using global proteomic analysis supported with complementary experimental approaches, we show that an essential pool of mitochondrial proteins is locally produced at the synapse indicating that mitochondrial protein biogenesis takes place locally to maintain functional mitochondria in axons and dendrites. Furthermore, we show that stimulation of synaptoneurosomes induces the local synthesis of mitochondrial proteins that are transported to the mitochondria and incorporated into the protein supercomplexes of the respiratory chain. Importantly, in a mouse model of fragile X syndrome, Fmr1 KO mice, a common disease associated with dysregulation of synaptic protein synthesis, we observed altered morphology and respiration rates of synaptic mitochondria. That indicates that the local production of mitochondrial proteins plays an essential role in synaptic functions.

Loss of serum response factor in mature neurons in the dentate gyrus alters the morphology of dendritic spines and hippocampus-dependent behavioral tasks.
Serum response factor (SRF) is a major transcription factor that regulates the expression of several plasticity-associated genes in the brain. Although the developmental expression of SRF in excitatory neurons is crucial for establishing proper hippocampal circuitry, no substantial evidence of its role in unstimulated mature neurons has been provided. The present study used time-controlled, conditional SRF knockout mice and found that the lack of SRF in adult neurons led to decreased actin levels and inactivation of the actin-severing protein cofilin 1 through its increase in phosphorylation at Ser3. The augmentation of cofilin 1 phosphorylation correlated with an alteration of dendritic spine morphology in the dentate gyrus, which was reflected by an increase in the number of spines that clustered into the long-spine category. The changes in spine

morphology coincided with a lower amplitude and frequency of miniature excitatory postsynaptic currents. Moreover, SRF knockout animals were hyperactive and exhibited impairments in hippocampus-dependent behaviors, such as digging, marble burying, and nesting. Altogether, our data indicate that the adult deletion of neuronal SRF leads to alterations of spine morphology and function and hippocampus-dependent behaviors. Thus, SRF deletion in adult neurons recapitulates some aspects of morphological, electrophysiological, and behavioral changes that are observed in such psychiatric disorders as schizophrenia and autism spectrum disorders.

Neuroligin 1, 2, and 3 Regulation at the Synapse: FMRP-Dependent Translation and Activity-Induced Proteolytic Cleavage.
Neuroligins (NLGNs) are cell adhesion molecules located on the postsynaptic side of the synapse that interact with their presynaptic partners neurexins to maintain trans-synaptic connection. Fragile X syndrome (FXS) is a common neurodevelopmental disease that often co-occurs with autism and is caused by the lack of fragile X mental retardation protein (FMRP) expression. To gain an insight into the molecular interactions between the autism-related genes, we sought to determine whether FMRP controls the synaptic levels of NLGNs. We show evidences that FMRP associates with Nlgn1, Nlgn2, and Nlgn3 mRNAs in vitro in both synaptoneurosomes and neuronal cultures. Next, we confirm local translation of Nlgn1, Nlgn2, and Nlgn3 mRNAs to be synaptically regulated by FMRP. As a consequence of elevated Nlgns mRNA translation Fmr1 KO mice exhibit increased incorporation of NLGN1 and NLGN3 into the postsynaptic membrane. Finally, we show that neuroligins synaptic level is precisely and dynamically regulated by their rapid proteolytic cleavage upon NMDA receptor stimulation in both wild type and Fmr1 KO mice. In aggregate, our study provides a novel approach to understand the molecular basis of FXS by linking the dysregulated synaptic expression of NLGNs with FMRP.

Novel calcineurin A (PPP3CA) variant associated with epilepsy, constitutive enzyme activation and downregulation of protein expression.
PPP3CA encodes calmodulin-binding catalytic subunit of calcineurin, a ubiquitously expressed calcium/calmodulin-regulated protein phosphatase. Recently de novo PPP3CA variants were reported as a cause of disease in 12 subjects presenting with epileptic encephalopathy and dysmorphic features. We describe a boy with similar phenotype and severe early onset epileptic encephalopathy in whom a novel de novo c.1324C>T (p.(Gln442Ter)) PPP3CA variant was found by whole exome sequencing. Western blot experiments in patient's cells (EBV transformed lymphocytes and neuronal cells derived through reprogramming) indicate that despite normal mRNA abundance the protein expression level is strongly reduced both for the mutated and wild-type protein. By in vitro studies with recombinant protein expressed in E. coli we show that c.1324C>T (p.(Gln442Ter)) results in constitutive activation of the enzyme. Our results confirm the role of PPP3CA defects in pathogenesis of a distinct neurodevelopmental disorder including severe epilepsy and dysmorphism and provide further functional clues regarding the pathogenic mechanism.

Rapid, experience-dependent translation of neurogranin enables memory encoding.
Experience induces de novo protein synthesis in the brain and protein synthesis is required for long-term memory. It is important to define the critical temporal window of protein synthesis and identify newly synthesized proteins required for memory formation. Using a behavioral paradigm that temporally separates the contextual exposure from the association with fear, we found that protein synthesis during the transient window of context exposure is required for contextual memory formation. Among an array of putative activity-dependent translational neuronal targets tested, we identified one candidate, a schizophrenia-associated candidate mRNA, neurogranin (Ng, encoded by the gene) responding to novel-context exposure. The Ng mRNA was recruited to the actively translating mRNA pool upon novel-context exposure, and its protein levels were rapidly increased in the hippocampus. By specifically blocking activity-dependent translation of Ng using virus-mediated molecular perturbation, we show that experience-dependent translation of Ng in the hippocampus is required for contextual memory formation. We further interrogated the molecular mechanism underlying the experience-dependent translation of Ng, and found that fragile-X mental retardation protein (FMRP) interacts with the 3'UTR of the mRNA and is required for activity-dependent translation of Ng in the synaptic compartment and contextual memory formation. Our results reveal that FMRP-mediated, experience-dependent, rapid enhancement of Ng translation in the hippocampus during the memory acquisition enables durable context memory encoding.

Adult Deletion of SRF Increases Epileptogenesis and Decreases Activity-Induced Gene Expression.
Although the transcription factor serum response factor (SRF) has been suggested to play a role in activity-dependent gene expression and mediate plasticity-associated structural changes in the hippocampus, no unequivocal evidence has been provided for its role in brain pathology, such as epilepsy. A genome-wide program of activity-induced genes that are regulated by SRF also remains unknown. In the present study, we show that the inducible and conditional deletion of SRF in the adult mouse hippocampus increases the epileptic phenotype in the kainic acid model of epilepsy, reflected by more severe and frequent seizures. Moreover, we observe a robust decrease in activity-induced gene transcription in SRF knockout mice. We characterize the genetic program controlled by SRF in neurons and using functional annotation, we find that SRF target genes are associated with synaptic plasticity and epilepsy. Several of these SRF targets function as regulators of inhibitory or excitatory balance and the structural plasticity of neurons. Interestingly, mutations in those SRF targets have found to be associated with such human neuropsychiatric disorders, as autism and intellectual disability. We also identify novel direct SRF targets in hippocampus: Npas4, Gadd45g, and Zfp36. Altogether, our data indicate that proteins that are highly upregulated by neuronal stimulation, identified in the present study as SRF targets, may function as endogenous protectors against overactivation. Thus, the lack of these effector proteins in SRF knockout animals may lead to uncontrolled excitation and eventually epilepsy.

Brain-derived neurotrophic factor induces matrix metalloproteinase 9 expression in neurons via the serum response factor/c-Fos pathway.
Brain-derived neurotrophic factor (BDNF) plays a pivotal role in the regulation of the transcription of genes that encode proplasticity proteins. In the present study, we provide evidence that stimulation of rat primary cortical neurons with BDNF upregulates matrix metalloproteinase 9 (MMP-9) mRNA and protein levels and increases enzymatic activity. The BDNF-induced MMP-9 transcription was dependent on extracellular signal-regulated kinase 1/2 (ERK1/2) pathway and c-Fos expression. Overexpression of AP-1 dimers in neurons led to MMP-9 promoter activation, with the most potent being those that contained c-Fos, whereas knockdown of endogenous c-Fos by small hairpin RNA (shRNA) reduced BDNF-mediated MMP-9 transcription. Additionally, mutation of the proximal AP-1 binding site in the MMP-9 promoter inhibited the activation of MMP-9 transcription. BDNF stimulation of neurons induced binding of endogenous c-Fos to the proximal MMP-9 promoter region. Furthermore, as the c-Fos gene is a known target of serum response factor (SRF), we investigated whether SRF contributes to MMP-9 transcription. Inhibition of SRF and its cofactors by either overexpression of dominant negative mutants or shRNA decreased MMP-9 promoter activation. In contrast, MMP-9 transcription was not dependent on CREB activity. Finally, we showed that neuronal activity stimulates MMP-9 transcription in a tyrosine kinase receptor B (TrkB)-dependent manner.

Highly pathogenic Alzheimer's disease presenilin 1 P117R mutation causes a specific increase in p53 and p21 protein levels and cell cycle dysregulation in human lymphocytes.
Cell cycle (CC) reentry in neurons precedes the formation of amyloid-β (Aβ) plaques in Alzheimer's disease (AD). CC alterations were also detected in lymphocytes from sporadic AD patients. In the present study, we investigated the influence of nine presenilin 1 (PS1) mutations (P117R, M139V, L153V, H163R, S170F, F177L, I213F, L226F, E318G) on CC and Aβ production in immortalized B-lymphocytes from familial AD (FAD) patients and in stably transfected human embryonic kidney cells. In both cell types, only the P117R mutation increased levels of key G1/S phase regulatory proteins, p53, and its effector p21, causing G1 phase prolongation with simultaneous S phase shortening, and lowering basal apoptosis. The CC changes were rescued by inhibition of p53, but not of γ-secretase. Moreover, the investigated PS1 mutants showed differences in the increased levels of secreted Aβ40 and Aβ42 and in Aβ42/Aβ40 ratios, but these differences did not correlate with CC patterns. Altogether, we found that both CC regulation and Aβ production differentiate PS1 mutations, and that CC PS1 activity is mediated by p53/p21 signaling but not by γ-secretase activity. The identified CC dysregulation linked with increased p53 and p21 protein levels distinguishes the highly pathogenic PS1 P117R mutation and may contribute to the specific severity of the clinical progression of FAD associated with the mutation in the PS1 117 site. These findings suggest that

impairment in lymphocyte CC might play a pathogenic function in AD and are relevant to the development of new diagnostic approaches and personalized therapeutic strategies.

Cell cycle regulation distinguishes lymphocytes from sporadic and familial Alzheimer's disease patients.
Cell cycle (CC) reactivation in neurons seems to underlie the development of Alzheimer's disease (AD). We analyzed whether CC alterations can be detected in immortalized lymphocytes from patients with the sporadic and the familial form of AD (SAD and FAD). Real-time polymerase chain reaction (PCR)-arrays, immunoblotting, and flow cytometry demonstrated differences in the regulation of G1/S phases between SAD lymphocytes and cells from nondemented subjects, as well as between SAD and FAD cells. SAD compared to FAD lymphocytes showed differences in expression profiles of the 90 CC genes, and a marked increase in the level of the p21 protein, which promotes G1-arrest. Accordingly, SAD but not FAD cells had a prolonged G1-phase. γ-secretase inhibition did not change the CC profiles of the cell lines. These data show that SAD involves a prolongation of the G1 phase driven by p21 pathway, which is not activated in FAD cells. Thus, the mechanism in SAD differs from FAD. Moreover, disturbances of the CC in lymphocytes have a potential diagnostic value.

ABERRANT LTP IN HTAU P301S MICE RESCUED BY ACUTE APPLICATION OF RECOMBINANT APPSα

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Jennifer Just[1], Susann Ludewig[1,2], Charlotte Bold[3], Ulrike Müller[3], Martin Korte[1,2]

Alzheimer's disease (AD) is a common neurodegenerative disease in the aging population. One of its hallmarks, in addition to Aβ plaques, is the accumulation of hyperphosphorylated Tau. Focusing on the tauopathy with the transgenic mouse model hTau.P301S we could show a progressive phenotype in hippocampal synaptic plasticity of these mice, including an aberrant long-term potentiation (LTP) and reduced basal synaptic transmission after stimulation at the Schaffer collaterals in aged mice while the long-term depression (LTD) was unaltered at the investigated ages (10-13/16-18 weeks). Previously, we could demonstrate the neuroprotective effect of the neurotrophic peptide APPsα, which is produced by the processing of the Amyloid precursor protein (APP) via α-secretases in the non-amyloidogenic pathway. In contrast to the neurodegenerative effect of Aβ, the APPsα molecule was shown to rescue phenotypes of various AD pathology models. In our approach the treatment of P301S hippocampal acute slices with a nanomolar concentration of recombinant APPsα was able to restore the increased LTP to control level. To further investigate the altered synaptic plasticity in P301S mice and its possibly missing inhibitory input, as well as to learn more about the neuro- and synaptoprotective effect of APPsα, we used a GABA receptor agonist treatment before stimulation and applied recAPPsα to wildtype acute slices. Taken together we show the potential of APPsα as a therapeutic for tauopathies in addition to its previously shown positive effect on Aβ-dependent AD phenotypes, as well as the disturbed neuronal circuits resulting in altered synaptic plasticity in the P301S model (DFG-supported, MU1457/14-1).

LINKING TEMPORALLY PROXIMAL MEMORIES: A PROCESS UNDERLAIN BY SYNAPTIC TAGGING AND CAPTURE MECHANISM

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Introduction: How is it that trivial events are sometimes remembered, which would otherwise be forgotten, when they occur temporally close to a memorable event? We investigate whether linking temporally proximal memories depends on the synaptic and tagging capture (STC) hypothesis, in which weakly stimulated cells benefit from plasticity-related proteins from temporally-close strong stimulations. **Methods:** We monitored cell ensemble activities in hippocampal CA1 using *in-vivo* Ca+ imaging while mice were allowed to freely explore to two different environments (A and B), with protein synthesis inhibition (anisomycin, 150mg/kg) introduced before environment B on day 1. The following day, mice were tested in both environments without inhibition. **Results**: Cells that were only activated in room B on day 1 displayed a significantly lower rate of reactivation on day 2 compared to cells activated in room A, suggesting that protein synthesis is critical for consolidating and retrieving cell ensembles recruited during encoding. Cells that were coactivated in both rooms on day 1 displayed a significantly higher reactivation on day 2 in room B compared to cells uniquely activated in room B on day 1. This suggests that cells coactive on day 1 benefited from the protein synthesis induced by room A, rescuing their incorporation into the cell ensemble associated to room B on day 2. **Conclusion:** These results demonstrate the existence of a STC-like mechanism in freely-exploring animals when they encode and consolidate two temporally-proximal memory traces. These findings suggest a functional role of this mechanism in temporal association of two memory traces.

ABNORMAL CHANGES IN HIPPOCAMPAL SYNAPTIC PLASTICITY ARE ACCOMPANIED BY PARVALBUMIN REDUCTIONS IN THE TGF344 RAT MODEL FOR ALZHEIMER'S DISEASE

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Yuhong Sun[1], Lauren Rimmer[1], John Gigg[2], Michael Harte[1]

Introduction: Hippocampal hyper-excitability is a causative factor in memory impairment and has been documented in many animal models for Alzheimer's disease (AD). Here, we sought to track AD-related prodromal changes in hippocampal synaptic strength and plasticity in the TgF344-AD rat model, which exhibits age-dependent beta-amyloid (Aß) aggregation, tauopathy and neuroinflammation. Methods: Electrophysiology: Evoked responses in dorsal CA1 were recorded following CA3 Schaffer stimulation in urethane-anaesthetised 6- and 9-month-old male TgF344-AD (TG) and wild-type (WT) rats, to determine the induction properties for short- and long-term synaptic plasticity and baseline connectivity. Post-mortem: Parvalbumin (PV) levels were measured in dorsal hippocampus by Simple Western analysis and immunohistochemistry of age-matched rats. Results: In contrast to 6 month-old TG rats, the 9-month-old TGs showed significantly smaller paired-pulse facilitation, and this cohort of TG animals also displayed an upwardly-shifted baseline input/output curve. Long-term potentiation induced by high-frequency stimulation was significantly reduced in CA1 of 6- and 9-month old TG rats. LTP depotentiation tested in 6-month old rats was much stronger in TG compared to WT. Immunohistochemical analysis revealed significantly lower PV levels in CA2/3 region, but not CA1 or dentate gyrus of the hippocampus in 9 month old TG rats. Work is underway to determine PV changes at 6 months old. Conclusions: These results suggest that reduced inhibition upstream of the CA3->CA1 synapse leads to abnormal changes in synaptic plasticity, which might imply a possible mechanism for disease progression at pre-symptomatic stage of AD.

Aims: Physiopathological cleavage of the amyloid precursor protein (APP) allows the secretion of Aβ but also of other peptides, including peptides secreted from the η-secretase pathway, named Aη peptides, described in Willem et al., Nature, 2015. These peptides acutely impair neuron function even at low nanomolar concentrations (Mensch et al. Alzheimers Res Ther., 2021). Here we analysed the consequences of chronic in vivo alterations of Aη peptide levels on hippocampal function. Methods: To modulate Aη levels in vivo two new mouse models were created. The first model, named MISEPA2, harbours a transgene expressing a secreted form of Aη-α allowing for a chronic increase of human Aη-α levels in the brain. The second model, named APPΔη, harbours a deletion of a portion of endogenous APP that prevents η-secretase processing. We characterized these models by analysing APP peptides levels by immunoblotting, synaptic plasticity by electrophysiology and spatial memory by submitting mice to the Morris water maze. Results: MISEPA2 mice exhibit normal levels of Aβ in the hippocampus. Long-term potentiation (LTP), long-term depression (LTD) and spatial memory are altered in these mice. APPΔη mice exhibit normal levels of Aβ in the hippocampus. LTP is normal, but LTD is absent and rescued upon acute application of synthetic Aη-α peptide. Spatial memory is impaired in these mice. Conclusions: These results show that a chronic increase of Aη-α is detrimental to hippocampal function. We also validate the hypothesis that the peptides secreted from the η-secretase pathway are necessary for endogenous modulation of synaptic communication and memory processing.

Ruhr-Universität Bochum, Department Of Neurophysiology, Bochum, Germany

Aims: The perirhinal cortex (PRC) critically engages in sensory information processing and object recognition, supported by its diverse efferent and afferent connections with other brain structures. Here, we investigated to what extent the cortical layers of areas 35 and 36 of the PRC are involved in the encoding of object dimensions. Methods: Rats explored either microscale (add item dimensions and partially concealed) or macroscale (add item dimensions and highly visible) objects for 5 min (Arc mRNA assessment). We then employed fluorescence in situ hybridization to examine the expression of nuclear Arc mRNA in the sublayers of the PRC along its rostro-caudal axis triggered by object exploration. Results: Whereas layers III and V-VI of the middle and caudal parts of area 35 showed a significant increase in nuclear Arc mRNA expression in response to both novel microscale and macroscale object exposure, only layer III of area 36 was activated when animals explored microscale objects. Conclusions: Our observations suggest a functional differentiation of areas 35 and 36 with regard to the encoding of object dimensions: Area 36 is only activated by information about smaller and less visible objects, whereas area 35 engages in object learning regardless of object dimension. Acknowledgements: This work was funded by a German Research Foundation grant to DMV (SFB874/B1; project no.: 122679504).

Type 4 serotonin receptors (5-HT_4R) have earned a place in the sun as a promising therapeutic target for the treatment of memory dysfunctions. Being highly expressed in the hippocampus, they are a target of choice to treat cognitive disorders. Beneficial effects have been described in rodents following their activation. Thus, pro-memory and anti-amnesic effects were observed in adult and aged animals, in healthy condition or in experimental models of memory deficits. To explore the underlying mechanisms, several approaches combining behavioral, optogenetic, electrophysiological and biochemical analyses, were used. We first confirmed that 5-HT_4R activation (RS67333, 1 mg/kg) before acquisition of an hippocampus-dependent memory test (object recognition), exerts beneficial effect. Besides, RS67333 showed efficacy to improve the location discrimination performances in a pattern separation task. Thereafter, electrophysiological investigations on hippocampal slices, revealed changes in long-term potentiation (LTP) magnitude following RS67333 treatment. Meanwhile, various hippocampal neurotransmitters involved in LTP were quantified by liquid chromatography coupled to tandem mass spectrometry. A significant increase in glutamate levels was measured after RS67333 administration. Overall, these observations support that the beneficial effects of 5-HT_4R activation on memory are intimately linked to changes in hippocampal synaptic plasticity. The latter are likely due to the observed variations in neurotransmitter levels. Although further experiments are needed, we here outline promising leads in the understanding of the molecular pathways involved in the beneficial effects of 5-HT_4R activation on memory.

Interplay between 5-HT4 Receptors and GABAergic System within CA1 Hippocampal Synaptic Plasticity.
The type 4 serotonin receptor (5-HT4R) is highly involved in cognitive processes such as learning and memory. Behavioral studies have shown a beneficial effect of its activation and conversely reported memory impairments by its blockade. However, how modulation of 5HT4R enables modifications of hippocampal synaptic plasticity remains elusive. To shed light on the mechanisms at work, we investigated the effects of the 5-HT4R agonist RS67333 on long-term potentiation (LTP) within the hippocampal CA1 area. Although high-frequency stimulation-induced LTP remained unaffected by RS67333, the magnitude of LTP induced by theta-burst stimulation was significantly decreased. This effect was blocked by the selective 5-HT4R antagonist RS39604. Further, 5-HT4R-induced decrease in LTP magnitude was fully abolished in the presence of bicuculline, a GABAAR antagonist; hence, demonstrating involvement of GABA neurotransmission. In addition, we showed that the application of a GABABR antagonist, CGP55845, mimicked the effect of 5-HT4R activation, whereas concurrent application of CGP55845 and RS67333 did not elicit an additive inhibition effect on LTP. To conclude, through investigation of theta burst induced functional plasticity, we demonstrated an interplay between 5-HT4R activation and GABAergic neurotransmission within the hippocampal CA1 area.

Memory Disorders Related to Hippocampal Function: The Interest of 5-HTRs Targeting.
The hippocampus has long been considered as a key structure for memory processes. Multilevel alterations of hippocampal function have been identified as a common denominator of memory impairments in a number of psychiatric and neurodegenerative diseases. For many years, the glutamatergic and cholinergic systems have been the main targets of therapeutic treatments against these symptoms. However, the high rate of drug development failures has left memory impairments on the sideline of current therapeutic strategies. This underscores the urgent need to focus on new therapeutic targets for memory disorders, such as type 4 serotonin receptors (5-HTRs). Ever since the discovery of their expression in the hippocampus, 5-HTRs have gained growing interest for potential use in the treatment of learning and memory

impairments. To date, much of the researched information gathered by scientists from both animal models and humans converge on pro-mnesic and anti-amnesic properties of 5-HTRs activation, although the mechanisms at work require more work to be fully understood. This review addresses a fundamental, yet poorly understood set of evidence of the potential of 5-HTRs to re-establish or limit hippocampal alterations related to neurological diseases. Most importantly, the potential of 5-HTRs is translated by refining hypotheses regarding the benefits of their activation in memory disorders at the hippocampal level.

The brain contains n-3 and n-6 polyunsaturated fatty acids (PUFAs), which have distinct biological activities. PUFAs are provided through the diet and aggregate in the brain since the perinatal period. Our previous data show that perinatal dietary n-3 PUFAs deficiency changes amounts of n-3 PUFAs in the hippocampus, alters spatial memory and impairs hippocampal neuronal plasticity in male mice at weaning (P21). Here, we aim at deciphering whether a n-3 PUFAs-sufficient diet reverses the effect of perinatal dietary n-3 PUFAs deficiency taking into account sex. Male and female mice were fed with n-3 PUFAs-deficient or sufficient diets until P21. Then, half of the n-3 PUFAs-deficient mice were fed with a n-3 PUFAs-sufficient diet until adulthood. We assessed spatial memory abilities, fatty acids and their metabolites in the hippocampus and plasticity. In addition, a genetically modified mouse model expressing iFat1, a C Elegans gene allowing to convert n-6 into n-3 PUFAs into Camk2-cre positive cells, was created to study whether a specific increase of n-3 PUFAs in glutamatergic neurons counteract the deleterious effect of n-3 PUFAs-deficient diet. A n-3 PUFAs-sufficient diet given at weaning restores plasticity in both male and female adult mice, while it partially restores hippocampal fatty acids levels and memory. Perinatal exposition to a deficient diet impairs hippocampal PUFAs levels, memory and plasticity. Interestingly, exposition to a sufficient diet from weaning reversed plasticity alterations and cognition as well as fatty acid levels in the brain but in a different way between the two sexes.

Ablation of nArgBP2, a candidate gene of intellectual disability (ID), caused defects in spine maturation and excitatory synapse formation in developing neurons. Surprisingly, nArgBP2 knockdown in mature neurons did not cause defects in spine morphogenesis, and its inhibitory effect was evident only when challenged with chemically-induced long-term potentiation (cLTP), raising the question of how it functions in mature neurons. Here, we found that nArgBP2 itself assembles into liquid condensates via intermolecular interaction between SH3 domains and proline-rich domains *in vitro* and in living cells. We further showed that condensate formation was counteracted by WAVE1 interaction, and regulated by calcium/calmodulin-dependent protein kinase IIα (CaMKIIα)-dependent phosphorylation. Finally, we showed that nArgBP2 also forms liquid droplets in the dendritic spines of living neurons, and these droplets were dispersed by cLTP, which coincides with spine enlargement. Blocking its interaction with WAVE abrogated spine enlargement during cLTP. Our results suggest that sequestered nArgBP2 by phase-separation at rest is dissolved by CaMKIIα-dependent phosphorylation during cLTP, which in turn interacts with WAVE1 to manifest spine enlargement. In addition to revealing the underlying mechanism of nArgBP2 functionality in mature neurons, our results also suggest its defect may contribute to the pathogenesis of ID.

A PROTEIN-DRIVEN HETEROSYNAPTIC RULE FOR SPIKING NEURAL NETWORKS

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Janko Petkovic[1,2], Maximilian Eggl[1,2], Tatjana Tchumatchenko[2,3]
[1]Collaborative Research Centre 1080, Institute Of Cell Biology And Neuroscience, Goethe University Frankfurt, Frankfurt am Main, Germany, [2]Institute of Physiological Chemistry, Mainz University Medical Center, Mainz, Germany, [3]University of Bonn Medical Center, Institute Of Experimental Epileptology And Cognition Research, Bonn, Germany

Aims: Conditions for synaptic plasticity have been extensively studied throughout the last decades to gain insight into superior cognitive functions like memory or learning and their functional drift during pathological conditions. However, a complete mechanistic model of their complex behavior has not yet been fully developed, and many state of the art modelisations still partially rely on purely heuristic rules.Therefore, our goal in this work is to investigate the molecular machinery that underlies the spatio-temporal long-term heterosynaptic plasticity evolving across hours. **Methods:** Inspired by results and experimental data presented in a related FENS abstract of our group, we will explore spatial dynamics of peri-synaptic calcium and the primary synaptic plasticity driving molecules (calmodulin, calcineurin, CaMKII). Thus, we can expand the diffusion-degradation formalism into a more complex spatio-temporal reaction-diffusion model and account for inter-protein catalytic events, spine-dendrite exchange and resource-bounded interplay. Linking this model to the spine growth rate - considered a synaptic strength proxy - will allow us to define a mathematically tractable, biologically plausible plasticity framework that will then be implemented in a feed-forward spiking neural network. **Results and conclusions:** Finally, the results obtained via the simulation will be illustrated in relation to the current literature, focusing on the direct connection between molecular species, circuit behaviour and eventual pathologic phenotype.

Aims: Age-dependent accumulation of extracellular matrix (ECM) molecules is implicated in the age-associated decline in synaptic and cognitive functions, which are common phenotypes of both normal or pathological aging. Therefore, we aimed to study age-associated changes in the expression of neural ECM-related genes and to validate new targets for rejuvenation of the aging brain and restoration of synaptic plasticity and cognition. **Methods:** In this study, we performed the qPCR analysis of major ECM-degrading and modifying enzymes in the hippocampus, behavioral analysis, electrophysiology, and immunohistochemistry. Three groups of C57BL6/J mice were studied 2- to 3-month-old (2-3M), 22- to 26-month-old (22-26M), and more than 30-month-old (>30M). **Results:** Using qPCR, we discovered a downregulation of ECM-degrading enzyme, a disintegrin, and metalloproteinase with thrombospondin motifs 5 (ADAMTS5) in hippocampal neurons and astrocytes of 24-26M and >30M mice. Therefore, we used AAV delivery to rejuvenate the hippocampus of 24-26M mice by overexpressing ADAMTS5, which indeed resulted in a loss of aggrecan and other lecticans in the perineuronal nets and improvements of the hippocampus-dependent cognitive functions. Electrophysiological studies demonstrated an enhanced long-term potentiation in the rejuvenated hippocampus of 24-26M mice. Further analysis revealed that ECM degradation in the aged brain inhibits signaling through the extrasynaptic GluN2B-NMDA receptors, which activation is known to impair LTP in aged brains. **Conclusion:** Altogether, we show that age-dependent dysregulation of the ECM proteolytic remodeling is one of the factors responsible for the accumulation of neural ECM, while stimulation of ECM remodeling by overexpression of ADAMTS5 improves hippocampal plasticity and cognitive function.

NMDA receptor-dependent long-term depression (NMDAR-LTD), a form of synaptic plasticity, has been found to be involved in processes including behavioural flexibility, reversal learning, and synaptic pruning. Despite recent advances in the understanding of this form of plasticity, its mechanisms haven't been fully elucidated. Our lab previously studied the novel role of Signal Transducer and Activator of Transcription 3 (STAT3) in NMDAR-LTD in rats. STAT3 was found to be necessary for LTD expression in the CA1 region of the hippocampus, though not in a transcription dependent manner, as determined through drug inhibition and shRNA treatment. The current study aimed to further this work by investigating the role of STAT3 in NMDAR-LTD specifically in mice using a genetic deletion approach. Mice harbouring a genetic deletion of STAT3 under the CamKII promoter were generated and confirmed through biochemical techniques. Due to the temporal expression of CamKII in CA1, 10-18-week-old male mice were used for experiments. To study the effect of STAT3 deletion on NMDAR-LTD, field recordings from stratum radiatum were performed on hippocampal slices from adult STAT3 control and knockout mice. Following treatment with 20 μM NMDA for three minutes, we found no decrease in the amount of LTD in knockout mice compared to controls. Western blotting of hippocampal slices treated with NMDA from control and knockout animals showed comparable dephosphorylation of the GluA1 subunit on S845, corroborating our electrophysiological findings. Together, these results suggest that STAT3 does not play a necessary role in NMDAR-LTD in CA1 in adult mice.

Activating transcription factor-4 promotes neuronal death induced by Parkinson's disease neurotoxins and α-synuclein aggregates.
Parkinson's disease (PD) is a neurodegenerative disease characterized by the loss of dopaminergic neurons in the substantia nigra resulting in severe and progressive motor impairments. However, the mechanisms underlying this neuronal loss remain largely unknown. Oxidative stress and ER stress have been implicated in PD and these factors are known to activate the integrated stress response (ISR). Activating transcription factor 4 (ATF4), a key mediator of the ISR, and has been reported to induce the expression of genes involved in cellular homeostasis. However, during prolonged activation ATF4 can also induce the expression of pro-death target genes. Therefore, in the present study, we investigated the role of ATF4 in neuronal cell death in models of PD. We demonstrate that PD neurotoxins (MPP+ and 6-OHDA) and α-synuclein aggregation induced by pre-formed human alpha-synuclein fibrils (PFFs) cause sustained upregulation of ATF4 expression in mouse cortical and mesencephalic dopaminergic neurons. Furthermore, we demonstrate that PD neurotoxins induce the expression of the pro-apoptotic factors Chop, Trb3, and Puma in dopaminergic neurons in an ATF4-dependent manner. Importantly, we have determined that PD neurotoxin and α-synuclein PFF induced neuronal death is attenuated in ATF4-deficient dopaminergic neurons. Furthermore, ectopic expression of ATF4 but not transcriptionally defective ATF4ΔRK restores sensitivity of ATF4-deficient neurons to PD neurotoxins. Finally, we demonstrate that the eIF2α kinase inhibitor C16 suppresses MPP+ and 6-OHDA induced ATF4 activation and protects against PD neurotoxin induced dopaminergic neuronal death. Taken together these results indicate that ATF4 promotes dopaminergic cell death induced by PD neurotoxins and pathogenic α-synuclein aggregates and highlight the ISR factor ATF4 as a potential therapeutic target in PD.

ENVIRONMENTAL ENRICHMENT INCREASES SPARSE CODING IN ADULT HIPPOCAMPUS

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Ekaterina Verdiyan, Meredith Lodge, Jan Michael Schulz, Josef Bischofberger
University of Basel, Department Of Biomedicine, Basel, Switzerland

Sparse activity and sparse coding in dentate gyrus (DG) of the hippocampus has been considered to play a key role in memory processing. Environmental enrichment, which includes larger housing and the presence of enrichment toys and running wheels, has been shown to improve hippocampus-dependent spatial learning and memory. However, how different housing conditions influence hippocampal network activity remains still largely unclear. Here we used cFos labeling to study the effect of prolonged environmental enrichment onto hippocampal network activity during exploration of a novel environment. First, we showed that exploration leads to increased activity in DG and CA1 in animals housed under both standard and enrichment conditions. However, cFos activity during exploration was lower in enriched animals in both, granule cells and CA1 pyramidal cells. Remarkably, the number of cFos-labeled cell assemblies in home cage was even more strongly decreased with enriched housing. This indicates that continuous enrichment does not increase overall hippocampal activity but improves sparse coding in DG as well as in CA1. To understand the underlying mechanisms, we explored the possibilities that inhibitory interneurons are involved. Previous data indicate that interneurons contribute to sparse coding partially via α5-subunit-containing $GABA_A$ receptors (Lodge et al. 2021, Cell Reports 37:109768). After we have blocked these receptors by applying a highly selective negative allosteric modulator α5-NAM, the number of active cells was strongly increased in enriched animals. Taken together, environmental enrichment decreases the size of hippocampal cell assemblies during spatial exploration. This might be partially mediated by increased inhibition via dendrite-targeting interneurons.

Study of the Peripheral Nerve Fibers Myelin Structure Changes during Activation of Schwann Cell Acetylcholine Receptors. In the present paper we consider a new type of mechanism by which neurotransmitter acetylcholine (ACh) regulates the properties of peripheral nerve fibers myelin. Our data show the importance of the relationship between the changes in the number of Schwann cell (SC) acetylcholine receptors (AChRs) and the axon excitation (different intervals between action potentials (APs)). Using Raman spectroscopy, an effect of activation of SC AChRs on the myelin membrane fluidity was investigated. It was found, that ACh stimulates an increase in lipid ordering degree of the myelin lipids, thus providing evidence for specific role of the "axon-SC" interactions at the axon excitation. It was proposed, that during the axon excitation, the SC membrane K+- depolarization and the Ca2+-influx led to phospholipase activation or exocytosis of intracellular membrane vesicles and myelin structure reorganization.

ARC INTERACTS WITH SPLICING FACTORS AND REGULATES ACTIVITY-DEPENDENT FORMATION OF PABP2 NUCLEAR SPECKLES

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Activity-regulated cytoskeleton associated protein (Arc/Arg3.1) is an immediate early gene which required for long-term memory formation and multiple forms of activity-dependent synaptic plasticity. Arc protein has been extensively studied in the cytoplasm and dendrites but, its role in the nucleus is little understood. In this study we performed structural, functional, and biochemical analysis to identify Arc`s nuclear interactome using rat dentate gyrus post high frequency stimulation, seize and using treated hippocampal neurons. Confocal microscopy showed that Arc occupies internal parts of the nucleus, closely associated with hnRNPs. Electron microscopy further revealed labeling at the peripheral areas of chromatin. Arc pulldown experiments performed in nuclear fractions suggest that Arc interacts with component of the splicing machinery. Collectively, our data suggest that nuclear Arc is involved in pre-mRNA processing. These data underscore multiple roles for Arc protein carried out within distinct subcellular domains.

A LOCAL DENDRITIC ROLE FOR MIR-218 IN THE REGULATION OF HOMEOSTATIC SYNAPTIC DOWNSCALING

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Homeostatic synaptic downscaling (HSD) is a negative feedback mechanism by which neurons reduce the overall strength of excitatory synapses in response to chronically elevated neuronal activity to keep their firing rates within a physiological range. Physiologically, HSD is involved during sleep in a process that promotes memory consolidation. Moreover, impairments in HSD have been associated with epilepsy and neurodevelopmental disorders. MicroRNAs (miRNAs) play an essential role in post-transcriptional gene regulation, mostly by inhibiting mRNA translation and inducing mRNA decay through the RISC complex. Among others, two activity-regulated miRNAs, miR-134 and miR-129, have previously been shown to mediate HSD. However, the relative contribution of local and cell-wide mechanisms of miRNA-dependent post-transcriptional regulation to HSD is still elusive. In this project, we performed a comprehensive multi-omics characterization of the somatic and process compartments of primary rat hippocampal neurons during HSD. By analyzing the enrichment of miRNA-binding motifs in genes displaying a compartment-specific regulation based on transcriptomics, we identified miR-218 as possible novel local regulator of HSD within neuronal dendrites. miR-218 is upregulated by PTX specifically in dendrites and required for PTX-dependent reduction in dendritic spine size. Currently, we are establishing local translation assay approaches which will allow us to investigate dendrite-specific regulation of miR-218 targets involved in HSD. Furthermore, we will assess the physiological role of miR-218 and its targets during sleep-regulated synaptic homeostasis and memory consolidation in mice. In conclusion, this project will provide novel insight into the role of local mechanisms in HSD and their relevance for cognition.

Pervasive compartment-specific regulation of gene expression during homeostatic synaptic scaling.
Synaptic scaling is a form of homeostatic plasticity which allows neurons to adjust their action potential firing rate in response to chronic alterations in neural activity. Synaptic scaling requires profound changes in gene expression, but the relative contribution of local and cell-wide mechanisms is controversial. Here we perform a comprehensive multi-omics characterization of the somatic and process compartments of primary rat hippocampal neurons during synaptic scaling. We uncover both highly compartment-specific and correlating changes in the neuronal transcriptome and proteome. Whereas downregulation of crucial regulators of neuronal excitability occurs primarily in the somatic compartment, structural components of excitatory postsynapses are mostly downregulated in processes. Local inhibition of protein synthesis in processes during scaling is confirmed for candidate synaptic proteins. Motif analysis further suggests an important role for trans-acting post-transcriptional regulators, including RNA-binding proteins and microRNAs, in the local regulation of the corresponding mRNAs. Altogether, our study indicates that, during synaptic scaling, compartmentalized gene expression changes might co-exist with neuron-wide mechanisms to allow synaptic computation and homeostasis.

Effects of increasing axial load on cervical motor control.
To investigate the effects of increasing axial load on cervical motor control. Surrogates of cervical motor control were active cervical range of motion (C-ROM) and joint position error (JPE) assessed in flexion, extension, lateroflexion and rotation directions in 49 healthy young men (mean age: 20.2 years). All measurements were executed with 0-, 1-, 2-, and 3-kg axial loads. Linear mixed models were used to assess the effects of axial loading and cervical movement-direction on C-ROM and JPE. Post-hoc analysis was performed to compare load levels. Axial loading ($p = 0.045$) and movement direction ($p < 0.001$) showed significant main effects on C-ROM as well as an interaction ($p < 0.001$). C-ROM significantly changed with 3-kg axial load by decreaseing extension (- 13.6%) and increasing lateroflexion (+ 9.9%). No significant main effect was observed of axial loading on JPE ($p = 0.139$). Cervical motor control is influenced by axial loading, which results in decreased

C-ROM in extension and increased C-ROM lateroflexion direction.

The forebrain synaptic transcriptome is organized by clocks but its proteome is driven by sleep.
Neurons have adapted mechanisms to traffic RNA and protein into distant dendritic and axonal arbors. Taking a biochemical approach, we reveal that forebrain synaptic transcript accumulation shows overwhelmingly daily rhythms, with two-thirds of synaptic transcripts showing time-of-day-dependent abundance independent of oscillations in the soma. These transcripts formed two sharp temporal and functional clusters, with transcripts preceding dawn related to metabolism and translation and those anticipating dusk related to synaptic transmission. Characterization of the synaptic proteome around the clock demonstrates the functional relevance of temporal gating for synaptic processes and energy homeostasis. Unexpectedly, sleep deprivation completely abolished proteome but not transcript oscillations. Altogether, the emerging picture is one of a circadian anticipation of messenger RNA needs in the synapse followed by translation as demanded by sleep-wake cycles.

The extracellular matrix (ECM) structure perineuronal net (PNN) is playing crucial roles in neuronal plasticity. Its composition undergoes regular modifications during the life-time, with two major periods noted: the critical period and the aging. These are associated with changes in sulfation composition of chondroitin sulphate proteoglycans. During aging, there is a significant decrease of chondroitin 6-sulfate (C6S) in the PNNs, shiftin the ratio of chondroitin 4-sulfate (C4S):C6S, concomitant with the reduction in neuronal plasticity and cognition. Using a conditional knockout model of *Chst11* (the gene coding the key enzyme for C4S synthesis, *Chst11KO)*, we have investigated the impact of decreased C4S/C6S ratio on learning, memory and general behaviour at 6- and 12-months using Morris water maze (MWM), spontaneous alternation, spontaneous novel object recognition (SOR) task, three chamber task and zero-maze. Immunohistochemically, synaptic connectivity on parvalbumin interneurons (vGLUT1/PSD95 vs vGAT/Gephyrin) and density of PNNs (WFA, aggrecan) were evaluated. Morever, the hippocampal fEPSP in acute slice was measured. In *Chst11KO* mice, a general increase of both short- and long-term memory was observed in all tasks, accompanied by preserved sociability and social novelty preference. In addition, a significant reduction of PNNs, alteration of synaptic connectivity of parvalbumin interneurons and increased fEPSPs were observed. Our results support the hypothesis that C4S restricts neuronal plasticity and provide a potential therapeutic avenue for cognitive decline in late aging and neurodegenerative disorders such as Alzheimer's disease.

Consistent and reliable encoding of sensory information is essential for an animal's survival. However, sensory input in an animal's environment is constantly changing, potentially altering the brain's molecules, synapses, and cellular circuitry. Thus, key questions concern the molecular and cellular mechanisms that dynamically maintain the functional stability of neural circuits in the brain. To address this question, we focused on the visual cortex of adult mice and took advantage of the daily sensory transitions from the dark of night to daylight and back to darkness during a single day. By using RNA-seq, patch clamp electrophysiology in acute slices, and *in vivo* longitudinal calcium imaging in awake mice, we monitor the light driven changes in molecules, synapses, and cells across a single day. At each of these levels (molecular, synaptic, and cellular), we find rapid sensory driven increases shortly after transition from darkness to light which are then normalized later in the day. Together with additional experiments in which we apply a novel genetic approach to knock-out genes overnight, our findings indicate that sensory-driven genetic changes maintain functional stability of neural circuits by regulating E/I ratio in excitatory neurons every day.

NDNF interneurons in layer 1 gain-modulate whole cortical columns according to an animal's behavioral state.
Processing of sensory information in neural circuits is modulated by an animal's behavioral state, but the underlying cellular mechanisms are not well understood. Focusing on the mouse visual cortex, here we analyze the role of GABAergic interneurons that are located in layer 1 and express Ndnf (L1 NDNF INs) in the state-dependent control over sensory processing. We find that the ongoing and sensory-evoked activity of L1 NDNF INs is strongly enhanced when an animal is aroused and that L1 NDNF INs gain-modulate local excitatory neurons selectively during high-arousal states by inhibiting their apical dendrites while disinhibiting their somata via Parvalbumin-expressing interneurons. Because active NDNF INs are evenly spread in L1 and can affect excitatory neurons across all cortical layers, this indicates that the state-dependent activation of L1 NDNF INs and the subsequent shift of inhibition in excitatory neurons toward their apical dendrites gain-modulate sensory processing in whole cortical columns.

effects of temperature on the heart and pyloric rhythms in the crab .
The heart and pyloric rhythms of crustaceans have been studied separately and extensively over many years. Local and hormonal neuromodulation and sensory inputs into these central pattern generator circuits play a significant role in an animal's response to perturbations, but are usually lost or removed during studies. To examine simultaneously the motor output of the crustacean heart and pyloric rhythms, we used photoplethysmography. In the population measured (=49), the heart rhythm frequency ranged from 0.3 to 2.3 Hz. The pyloric rhythm varied from 0.2 to 1.6 Hz. We observed a weak correlation between the frequencies of the heart and pyloric rhythms. During multiple hour-long recordings, many animals held at a controlled temperature showed strong inhibitory bouts in which the heart decreased in frequency or become quiescent and the pyloric rhythm decreased in frequency. We measured the simultaneous responses of the rhythms to temperature ramps by heating or cooling the saline bath while recording both the heart and pyloric muscle movements. , critical temperature (temperature at which muscle function is compromised) and changes in frequency were calculated for each of the rhythms tested. The heart rhythm was more robust to high temperature than the pyloric rhythm.

Learning-Related Plasticity in Dendrite-Targeting Layer 1 Interneurons.

A wealth of data has elucidated the mechanisms by which sensory inputs are encoded in the neocortex, but how these processes are regulated by the behavioral relevance of sensory information is less understood. Here, we focus on neocortical layer 1 (L1), a key location for processing of such top-down information. Using Neuron-Derived Neurotrophic Factor (NDNF) as a selective marker of L1 interneurons (INs) and in vivo 2-photon calcium imaging, electrophysiology, viral tracing, optogenetics, and associative memory, we find that L1 NDNF-INs mediate a prolonged form of inhibition in distal pyramidal neuron dendrites that correlates with the strength of the memory trace. Conversely, inhibition from Martinotti cells remains unchanged after conditioning but in turn tightly controls sensory responses in NDNF-INs. These results define a genetically addressable form of dendritic inhibition that is highly experience dependent and indicate that in addition to disinhibition, salient stimuli are encoded at elevated levels of distal dendritic inhibition. VIDEO ABSTRACT.

MOLECULAR MECHANISMS OF STRUCTURAL MAINTENANCE AND PLASTICITY IN NEURONS

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Bahar Aksan[1], Jing Yan[1], Javier Sanchez-Romero[1], Dimitris Missirlis[2,3], Daniela Mauceri[1]
[1]Heidelberg University, Izn Neurobiology, Heidelberg, Germany, [2]Max Planck Institute for Medical Research, Department Of Cellular Biophysics, Heidelberg, Germany, [3]Heidelberg University, Department Of Biophysical Chemistry, Heidelberg, Germany

Pathological changes of the dendrite architecture are hallmarks of many neurological disorders. Despite the fact that dendrites are mostly stable in adult neurons, little is known on the molecular mechanisms of dendrite maintenance and even less on its relation to structural plasticity. Previously, we identified Vascular Endothelial Growth Factor D (VEGFD) – an angio- and lymphangiogenic factor- as a crucial factor for the maintenance of dendritic morphology and the ability to form long-term memories. In neurodegeneration, such as stroke or in the excitotoxic retina, VEGFD expression is reduced and nasal or intravitreal delivery of VEGFD protects against stroke-induced damage or retinal ganglion cell death, respectively. The mechanisms of VEGFD-mediated dendrite stabilization are, however, not known. We now found that VEGFD acts like a molecular brake on neuronal morphology: normal expression of VEGFD maintains the dendritic architecture while VEGFD downregulation allows dendritic remodeling. We revealed that VEGFD stabilizes both actin and microtubules by performing atomic force microscopy as well as time-lapse live imaging in hippocampal neurons. Moreover, a phosphoproteomic screen identified several potentially VEGFD-regulated cytoskeleton-associated proteins. We functionally characterized the identified targets using gain of function and loss of function approaches. In addition, we monitored the VEGFD-regulated dynamics of dendrite structure using a machine-learning based algorithm for automatic dendrite segmentation in time-lapse series. Our study revealed the mechanisms of VEGFD-mediated dendrite maintenance and thereby contributes to our understanding of pathological dendrite aberrations.

Cyclase-associated protein 2 dimerization regulates cofilin in synaptic plasticity and Alzheimer's disease.
Regulation of actin cytoskeleton dynamics in dendritic spines is crucial for learning and memory formation. Hence, defects in the actin cytoskeleton pathways are a biological trait of several brain diseases, including Alzheimer's disease. Here, we describe a novel synaptic mechanism governed by the cyclase-associated protein 2, which is required for structural plasticity phenomena and completely disrupted in Alzheimer's disease. We report that the formation of cyclase-associated protein 2 dimers through its Cys is important for cyclase-associated protein 2 binding to cofilin and for actin turnover. The Cys-dependent cyclase-associated protein 2 homodimerization and association to cofilin are triggered by long-term potentiation and are required for long-term potentiation-induced cofilin translocation into spines, spine remodelling and the potentiation of synaptic transmission. This mechanism is specifically affected in the hippocampus, but not in the superior frontal gyrus, of both Alzheimer's disease patients and APP/PS1 mice, where cyclase-associated protein 2 is down-regulated and cyclase-associated protein 2 dimer synaptic levels are reduced. Notably, cyclase-associated protein 2 levels in the cerebrospinal fluid are significantly increased in Alzheimer's disease patients but not in subjects affected by frontotemporal dementia. In Alzheimer's disease hippocampi, cofilin association to cyclase-associated protein 2 dimer/monomer is altered and cofilin is aberrantly localized in spines. Taken together, these results provide novel insights into structural plasticity mechanisms that are defective in Alzheimer's disease.

VEGFD Protects Retinal Ganglion Cells and, consequently, Capillaries against Excitotoxic Injury.
In the central nervous system, neurons and the vasculature influence each other. While it is well described that a functional vascular system is trophic to neurons and that vascular damage contributes to neurodegeneration, the opposite scenario in which neural damage might impact the microvasculature is less defined. In this study, using an excitotoxic approach in adult mice as a tool to cause specific damage to retinal ganglion cells, we detected subsequent damage to endothelial cells in

retinal capillaries. Furthermore, we detected decreased expression of vascular endothelial growth factor D (VEGFD) in retinal ganglion cells. VEGFD supplementation via neuronal-specific viral-mediated expression or acute intravitreal delivery of the mature protein preserved the structural and functional integrity of retinal ganglion cells against excitotoxicity and, additionally, spared endothelial cells from degeneration. Viral-mediated suppression of expression of the VEGFD-binding receptor VEGFR3 in retinal ganglion cells revealed that VEGFD exerts its protective capacity directly on retinal ganglion cells, while protection of endothelial cells is the result of upheld neuronal integrity. These findings suggest that VEGFD supplementation might be a novel, clinically applicable approach for neuronal and vascular protection.

Histone Deacetylases Contribute to Excitotoxicity-Triggered Degeneration of Retinal Ganglion Cells In Vivo.
Excitotoxicity is known to modulate the nuclear accumulation, and thus activity state, of histone deacetylases (HDACs) in pyramidal neurons. In the retina, deregulation in activity and expression of different HDACs has been linked to pathological conditions such as retinitis pigmentosa, retinal ischemia, glaucoma, and acute optic nerve injury. Up to now, however, the effects of in vivo excitotoxicity on the different HDACs in retinal ganglion cells (RGCs) have not been thoroughly investigated. Here, we injected adult mice intravitreally with N-methyl-D-aspartate (NMDA) as a mean to trigger excitotoxicity-mediated RGC degeneration and we detected time-dependent loss of RGCs at 1 and 7 days after the insult. Further, we characterized the subcellular localization of HDACs belonging to class I (HDAC1, HDAC3), IIa (HDAC4, HDAC5, HDAC7, HDAC9), IIb (HDAC6, HDAC10), and IV (HDAC11) in RGCs. Our analyses revealed a differential pattern of HDACs nuclear distribution in RGCs following excitotoxicity. After 1 day, HDAC3, HDAC5, HDAC6, HDAC7, and HDAC11 showed altered subcellular localization in RGCs while 7 days after the excitotoxic insult, HDAC4 and HDAC9 were the only HDACs displaying changes in their subcellular distribution. Moreover, we found that in vivo selective inhibition of HDAC1/3 or HDAC4/5 via MS-275 (entinostat) or LMK-235, respectively, could prevent ongoing RGC degeneration. In conclusion, our results point towards a role of HDACs in RGC degeneration and identify HDAC1/3 and HDAC4/5 as potential therapeutic targets to treat degenerative retinal diseases.

Neuroprotective effect of acute ethanol intoxication in TBI is associated to the hierarchical modulation of early transcriptional responses.
Ethanol intoxication is a risk factor for traumatic brain injury (TBI) but clinical evidence suggests that it may actually improve the prognosis of intoxicated TBI patients. We have employed a closed, weight-drop TBI model of different severity (2cm or 3cm falling height), preceded (-30min) or followed (+20min) by ethanol administration (5g/Kg). This protocol allows us to study the interaction of binge ethanol intoxication in TBI, monitoring behavioral changes, histological responses and the transcriptional regulation of a series of activity-regulated genes (immediate early genes, IEGs). We demonstrate that ethanol pretreatment before moderate TBI (2cm) significantly reduces neurological impairment and accelerates recovery. In addition, better preservation of neuronal numbers and cFos+cells was observed 7days after TBI. At transcriptional level, ethanol reduced the upregulation of a subset of IEGs encoding for transcription factors such as Atf3, c-Fos, FosB, Egr1, Egr3 and Npas4 but did not affect the upregulation of others (e.g. Gadd45b and Gadd45c). While a subset of IEGs encoding for effector proteins (such as Bdnf, InhbA and Dusp5) were downregulated by ethanol, others (such as Il-6) were unaffected. Notably, the majority of genes were sensitive to ethanol only when administered before TBI and not afterwards (the exceptions being c-Fos, Egr1 and Dusp5). Furthermore, while severe TBI (3cm) induced a qualitatively similar (but quantitatively larger) transcriptional response to moderate TBI, it was no longer sensitive to ethanol pretreatment. Thus, we have shown that a subset of the TBI-induced transcriptional responses were sensitive to ethanol intoxication at the instance of trauma (ultimately resulting in beneficial outcomes) and that the effect of ethanol was restricted to a certain time window (pre TBI treatment) and to TBI severity (moderate). This information could be critical for the translational value of ethanol in TBI and for the design of clinical studies aimed at disentangling the role of ethanol intoxication in TBI.

STRUCTURAL PLASTICITY DURING VISION-DEPENDENT LEARNING IN MOUSE VISUAL CORTEX

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Diane Bissen, Gina Turrigiano
Brandeis University, Biology, Waltham, United States of America

Plasticity is a core feature of neurons and neuronal networks. While functionally distinct forms of plasticity have been intensively studied in isolation, much remains elusive about how they cooperate to refine circuit function. For instance, it is still poorly understood how Hebbian and homeostatic plasticity cooperate to ensure memory encoding and consolidation during and after learning – i.e., how connectivity can change without destabilizing network activity and function. Furthermore, while Hebbian learning is implemented by morphological changes embodying the new memory, the structural correlates of homeostatic plasticity remain unclear. Here, we investigate structural plasticity *in vivo* during cricket hunting, a vision-dependent, intrinsically rewarding and ethologically relevant learning paradigm. Cricket hunting induces a dramatic perturbation to network activity followed by a slow return to baseline, consistent with sequential Hebbian learning and homeostatic scaling down. We show that during the critical period, when experience-dependent plasticity is at its peak, mice learn to hunt crickets in a few consecutive sessions and retain that skill after a break. Using chronic two-photon imaging in awake critical-period animals, we assess changes in spine density and morphology of pyramidal neurons in the primary visual cortex of mice as they encode and memorize their new hunting skill. These experiments allow us to tease apart the respective contributions of Hebbian and homeostatic mechanisms to structural plasticity and memory encoding and consolidation in a natural and self-rewarding learning paradigm.

AMPA receptors and their minions: auxiliary proteins in AMPA receptor trafficking.
To correctly transfer information, neuronal networks need to continuously adjust their synaptic strength to extrinsic stimuli. This ability, termed synaptic plasticity, is at the heart of their function and is, thus, tightly regulated. In glutamatergic neurons, synaptic strength is controlled by the number and function of AMPA receptors at the postsynapse, which mediate most of the fast excitatory transmission in the central nervous system. Their trafficking to, at, and from the synapse, is, therefore, a key mechanism underlying synaptic plasticity. Intensive research over the last 20 years has revealed the increasing importance of interacting proteins, which accompany AMPA receptors throughout their lifetime and help to refine the temporal and spatial modulation of their trafficking and function. In this review, we discuss the current knowledge about the roles of key partners in regulating AMPA receptor trafficking and focus especially on the movement between the intracellular, extrasynaptic, and synaptic pools. We examine their involvement not only in basal synaptic function, but also in Hebbian and homeostatic plasticity. Included in our review are well-established AMPA receptor interactants such as GRIP1 and PICK1, the classical auxiliary subunits TARP and CNIH, and the newest additions to AMPA receptor native complexes.

EphrinB2 and GRIP1 stabilize mushroom spines during denervation-induced homeostatic plasticity.
Despite decades of work, much remains elusive about molecular events at the interplay between physiological and structural changes underlying neuronal plasticity. Here, we combined repetitive live imaging and expansion microscopy in organotypic brain slice cultures to quantitatively characterize the dynamic changes of the intracellular versus surface pools of GluA2-containing α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptors (AMPARs) across the different dendritic spine types and the shaft during hippocampal homeostatic plasticity. Mechanistically, we identify ephrinB2 and glutamate receptor interacting protein (GRIP) 1 as mediating AMPAR relocation to the mushroom spine surface following lesion-induced denervation. Moreover, stimulation with the ephrinB2 specific receptor EphB4 not only prevents the lesion-induced disappearance of mushroom spines but is also sufficient to shift AMPARs to the surface and rescue spine recovery in a GRIP1 dominant-negative background. Thus, our results unravel a crucial role for ephrinB2 during homeostatic plasticity and identify a potential pharmacological target to improve dendritic spine plasticity upon injury.

GRIP1 Binds to ApoER2 and EphrinB2 to Induce Activity-Dependent AMPA Receptor Insertion at the Synapse.
Regulation of α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptor trafficking in response to neuronal activity is critical for synaptic function and plasticity. Here, we show that neuronal activity induces the binding of ephrinB2 and ApoER2 receptors at the postsynapse to regulate de novo insertion of AMPA receptors. Mechanistically, the multi-PDZ adaptor glutamate-receptor-interacting protein 1 (GRIP1) binds ApoER2 and bridges a complex including ApoER2, ephrinB2, and AMPA receptors. Phosphorylation of ephrinB2 in a serine residue (Ser-9) is essential for the stability of such a complex. In vivo, a mutation on ephrinB2 Ser-9 in mice results in a complete disruption of the complex, absence of ApoER2 downstream signaling, and impaired activity-induced and ApoER2-mediated AMPA receptor insertion. Using compound genetics, we show the requirement of this complex for long-term potentiation (LTP). Together, our findings uncover a cooperative ephrinB2 and ApoER2 signaling at the synapse, which serves to modulate activity-dependent AMPA receptor dynamic changes during synaptic plasticity.

EphrinB2 regulates VEGFR2 during dendritogenesis and hippocampal circuitry development.
Vascular endothelial growth factor (VEGF) is an angiogenic factor that play important roles in the nervous system, although it is still unclear which receptors transduce those signals in neurons. Here, we show that in the developing hippocampus VEGFR2 (also known as KDR or FLK1) is expressed specifically in the CA3 region and it is required for dendritic arborization and spine morphogenesis in hippocampal neurons. Mice lacking VEGFR2 in neurons () show decreased dendritic arbors and spines as well as a reduction in long-term potentiation (LTP) at the associational-commissural - CA3 synapses. Mechanistically, VEGFR2 internalization is required for VEGF-induced spine maturation. In analogy to endothelial cells, ephrinB2 controls VEGFR2 internalization in neurons. VEGFR2-ephrinB2 compound mice () show reduced dendritic branching, reduced spine head size and impaired LTP. Our results demonstrate the functional crosstalk of VEGFR2 and ephrinB2 in vivo to control dendritic arborization, spine morphogenesis and hippocampal circuitry development.

HOXA5 localization in postnatal and adult mouse brain is suggestive of regulatory roles in postmitotic neurons.
Hoxa5 is a member of the Hox gene family, which plays critical roles in successive steps of the central nervous system formation during embryonic and fetal development. Hoxa5 expression in the adult mouse brain has been reported, suggesting that this gene may be functionally required in the brain after birth. To provide further insight into the Hoxa5 expression pattern and potential functions in the brain, we have characterized its neuroanatomical profile from embryonic stages to adulthood. While most Hox mapping studies have been based solely on transcript analysis, we extended our analysis to HOXA5 protein localization in adulthood using specific antibodies. Our results show that Hoxa5 expression appears in the most caudal part of the hindbrain at fetal stages, where it is maintained until adulthood. In the medulla oblongata and pons, we detected Hoxa5 expression in many precerebellar neurons and in several nuclei implicated in the control of autonomic functions. In these territories, the HOXA5 protein is present solely in neurons, specifically in γ-aminobutyric acid (GABA)ergic, glutamatergic, and catecholaminergic neurons. Finally, we also detected Hoxa5 transcripts, but not the HOXA5 protein, in the thalamus and the cortex, from postnatal stages to adult stages, and in the cerebellum at adulthood. We provide evidence that some larger variants of Hoxa5 transcripts are present in these territories. Our mapping analysis allowed us to build hypotheses regarding HOXA5 functions in the nervous system after birth, such as a potential role in the establishment and refinement/plasticity of precerebellar circuits during postnatal and adult life. Vangl2, a core protein of the Wnt/PCP pathway, is a known key player in morphogenesis. One of our recent studies has also linked it to the regulation of cognitive function. However, we lack information on the precise role of Vangl2 in different types of synapses associated to specific cognitive processes. Here, we found that Vangl2 is essential to the development and function of a specific hippocampal connexion, the MFB/TE synapse. We show that Vangl2 is enriched in the postnatal hippocampus, specifically in the DG and CA3. Using 3D reconstruction of both confocal and SBFSEM acquisitions, we show that the early genetic ablation of *vangl2* in mice leads to aberrant morphogenesis of the MFB synapse with long lasting consequences on its structural plasticity. This morphological defect is accompanied by molecular modifications in both pre- and post-synaptic compartments, as well as basal transmission deficits. Lastly, we show that the early loss of Vangl2 leads to specific reference memory deficits in adult animals. Altogether, we show that Vangl2-dependent mechanisms are critical for the correct postnatal morphogenesis and function of the MFB/TE synapse, and altering those mechanisms have long lasting consequences on the flexibility of reference memory. Our data uncover the importance of the PCP pathway in the establishment of hippocampal synaptic connexions and in long term memory.

GRANULE CELLS OF TUMOR NECROSIS FACTOR (TNF)-DEFICIENT MICE SHOW ALTERATIONS IN SPINE DENSITY AND SIZE

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Dinko Smilović[1], Michael Rietsche[2], Alexander Drakew[2], Thomas Deller[2], Mario Vukšić[1]

Aims: Spines are sites of synaptic transmission and synaptic plasticity. Recent findings suggest that the spine population should be viewed as a continuum. Furthermore, the size of the spine head is tightly correlated with AMPA-R density and the strength of synaptic transmission. Since TNF is important in synaptic transmission, we wondered how a lack of constitutive levels of TNF affects spine head size and spine density of dentate granule cells. We extended our investigations to the actin-modulating protein Synaptopodin (SP), which labels the spine apparatus organelle and is a component of stable and strong spines. Methods: Perfusion fixed hippocampal sections of adult male wildtype and TNF-/- mice were used. Single granule cells were injected with fluorescent dye, immunolabeled for SP, imaged in a confocal microscope, and single dendritic segments were analyzed by an investigator blind to genotype. Results: Compared to WTs, TNF-/- segments had ~20% fewer spines. Furthermore, the distribution of spines was changed: The fractions of large and small spines were increased, while the fraction of medium-sized spines was decreased. Large spines also contained larger SP clusters, whereas small spines were almost devoid of SP. Conclusions: TNF-/- granule cells exhibit fewer spines and an increase in the population of large spines. This change is similar to the response of granule cells to entorhinal denervation. In both settings, granule cells may increase the size of their large spines (and the size of SP clusters) to homeostatically compensate for spine loss.

Constitutive tumor necrosis factor (TNF)-deficiency causes a reduction in spine density in mouse dentate granule cells accompanied by homeostatic adaptations of spine head size.
The majority of excitatory synapses terminating on cortical neurons are found on dendritic spines. The geometry of spines, in particular the size of the spine head, tightly correlates with the strength of the excitatory synapse formed with the spine. Under conditions of synaptic plasticity, spine geometry may change, reflecting functional adaptations. Since the cytokine tumor necrosis factor (TNF) has been shown to influence synaptic transmission as well as Hebbian and homeostatic forms of synaptic plasticity, we speculated that TNF-deficiency may cause concomitant structural changes at the level of dendritic spines. To address this question, we analyzed spine density and spine head area of Alexa568-filled granule cells in the dentate gyrus of adult C57BL/6J and TNF-deficient (TNF-KO) mice. Tissue sections were double-stained for the actin-modulating and plasticity-related protein synaptopodin (SP), a molecular marker for strong and stable spines. Dendritic segments of TNF-deficient granule cells exhibited ~20% fewer spines in the outer molecular layer of the dentate gyrus compared to controls, indicating a reduced afferent innervation. Of note, these segments also had larger spines containing larger SP-clusters. This pattern of changes is strikingly similar to the one seen after denervation-associated spine loss following experimental entorhinal denervation of granule cells: Denervated granule cells increase the SP-content and strength of their remaining spines to homeostatically compensate for those that were lost. Our data suggest a similar compensatory mechanism in TNF-deficient granule cells in response to a reduction in their afferent innervation.

Transient Subplate Sublayer Forms Unique Corridor for Differential Ingrowth of Associative Pulvinar and Primary Visual Projection in the Prospective Visual Cortical Areas of the Human Fetal Occipital Lobe.
Cytoarchitectonical parcellation of the visual cortex into the striate and extrastriate cortex requires complex histogenetic events within a precise spatio-temporal frame to attain the specification of areal domains and associated thalamocortical connections during the fetal brain development. We analyzed a deep subplate cellular monolayer (subplate "corridor" cells) present during a restricted period of 13-15 postconceptional weeks, showing the 3D caudo-ventro-medial position in the human fetal occipital lobe, corresponding to the segregation point of pulvinocortical and geniculocortical fibers at the

prospective area 17/18 border. Immunofluorescence stainings revealed subplate "corridor" cells as the specific class of the deepest subplate neurons (NeuN+, Tbr1+, Cplx3+) expressing axon guidance molecules (Sema-3A+, EphA6+), presumably for the attraction of pulvinocortical axons and the repulsion of geniculocortical axons growing at that time (SNAP25+, Syn+, FN+). Furthermore, quantitative analysis of the subplate "corridor" region of interest, considering cell number, immunofluorescence signal intensity per cell and per region, revealed significant differences to other regions across the tangential circumference of the developing cerebral wall. Thus, our study sheds new light on the deepest subplate sublayer, strategically aligned along the growing axon systems in the prospective visual system, suggesting the establishment of the area 17/18 border by differential thalamocortical input during the fetal brain development.

The actin-modulating protein synaptopodin mediates long-term survival of dendritic spines.
Large spines are stable and important for memory trace formation. The majority of large spines also contains synaptopodin (SP), an actin-modulating and plasticity-related protein. Since SP stabilizes F-actin, we speculated that the presence of SP within large spines could explain their long lifetime. Indeed, using 2-photon time-lapse imaging of SP-transgenic granule cells in mouse organotypic tissue cultures we found that spines containing SP survived considerably longer than spines of equal size without SP. Of note, SP-positive (SP+) spines that underwent pruning first lost SP before disappearing. Whereas the survival time courses of SP+ spines followed conditional two-stage decay functions, SP-negative (SP-) spines and all spines of SP-deficient animals showed single-phase exponential decays. This was also the case following afferent denervation. These results implicate SP as a major regulator of long-term spine stability: SP clusters stabilize spines, and the presence of SP indicates spines of high stability.

Molecular Mechanisms of Neurodegeneration Related to Hexanucleotide Repeat Expansion.
Two clinically distinct diseases, amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD), have recently been classified as two extremes of the FTD/ALS spectrum. The neuropathological correlate of FTD is frontotemporal lobar degeneration (FTLD), characterized by tau-, TDP-43-, and FUS-immunoreactive neuronal inclusions. An earlier discovery that a hexanucleotide repeat expansion mutation in chromosome 9 open reading frame 72 () gene causes ALS and FTD established a special subtype of ALS and FTLD with TDP-43 pathology (C9FTD/ALS). Normal individuals carry 2-10 hexanucleotide GGGGCC repeats in the gene, while more than a few hundred repeats represent a risk for ALS and FTD. The proposed molecular mechanisms by which repeat expansions induce neurodegenerative changes are C9orf72 loss-of-function through haploinsufficiency, RNA toxic gain-of-function, and gain-of-function through the accumulation of toxic dipeptide repeat proteins. However, many more cellular processes are affected by pathological processes in C9FTD/ALS, including nucleocytoplasmic transport, RNA processing, normal function of nucleolus, formation of membraneless organelles, translation, ubiquitin proteasome system, Notch signalling pathway, granule transport, and normal function of TAR DNA-binding protein 43 (TDP-43). Although the exact molecular mechanisms through which repeat expansions account for neurodegeneration have not been elucidated, some potential therapeutics, such as antisense oligonucleotides targeting hexanucleotide GGGGCC repeats in mRNA, were successful in preclinical trials and are awaiting phase 1 clinical trials. In this review, we critically discuss each proposed mechanism and provide insight into the most recent studies aiming to elucidate the molecular underpinnings of C9FTD/ALS.

REORGANIZATION OF FOREBRAIN POPULATIONS IN A MODEL OF CHRONIC EPILEPSY INDUCED BY STATUS EPILEPTICUS.

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Joana I. Soares[1,2,3,4], Catarina Da Costa[2], Ítalo Rosal Lustosa[5], Nikolay Lukoyanov[1,2]
[1]Neuronal Networks, Institute for Research and Innovation in Health, University Of Porto, Porto, Portugal, [2]Biomedicine, Faculty of Medicine, University Of Porto, Porto, Portugal, [3]Polytechnic Coimbra, Coimbra Health School, Coimbra, Portugal, [4]Hospital de Santa Maria Maior, Barcelos, Braga, Portugal, [5]Federal University of Ceará, Center For Drug Research And Development Laboratory Of Neuropharmacology, Fortaleza, Brazil

Aim: Temporal lobe epilepsy (TLE) is the most common form of symptomatic epilepsy where more than 80% of patients develop pharmacoresistance. Although hippocampal sclerosis is one of the morphological hallmarks in TLE, forebrain nuclei are also an important target of epileptogenic mechanisms. The aim of this study was to evaluate the epilepsy-related plasticity in basal forebrain nuclei based on a possible functional interaction between the GABAergic and cholinergic systems. **Methods:** Adult Wistar rats were treated with kainic acid (KA) to induce status epilepticus, leading to the development of chronic epilepsy. Sections were analyzed for parvalbumin-immunostained cells (number and density) and cholinergic varicosity density on the medial septum. MANOVA was used for statistical comparison, with subsequent ANOVAs for significant results, at a significance level of .05. **Results:** A total of 6 control and 5 epileptic animals were analyzed. A reduction in parvalbumin cell number (12849±2715 vs. 9372±1336) and density (16.2±2.62 vs. 10.5±1.00) was observed in KA-group, opposing to an increase in cholinergic varicosities (47.9±11.1 vs. 69.4±17.8 per 30000μm^2). MANOVA showed a significant effect of group on the three dependent variables (Wilks' lambda=.19, $F(3,7)=9.71$, $p=.007$, $\eta_p^2=.81$). ANOVA revealed significant differences between groups on parvalbumin cell number ($F(1,9)=6.74$, $p=.029$, $\eta_p^2=.43$) and density ($F(1,9)=21.2$, $p=.001$, $\eta_p^2=.70$), and cholinergic varicosities ($F(1,9)=6.03$, $p=.036$, $\eta_p^2=.40$). **Conclusion:** In epileptic rats, basal forebrain plasticity appears to be a key mechanism during epileptogenesis. The reduction in GABAergic population and the increased density of cholinergic fibers in this region can partly account for the enhanced excitability of hippocampal circuits in epilepsy.

MORPHOLOGICAL CHARACTERIZATION OF PYRAMIDAL NEURONS IN THE PREFRONTAL CORTEX OF CYLD KNOCKOUT MOUSE MODEL.

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Lorenzo Mattioni[1], Leonardo Nardi[1], Giulia Treccani[1,2], Michael Schmeisser[1]
[1]University Medical Center of the Johannes Gutenberg-University Mainz, Institute For Microscopic Anatomy And Neurobiology, Mainz, Germany, [2]University Medical Center Mainz, Department Of Psychiatry And Psychotherapy, Mainz, Germany, Germany

Cylindromatosis lysine 63 deubiquitinase (CYLD) is highly expressed in the brain, particularly at the postsynaptic density (PSD). CYLD plays a key role in the brain by modulating the mammalian target of rapamycin (mTOR) signaling and autophagy at the synapse. CYLD deletion in mice causes a reduction in hippocampal network excitability and long-term potentiation together with a decrease of dendrite total length and in the total number of basal spines CA1 pyramidal neurons. Furthermore, CYLD Knockout (KO) mice display autism-like phenotypes including impaired social communication, increased repetitive behavior, and cognitive dysfunction.
To identify possible morphological correlates of the observed abnormalities of behavior and cognition and since cortical areas in CYLD KO mice have not been investigated yet, the morphology of pyramidal neurons in cortical layer 2/3 of the medial prefrontal cortex (mPFC) was analyzed.
A double transgenic mouse line CYLD KO Thy1-GFP line M was used to characterize the excitatory cortical neurons in the mPFC.
Since synapse elimination has been shown to be altered in the cortex of mouse models of autism spectrum disorder, mice at postnatal day 42, who are characterized by a period of extensive synaptic pruning, were employed to determine if CYLD deletion influences dendritic branches and spine morphology changes of pyramidal neurons.
This study will shed light on the role of the CYLD gene in prefrontal cortex synaptic plasticity in adolescent mice that, if altered, may contribute to the already observed autism-like phenotypes.

Abnormal Whisker-Dependent Behaviors and Altered Cortico-Hippocampal Connectivity in Shank3b-/- Mice.
Abnormal tactile response is an integral feature of Autism Spectrum Disorders (ASDs), and hypo-responsiveness to tactile stimuli is often associated with the severity of ASDs core symptoms. Patients with Phelan-McDermid syndrome (PMS), caused by mutations in the SHANK3 gene, show ASD-like symptoms associated with aberrant tactile responses. The neural underpinnings of these abnormalities are still poorly understood. Here we investigated, in Shank3b-/- adult mice, the neural substrates of whisker-guided behaviors, a key component of rodents' interaction with the surrounding environment. We assessed whisker-dependent behaviors in Shank3b-/- adult mice and age-matched controls, using the textured novel object recognition (tNORT) and whisker nuisance (WN) test. Shank3b-/- mice showed deficits in whisker-dependent texture discrimination in tNORT and behavioral hypo-responsiveness to repetitive whisker stimulation in WN. Sensory hypo-responsiveness was accompanied by a significantly reduced activation of the primary somatosensory cortex (S1) and hippocampus, as measured by c-fos mRNA induction, a proxy of neuronal activity following whisker stimulation. Moreover, resting-state fMRI showed a significantly reduced S1-hippocampal connectivity in Shank3b mutants, in the absence of altered connectivity between S1 and other somatosensory areas. Impaired crosstalk between hippocampus and S1 might underlie Shank3b-/- hypo-reactivity to whisker-dependent cues, highlighting a potentially generalizable somatosensory dysfunction in ASD.

OPTOGENETIC NEURAL PLASTICITY IN SOMATOSTATIN-EXPRESSING INTERNEURONS TO SUPPRESS COCAINE-SEEKING BEHAVIOUR

POSTER SESSION 01 - SECTION: SYNAPTIC PLASTICITY AND COGNITION

Giuliano Didio[1], Ella Porra[1], Teemu Aitta-Aho[2], Juzoh Umemori[1], Eero Castren[3]
[1]University of Helsinki, Neuroscience Center, Helsinki, Finland, [2]University of Helsinki, Department Of Pharmacology, Faculty Of Medicine, Helsinki, Finland, [3]University of Helsinki, Neuroscience Center, Hilife, Helsinki, Finland

Addiction is a highly debilitating condition and one of its most challenging features is the high rate of relapse, even after a long time from the last substance use.
Research showed that both the plasticity-related trophic factor BDNF and its receptor TrkB are needed for the development of a reward-seeking behaviour in animal models, and that plasticity in the Ventro-Medial Pre-Frontal Cortex (vmPFC) is involved in the extinction of the cocaine conditioning and in the reduction of relapse in cocaine-conditioned animals.
Somatostatin (SST) expressing interneurons have a role in modulating the cocaine-seeking behaviour in mice, and they are involved in neuronal plasticity and connection wiring. The role plasticity in SST neurons in the extinction and relapse of the cocaine conditioning, however, has still not been investigated.
Using a Conditional Place Preference (CPP) paradigm, with mice in which TrkB has been knocked-down in SST neurons, we demonstrated that blocking plasticity in SST neurons impairs the cocaine-conditioning extinction normally seen in extinction-trained mice.
After this observation we asked whether by boosting plasticity in SST neurons in the vmPFC we could not only facilitate the extinction of the cocaine-conditioning but consolidate it and make it long-lasting.
With a new type of optogenetic tool that allows for a light-induced activation of neural plasticity in SST neurons during the cocaine-conditioning extinction training, we aim to consolidate the “extinction” network, making it long-lasting and reduce the rate of relapse, one of the main challenges when treating addictive behaviors.

Pharmacological and optical activation of TrkB in Parvalbumin interneurons regulate intrinsic states to orchestrate cortical plasticity.
Elevated states of brain plasticity typical for critical periods of early postnatal life can be reinstated in the adult brain through interventions, such as antidepressant treatment and environmental enrichment, and induced plasticity may be critical for the antidepressant action. Parvalbumin-positive (PV) interneurons regulate the closure of developmental critical periods and can alternate between high and low plasticity states in response to experience in adulthood. We now show that PV plasticity states and cortical networks are regulated through the activation of TrkB neurotrophin receptors. Visual cortical plasticity induced by fluoxetine, a widely prescribed selective serotonin reuptake inhibitor (SSRI) antidepressant, was lost in mice with reduced expression of TrkB in PV interneurons. Conversely, optogenetic gain-of-function studies revealed that activation of an optically activatable TrkB (optoTrkB) specifically in PV interneurons switches adult cortical networks into a state of elevated plasticity within minutes by decreasing the intrinsic excitability of PV interneurons, recapitulating the effects of fluoxetine. TrkB activation shifted cortical networks towards a low PV configuration, promoting oscillatory synchrony, increased excitatory-inhibitory balance, and ocular dominance plasticity. OptoTrkB activation promotes the phosphorylation of Kv3.1 channels and reduces the expression of Kv3.2 mRNA providing a mechanism for the lower excitability. In addition, decreased expression and puncta of Synaptotagmin2 (Syt2), a presynaptic marker of PV interneurons involved in Ca-dependent neurotransmitter release, suggests lower inputs onto pyramidal neurons suppressing feed-forward inhibition. Together, the results provide mechanistic insights into how TrkB activation in PV interneurons orchestrates the activity of cortical networks and mediating antidepressant responses in the adult brain.

iPlasticity: Induced juvenile-like plasticity in the adult brain as a mechanism of antidepressants.

FENS Forum 2022
9-13 July 2022 | Paris, France

The network hypothesis of depression proposes that mood disorders reflect problems in information processing within particular neural networks. Antidepressants (AD), including selective serotonin reuptake inhibitors (SSRI), function by gradually improving information processing within these networks. AD have been shown to induce a state of juvenile-like plasticity comparable to that observed during developmental critical periods: Such critical-period-like plasticity allows brain networks to better adapt to extrinsic and intrinsic signals. We have coined this drug-induced state of juvenile-like plasticity 'iPlasticity.' A combination of iPlasticity induced by chronic SSRI treatment together with training, rehabilitation, or psychotherapy improves symptoms of neuropsychiatric disorders and issues underlying the developmentally or genetically malfunctioning networks. We have proposed that iPlasticity might be a critical component of AD action. We have demonstrated that iPlasticity occurs in the visual cortex, fear erasure network, extinction of aggression caused by social isolation, and spatial reversal memory in rodent models. Chronic SSRI treatment is known to promote neurogenesis and to cause dematuration of granule cells in the dentate gyrus and of interneurons, especially parvalbumin interneurons enwrapped by perineuronal nets in the prefrontal cortex, visual cortex, and amygdala. Brain-derived neurotrophic factor (BDNF), via its receptor tropomyosin kinase receptor B, is involved in the processes of synaptic plasticity, including neurogenesis, neuronal differentiation, weight of synapses, and gene regulation of synaptic formation. BDNF can be activated by both chronic SSRI treatment and neuronal activity. Accordingly, the BDNF/tropomyosin kinase receptor B pathway is critical for iPlasticity, but further analyses will be needed to provide mechanical insight into the processes of iPlasticity.

Until the process synaptogenesis, brain development is largely controlled at the transcriptional level. Mutations in transcription factors may cause dysregulation of gene expression programs and disrupt the structure and/or function of spiny synapses, which may be an important substrate in the pathogenesis of neurodevelopmental disorders such as autism or schizophrenia. Thus, disentangling the mechanisms underlying developmental dendritic spine maturation is crucial to better understand neuropsychiatric diseases. Here, we demonstrate the novel role of the major transcriptional regulator - **Serum Response Factor (SRF)** in the regulation of molecular, structural, and functional aspects of developmental glutamatergic synapse maturation. We used *in vivo* and *in vitro* models of SRF deletion enabling specific, time-controlled, neuronal SRF depletion in order to precede the stage of intense spinogenesis and study long-term consequences of SRF-deficiency for neuronal plasticity. By implementing molecular, imaging, and behavioral techniques we show that early, postnatal SRF deletion in the hippocampus increased the percentage of immature dendritic spines, downregulated the level of AMPA receptors – GluA1 and GluA2, and decreased the number of functional synapses. Additionally, our preliminary multichannel recording data suggest that SRF knock-down may impair general neuronal network activity. Moreover, the time-controlled SRF loss had a profound impact on animals' social behavior. Molecular and behavioral phenotype described in SRF-deficient mice shares similar characteristics with ASD mice models. Altogether, developmental SRF-dependent modulation of excitatory synapse structure and function exerts long-term consequences on animals social behavior later in life.

S-Palmitoylation of Synaptic Proteins as a Novel Mechanism Underlying Sex-Dependent Differences in Neuronal Plasticity. Although sex differences in the brain are prevalent, the knowledge about mechanisms underlying sex-related effects on normal and pathological brain functioning is rather poor. It is known that female and male brains differ in size and connectivity. Moreover, those differences are related to neuronal morphology, synaptic plasticity, and molecular signaling pathways. Among different processes assuring proper synapse functions are posttranslational modifications, and among them, S-palmitoylation (S-PALM) emerges as a crucial mechanism regulating synaptic integrity. Protein S-PALM is governed by a family of palmitoyl acyltransferases, also known as DHHC proteins. Here we focused on the sex-related functional importance of DHHC7 acyltransferase because of its S-PALM action over different synaptic proteins as well as sex steroid receptors. Using the mass spectrometry-based PANIMoni method, we identified sex-dependent differences in the S-PALM of synaptic proteins potentially involved in the regulation of membrane excitability and synaptic transmission as well as in the signaling of proteins involved in the structural plasticity of dendritic spines. To determine a mechanistic source for obtained sex-dependent changes in protein S-PALM, we analyzed synaptoneurosomes isolated from DHHC7-/- (DHHC7KO) female and male mice. Our data showed sex-dependent action of DHHC7 acyltransferase. Furthermore, we revealed that different S-PALM proteins control the same biological processes in male and female synapses.

Prophylactic Ketamine Treatment Promotes Resilience to Chronic Stress and Accelerates Recovery: Correlation with Changes in Synaptic Plasticity in the CA3 Subregion of the Hippocampus.
Ketamine is an -methyl-d-aspartate receptor antagonist that has gained wide attention as a potent antidepressant. It has also been recently reported to have prophylactic effects in animal models of depression and anxiety. Alterations of neuroplasticity in different brain regions; such as the hippocampus; prefrontal cortex; and amygdala; are a hallmark of stress-related disorders; and such changes may endure beyond the treatment of symptoms. The present study investigated whether a prophylactic injection of ketamine has effects on structural plasticity in the brain in mice that are subjected to chronic unpredictable stress followed by an 8-day recovery period. Ketamine administration (3 mg/kg body weight) 1 h before stress exposure increased the number of resilient animals immediately after the cessation of stress exposure and positively influenced the recovery of susceptible animals to hedonic deficits. At the end of the recovery period; ketamine-treated animals exhibited significant differences in dendritic spine density and dendritic spine morphology in brain regions associated with depression compared with saline-treated animals. These results confirm previous findings of the prophylactic effects of ketamine and provide further evidence of an association between the antidepressant-like effect of ketamine and alterations of structural plasticity in the brain.

A dominant dendrite phenotype caused by the disease-associated G253D mutation in doublecortin (DCX) is not due to its endocytosis defect.
Doublecortin (DCX) is a protein needed for cortical development, and mutations cause cortical malformations in humans. The microtubule-binding activity of DCX is well-described and is important for its function, such as supporting neuronal migration and dendrite growth during development. Previous work showed that microtubule binding is not sufficient for DCX-mediated promotion of dendrite growth and that domains in DCX's C terminus are also required. The more C-terminal regions of DCX bind several other proteins, including the adhesion receptor neurofascin and clathrin adaptors. We recently identified a role for DCX in endocytosis of neurofascin. The disease-associated DCX-G253D mutant protein is known to be deficient in binding neurofascin, and we now asked if disruption of neurofascin endocytosis underlies the DCX-G253D-associated pathology. We first demonstrated that DCX functions in endocytosis as a complex with both the clathrin adaptor AP-2 and neurofascin: disrupting either clathrin adaptor binding (DCX-ALPA) or neurofascin binding (DCX-G253D) decreased neurofascin endocytosis in primary neurons. We then investigated a known function for DCX, namely, increasing dendrite growth in cultured neurons. Surprisingly, we found that the DCX-ALPA and DCX-G253D mutants yield distinct dendrite phenotypes. Unlike DCX-ALPA, DCX-G253D caused a dominant-negative dendrite growth phenotype. The endocytosis defect of DCX-G253D thus was separable from its detrimental effects on dendrite growth. We recently identified as a dominant allele and can now classify as a second allele that acts dominantly to cause pathology, but does so via a different mechanism.

Quantitative 3-D morphometric analysis of individual dendritic spines.
The observation and analysis of dendritic spines morphological changes poses a major challenge in neuroscience studies. The alterations of their density and/or morphology are indicators of the cellular processes involved in neural plasticity underlying learning and memory, and are symptomatic in neuropsychiatric disorders. Despite ongoing intense investigations in imaging approaches, the relationship between changes in spine morphology and synaptic function is still unknown. The existing quantitative analyses are difficult to perform and require extensive user intervention. Here, we propose a new method for (1) the three-dimensional (3-D) segmentation of dendritic spines using a multi-scale opening approach and (2) define 3-D morphological attributes of individual spines for the effective assessment of their structural plasticity. The method was validated using confocal light microscopy images of dendritic spines from dissociated hippocampal cultures and brain slices (1) to evaluate accuracy relative to manually labeled ground-truth annotations and relative to the state-of-the-art Imaris tool, (2) to analyze reproducibility of user-independence of the segmentation method, and (3) to quantitatively analyze morphological changes in individual spines before and after chemically induced long-term potentiation. The method was monitored and used to precisely describe the morphology of individual spines in real-time using consecutive images of the same dendritic fragment.

Computational Approach to Dendritic Spine Taxonomy and Shape Transition Analysis.
The common approach in morphological analysis of dendritic spines of mammalian neuronal cells is to categorize spines into subpopulations based on whether they are stubby, mushroom, thin, or filopodia shaped. The corresponding cellular models of synaptic plasticity, long-term potentiation, and long-term depression associate the synaptic strength with either spine enlargement or spine shrinkage. Although a variety of automatic spine segmentation and feature extraction methods were developed recently, no approaches allowing for an automatic and unbiased distinction between dendritic spine subpopulations and detailed computational models of spine behavior exist. We propose an automatic and statistically based method for the unsupervised construction of spine shape taxonomy based on arbitrary features. The taxonomy is then utilized in the newly introduced computational model of behavior, which relies on transitions between shapes. Models of different populations are compared using supplied bootstrap-based statistical tests. We compared two populations of spines at two time points. The first population was stimulated with long-term potentiation, and the other in the resting state was used as a control. The comparison of shape transition characteristics allowed us to identify the differences between population behaviors. Although some extreme changes were observed in the stimulated population, statistically significant differences were found only when whole models were compared. The source code of our software is freely available for non-commercial use.

Different Doublecortin (DCX) Patient Alleles Show Distinct Phenotypes in Cultured Neurons: EVIDENCE FOR DIVERGENT LOSS-OF-FUNCTION AND "OFF-PATHWAY" CELLULAR MECHANISMS.
Doublecortin on the X-chromosome (DCX) is a neuronal microtubule-binding protein with a multitude of roles in neurodevelopment. In humans, DCX is a major genetic locus for X-linked lissencephaly. The best studied defects are in neuronal migration during corticogenesis and in the hippocampus, as well as axon and dendrite growth defects. Much effort has been directed at understanding the molecular and cellular bases of DCX-linked lissencephaly. The focus has been in particular on defects in microtubule assembly and bundling, using knock-out mice and expression of WT and mutant Dcx in non-neuronal cells. Dcx also binds other proteins besides microtubules, such as spinophilin (abbreviated spn; gene name Ppp1r9b protein phosphatase 1 regulatory subunit 9b) and the clathrin adaptors AP-1 and AP-2. Even though many non-sense and missense mutations of Dcx are known, their molecular and cellular defects are still only incompletely understood. It is also largely unknown how neurons are affected by expression of DCX patient alleles. We have now characterized several patient DCX alleles (DCX-R89G, DCX-R59H, DCX-246X, DCX-272X, and DCX-303X) using a gain-of-function dendrite growth assay in cultured rat neurons in combination with the determination of molecular binding activities and subcellular localization in non-neuronal and neuronal cells. First, we find that several mutants (Dcx-R89G and Dcx-272X) were loss-of-function alleles (as had been postulated) but surprisingly acted via different cellular mechanisms. Second, one allele (Dcx-R59H) formed cytoplasmic aggregates, which contained Hspa1B (heat shock protein 1B hsp70) and ubiquitinated proteins, trapped other cytoskeletal proteins, including spinophilin, and led to increased autophagy. This allele could thus be categorized as "off-pathway"/possibly neomorph. Our findings thus suggested that distinct DCX alleles caused dysfunction by different mechanisms.

CD44: a novel synaptic cell adhesion molecule regulating structural and functional plasticity of dendritic spines.
Synaptic cell adhesion molecules regulate signal transduction, synaptic function, and plasticity. However, their role in neuronal interactions with the extracellular matrix (ECM) is not well understood. Here we report that the CD44, a transmembrane receptor for hyaluronan, modulates synaptic plasticity. High-resolution ultrastructural analysis showed that CD44 was localized at mature synapses in the adult brain. The reduced expression of CD44 affected the synaptic excitatory transmission of primary hippocampal neurons, simultaneously modifying dendritic spine shape. The frequency of miniature excitatory postsynaptic currents decreased, accompanied by dendritic spine elongation and thinning. These structural and functional alterations went along with a decrease in the number of presynaptic Bassoon puncta, together with a reduction of PSD-95 levels at dendritic spines, suggesting a reduced number of functional synapses. Lack of CD44 also abrogated spine head enlargement upon neuronal stimulation. Moreover, our results indicate that CD44 contributes to proper dendritic spine shape and function by modulating the activity of actin cytoskeleton regulators, that is, Rho GTPases (RhoA, Rac1, and Cdc42). Thus CD44 appears to be a novel molecular player regulating functional and structural plasticity of dendritic spines.

2dSpAn: semiautomated 2-d segmentation, classification and analysis of hippocampal dendritic spine plasticity.

Accurate and effective dendritic spine segmentation from the dendrites remains as a challenge for current neuroimaging research community. In this article, we present a new method (2dSpAn) for 2-d segmentation, classification and analysis of structural/plastic changes of hippocampal dendritic spines. A user interactive segmentation method with convolution kernels is designed to segment the spines from the dendrites. Formal morphological definitions are presented to describe key attributes related to the shape of segmented spines. Spines are automatically classified into one of four classes: Stubby, Filopodia, Mushroom and Spine-head Protrusions.

CD44 regulates dendrite morphogenesis through Src tyrosine kinase-dependent positioning of the Golgi.
The acquisition of proper dendrite morphology is a crucial aspect of neuronal development towards the formation of a functional network. The role of the extracellular matrix and its cellular receptors in this process has remained enigmatic. We report that the CD44 adhesion molecule, the main hyaluronan receptor, is localized in dendrites and plays a crucial inhibitory role in dendritic tree arborization in vitro and in vivo. This novel function is exerted by the activation of Src tyrosine kinase, leading to the alteration of Golgi morphology. The mechanism operates during normal brain development, but its inhibition might have a protective influence on dendritic trees under toxic conditions, during which the silencing of CD44 expression prevents dendritic shortening induced by glutamate exposure. Overall, our results indicate a novel role for CD44 as an essential regulator of dendritic arbor complexity in both health and disease.

Aim: Traumatic brain injury (TBI) remains a leading cause of long-term neurological disability in the world and the strongest environmental risk factor for the development of dementia. Mild TBI makes up at least 75% of these injuries and is associated with a >2-fold increase in the risk of dementia diagnosis. The pathophysiology of TBI is complex, resulting in chronic behavioral and cognitive impairments that diminish quality of life. To date, no treatments have been identified to prevent, reverse, or mitigate the long-term consequences resulting from TBI. We previously demonstrated that the integrated stress response (ISR), a conserved pathway involved in cellular response to stress, is activated after TBI and inhibition of the ISR can reverse cognitive deficits. However, the cellular mechanisms by which cognitive functions are affected after TBI and ISR inhibition are unknown.
Methods: Here we used Thy1-YFP-H transgenic mice for longitudinal two-photon imaging *in vivo* after concussive injury to study spine dynamics in the parietal cortex, a brain region involved in working memory, specifically short-term working memory.
Results: Concussive injury altered spine dynamics and density measured up to a month after injury. Strikingly, brief pharmacological treatment with the drug-like small-molecule ISR inhibitor ISRIB reversed the neuronal structural changes measured in vivo in the parietal cortex and restored short-term memory functions.
Conclusion: These findings demonstrate that the short-term working memory deficits resulting from concussive injury are paralleled by altered spine dynamics in the parietal cortex. Importantly, ISR inhibition can rapidly and persistently reverse these effects.

The Integrated Stress Response: A Central Memory Switch in Down Syndrome.
Genetic and pharmacological evidence causally demonstrate that the integrated stress response (ISR) is a central molecular switch for long-term memory formation across different species. Zhu et al. (2019) recently demonstrated that persistent activation of the ISR could explain the long-term memory and synaptic plasticity deficits in a mouse model of Down syndrome, the most common genetic cause of intellectual disability.

Integrated Stress Response Inhibitor Reverses Sex-Dependent Behavioral and Cell-Specific Deficits after Mild Repetitive Head Trauma.
Mild repetitive traumatic brain injury (rTBI) induces chronic behavioral and cognitive alterations and increases the risk for dementia. Currently, there are no therapeutic strategies to prevent or mitigate chronic deficits associated with rTBI. Previously we developed an animal model of rTBI that recapitulates the cognitive and behavioral deficits observed in humans. We now report that rTBI results in an increase in risk-taking behavior in male but not female mice. This behavioral phenotype is associated with chronic activation of the integrated stress response and cell-specific synaptic alterations in the type A subtype of layer V pyramidal neurons in the medial prefrontal cortex. Strikingly, by briefly treating animals weeks after injury with ISRIB, a selective inhibitor of the integrated stress response (ISR), we (1) relieve ISR activation, (2) reverse the increased risk-taking behavioral phenotype and maintain this reversal, and (3) restore cell-specific synaptic function in the affected mice. Our results indicate that targeting the ISR even at late time points after injury can permanently reverse behavioral

changes. As such, pharmacological inhibition of the ISR emerges as a promising avenue to combat rTBI-induced behavioral dysfunction.

Female mice are protected from space radiation-induced maladaptive responses.
Interplanetary exploration will be humankind's most ambitious expedition and the journey required to do so, is as intimidating as it is intrepid. One major obstacle for successful deep space travel is the possible negative effects of galactic cosmic radiation (GCR) exposure. Here, we investigate for the first time how combined GCR impacts long-term behavioral and cellular responses in male and female mice. We find that a single exposure to simulated GCR induces long-term cognitive and behavioral deficits only in the male cohorts. GCR exposed male animals have diminished social interaction, increased anxiety-like phenotype and impaired recognition memory. Remarkably, we find that the female cohorts did not display any cognitive or behavioral deficits after GCR exposure. Mechanistically, the maladaptive behavioral responses observed only in the male cohorts correspond with microglia activation and synaptic loss in the hippocampus, a brain region involved in the cognitive domains reported here. Furthermore, we measured reductions in AMPA expressing synaptic terminals in the hippocampus. No changes in any of the molecular markers measured here are observed in the females. Taken together these findings suggest that GCR exposure can regulate microglia activity and alter synaptic architecture, which in turn leads to a range of cognitive alterations in a sex dependent manner. These results identify sex-dependent differences in behavioral and cognitive domains revealing promising cellular and molecular intervention targets to reduce GCR-induced chronic cognitive deficits thereby boosting chances of success for humans in deep space missions such as the upcoming Mars voyage.

Bioenergetic regulation of microglia.
Microglia have diverse actions, ranging from synapse pruning in development to cytotoxic effects in disease. Brain energy metabolism and substrate availability vary under normal and disease states, but how these variations influence microglial function is relatively unknown. Microglia, like most other cell types, express the full complement of gene products required for both glycolytic and oxidative metabolism. Evidence suggests that microglia increase aerobic glycolysis and decrease respiration when activated by various stimuli. Mitochondrial function, glucose availability, and glycolytic rate influence pro-inflammatory gene expression at both transcriptional and post-translational levels. These effects are mediated through CtBP, an NADH-sensitive transcriptional co-repressor; through effects on NLRP3 inflammasome assembly and caspase-1 activation; through formation of advanced glycation end-products; and by less well-defined mechanisms. In addition to these transcriptional effects, microglial glucose metabolism is also required for superoxide production by NADPH oxidase, as glucose is the obligate substrate for regenerating NADPH in the hexose monophosphate shunt. Microglia also metabolize acetoacetate and β-hydroxybutyrate, which are generated during fasting or ketogenic diet, and respond to these ketones as metabolic signals. β-Hydroxybutyrate inhibits histone de-acetylases and activates microglial GRP109A receptors. These actions suppress microglia activation after brain injury and promote neuroprotective microglia phenotypes. As our understanding of microglial activation matures, additional links between energy metabolism and microglial function are likely to be identified.

GLT-1-Dependent Disruption of CNS Glutamate Homeostasis and Neuronal Function by the Protozoan Parasite Toxoplasma gondii.
The immune privileged nature of the CNS can make it vulnerable to chronic and latent infections. Little is known about the effects of lifelong brain infections, and thus inflammation, on the neurological health of the host. Toxoplasma gondii is a parasite that can infect any mammalian nucleated cell with average worldwide seroprevalence rates of 30%. Infection by Toxoplasma is characterized by the lifelong presence of parasitic cysts within neurons in the brain, requiring a competent immune system to prevent parasite reactivation and encephalitis. In the immunocompetent individual, Toxoplasma infection is largely asymptomatic, however many recent studies suggest a strong correlation with certain neurodegenerative and psychiatric disorders. Here, we demonstrate a significant reduction in the primary astrocytic glutamate transporter, GLT-1, following infection with Toxoplasma. Using microdialysis of the murine frontal cortex over the course of infection, a significant increase in extracellular concentrations of glutamate is observed. Consistent with glutamate dysregulation, analysis of neurons reveal changes in morphology including a reduction in dendritic spines, VGlut1 and NeuN immunoreactivity. Furthermore, behavioral testing and EEG recordings point to significant changes in neuronal output. Finally, these changes in neuronal connectivity are dependent on infection-induced downregulation of GLT-1 as treatment with the ß-lactam antibiotic

ceftriaxone, rescues extracellular glutamate concentrations, neuronal pathology and function. Altogether, these data demonstrate that following an infection with T. gondii, the delicate regulation of glutamate by astrocytes is disrupted and accounts for a range of deficits observed in chronic infection.

Synthesis, characterization, and stability of iron (III) complex ions possessing phenanthroline-based ligands.
It has previously been demonstrated that phenanthroline-based ligands used to make gold metallotherapuetics have the ability to exhibit cytotoxicity when not coordinated to the metal center. In an effort to help assess the mechanism by which these ligands may cause tumor cell death, iron binding and removal experiments have been considered. The close linkage between cell proliferation and intracellular iron concentrations suggest that iron deprivation strategies may be a mechanism involved in inhibiting tumor cell growth. With the creation of iron (III) phen complexes, the iron binding abilities of three polypyridal ligands [1,10-phenanthroline (phen), 2,9-dimethyl-1, 10-phenanthroline (phen), and 2,9-di-butyl-1, 10-phenanthroline (phen)] can be tested via a competition reaction with a known iron chelator. Therefore, iron (III) complexes possessing all three ligands were synthesized. Initial mass spectrometric and infrared absorption data indicate that iron (III) tetrachloride complex ions with protonated phen ligands (phenH) were formed: [phenH][FeCl], [phenH][FeCl], [phenH][FeCl]. UV-Vis spectroscopy was used to monitor the stability of the complex ions, and it was found that the pheniron complex was more stable than the phen and phen analogues. This was based on the observation that free ligand was observed immediately upon the addition of EDTA to the [phenH][FeCl] and [phenH] [FeCl] complex ions.
