Introduction: Machado-Joseph Disease (MJD), an autosomal dominant neurodegenerative disease caused by an expansion of a CAG repeat tract in the ataxin-3 gene (ATXN3), is mainly characterized by a late onset of motor dysfunction. Currently, no disease-modifying therapy is available. Recent findings showed that NLX-112, a highly selective and fully efficacious 5-HT_{1A}R agonist, improved motor dysfunction and reduced mutant ATXN3 aggregation in a *Caenorhabditis elegans* MJD model. **Aims:** This study aims to analyze the therapeutic impact of NLX-112 in the CMVMJD135 MJD mice motor function. **Methods:** After selection of drug doses, based on plasma/brain exposure levels and animal welfare, two preclinical trials were performed: WT and MJD animals were treated with NLX-112 pre-symptomatically via drinking water for 35weeks, using tandospirone as reference, and post-symptomatically via intraperitoneal injections for 16weeks. Animals' welfare, body weight and temperature were regularly assessed, along with motor function using the beam walking (BWT) and motor swimming (MST) tests. **Results:** These experiments revealed that doses up to 8mg/kg for NLX-112 and 80mg/kg for TD were safe and well-tolerated. Pre-symptomatically, NLX-112 significantly improved motor coordination and balance of MJD animals in the BWT, at advanced stages of the disease. Contrarily, TD exhibited no therapeutic effect on motor function. Post-symptomatically, NLX-112-treated animals' coordination was improved in the MST early on the disease, while minor alterations were observed in other motor parameters. **Conclusions:** Overall, NLX-112 showed a beneficial effect on the motor function of MJD mice, reinforcing the potential role of serotonergic signaling modulation as a promising therapeutic target for MJD.

NUCLEAR ATXN3 DUB PHYSIOLOGICAL SUBSTRATES: TOWARDS UNDERSTANDING THEIR ROLE IN THE CONTEXT OF MACHADO-JOSEPH DISEASE

POSTER SESSION 07 - SECTION: NEURODEGENERATIVE DISEASES

Liliana Meireles-Costa[1,2], Andreia Neves-Carvalho[1,2,3], Bruno Almeida[1,2], Andreia Teixeira-Castro[1,2], Patrícia Maciel[1,2]

Background: Machado-Joseph disease (MJD) is a neurodegenerative disorder caused by expansion of a polyglutamine tract within the deubiquitinating enzyme (DUB) ataxin-3 (ATXN3). Strong evidence in cellular and animal models of MJD support the nuclear presence of ATXN3 as key for inducing pathogenesis. However, the mechanisms through which ATXN3 exerts its deleterious effects in the nucleus of neuronal cells remain mostly unknown, which challenges the development of disease modifying therapies. **Aims**: To characterize nuclear ATXN3s interactors and substrates relevant for MJD. **Methods:** We used proteomics approaches and biochemical and biophysical methods to identify novel nuclear ATXN3 interactors and substrates and characterize the interactions. **Results:** Using the proximity ligation (PLA) assay, we have validated potential nuclear interactors of ATXN3, such as SRSF7, GR, CUL1 and FUS. To confirm and further characterize these interactions, we are currently developing a new tool, using an inducible cellular model overexpressing both normal and expanded ATXN3 with a tandem affinity tag, allowing at the same time the validation of interactions, the identification of other proteins present in large complexes together with ATXN3, and to uncover their differential affinity to the mutant form of ATXN3. This will help the identification of specific targets in the disease context. **Conclusion:** In addition to bringing novel insight into the physiological function of ATXN3, we will increase our understanding of MJD pathogenesis, which may contribute for the development of more efficient therapeutic strategies.

Autism spectrum disorder (ASD) is an abnormal neurodevelopmental process in which the cerebellum is a structure to bear in mind in the study of ASD for both its motor function and its involvement in cognitive, affective and social behaviour. ASD patients have a specific loss of Purkinje cells, combined with an affectation of neurotrophic factors (NF). This work aims at studying the cerebellar destructuration employing the PCD mutant mouse, an animal model that presents a specific loss of Purkinje cells. For the analysis of the relationship between NF and cerebellar damage, both gene and protein expression of the NF insulin growth factor 1 (IGF-1) and vascular endothelial growth factor B (VEGF-B) were analysed before and during the Purkinje cell loss, thus finding statistically significant differences for both NF. These data have been used to carry out a pharmacological treatment with recombinant human IGF-1 (rhIGF-1) and recombinant human VEGF-B (rhVEGF-B). We observed an improvement in both motor coordination and Purkinje Cells survival when we treated PCD mice with rhVEGF-B. One of the functions of this NF is the inhibition of the intrinsic pathway of the apoptotic process, as we demonstrated by qPCR analyses. Then, we analysed the mitochondrial morphology and function in PCD mice and how it may contribute to the enhancement of motor coordination after rhVEGF-B treatment. Our preliminary results showed alterations in mitochondrial morphology of PCD mice, as well as decreased motility and/or fusion capacity. rhVEGF-B treatment seemed to decrease such impairments E-mail: lauraprev@usal.es; ddiaz@usal.es; jralonso@usal.es

Secretagogin expression in the mouse olfactory bulb under sensory impairments.
The interneurons of the olfactory bulb (OB) are characterized by the expression of different calcium-binding proteins, whose specific functions are not fully understood. This is the case of one of the most recently discovered, the secretagogin (SCGN), which is expressed in interneurons of the glomerular and the granule cell layers, but whose function in the olfactory pathway is still unknown. To address this question, we examined the distribution, generation and activity of SCGN-positive interneurons in the OB of two complementary models of olfactory impairments: Purkinje Cell Degeneration (PCD) and olfactory-deprived mice. Our results showed a significant increase in the density of SCGN-positive cells in the inframitral layers of olfactory-deprived mice as compared to control animals. Moreover, BrdU analyses revealed that these additional SCGN-positive cells are not newly formed. Finally, the neuronal activity, estimated by c-Fos expression, increased in preexisting SCGN-positive interneurons of both deprived and PCD mice -being higher in the later- in comparison with control animals. Altogether, our results suggest that the OB possesses different compensatory mechanisms depending on the type of alteration. Particularly, the SCGN expression is dependent of olfactory stimuli and its function may be related to a compensation against a reduction in sensory inputs.

The Selective Loss of Purkinje Cells Induces Specific Peripheral Immune Alterations.
The progression of neurodegenerative diseases is reciprocally associated with impairments in peripheral immune responses. We investigated different contexts of selective neurodegeneration to identify specific alterations of peripheral immune cells and, at the same time, discover potential biomarkers associated to this pathological condition. Consequently, a model of human cerebellar degeneration and ataxia -the Purkinje Cell Degeneration (PCD) mouse- has been employed, as it allows the study of different processes of selective neuronal death in the same animal, i.e., Purkinje cells in the cerebellum and

mitral cells in the olfactory bulb. Infiltrated leukocytes were studied in both brain areas and compared with those from other standardized neuroinflammatory models obtained by administering either gamma radiation or lipopolysaccharide. Moreover, both myeloid and lymphoid splenic populations were analyzed by flow cytometry, focusing on markers of functional maturity and antigen presentation. The severity and type of neural damage and inflammation affected immune cell infiltration. Leukocytes were more numerous in the cerebellum of PCD mice, being located predominantly within those cerebellar layers mostly affected by neurodegeneration, in a completely different manner than the typical models of induced neuroinflammation. Furthermore, the milder degeneration of the olfactory bulb did not foster leukocyte attraction. Concerning the splenic analysis, in PCD mice we found: (1) a decreased percentage of several myeloid cell subsets, and (2) a reduced mean fluorescence intensity in those myeloid markers related to both antigen presentation and functional maturity. In conclusion, the selective degeneration of Purkinje cells triggers a specific effect on peripheral immune cells, fostering both attraction and functional changes. This fact endorses the employment of peripheral immune cell populations as concrete biomarkers for monitoring different neuronal death processes.

About 30 neurodegenerative disorders are like to mutations in genes linked to DNA damage response. In our lab, we study Ataxia-telangiectasia (A-T), a rare genetic disorder caused by loss-of-function mutations in ATM, a kinase involved in the reponse to cytotoxic double strand breaks. This multi-system disease is characterised by genome instability, immune dysfunction, metabolic abnormalities and cancer susceptibility. However, one of the most devastating phenotypes of A-T is the progressive loss of cerebellar neurons leading most patients to use a wheelchair by early teenage years. The mechanisms of neurological defects in A-T are not well understood. Here, we demonstrate that aberrant activities of normally neuroprotective microglia, immune cells of the central nervous system, contribute to neurodegeneration in A-T. Increased levels of DNA damage and oxidative stress associated with loss of ATM, or its activity, promote sustained microglial activation. This activation is linked with increased: i) production of pro-inflammatory cytokines and ii) clearance activities, resulting in aberrant removal of healthy neurons and neurites by human microglia. Mechanistically, aberrant microglial activation in the absence of ATM is mediated by the pro-inflammatory RELB/p52 non-canonical NF-κB transcriptional pathway. Activation of the RELB/p52 pathway in ATM-deficient microglia is driven by persistent DNA damage. Persistent activation of the RELB/p52 pathway associated with ATM deficiency promotes chronic neuroinflammation with neurotoxic consequences. Activation of non-canonical NF-κB signalling is also observed in cerebellar microglia of individuals with Ataxia telangiectasia. These results provide novel mechanistic insights into the microglial dysfunction which contributes to progressive neurodegeneration in A-T.

INCREASED PKCGAMMA KINASE ACTIVITY CAUSES ABNORMAL PURKINJE CELL MATURATION AND CEREBELLAR ATAXIA

POSTER SESSION 07 - SECTION: NEURODEGENERATIVE DISEASES

Etsuko Shimobayashi, Josef Kapfhammer
Institute of Anatomy, Department Of Biomedicine, Basel, Switzerland

Spinocerebellar ataxias (SCAs) are neurodegenerative diseases characterized by cerebellar atrophy and dysfunction and loss of Purkinje cells. Among SCAs, Spinocerebellar ataxia type 14 (SCA14) is caused by missense mutations or deletions in the protein kinase C-gamma (PKCγ) gene which is a crucial signaling molecule in Purkinje cells. Although a variety of mutations or deletions have been found in SCA14 patients, it is not well understood how these mutations in PKCγ lead to Purkinje cell degeneration and ataxia. In order to study the role of increased PKCγ activity we generated a knock-in mouse model related to SCA14 with a mutation in the pseudosubstrate domain in PKCγ, PKCγ^{A24E}, known to induce a constitutive PKCγ activation in vitro assay. The kinase domain of PKCγ^{A24E} is open and activated but the protein is subject to dephosphorylation and degradation. PKCγ^{A24E} mice show indeed increased biological PKCγ activity, abnormal Purkinje cell maturation and ataxia while at the same time PKCγ protein expression is drastically reduced with the degradation. These unique phenotypes of PKCγ^{A24E} mice call for a further investigation of mutant PKCγ biological activity and protein stability. In order to address how PKCγ^{A24E} protein kinase activity and stability are controlled, we introduced additional mutations in the regulatory domain or at the phosphorylation sites in the kinase domain of PKCγ^{A24E}. Our preliminary data show that additional mutations in PKCγ^{A24E} affect kinase activity in Purkinje cells and can modify PKCγ protein expression. These data will provide new insights about the regulation of PKCγ activity and stability.

EXERCISE ACTS VIA BDNF-TRKB SIGNALLING TO RESCUE BEHAVIOURAL AND PURKINJE CELL FIRING DEFICITS IN A MOUSE MODEL OF SPINOCEREBELLAR ATAXIA TYPE 6

POSTER SESSION 07 - SECTION: NEURODEGENERATIVE DISEASES

Anna Cook, Sriram Jayabal, Kc Jacky Sheng, Alanna Watt
McGill University, Biology, Montreal, Canada

Spinocerebellar ataxia type 6 (SCA6) is an inherited neurodegenerative disease with mid-life onset of motor coordination impairment, eventual cerebellar degeneration, and limited treatment options. We used a knock in mouse model of the disease ($SCA6^{84Q/84Q}$) to characterize SCA6 pathophysiology and identify potential therapeutics. At 7 months these mice display significant deficits in motor coordination as well as alterations in Purkinje cell firing. We found that one month of voluntary exercise rescued deficits in motor behaviour and Purkinje cell firing frequency in $SCA6^{84Q/84Q}$ mice. But how does exercise act therapeutically in the $SCA6^{84Q/84Q}$ model? Brain-derived neurotrophic factor (BDNF) is known to be upregulated by exercise in the brain, and BDNF RNA levels are reduced in post-mortem brain tissue from SCA6 patients (Takahashi *et al.,* 2012). We found that $SCA6^{84Q/84Q}$ mice had reduced levels of cerebellar BDNF, and this was reversed by exercise. To determine whether BDNF signalling mediates the effect of exercise in $SCA6^{84Q/84Q}$ mice, we administered 7,8-dihydroxyflavone (7,8-DHF), a small molecule that mimics BDNF as an agonist of the TrkB receptor. Chronic 7,8-DHF treatment rescued deficits in both motor coordination and Purkinje cell firing frequency. Treatment with 7,8-DHF was most effective when it was started early in disease progression, and could continue to rescue deficits for several months. By identifying a pathway by which exercise acts in the SCA6 cerebellum, we have identified novel therapeutic targets for SCA6.

Molecular Identity and Location Influence Purkinje Cell Vulnerability in Autosomal-Recessive Spastic Ataxia of Charlevoix-Saguenay Mice.
Patterned cell death is a common feature of many neurodegenerative diseases. In patients with autosomal-recessive spastic ataxia of Charlevoix-Saguenay (ARSACS) and mouse models of ARSACS, it has been observed that Purkinje cells in anterior cerebellar vermis are vulnerable to degeneration while those in posterior vermis are resilient. Purkinje cells are known to express certain molecules in a highly stereotyped, patterned manner across the cerebellum. One patterned molecule is zebrin, which is expressed in distinctive stripes across the cerebellar cortex. The different zones delineated by the expression pattern of zebrin and other patterned molecules have been implicated in the patterning of Purkinje cell death, raising the question of whether they contribute to cell death in ARSACS. We found that zebrin patterning appears normal prior to disease onset in mice, suggesting that zebrin-positive and -negative Purkinje cell zones develop normally. We next observed that zebrin-negative Purkinje cells in anterior lobule III were preferentially susceptible to cell death, while anterior zebrin-positive cells and posterior zebrin-negative and -positive cells remained resilient even at late disease stages. The patterning of Purkinje cell innervation to the target neurons in the cerebellar nuclei (CN) showed a similar pattern of loss: neurons in the anterior CN, where inputs are predominantly zebrin-negative, displayed a loss of Purkinje cell innervation. In contrast, neurons in the posterior CN, which is innervated by both zebrin-negative and -positive puncta, had normal innervation. These results suggest that the location and the molecular identity of Purkinje cells determine their susceptibility to cell death in ARSACS.

Losing the Beat: Contribution of Purkinje Cell Firing Dysfunction to Disease, and Its Reversal.
The cerebellum is a brain structure that is highly interconnected with other brain regions. There are many contributing factors to cerebellar-related brain disease, such as altered afferent input, local connectivity, and/or cerebellar output. Purkinje cells (PC) are the principle cells of the cerebellar cortex, and fire intrinsically; that is, they fire spontaneous action potentials at high frequencies. This review paper focuses on PC intrinsic firing activity, which is altered in multiple neurological diseases, including ataxia, Huntington Disease (HD) and autism spectrum disorder (ASD). Notably, there are several cases where interventions that restore or rescue PC intrinsic activity also improve impaired behavior in these mouse models of disease.

These findings suggest that rescuing PC firing deficits themselves may be sufficient to improve impairment in cerebellar-related behavior in disease. We propose that restoring PC intrinsic firing represents a good target for drug development that might be of therapeutic use for several disorders.

Exploring the significance of morphological diversity for cerebellar granule cell excitability.
The relatively simple and compact morphology of cerebellar granule cells (CGCs) has led to the view that heterogeneity in CGC shape has negligible impact upon the integration of mossy fibre (MF) information. Following electrophysiological recording, 3D models were constructed from high-resolution imaging data to identify morphological features that could influence the coding of MF input patterns by adult CGCs. Quantification of MF and CGC morphology provided evidence that CGCs could be connected to the multiple rosettes that arise from a single MF input. Predictions from our computational models propose that MF inputs could be more densely encoded within the CGC layer than previous models suggest. Moreover, those MF signals arriving onto the dendrite closest to the axon will generate greater CGC excitation. However, the impact of this morphological variability on MF input selectivity will be attenuated by high levels of CGC inhibition providing further flexibility to the MF → CGC pathway. These features could be particularly important when considering the integration of multimodal MF sensory input by individual CGCs.

PATHOPHYSIOLOGICAL MECHANISMS OF CORTICAL SPREADING DEPOLARIZATION IN AN SLC1A3/EAAT1 MOUSE MODEL FOR EPISODIC ATAXIA, EPILEPSY AND HEMIPLEGIC MIGRAINE

POSTER SESSION 07 - SECTION: NEURODEGENERATIVE DISEASES

Daniela Miely[1], Peter Kovermann[2], Christoph Fahlke[2], Holger Lerche[1], Ulrike Hedrich[1]
[1]Hertie Institute for Clinical Brain Research, University of Tübingen, Dept. Of Neurology And Epileptology, Tübingen, Germany, [2]Forschungszentrum Jülich, Institute Of Biological Information Processing, Molekular- Und Zellphysiologie (ibi-1), Jülich, Germany

The rare neurological disorder Episodic Ataxia type 6 is associated with variants in the *SLC1A3* gene, encoding the excitatory amino acid transporter 1 (EAAT1). The variant P290R, which increases anion channel function and impairs glutamate transport, leads to a complex clinical phenotype, including ataxia, epileptic seizures and hemiplegic migraine attacks. Cortical Spreading Depolarization (CSD), the correlate of migraine aura, is a wave of cellular depolarization, followed by suppression of cortical activity. To clarify the mechanisms of CSD caused by altered glutamate and chloride homeostasis, we studied a mouse model carrying the respective variant. *In vitro* CSD characteristics using acute cortical slices were examined by combining intrinsic optical signal imaging with extracellular and potassium-sensitive recordings. We investigated synaptic transmission in the somatosensory cortex (layer 2/3) using whole-cell patch clamp recordings in acute slices of P15-20 animals. Brain slice recordings from *Slc1a3*$^{P290R/+}$ mice before disease onset (P15-20) revealed an increase in CSD susceptibility and propagation speed as well as rapid K^+-dynamics. Our findings on spontaneous and miniature synaptic currents clarified if the migraine phenotype *in vitro* was caused by an imbalance between excitation and inhibition on the cellular level. In the cortex, EAAT1 is mainly expressed in astrocytes, which decisively regulate tonic inhibition. Thus, we finally investigated alterations of tonic GABAergic currents. Our data show that, along with the epileptic and ataxic phenotype, *Slc1a3*$^{P290R/+}$ animals also display a clear hemiplegic migraine phenotype *in vitro* and therefore, resemble patients carrying the P290R variant. However, the consequences *in vivo* have not been unravelled, yet.

Hyperexcitable interneurons trigger cortical spreading depression in an Scn1a migraine model.
Cortical spreading depression (CSD), a wave of depolarization followed by depression of cortical activity, is a pathophysiological process implicated in migraine with aura and various other brain pathologies, such as ischemic stroke and traumatic brain injury. To gain insight into the pathophysiology of CSD, we generated a mouse model for a severe monogenic subtype of migraine with aura, familial hemiplegic migraine type 3 (FHM3). FHM3 is caused by mutations in SCN1A, encoding the voltage-gated Na+ channel NaV1.1 predominantly expressed in inhibitory interneurons. Homozygous Scn1aL1649Q knock-in mice died prematurely, whereas heterozygous mice had a normal lifespan. Heterozygous Scn1aL1649Q knock-in mice compared with WT mice displayed a significantly enhanced susceptibility to CSD. We found L1649Q to cause a gain-of-function effect with an impaired Na+-channel inactivation and increased ramp Na+ currents leading to hyperactivity of fast-spiking inhibitory interneurons. Brain slice recordings using K+-sensitive electrodes revealed an increase in extracellular K+ in the early phase of CSD in heterozygous mice, likely representing the mechanistic link between interneuron hyperactivity and CSD initiation. The neuronal phenotype and premature death of homozygous Scn1aL1649Q knock-in mice was partially rescued by GS967, a blocker of persistent Na+ currents. Collectively, our findings identify interneuron hyperactivity as a mechanism to trigger CSD.

DYNAMICS OF TDP43 AXONAL TRANSPORT AND ITS INTERACTION WITH THE KINESIN-1 MOTOR MACHINERY

POSTER SESSION 07 - SECTION: NEURODEGENERATIVE DISEASES

Monica Feole, Victorio Pozo Devoto, Pratiksha V Bhat, Neda Dragišić, Gorazd Stokin
Fakultni nemocnice u sv. Anny- International Clinical Research Center (FNUSA-ICRC), Center For Translational Medicine (ctm), Brno, Czech Republic

Transport of cargoes has been extensively studied, particularly from the point of view of the motor proteins. However, much less is known about the behavior of specific cargoes, the malfunctioning of their transport and role in neuropathological mechanisms. Here, we focus on TDP43, an important mRNA homeostasis regulator related to Amyotrophic Lateral Sclerosis (ALS) pathology. **AIM** The aim of this study is to define the machinery involved in the transport of TDP43, and how this mechanism is possibly disrupted in presence of disease-linked mutations. **METHODS** Stem cells-derived human neurons and real-time imaging of GFP-tagged cargoes were used to record their axonal transport. Time-lapse movies were analyzed using tracking algorithms to describe movement parameters. Co-IPs and Proximity Ligation Assays (PLAs) were performed to identify interactions between TDP43 and other components of the canonical anterograde/retrograde transport machinery. **RESULTS** We characterize TDP43 axonal transport by comparing it with Synaptophysin, Rab5 and APP. Our results on proteins movement reveal characteristics of the TDP43 transport behavior, which is bi-directional with high number of reversions and low pause frequency. On the other hand, TDP43 showed velocities and run lengths akin to those of kinesin-1 transported cargoes. Furthermore, Co-IPs and PLAs confirmed that TDP43 is part of both kinesin and dynein motor complexes. Last, we described how ALS-linked TDP43 mutations affect its transport and its distribution throughout the neuron. **CONCLUSIONS** This study contributes to elucidate mechanisms regulating the functionality and localization of TDP43 and ultimately to understand the pathogenesis of ALS.

A FORWARD GENETIC SCREEN IN DROSOPHILA TO IDENTIFY GENES REQUIRED FOR AXONAL MAINTENANCE

POSTER SESSION 07 - SECTION: NEURODEGENERATIVE DISEASES

Marije Been, Erik Storkebaum
Donders Institute, Radboud University, Molecular Neurobiology, Nijmegen, Netherlands

Many genes involved in motor neurodegenerative disease remain unidentified, and the molecular mechanisms underlying axonal degeneration are incompletely understood. In order to gain novel insight into the molecular pathogenesis of axonal degeneration and to identify novel disease-causing genes, we performed an EMS-based forward genetic screen, focusing on essential genes on the Drosophila X chromosome. Visualization of homozygously mutant motor axon clones allowed to identify axonal degeneration in the adult fly leg. This resulted in the identification of 72 unique mutants with motor axon degenerative phenotypes. Thus far, whole genome sequencing allowed identification of the disease-causing gene for 40 mutants. 96% of these genes have human orthologues, whereas 65% have been associated with disease in OMIM. These proteins are involved in a broad range of molecular pathways, including metabolism, axonal transport and transcriptional regulation. Interestingly, we have identified 11 genes that have neither been linked to human disease nor were found in any similar Drosophila screenings, indicating these could be novel players involved in axonal maintenance. We are currently evaluating whether the human orthologues of these genes may be associated with human disease.

FUS-mediated regulation of acetylcholine receptor transcription at neuromuscular junctions is compromised in amyotrophic lateral sclerosis.
Neuromuscular junction (NMJ) disruption is an early pathogenic event in amyotrophic lateral sclerosis (ALS). Yet, direct links between NMJ pathways and ALS-associated genes such as FUS, whose heterozygous mutations cause aggressive forms of ALS, remain elusive. In a knock-in Fus-ALS mouse model, we identified postsynaptic NMJ defects in newborn homozygous mutants that were attributable to mutant FUS toxicity in skeletal muscle. Adult heterozygous knock-in mice displayed smaller neuromuscular endplates that denervated before motor neuron loss, which is consistent with 'dying-back' neuronopathy. FUS was enriched in subsynaptic myonuclei, and this innervation-dependent enrichment was distorted in FUS-ALS. Mechanistically, FUS collaborates with the ETS transcription factor ERM to stimulate transcription of acetylcholine receptor genes. Co-cultures of induced pluripotent stem cell-derived motor neurons and myotubes from patients with FUS-ALS revealed endplate maturation defects due to intrinsic FUS toxicity in both motor neurons and myotubes. Thus, FUS regulates acetylcholine receptor gene expression in subsynaptic myonuclei, and muscle-intrinsic toxicity of ALS mutant FUS may contribute to dying-back motor neuronopathy.

The Drosophila FUS ortholog cabeza promotes adult founder myoblast selection by Xrp1-dependent regulation of FGF signaling.
The number of adult myofibers in Drosophila is determined by the number of founder myoblasts selected from a myoblast pool, a process governed by fibroblast growth factor (FGF) signaling. Here, we show that loss of cabeza (caz) function results in a reduced number of adult founder myoblasts, leading to a reduced number and misorientation of adult dorsal abdominal muscles. Genetic experiments revealed that loss of caz function in both adult myoblasts and neurons contributes to caz mutant muscle phenotypes. Selective overexpression of the FGF receptor Htl or the FGF receptor-specific signaling molecule Stumps in adult myoblasts partially rescued caz mutant muscle phenotypes, and Stumps levels were reduced in caz mutant founder myoblasts, indicating FGF pathway deregulation. In both adult myoblasts and neurons, caz mutant muscle phenotypes were mediated by increased expression levels of Xrp1, a DNA-binding protein involved in gene expression regulation. Xrp1-induced phenotypes were dependent on the DNA-binding capacity of its AT-hook motif, and increased Xrp1

levels in founder myoblasts reduced Stumps expression. Thus, control of Xrp1 expression by Caz is required for regulation of Stumps expression in founder myoblasts, resulting in correct founder myoblast selection.

tRNA overexpression rescues peripheral neuropathy caused by mutations in tRNA synthetase.
Heterozygous mutations in six transfer RNA (tRNA) synthetase genes cause Charcot-Marie-Tooth (CMT) peripheral neuropathy. CMT mutant tRNA synthetases inhibit protein synthesis by an unknown mechanism. We found that CMT mutant glycyl-tRNA synthetases bound tRNA but failed to release it, resulting in tRNA sequestration. This sequestration potentially depleted the cellular tRNA pool, leading to insufficient glycyl-tRNA supply to the ribosome. Accordingly, we found ribosome stalling at glycine codons and activation of the integrated stress response (ISR) in affected motor neurons. Moreover, transgenic overexpression of tRNA rescued protein synthesis, peripheral neuropathy, and ISR activation in and mouse CMT disease type 2D (CMT2D) models. Conversely, inactivation of the ribosome rescue factor GTPBP2 exacerbated peripheral neuropathy. Our findings suggest a molecular mechanism for CMT2D, and elevating tRNA levels may thus have therapeutic potential.

Hereditary spastic paraplegias (HSP) are a group of neurodegenerative diseases characterized by rigidity in lower limbs and motor dysfunction. Mutations in the SPG11 gene account for the most common form of autosomal recessive HSP, which is characterized by a gait disorder as well as cognitive impairment due to various brain alterations[(1)]. We generated a *Spg11* knock-out (KO) mouse model that develops the main symptoms found in SPG11 patients[(2)]. In this *Spg11* KO mouse model, neurodegeneration is associated with accumulation of some lipids, simple gangliosides, in lysosomes[(3)]. Moreover, decreasing ganglioside synthesis *in vitro* prevents neuronal death, suggesting that decreasing ganglioside synthesis could be a therapeutic option.
To test this hypothesis we downregulated key enzyme involved in this pathway, the ST3GAL5/GM3 synthase. To provide the proof of concept, we expressed a miRNA downregulated GM3 synthase using AAV-PHP-eB viral vectors that are able to transduce most cells in the body.
Behavioral investigations reveal that preventing ganglioside synthesis delays the onset of motor and cognitive symptoms of *Spg11* KO mouse. Moreover, miRNA treatment in *Spg11* KO mouse decreases ganglioside and autophagic marker accumulation that could be link to neuronal death.
This work shows promising results and could identify the first disease modifying therapeutic strategy for HSP.

CONTEXTUAL MEMORY DECLINE IN A COMBINED MOUSE MODEL FOR ISCHEMIC STROKE AND ALZHEIMER'S DISEASE

POSTER SESSION 07 - SECTION: NEURODEGENERATIVE DISEASES

Robin Gens[1,2,3], Fatemeh Nejati[4], Sylvie De Raedt[2,4], Sebastiaan Engelborghs[2,3,4], Ron Kooijman[1], Dimitri De Bundel[5]
[1]Vrije Universiteit Brussel, Research Group Experimental Pharmacology, Center For Neurosciences (c4n), Brussels, Belgium, [2]Universitair Ziekenhuis Brussel, Neurology, Brussels, Belgium, [3]Universiteit Antwerpen, Department Of Biomedical Sciences, Wilrijk, Belgium, [4]Vrije Universiteit Brussel, Center For Neurosciences (c4n), Brussels, Belgium, [5]Vrije Universiteit Brussel, Department Of Pharmaceutical And Pharmacological Sciences, Research Group Experimental Pharmacology, Brussels, Belgium

Background and aims: Ischemic stroke (IS) is a risk factor for Alzheimer's disease (AD). Contextual memory deficits have been shown in mouse models for IS and AD. Hippocampal neurogenesis seems to be a key feature in both conditions, but with potentially contrasting roles. In our pilot study, we studied memory retrieval in a contextual fear conditioning (CFC) paradigm to explore mechanistic interaction in the combined IS/3xTg-AD mouse model. Methods: IS was induced by permanent middle cerebral artery occlusion (pMCAO) in 4-months-old male and female 3xTg-AD vs control (B6129SF2/J) mice (n=4-8). Prior to pMCAO, mice were subjected to CFC. Memory retrieval was evaluated by freezing behavior (%) during a 5-minute retrieval test 24h after conditioning and 8 weeks after pMCAO. Infarct size was determined by Nissl-staining. Results: Twenty-four hours after CFC, freezing behavior was high in all groups (>80%), suggesting successful conditioning. Eight weeks after pMCAO, mice showed full motor recovery. B6129SF2/J mice subjected to pMCAO displayed less freezing behavior compared to shams. In 3xTg-AD sham mice, freezing percentage was lower compared to B6129SF2/J shams, but in contrast to B6129SF2/J mice, no effect of pMCAO could be detected. Subgroup analysis suggests that pMCAO in AD mice only deteriorates fear memory in males, whereas pMCAO does not seem to alter freezing behavior in females. Infarct size was comparable between 3xTg-AD and control mice. Conclusion: Our preliminary results suggest that pMCAO in 4-months-old mice affects contextual memory in B6129SF2/J, but we found no clear evidence for memory decline following pMCAO in 3xTg-AD mice.

THE UBIQUITIN PROTEASOME SYSTEM AS A REGULATOR OF MOTONEURON FUNCTION

POSTER SESSION 07 - SECTION: NEURODEGENERATIVE DISEASES

Katie Puddefoot[1], Will Norton[2], Jonathan Mcdearmid[1]
[1]University of Leicester, Dept. Of Neuroscience, Psychology And Behaviour, Leicester, United Kingdom, [2]University of Leicester, Department Of Genetics And Genome Biology, Leicester, United Kingdom

Homeostatic balance between protein synthesis, turn over and degradation is vital for the stability and viability of all living cells. Most eukaryotic cellular proteins are degraded by either the lysosome or the proteasome, with the proteasome primarily used to degrade misfolded proteins, damaged polypeptides or transient proteins commonly used in cellular signalling. Whilst the Ubiquitin Proteasome System (UPS) has a primary function to degrade proteins, this role has far-reaching outcomes for cell fate and survival. This is especially the case for neurons, which appear to be particularly susceptible to UPS perturbation evidenced by the role of UPS in neurodegenerative diseases such as Alzheimer's and Parkinson's disease. However, there is also mounting evidence for the role of the UPS in the healthy functioning of neurons, including in shaping neurotransmitter release, receptor trafficking and the regulation of axonal and dendritic growth during development. In this study, whole-cell patch clamp technique has been used to determine how pharmacological inhibition of the proteasome influences the intrinsic properties of primary motor neurons (PMNs) in larval zebrafish. Pharmacological inhibition of the proteasome reliably increased the frequency of glycine miniature inhibitory post-synaptic currents (mIPSCs) without affecting their kinetic properties. However, glutamatergic miniature excitatory post-synaptic currents (mEPSCs) were not affected by proteasome inhibition. Similarly, pharmacological inhibition of the proteasome did not affect action potential parameters. These results show that there is selective regulation of glycinergic signalling in the spinal cord of larval zebrafish upon inhibition of the proteasome.

Aim: To identify the association between vitamin D (VD) status and glucocorticoid (GC)-induced brain structural and functional changes. **Methods:** Female Wistar rats received prednisolone (5 mg/kg b.w.) with or without VD (1000 IU/kg b.w., 30 days). Forced swim (FST) and open-field (OFT) behavioral tests, H&E or Toluidine blue histological staining, microelectrode array recordings of extracellular potential, western blotting, qRT-PCR and ELISA were performed. Statistical differences were evaluated by ANOVA with Tukey post-hoc test. **Results:** There was no difference in OFT parameters, while FST demonstrated increased immobility time and decreased active behavior in GC-treated rats, indicative of depressive changes. No differences were found in cytoarchitectonics of cerebral cortex and posterior thalamic nucleus. However, prednisolone increased perikaryon area, enlarged nuclei and reduced cell density of CA1-CA3 hippocampal fields vs. control. This correlated with a down-regulated long-term plasticity of CA1-CA3 hippocampal synapses, declined amplitude of high-K^+-stimulated exocytosis, and lowered rate of Ca^{2+}-dependent fusion of isolated synaptic vesicles with plasma membrane vs. control. GC led to 3.2-, 2.0-, and 2.2-fold depletion of 25-hydroxyvitamin D (25OHD) pool in serum, cerebrospinal fluid and brain tissue, respectively, as well as elevated VDR and CYP27B1, and lowered CYP24A1 and VDBP levels. VD treatment reduced immobility time and stimulated active behavior. It caused a decrease in CA1 perikaryon and nucleus areas, restored /ong-term synaptic plasticity in hippocampus and depolarization-induced synaptic vesicle release that was accompanied by partial normalization of 25OHD circulating pool, VDBP and VDR levels. **Conclusions:** Normalization of VD status may be effective in prevention of GC-induced brain structural/functional/behavioral changes.

Targeting hippocampal amyloidogenesis with SV2A protein modulator levetiracetam.
Cerebral amyloid β (Aβ) proteostasis is compromised under neuronal overexcitation, long-term neuroinflammation and brain aging. Using the animal model of LPS-induced neuroinflammation we demonstrated that treatment with levetiracetam, a specific modulator of synaptic vesicle glycoprotein SV2A, rescues abnormal synaptic vesicle (SV) fusion and neurotransmitter release, decreasing elevated hippocampal APP levels in vivo. Therapy with levetiracetam upregulates the SV2A in hippocampus and restores the level of apolipoprotein E, involved in brain Aβ aggregation/clearance and resolution of inflammation. We demonstrated that oligomers of Aβ and Aβ peptides promote SV clustering, which reduces the rate and plateau level of subsequent homo- and heterotypic SNARE-mediated SV fusion. Oligomeric Aβ lowered ΔpH gradient across the vesicular membrane, thus affecting their neurotransmitter storage capacity. In contrast, monomers of Aβ and Aβ had negligible impact on studied processes. Our data suggests that in the course of progression of neuroinflammation oligomeric forms of Aβ and Aβ can compromise the SV fusion machinery and that antiepileptic agent levetiracetam, acting on SV recycling and restricting overexcitation, is able to affect APP processing and Aβ generation within the hippocampus in vivo.

Vitamin D Auto-/Paracrine System Is Involved in Modulation of Glucocorticoid-Induced Changes in Angiogenesis/Bone Remodeling Coupling.

Osteoporosis is a devastating side effect of chronic glucocorticoid (GC) treatment. Despite the crucial role of vitamin D (VD) in bone homeostasis, the precise molecular mechanisms of its action on GC-induced disturbances of bone remodeling remain undefined. The study was performed to elucidate the relation of VD status to GC-induced changes of the angiogenesis/osteogenesis/bone resorption coupling in bone tissue. Female Wistar rats received prednisolone (5 mg/kg of b.w.) with or without VD (1000 IU/kg of b.w., for 30 days). Biomechanical parameters of rat femurs were assessed by the three-point bending test. The levels of calcium, inorganic phosphate, activity of total alkaline phosphatase (ALP), and its isoenzymes were determined spectrophotometrically. Vascular endothelial growth factor-A (VEGF-A) and caspase-3 protein levels were detected by western blotting. and mRNAs were measured by qRT-PCR. Receptor activator of nuclear factor B (RANK) expression in bone sections was visualized immunohistochemically. Serum 25(OH)D was assayed by ELISA. GC administration led to a decrease in maximal load (by 1.2-fold) and stiffness and toughness (by 1.3-fold), which was accompanied by a 3-fold reduction of 25(OH)D level, an elevation of the ALP bone isoenzyme activity in serum, hypocalcaemia, and hypophosphatemia. Along with prednisolone-induced VD deficiency, an impaired synthesis of (-30%) and (+71%) mRNA was observed, reflecting deregulation of bone tissue VD-auto-/paracrine system. GC caused an increase in caspase-3 content, suppressed the synthesis of the osteoclastic marker RANK, and altered angiogenesis/osteogenesis coupling by significantly reducing the level of VEGF-A.VD treatment restored serum 25(OH)D content and the expression of key components of the VD-auto-/paracrine system. VD supplementation diminished cell apoptosis and strongly improved angiogenesis/osteogenesis coupling as well as mineral metabolism and biomechanical parameters of femurs in GC-administered rats. Thus, VD can have a beneficial effect on the correction of GC-induced pathological changes in bone remodeling.

The regulatory role of the RANKL/RANK/OPG signaling pathway in the mechanisms of tooth eruption in patients with impacted teeth.
Tooth impaction is a common problem in orthodontic practice and in some cases accompanied by pain and pathological changes of surrounding teeth. Understanding the cellular and molecular mechanisms underlying tooth impaction allows finding the most effective orthodontic treatment for patients with impacted teeth (IT). RANK (receptor activator of NF-κB) / RANKL (RANK ligand) / OPG (osteoprotegerin) signaling pathway controls bone resorption and may be involved in the regulation of tooth eruption. The study aimed to evaluate bone remodeling based on the assessment of the RANKL/RANK/OPG status in patients with IT.

Vitamin D deficiency induces the excitation/inhibition brain imbalance and the proinflammatory shift.
Vitamin D is among the major neurosteroids whose role in developing and adult brain is intensively studied now. Its active form 1,25(OH)D regulates the expression and functioning of a range of brain-specific proteins, which orchestrate the neurotransmitter turnover, neurogenesis and neuroplasticity. Despite numerous studies of the vitamin D role in normal and pathological brain function, there is little evidence on the mechanisms of alterations in excitatory and inhibitory neurotransmission under vitamin D deficiency (VDD). Using the animal model we characterized the dysfunction of excitatory and inhibitory neurotransmission under alimentary VDD. The shift between unstimulated and evoked GABA release under VDD was largely reversed after treatment of VDD, whereas the impairments in glutamatergic system were only partially recovered after 1-month vitamin D supplementation. The increase of the external glutamate level and unstimulated GABA release in brain nerve terminals was associated with intensified ROS production and higher [Ca] in presynapse. The negative allosteric modulation of presynaptic mGlu7 receptors significantly enhanced exocytotic GABA release, which was decreased under VDD, thereby suggesting the neuroprotective effect of such modulation of inhibitory neurotransmission. Synaptic plasma membranes and cytosolic proteins contribute to the decreased stimulated release of neurotransmitter, by being the crucial components, whose functional state is impaired under VDD. The critical changes with synaptic vesicles occurred at the docking step of the process, whereas malfunctioning of synaptic cytosolic proteins impacted the fusion event foremost. The decreased amplitude of exocytosis was inherent for non-excitable cells as well, as evidenced by lower platelet degranulation. Our data suggest the presynaptic dysfunction and proinflammatory shift as the early events in the pathogenesis of VDD-associated disorders and provide evidences for the neuroprotective role of vitamin D.

Vitamin D Modulates Impaired Crosstalk Between RANK and Glucocorticoid Receptor Signaling in Bone Marrow Cells After Chronic Prednisolone Administration.
The effectiveness of vitamin D (cholecalciferol) in counteracting the side effects of glucocorticoid (GC) therapy has been demonstrated previously. Abnormalities in systemic hormonal and local (cytokine) regulation of bone marrow (BM) cells may

underlie GC-induced imbalance between osteosynthesis and bone resorption. The cytokine system receptor activator of nuclear factor kappa-B (RANK)/RANK ligand (RANKL)/osteoprotegerin (OPG) is considered as an integrating link in the NF-κB-mediated interaction of various cells involved in maintaining osteoblastic-osteoclastic balance, which makes it a pharmacological target for regulation and correction of the bone remodeling process. We studied GC-induced impairments of the RANKL/RANK/OPG axis in BM cells depending on vitamin D bioavailability and whether these changes were mediated by glucocorticoid (GR) and/or vitamin D (VDR) receptors. Female Wistar rats administered with prednisolone (5 mg/kg b.w., 30 days) showed a decrease in the GR protein level and the number of GR-positive BM cells. GC caused a marked elevation of RANKL and RANK levels in BM, while OPG decreased. Flow cytometry data indicated GC-elicited increase in the number of circulating RANK-positive osteoclast precursors (OCPs) in BM, peripheral blood, and spleen. In full accordance with the data that the interaction of RANKL-RANK leads to transcriptional activation of NF-κB and subsequent differentiation of osteoclasts, we found an increase in the level of phosphorylated p65 subunit of NF-κB with a simultaneous decrease in the NF-κB inhibitor (IκB) level. These changes were accompanied by vitamin D insufficiency and downregulated expression of CYP27B1 and VDR, which are responsible for synthesis and hormonal signaling of 1,25(OH)D. Notably, we observed VDR and RANK co-localization in OCPs. Cholecalciferol co-administration (1,000 IU/kg b.w., 30 days) with prednisolone resulted in elevated GR synthesis in BM. Cholecalciferol prevented prednisolone-elicited disturbances of the RANKL/RANK/OPG, which correlated with improved bioavailability and vitamin D signaling through VDR. This caused the lowering of phosphoNF-κB p65 level and inhibiting NF-κB translocation to the nucleus that could reduce the circulating OCPs pool in BM, peripheral blood, and spleen. Our findings suggest that prednisolone-induced abnormalities in GR and RANKL/RANK/OPG signaling pathways are associated with the impairments of vitamin D auto/paracrine system in BM cells and can be ameliorated by cholecalciferol supplementation.

Vitamin D protects against prednisolone-induced liver injury associated with the impairment of the hepatic NF-κB/iNOS/NO pathway.
The study was carried out to define whether prednisolone-induced damage to hepatic cells is accompanied by excessive nitric oxide (NO) levels associated with nuclear factor kappa B (NF-κB)/inducible NO synthase (iNOS) activation and evaluate the efficacy of the treatment with vitamin D. Histopathological examination, activities of liver transaminases (alanine aminotransferase and aspartate aminotransferase), and cell death assays consistently showed that prednisolone (5 mg/kg body weight, 30 days) induces chronic liver injury in female Wistar rats. Specifically, increased hepatocellular necrosis and caspase-3-dependent apoptosis were observed. Prednisolone enhanced iNOS protein expression, NO generation, and tyrosine nitration in liver cells. Despite unchanged hepatic level of the NF-κB/p65 protein, prednisolone increased inhibitory κB-α (IκB-α) degradation, nuclear translocation, and phosphorylation of NF-κB/p65 at Ser311, indicating that NF-κB activation can be involved in the induction of iNOS/NO. All changes were associated with a 2.9-fold decrease in the serum content of 25-hydroxyvitamin D and significant reduction of hepatic vitamin D receptor (VDR) expression that points reliably to vitamin D deficiency and failures in VDR signaling. Vitamin D co-administration (100 IU/rat, 30 days) prevented glucocorticoid-evoked abnormalities in hepatic tissue. In conclusion, prednisolone-induced liver disturbances were associated with the impairment of NF-κB/iNOS/NO responses that can be ameliorated by vitamin D treatment through VDR-mediated mechanisms.

Prednisolone and vitamin D(3) modulate oxidative metabolism and cell death pathways in blood and bone marrow mononuclear cells.
The study was designed to evaluate reactive oxygen species (ROS)/nitric oxide (NO) formation and apoptotic/necrotic cell death elicited by prednisolone in peripheral blood and bone marrow mononuclear cells and to define the efficacy of vitamin D3 to counter glucocorticoid (GC)-induced changes. It was shown that prednisolone (5 mg per kg of female Wistar rat's body weight for 30 days) evoked ROS and NO overproduction by blood mononuclear cells (monocytes and lymphocytes) that correlated with increased cell apoptosis and necrosis. In contrast, prednisolone did not affect ROS/NO levels in bone marrow mononuclear cells that corresponded to lower level of cell death than in the control. Alterations of prooxidant processes revealed in mononuclear cells and associated with GC action were accompanied by vitamin D3 deficiency in animals, which was assessed by the decreased level of blood serum 25-hydroxivitamin D3 (25OHD3). Vitamin D3 administration (100 IU per

rat daily for 30 days, concurrently with prednisolone administration) completely restored 25OHD3 content to the control values and significantly reversed ROS and NO formation in blood mononuclear cells, thus leading to decreased apoptosis. In bone marrow, vitamin D3 activated ROS/NO production and protein nitration that may play a role in prevention of prednisolone-elicited increase in bone resorption. We conclude that vitamin D3 shows a profound protection against GC-associated cellular damage through regulating intracellular ROS/NO formation and cell death pathways.

EXAMINING CALPAIN ACTIVITY IN SPINOCEREBELLAR ATAXIA-3 THROUGH USE OF A NOVEL FIBRE PHOTOMETRY METHODOLOGY

POSTER SESSION 07 - SECTION: NEURODEGENERATIVE DISEASES

Katherine Robinson, Amanda Wright, Holly Ahel, Stuart Plenderleith, Andrea Kuriakose, Maxinne Watchon, Anita Turner, Simon Mcmullan, Angela Laird
Macquarie University, Macquarie Medical School, Macquarie University, Australia

Aberrant cleavage of full-length proteins into shorter fragments is common to many neurodegenerative diseases, including spinocerebellar ataxia type 3 (SCA3). Calcium-activated calpain proteases are known to cleave proteins and thus may contribute to protein aggregate formation and neurodegeneration. In this study, we aimed to determine whether overactivity of calpain proteases was a disease mechanism present in SCA3 transgenic mice. We obtained longitudinal blood samples from mice throughout disease development and investigated if plasmatic levels of cleaved α-spectrin, a marker of calpain activity, changed with disease progression. We found no significant differences in levels of cleaved α-spectrin in pre-symptomatic SCA3 mice (< 8 weeks of age) when compared to wildtype littermates. At 12 weeks of age, levels of cleaved α-spectrin were significantly increased in SCA3 animals, coinciding with the onset of neurological symptoms. Western blotting of cerebellum tissue obtained from 15-week SCA3 mice showed further differences in markers of calpain activity, providing further evidence that calpain proteases may play a pathogenic role in SCA3. Next, we used fibre photometry and a FRET-based biosensor to investigate changes in protein cleavage *in vivo*. Using this novel fibre photometry approach, we examined the effect of administration of different doses of calpeptin within the same experimental animals across different test sessions. Our findings confirmed that our approach can be used to measure calpain activity in vivo and identify the most efficacious dose of calpeptin. Insights from our study will aid our understanding of SCA3 disease mechanisms and the future testing of novel calpain inhibitors.

FATIGUE AND SLEEPINESS MEASURES IN MYOTONIC DYSTROPHY TYPE 1 PATIENTS TREATED WITH COGNITIVE BEHAVIORAL THERAPY AND GRADED EXERCISE THERAPY

POSTER SESSION 07 - SECTION: NEURODEGENERATIVE DISEASES

Niamh Mahon[1], Baziel Van Engelen[2], Jayne Carberry[1], Jeffrey Glennon[1,3]
[1]University College Dublin, School Of Medicine, Dublin, Ireland, [2]Donders Institute for Brain Cognition and Behaviour, Department Of Neurology, Nijmegen, Netherlands, [3]University College Dublin, Conway Institute Of Biomolecular And Biomedical Research, Dublin, Ireland

Aims: Myotonic dystrophy 1 (DM1) is a relatively common neuromuscular disorder in adults. It is characterised by muscle weakness, sleep disorders (~80%), cataracts, and cardiac problems. Effective treatments to alleviate disease burden are currently an unmet clinical need and life expectancy is around 50 years. We aim to investigate fatigue and sleepiness measures for benefit in response to cognitive behavioural therapy (CBT) and graded exercise therapy (GET). Methods: The OPTIMISTIC trial (NCT02118779) included 255 DM1 participants who were randomised to standard care or CBT, with the aim of increasing activity and social participation. Two of the sites offered additional GET to those in the CBT group. Fatigue and daytime sleepiness scale (FDSS) and Checklist Individual Strength subscale Fatigue (CIS Fatigue) measures were taken at baseline, 5, 10 and 16 months. Measures were compared across the treatment groups using Mann Whitney U tests. Scores were also split by median age and gender. Causal mediation analysis was carried out for factors mediating FDSS change in response to CBT+GET. Results: There was a significant reduction in mean FDSS score with CBT+GET (n=33) compared to standard care (n=125) at 5, 10, and 16 months ($P < .001$). In contrast, CBT alone (n=96) showed a significant improvement over standard care at 5 months only ($P < .05$). This pattern was replicated in CIS fatigue scores. Both genders and age groups responded well to CBT+GET. Conclusions: CBT and GET reduces fatigue and daytime sleepiness in participants with DM1 who were classified as severely fatigued.

Myotonic dystrophy type 1 (DM1) is a dominantly inherited neuromuscular disease caused by the abnormal expansion of CTG-repeats in the 3'-untranslated region of the *DMPK* gene, characterized by multisystemic symptoms including muscle weakness, myotonia, cardio-respiratory problems, hypersomnia, cognitive dysfunction and behavioural abnormalities. DMSXL mice carry a mutated human *DMPK* transgene resulting in >1000 CTG-repeats. They exhibit a pathologic neuromuscular phenotype and also synaptic dysfunction resulting in neurological and behavioural deficits similar to those observed in patients. To further explore additional phenotypes of this DM1 mouse model we developed a comprehensive battery of tests that included the evaluation of several brain functions: exploratory and motor activity, fine motor skills, neuromuscular strength, anxiety, working memory, fear learning, sensorimotor processing, spatial memory, home-cage rest behaviour. Additionally, skeletal and cranio-facial morphology as well as body composition and bone mineral density were assessed using DEXA and micro-CT. Male and female DMSXL mice tested between 7 and 20 weeks of age showed, compared to wild-type littermates: lower body weight, reduced grip strength and running wheel activity and increased anxiety, consistently with previously published data. Interestingly, they also presented some new phenotypes remarkably similar to the characteristic features of the human disease: skeletal and cranio-facial dysmorphology with teeth misalignment, abnormalities in sensorimotor processing and rest-related disturbances during the active phase. These phenotypes confirm the reliability of DMSXL mice to model clinical features of DM1 and open new opportunities to verify the efficacy of novel therapies based on CRISPR/Cas9-mediated gene editing strategies currently under study in our group.

Aims In the mouse spinal cord, homeoprotein transcription factor EN1 is expressed in V1 interneurons that synapse on alpha-motoneurons (aMNs) and may, as is the case for midbrain neurons, exert neuroprotection following intercellular transfer. We thus evaluated the non-cell autonomous activity of EN1 on aMN physiology and survival. **Methods** We analyzed mice heterozygous for *En1* (*En1*$^{+/-}$) and also neutralized extracellular EN1 in the spinal cord of WT mice by expressing a single chain anti-EN1 antibody (scFvEN1). Neuromuscular junction morphology (NMJ) and aMN number were analyzed. Forepaw grip strength, time hanging onto an inverted grid and the hind limb extensor reflex were evaluated. hEN1 (1µg) was injected intrathecally at lumbar 5 level and scFvEN1 virally expressed in the astrocytes. **Results** *En1*$^{+/-}$ mice display reduced muscle strength and an abnormal extensor reflex starting at 2 months of age, NMJ denervation at 3 months of age and significant aMN loss at 4.5 months of age, associated with an increased expression of the p62/SQTSM1 autophagy mark. Six weeks after a single intrathecal administration of hEN1 at 3 months of age, both muscle strength and extensor reflex are restored and aMN loss is prevented. Phenotypic rescue is maintained for 3 months and can be prolonged via a second injection. Neutralizing spinal extracellular EN1 by expression of scFvEN1 phenocopies the *En1*$^{+/-}$ phenotype. **Conclusions** Our data demonstrate that non-cell autonomous EN1 is an adult aMN neurotrophic factor with potential interest for the treatment of MN diseases.

Control of lipid metabolism by NGF/p75NTR signaling in neuron-glia network: novel targets for neurodegenerative diseases A prominent factor in cognitive abnormalities associated with various neurodegenerative diseases, including Alzheimer's Disease (AD) and Type 2 Diabetes (T2D), is the disruption of cholesterol metabolism in the neuron-glia network. Cholesterol dysmetabolism and associated brain insulin resistance have been linked to the cognitive decline produced by cholinergic deficits and astrocytosis in AD. The goal of the current research is to investigate the neurotrophic pathway in the protection of the neuro-glia network from the effect of the cholesterol metabolite 27-hydroxycholesterol (27-OH), the major circulating oxygenated cholesterol derivative, and a brain sensor of circulating cholesterol. In line, 27-OH is detected in high amount in the early stage AD brain, possibly contributing to cognitive deterioration. We discovered that 27-OH (1mM; 6-24 hours) inhibits NGF/TrkA signaling in NGF-responsive cholinergic neurons and human iPS-derived astrocytes by affecting the metabolism of amyloid precursor protein, and promotes the buildup of lipid rafts in the neuroglia network. We also found that 27-OH elicits nuclear translocation of the common neurotrophic receptor (p75NTR) in astrocytes before lipid rafts are loaded. On the other hand, both NGF (100ng/ml) and the selective p75NTR modulator LM11A-31 (100nM) can prevent p75NTR accumulation in the nucleus and subsequent lipid raft buildup, pinpointing that the NGF and p75NTR signalings play opposite roles in AD. Overall, NGF-based treatment and/or p75NTR-specific modulation are possible avenues to improve lipid metabolism and reduce cognitive decline in AD and T2D.

ASYMMETRIC ENCODING DYNAMICS IN THE STRIATAL DIRECT AND INDIRECT PATHWAYS DURING SPONTANEOUS BEHAVIOUR

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Christophe Varin, Amandine Cornil, Delphine Houtteman, Patricia Bonnavion, Alban De Kerchove D'Exaerde
Université Libre de Bruxelles, Laboratoire De Neurophysiologie, Bruxelles, Belgium

The basal ganglia are notorious for their influence on action control and modulation of movements. Proper organization of neuronal activity within the two efferent pathways of the dorsal striatum, a major input of basal ganglia, is critical for appropriate behavioral control. The classical model of basal ganglia suggests that striatal indirect and direct pathways exert opposite action on the thalamo-cortical activation triggering motor control. Recent studies challenged this view by describing conjoint neuronal activities during action initiation or decision-making. Therefore, additional investigations are needed to clarify the function of these two pathways. In the present work, using large-scale in vivo calcium imaging (Inscopix), we evaluated how direct and indirect pathway striatal projection neurons (SPNs) in the dorsal striatum encode behaviors during self-paced spontaneous exploration of an open-field. We observe that both striatal pathways diverge in their tuning properties to spontaneous behaviors. Using supervised leaning algorithms, we found that direct pathway SPNs encode behaviors through their activation, whereas behavior-relevant SPNs of the indirect pathway are consistently silent. Our findings demonstrate an opposite yet cooperative organization of behaviors encoding within striatal output pathways that solves questions raised by recent correlative studies. Altogether our results generate a new framework to understand striatal physiology and its dysfunction.

In the classical model of the basal ganglia (BG) two segregated and functionally opposing pathways connect its input, the striatum with its midbrain outputs the substantia nigra (SNr) and entopenduncular nucleus (EP). Direct pathway spiny projection neurons (dSPNs) project to the SNr and EP while indirect pathway iSPNs project to the GPe. However, many recent studies have challenged both the functional dichotomy and the anatomical organization delineated by the classical BG model. For instance, all major BG nuclei send arborized axons collateralizing into one to four BG target regions. These axon collaterals could help shape BG information flow by sending copies of the same signals to distinct brain regions. Axonal “bridging” collaterals arising from dSPNs are a prominent example: axonal fibers arising from SNr-projecting tracts, yet targeting the GPe, the classical projection area of iSPNs. They generate half the density of GPe terminals produced by iSPNs, but their significance for behavior is still unknown. Here, we use *in vivo* optical and chemogenetic tools combined with deep-learning approaches to dissect the roles of bridging collaterals in motor function. We found that dSPNs projecting to the SNr send synchronous motor-related information to the GPe via axon collaterals. We then found that inhibition of native activity in dSPN GPe terminals impaired motor activity and function via regulation of pallidostriatal Npas1 neurons. We propose a model by which dSPN GPe collaterals act in concert with the canonical terminals in the SNr to support motor control by inhibiting Npas1 signals going back to the striatum.

MOTOR SKILL LEARNING AND EXECUTION IN A DISTRIBUTED BRAIN NETWORK

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Steffen Wolff[1,2], Ashesh Dhawale[2], Raymond Ko[2], Bence Ölveczky[2]
[1]University of Maryland School of Medicine, Pharmacology, Baltimore, United States of America, [2]Harvard University, Organismic And Evolutionary Biology, Cambridge, United States of America

The brain's remarkable capacity to acquire and execute motor skills depends on a distributed network. While many components are identified, less is known about their specific roles and interactions during skill learning and execution. We probe this network through the lens of complex, spatiotemporally precise motor sequences we train in rats. We focus on the basal ganglia (BG) and their main inputs from motor cortex and thalamus. Using electrophysiological recordings, we find that the dorsolateral striatum (DLS), the BG's main motor-related input nucleus, encodes the detailed kinematic structure of learned motor sequences. We further show that a loss of the DLS renders animals unable to execute the learned idiosyncratic motor patterns, causing them to revert to simple species-typical behaviors. In addition, we find that not only the DLS, but also its motor cortical inputs are necessary for skill learning. This pathway, however, becomes dispensable after the behaviors are acquired. In line with this, the loss of motor cortical inputs leaves DLS activity encoding the kinematic structure largely unaffected. In contrast, thalamic inputs remain crucial for skill generation and their loss disrupts performance akin to DLS lesions. Together, our results suggest that the BG can play a role in the control of complex learned behaviors beyond traditional models of BG function. They further suggest that motor cortex 'tutors' sub-cortical circuits during learning, potentially by guiding plasticity at thalamostriatal synapses. Such adaptive reprogramming of lower-level motor circuits may broaden their flexibility and allow them to store and generate complex learned motor skills.

INPUT-OUTPUT RELATIONSHIPS OF THE PARAFASCICULAR THALAMIC NUCLEUS IN THE MOUSE

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Enrique Gonzalo-Martín, Francisco Clascá, Lucía Prensa
School of Medicine. Autonomous University of Madrid, Department Of Anatomy And Neuroscience, Madrid, Spain

Introduction. The parafascicular thalamic nucleus (Pf) is a massive source of subcortical excitatory inputs to the striatum. Pf neurons simultaneously innervate the cerebral cortex as well, but the functional logic of this divergent projection is currently unclear. Likewise, sources of input to Pf neurons remain poorly defined. **Aims.** Using wild-type adult C57BL/6 male mice as experimental subjects, we set out to a) map Pf afferents; b) sort out the relationship between Pf subregions and the cortical + striatal territories targeted by their projections; and c) investigate possible differences in Pf axon varicosities within specific cortical and/or striatal target domains. **Methods.** We made selective microinjections of biotin dextran amine (BDA) or BDA + cholera toxin B subunit (CTb) in different Pf subdomains to visualize their efferent and afferent projections. We applied different (immuno)stainings to delineate relevant brain territories. **Results.** Our data show that the mouse Pf receives massive inputs from layers 5b and 6b of sensorimotor, frontal association and cingulate cortices and the multimodal intermediate/deep layers of the superior colliculus. Pf projections to striatum and cortex are organized in congruent fashion in both structures, yet the cortical projections are far less abundant or convergent. Axonal varicosity sizes vary depending on the target structure and the origin of the axons within the various Pf subregions. **Conclusions.** These observations show that the divergent Pf output to the striatum and cortex is segregated into parallel, somatotopically-related subcircuits and suggest that the synaptic strength of Pf projections may vary amongst its different target territories.

CONTRIBUTION OF DOPAMINE NEURONS TO ACTION EXECUTION

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Clara Besserer[1,2], Sophie Gauthier[1], Nicolas Mallet[2]
[1]Université de Bordeaux, Institut Des Maladies Neurodégénératives, Bordeaux, France, [2]CNRS UMR 5293, Institut Des Maladies Neurodégénératives, Bordeaux, France

The midbrain dopaminergic neurons (DANs) are essential for goal-directed actions with key contribution to functions ranging from motivation to movement vigor. Studies have shown that the activity of DANs located in the substantia nigra pars compacta (SNc) is modulated around movement onset and can change during movements but in a heterogeneous manner. Moreover, cell-type specific manipulation of their activity before a movement will impact the vigor at which it is executed. In this study, we sought to investigate the functional heterogeneity of SNc DANs responses during action execution. As such, we recorded the extracellular activity of DANs using an optotagging strategy and high-density silicon probes in head-fixed TH-Cre rats trained to perform a reach-and-grasp fine motor task. We found that the activity of DANs is principally modulated by cue sound instructing the start of the trial and not by motor parameters.

The central function of the striatum and its dopaminergic (DA) afference in motor control and integration of cognitive and emotional processes is commonly explained by the two striatal efferent pathways characterized by striatal projection neurons (SPNs) expressing DA D1 receptor- and D2 receptor (D1-SPNs and D2-SPNs), respectively, regardless of SPNs co-expressing these two receptors (D1/D2-SPNs). Here, after developing an approach that enables to target these hybrid SPNs, we demonstrated that, although these SPNs are rare, they play a major role in guiding the motor function of the other two main populations and convey a DA-mediated antagonistic motor brake. D1/D2-SPNs project exclusively to the external globus pallidus (GPe) and have specific electrophysiological features with distinctive integration of DA signals. Optogenetic stimulation and loss-of-function experiments indicated that D1/D2-SPNs potentiate the prokinetic and antikinetic functions of D1-SPNs and D2-SPNs, respectively, and restrain the integrated motor response to psychostimulants. Overall, our findings demonstrate the essential role of this third unacknowledged population of D1/D2 co-expressing neurons, which orchestrates the fine-tuning of DA regulation in the thalamo-cortico-striatal loops.

Corticostriatal connectivity is key for cognitive and motor processes, such as reinforcement or action selection, initiation and invigoration. The cortical input to the striatum arises from two major cortical populations: intratelencephalic (IT) and pyramidal tract (PT) neurons. Here, using electrophysiology, circuit mapping and pharmacological methods, we described a new corticostriatal polysynaptic circuit, running in parallel to the canonical monosynaptic corticostriatal connection. In this circuit, PT cortical neurons convey excitation to spiny projection neurons (SPNs) in the striatum, through cholinergic interneurons (ChIs). This motif elicits a second phase of excitation onto SPNs by promoting acetylcholine-dependent glutamate release from long-range axons reaching the striatum. This release depends on α4-containing nicotinic receptors and results in biphasic corticostriatal signals. Using subcellular ChannelRhodopsin-2 Assisted Circuit Mapping (sCRACM), we uncovered that these biphasic signals are a hallmark of PT neurons, because they preferentially contact ChIs, when compared to IT neurons. These results describe a previously unknown circuit mechanism by which PT activity amplifies excitation to the striatum, with potential implications for behavior, plasticity and learning.

DOPAMINE DYNAMICS IN THE MOUSE DORSAL STRIATUM DURING LOCOMOTION AND POSTURAL SHIFTS

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Guy Yona, David Bergin, Calum Mulveen, Peter Magill
University of Oxford, Mrc Brain Network Dynamics Unit, Oxford, United Kingdom

Dopamine (DA) is an important neuromodulator which is classically associated with learning and reward prediction error. Several recent works have begun to uncover the complex role DA also has in controlling motor behaviour. In the last couple of years, the development of new fluorescent molecular markers for DA, such as dLight, has greatly facilitated the recording of DA in vivo in behaving animals. We have developed an experimental framework based on a dual fibre-photometry system, EMG recording and a freewheeling linear treadmill to explore the dynamics of DA signalling during spontaneous locomotion and postural shifts in head-fixed mice. In this work, we find high correlations between the striatal DA signalling in both hemispheres. We show distinct transient decreases in the DA signal prior to initiation of locomotion, as well as increases in the signal after termination of locomotion. During postural shifts, we measure a characteristic tri-phasic signal, closely matching the signal predicted from the firing pattern of midbrain dopaminergic cells in earlier work. In addition, we examine how these features of DA signalling are disrupted in a mouse model of Parkinson's Disease, induced by intracerebral injection of pre-formed fibrils of alpha-synuclein, a protein commonly found in pathologic inclusions (Lewy bodies) in cells of human patients. This will help us gain a better understanding of the first stages in the progression of the disease, prior to the onset of symptoms.

Utah optrode array customization using stereotactic brain atlases and 3-D CAD modeling for optogenetic neocortical interrogation in small rodents and nonhuman primates.
As the optogenetic field expands, the need for precise targeting of neocortical circuits only grows more crucial. This work demonstrates a technique for using Solidworks computer-aided design (CAD) and readily available stereotactic brain atlases to create a three-dimensional (3-D) model of the dorsal region of area visual cortex 4 (V4D) of the macaque monkey () visual cortex. The 3-D CAD model of the brain was used to customize an [Formula: see text] Utah optrode array (UOA) after it was determined that a high-density ([Formula: see text]) UOA caused extensive damage to marmoset () primary visual cortex as assessed by electrophysiological recording of spiking activity through a 1.5-mm-diameter through glass via. The [Formula: see text] UOA was customized for optrode length ([Formula: see text]), optrode width ([Formula: see text]), optrode pitch ([Formula: see text]), backplane thickness ([Formula: see text]), and overall form factor ([Formula: see text]). Two [Formula: see text] UOAs were inserted into layer VI of macaque V4D cortices with minimal damage as assessed in fixed tissue cytochrome oxidase staining in nonrecoverable surgeries. Additionally, two [Formula: see text] arrays were implanted in mice () motor cortices, providing early evidence for long-term tolerability (over 6 months), and for the ability to integrate the UOA with a Holobundle light delivery system toward patterned optogenetic stimulation of cortical networks.

Realistic Numerical and Analytical Modeling of Light Scattering in Brain Tissue for Optogenetic Applications(1,2,3).
In recent years, optogenetics has become a central tool in neuroscience research. Estimating the transmission of visible light through brain tissue is of crucial importance for controlling the activation levels of neurons in different depths, designing optical systems, and avoiding lesions from excessive power density. The Kubelka-Munk model and Monte Carlo simulations have previously been used to model light propagation through rodents' brain tissue, however, these prior attempts suffer from fundamental shortcomings. Here, we introduce and study two modified approaches for modeling the distributions of light emanating from a multimode fiber and scattering through tissue, using both realistic numerical Monte Carlo simulations and an analytical approach based on the beam-spread function approach. We demonstrate a good agreement of the new methods' predictions both with recently published data, and with new measurements in mouse brain cortical slices, where our results yield a new cortical scattering length estimate of ~47 μm at λ = 473 nm, significantly shorter than ordinarily assumed

in optogenetic applications.

Autonomous University of Madrid (UAM), Department Of Anatomy, Histology And Neuroscience, Madrid, Spain, [2]Lintong Shiyoucheng, General Clinic, Xi'an, China, [3]PhD Program in Neuroscience, UAM, Dept Of Anatomy, Histology & Neuroscience, Madrid, Spain, [4]The Instituto de Investigaciones Biomédicas "Alberto Sols" (IIBM), Department Of Pathophysiology Endocrine And Nervous System, Madrid, Spain, [5]School of Medicine. Universidad Autónoma de Madrid. Spain., Department Of Anatomy, Histology And Neuroscience, Madrid, Spain

Monocarboxylate transporter 8 (MCT8) and organic anion transporting polypeptide 1C1 (OATP1C1) are thyroid hormone (TH) transporters that facilitate TH to cross the plasma membrane to perform its bioactivity. So far it is unknown the nature of the neural cells in which these transporters are expressed in the adult monkey and human basal ganglia and motor related structures. We performed immunohistochemistry, histochemistry or immunofluorescence on brain sections from cynomolgus monkeys and humans. The immunolabeling results were plotted in distribution maps by means of Neurolucida system. MCT8 and OATP1C1 are expressed in several kinds of neurons with different morphologies in both human and monkey neostriatum.MCT8 expression is in general less abundant than OATP1C1. MCT8 is expressed in medium-sized aspiny non-NOS GABAergic interneurons in human and monkey, while OATP1C1 is expressed in NOS GABAergic interneurons in human. Both transporters colocalize with acetyl choline in large caudate-putamen neurons. OATP1C1 colocalizes with IBA-1 in microglial cells. In addition, we have noticed that both transporters are strongly expressed in substantia nigra in the monkey and in cholinergic neurons in the nucleus basalis of Meynert in human and monkey. MCT8 but not OATP1C1 is expressed extensively in the endothelial cells of the various size vessels and capillaries in the basal ganglia and thalamus. Our study provides the first evidence for the abundance of TH transporters MCT8 and OATP1C1 in the basal ganglia and thalamic neurons in the adult human and non-human primates, which suggests their important role in the motor system functionality.

AN IN VIVO CALCIUM IMAGING STUDY OF IMSN INVOLVMENT IN THE STRIATAL ENCODING OF MOUSE LOCOMOTOR ACTIVITY

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Miriam Cavagnini[1], Paolo Pozzi[1], Alban De Kerchove D'Exaerde[2], Michele Zoli[1]
[1]University of Modena and Reggio Emilia, Dept. Of Biomedical, Metabolical And Neural Sciences, Modena, Italy, [2]Université Libre de Bruxelles, Faculté De Médecine, Bruxelles, Belgium

Striatum is the main input nucleus of the basal ganglia and 95% of its neurons are GABAergic medium spiny neurons (MSNs). MSNs are subdivided into neurons of the direct and indirect pathway. According to the classical model, these two pathways exert an opposite effect on movement regulation: the direct pathway promotes activity of the cortex, and therefore movement initiation, while the indirect pathway inhibits cortical activity and movement. Recent studies have challenged this interpretation and demonstrated that both pathways are co-activated during movement initiation (Bonnavion 2019, Tecuapetla 2016, Parker 2018). Yet, while the role of these two pathways is globally understood, cell-specific mechanisms and their interaction in relation to movement are only partially known. We present a study investigating the role of murine striatum in locomotion, and in particular the involvement of MSNs of the indirect pathway (iMSNs), through *in-vivo* Ca^{2+} imaging with head-mounted microscopes and chronically implanted endoscopes in freely behaving mice. Locomotor activity was tested by behavioural experiments and the GABAergic iMSN activity was stimulated by a psychostimulant drug, d-Amphetamine, at different doses. A2AGCaMP6s mice expressing GCaMP in iMSNs were used as an animal model. Analysis of the acquired datasets showed that acute intraperitoneal injection of d-Amphetamine at 3 mg/kg dose decreased the average number of active iMSNs and increased the average spike duration, and demonstrated that iMSNs contribute to the encoding of movement initiation and termination, confirming the notion of direct-indirect pathway co-activation in movement control.

Experimental determination of shift-less aberration bases for sensorless adaptive optics in nonlinear microscopy.
Adaptive optics can improve the performance of optical systems and devices by correcting phase aberrations. While in most applications wavefront sensing is employed to drive the adaptive optics correction, some microscopy methods may require sensorless optimization of the wavefront. In these cases, the correction is performed by describing the aberration as a linear combination of a base of influence functions, optimizing an image quality metric as a function of the coefficients. The influence functions base is generally chosen to either efficiently represent the adaptive device used or to describe generic wavefronts in an orthogonal fashion. A rarely discussed problem is that most correction bases have elements which introduce, together with a correction of the aberration, a shift of the imaging field of view in three dimensions. While simple methods to solve the problem are available for linear microscopy methods, nonlinear microscopy techniques such as multiphoton or second harmonic generation microscopy require non-trivial base determination. In this paper, we discuss the problem, and we present a method for calibrating a shift-less base on a spatial light modulator for two-photon microscopy.

EXPERIMENTAL INVESTIGATION INTO THE ROLE OF THE SUBTHALAMIC NUCLEUS (STN) USING OPTOGENETICS IN MICE

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Gian Pietro Serra[1], Adriane Guillaumin[2], Alessia Ricci[1], Eleonora Rubino[1], Marie Englund[1], Jérôme Baufreton[3], François Georges[3], Åsa Wallén-Mackenzie[1]
[1]Uppsala University, Department Of Organismal Biology, Uppsala, Sweden, [2]Universit´e de Bordeaux, Institut Des Maladies Neurod´eg´en´eratives, Bordeaux, France, [3]Institute of Neurodegenerative Disease, Gironde, Bordeaux, France

Aims: Most knowledge about the STN has been gained through functional knowledge of the Subthalamic Nucleus (STN) has been gained from pathological conditions and models, primarily parkinsonian, experimental evidence for its role in normal motor control has remained sparse. The aim of this study was to tease out the selective impact of the STN on several motor parameters required to achieve intended movement, including locomotion, balance and motor coordination. **Methods:** Optogenetic excitation and inhibition using both bilateral and unilateral stimulations of the STN were implemented in freely-moving mice. **Results:** The results demonstrate that selective optogenetic inhibition of the STN enhances locomotion while its excitation reduces locomotion. In addition, optogenetic excitation in freely-exploring mice induced self-grooming, disturbed gait and a jumping/escaping behavior, while causing reduced motor coordination in advanced motor tasks, independent of grooming and jumping. In addition, we found that, when given a choice, mice avoided excitation of the STN. **Conclusions:** These findings lend experimental support to basal ganglia models of the STN in terms of locomotion. Avoidance response suggests that the STN can play a crucial role within the brain aversion and emotion systems establishing a critical brain hub for motor, cognitive and emotional functions.

CELL-TYPE SPECIFIC ELECTROPHYSIOLOGICAL AND BEHAVIOURAL ALTERATIONS IN THE GLOBUS PALLIDUS OF MICE FOLLOWING STRIATOPALLIDAL PATHWAY ABLATION.

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Marine Chazalon[1], Patricia Bonnavion[2], Alban De Kerchove D'Exaerde[1], Serge Schiffmann[1]
[1]université libre de Bruxelles, Laboratoire De Neurophysiologie, BRUXELLES, Belgium, [2]Université Libre de Bruxelles, Laboratoire De Neurophysiologie, Bruxelles, Belgium

The basal ganglia (BG) is a group of sub-cortical nuclei involved in motor control, learning and reward processing. Current models postulate that the BG modulate the cerebral cortex indirectly via an inhibitory input to the thalamus, bidirectionally controlled by direct- and indirect-pathway striatal projection neurons (MSNs). The direct pathway, composed of the striatonigral MSN (dMSNs) facilitates and the indirect pathway composed of the striatopallidal MSNs (iMSNs) inhibits thalamus outputs to the cortex. In this model, the GABAergic globus pallidus (GP - external globus pallidus in the primates), which is the major target nucleus of iMSNs, is centrally positioned in the basal ganglia circuitry. It receives, processes and distributes cortico-striatal information to the entire network through its widespread axonal projections, thereby influencing basal ganglia nuclei output during voluntary movement and executive functions. Previously considered as a homogenous nucleus, most recent evidences indicate that the GP contains two main types of GABAergic projection cells named “Prototypic” and “Arkypallidal” neurons with specialized molecular, physiological properties and specific target structures. Here, we investigate by in vitro electrophysiology coupled with optogenetics and by using a genetic mouse model of selective iMSNs ablation, the A_{2A}iDTR mice, how prototypic pallidal neurons are affected by the selective depletion of iMSNs and examine the involvement of parvalbumin pallidal neurons - a subpopulation of prototypic population - on motor function and amphetamine-induced locomotion.

Mammalian Target of Rapamycin-RhoA Signaling Impairments in Direct Striatal Projection Neurons Induce Altered Behaviors and Striatal Physiology in Mice.
As an integrator of molecular pathways, mTOR (mammalian target of rapamycin) has been associated with diseases including neurodevelopmental, psychiatric, and neurodegenerative disorders such as autism spectrum disorder, schizophrenia, and Huntington's disease. An important brain area involved in all these diseases is the striatum. However, the mechanisms behind how mTOR is involved in striatal physiology and its relative role in distinct neuronal populations in these striatal-related diseases still remain to be clarified.

Primary proprioceptive neurons from human induced pluripotent stem cells: a cell model for afferent ataxias.
Human induced pluripotent stem cells (iPSCs) are used to generate models of human diseases that recapitulate the pathogenic process as it occurs in affected cells. Many differentiated cell types can currently be obtained from iPSCs, but no validated protocol is yet available to specifically generate primary proprioceptive neurons. Proprioceptors are affected in a number of genetic and acquired diseases, including Friedreich ataxia (FRDA). To develop a cell model that can be applied to conditions primarily affecting proprioceptors, we set up a protocol to differentiate iPSCs into primary proprioceptive neurons. We modified the dual-SMAD inhibition/WNT activation protocol, previously used to generate nociceptor-enriched cultures of primary sensory neurons from iPSCs, to favor instead the generation of proprioceptors. We succeeded in substantially enriching iPSC-derived primary sensory neuron cultures for proprioceptors, up to 50% of finally differentiated neurons, largely exceeding the proportion of 7.5% normally represented by these cells in dorsal root ganglia. We also showed that almost pure populations of proprioceptors can be purified from these cultures by fluorescence-activated cell sorting. Finally, we demonstrated that the protocol can be used to generate proprioceptors from iPSCs from FRDA patients, providing a cell model for this genetic sensory neuronopathy.

Dysregulation of external globus pallidus-subthalamic nucleus network dynamics in parkinsonian mice during cortical slow-wave activity and activation.
Reciprocally connected GABAergic external globus pallidus (GPe) and glutamatergic subthalamic nucleus (STN) neurons form a key network within the basal ganglia. In Parkinson's disease and its models, abnormal rates and patterns of GPe-STN network activity are linked to motor dysfunction. Using cell class-specific optogenetic identification and inhibition during cortical slow-wave activity and activation, we report that, in dopamine-depleted mice, (1) D2 dopamine receptor expressing striatal projection neurons (D2-SPNs) discharge at higher rates, especially during cortical activation, (2) prototypic parvalbumin-expressing GPe neurons are excessively patterned by D2-SPNs even though their autonomous activity is upregulated, (3) despite being disinhibited, STN neurons are not hyperactive, and (4) STN activity opposes striatopallidal patterning. These data argue that in parkinsonian mice abnormal, temporally offset prototypic GPe and STN neuron firing results in part from increased striatopallidal transmission and that compensatory plasticity limits STN hyperactivity and cortical entrainment.

Cellular and Synaptic Dysfunctions in Parkinson's Disease: Stepping out of the Striatum.
The basal ganglia (BG) are a collection of interconnected subcortical nuclei that participate in a great variety of functions, ranging from motor programming and execution to procedural learning, cognition, and emotions. This network is also the region primarily affected by the degeneration of midbrain dopaminergic neurons localized in the substantia nigra pars compacta (SNc). This degeneration causes cellular and synaptic dysfunctions in the BG network, which are responsible for the appearance of the motor symptoms of Parkinson's disease. Dopamine (DA) modulation and the consequences of its loss on the striatal microcircuit have been extensively studied, and because of the discrete nature of DA innervation of other BG nuclei, its action outside the striatum has been considered negligible. However, there is a growing body of evidence supporting functional extrastriatal DA modulation of both cellular excitability and synaptic transmission. In this review, the functional relevance of DA modulation outside the striatum in both normal and pathological conditions will be discussed.

The GABAergic Gudden's dorsal tegmental nucleus: A new relay for serotonergic regulation of sleep-wake behavior in the mouse.
Serotonin (5-HT) neurons are involved in wake promotion and exert a strong inhibitory influence on rapid eye movement (REM) sleep. Such effects have been ascribed, at least in part to the action of 5-HT at post-synaptic 5-HT receptors (5-HTR) in the brainstem, a major wake/REM sleep regulatory center. However, the neuroanatomical substrate through which 5-HTR influence sleep remains elusive. We therefore investigated whether a brainstem structure containing a high density of 5-HTR mRNA, the GABAergic Gudden's dorsal tegmental nucleus (DTg), may contribute to 5-HT-mediated regulatory mechanisms of sleep-wake stages. We first found that bilateral lesions of the DTg promote wake at the expense of sleep. In addition, using local microinjections into the DTg in freely moving mice, we showed that local activation of 5-HTR by the prototypical agonist 8-OH-DPAT enhances wake and reduces deeply REM sleep duration. The specific involvement of 5-HTR in the latter effects was further demonstrated by ex vivo extracellular recordings showing that the selective 5-HTR antagonist WAY 100635 prevented DTg neuron inhibition by 8-OH-DPAT. We next found that GABAergic neurons of the ventral DTg exclusively targets glutamatergic neurons of the lateral mammillary nucleus (LM) in the posterior hypothalamus by means of anterograde and retrograde tracing techniques using cre driver mouse lines and a modified rabies virus. Altogether, our findings strongly support the idea that 5-HT-driven enhancement of wake results from 5-HTR-mediated inhibition of DTg GABAergic neurons that would in turn disinhibit glutamatergic neurons in the mammillary bodies. We therefore propose a Raphe→DTg→LM pathway as a novel regulatory circuit underlying 5-HT modulation of arousal.

Inhaling xenon ameliorates l-dopa-induced dyskinesia in experimental parkinsonism.
Parkinson's disease motor symptoms are treated with levodopa, but long-term treatment leads to disabling dyskinesia. Altered synaptic transmission and maladaptive plasticity of corticostriatal glutamatergic projections play a critical role in the pathophysiology of dyskinesia. Because the noble gas xenon inhibits excitatory glutamatergic signaling, primarily through allosteric antagonism of the N-methyl-d-aspartate receptors, we aimed to test its putative antidyskinetic capabilities. We first studied the direct effect of xenon gas exposure on corticostriatal plasticity in a murine model of levodopa-induced dyskinesia We then studied the impact of xenon inhalation on behavioral dyskinetic manifestations in the gold-standard rat and primate models of PD and levodopa-induced dyskinesia. Last, we studied the effect of xenon inhalation on axial gait and posture

deficits in a primate model of PD with levodopa-induced dyskinesia. This study shows that xenon gas exposure (1) normalized synaptic transmission and reversed maladaptive plasticity of corticostriatal glutamatergic projections associated with levodopa-induced dyskinesia, (2) ameliorated dyskinesia in rat and nonhuman primate models of PD and dyskinesia, and (3) improved gait performance in a nonhuman primate model of PD. These results pave the way for clinical testing of this unconventional but safe approach. © 2018 The Authors. GAT-3 Dysfunction Generates Tonic Inhibition in External Globus Pallidus Neurons in Parkinsonian Rodents.
The external globus pallidus (GP) is a key GABAergic hub in the basal ganglia (BG) circuitry, a neuronal network involved in motor control. In Parkinson's disease (PD), the rate and pattern of activity of GP neurons are profoundly altered and contribute to the motor symptoms of the disease. In rodent models of PD, the striato-pallidal pathway is hyperactive, and extracellular GABA concentrations are abnormally elevated in the GP, supporting the hypothesis of an alteration of neuronal and/or glial clearance of GABA. Here, we discovered the existence of persistent GABAergic tonic inhibition in GP neurons of dopamine-depleted (DD) rodent models. We showed that glial GAT-3 transporters are downregulated while neuronal GAT-1 function remains normal in DD rodents. Finally, we showed that blocking GAT-3 activity in vivo alters the motor coordination of control rodents, suggesting that GABAergic tonic inhibition in the GP contributes to the pathophysiology of PD.

Alteration of GABAergic neurotransmission in Huntington's disease.
Hereditary Huntington's disease (HD) is characterized by cell dysfunction and death in the brain, leading to progressive cognitive, psychiatric, and motor impairments. Despite molecular and cellular descriptions of the effects of the HD mutation, no effective pharmacological treatment is yet available. In addition to well-established alterations of glutamatergic and dopaminergic neurotransmitter systems, it is becoming clear that the GABAergic systems are also impaired in HD. GABA is the major inhibitory neurotransmitter in the brain, and GABAergic neurotransmission has been postulated to be modified in many neurological and psychiatric diseases. In addition, GABAergic neurotransmission is the target of many drugs that are in wide clinical use. Here, we summarize data demonstrating the occurrence of alterations of GABAergic markers in the brain of HD carriers as well as in rodent models of the disease. In particular, we pinpoint HD-related changes in the expression of GABA receptors (GABA Rs). On the basis that a novel GABA pharmacology of GABA Rs established with more selective drugs is emerging, we argue that clinical treatments acting specifically on GABAergic neurotransmission may be an appropriate strategy for improving symptoms linked to the HD mutation.

Early GABAergic transmission defects in the external globus pallidus and rest/activity rhythm alteration in a mouse model of Huntington's disease.
Huntington's disease (HD) is characterized by progressive motor symptoms preceded by cognitive deficits and is regarded as a disorder that primarily affects the basal ganglia. The external globus pallidus (GPe) has a central role in the basal ganglia, projects directly to the cortex, and is majorly modulated by GABA. To gain a better understanding of the time course of HD progression and gain insight into the underlying mechanisms, we analyzed GABAergic neurotransmission in the GPe of the R6/1 mouse model at purportedly asymptomatic and symptomatic stages (i.e., 2 and 6months). Western blot and quantitative polymerase chain reaction (PCR) analyses revealed alterations in the GPe of male R6/1 mice compared with wild-type littermates. Expression of proteins involved in pre- and post-synaptic GABAergic compartments as well as synapse number were severely decreased at 2 and 6months. At both ages, patch-clamp electrophysiological recordings showed a decrease of spontaneous and miniature inhibitory post-synaptic currents (IPSCs) suggesting that HD mutation has an early effect on the GABA signaling in the brain. Therefore, we performed continuous locomotor activity recordings from 2 to 4months of age. Actigraphy analyses revealed rest/activity fragmentation alterations that parallel GABAergic system impairment at 2months, while the locomotor deficit is evident only at 3months in R6/1 mice. Our results reveal early deficits in HD and support growing evidence for a critical role played by the GPe in physiological and pathophysiological states. We suggest that actimetry may be used as a non-invasive tool to monitor early disease progression.

Somatostatin triggers rhythmic electrical firing in hypothalamic GHRH neurons.
Hypothalamic growth hormone-releasing hormone (GHRH) neurons orchestrate body growth/maturation and have been

implicated in feeding responses and ageing. However, the electrical patterns that dictate GHRH neuron functions have remained elusive. Since the inhibitory neuropeptide somatostatin (SST) is considered to be a primary oscillator of the GH axis, we examined its acute effects on GHRH neurons in brain slices from male and female GHRH-GFP mice. At the cellular level, SST irregularly suppressed GHRH neuron electrical activity, leading to slow oscillations at the population level. This resulted from an initial inhibitory action at the GHRH neuron level via K(+) channel activation, followed by a delayed, sst1/sst2 receptor-dependent unbalancing of glutamatergic and GABAergic synaptic inputs. The oscillation patterns induced by SST were sexually dimorphic, and could be explained by differential actions of SST on both GABAergic and glutamatergic currents. Thus, a tripartite neuronal circuit involving a fast hyperpolarization and a dual regulation of synaptic inputs appeared sufficient in pacing the activity of the GHRH neuronal population. These "feed-forward loops" may represent basic building blocks involved in the regulation of GHRH release and its downstream sexual specific functions.

Aims: Dystonia is a movement disorder characterized by involuntary muscle contractions that has been linked to basal ganglia dysfunction. It has been proposed that the basal ganglia are involved in action selection by selecting an appropriate action through the activity of the direct pathway, while simultaneously inhibiting competing actions through the activity of the indirect pathway. Thus, an imbalance between the direct (D1 medium spiny neurons (MSNs)) and indirect pathways (D2 MSNs) could lead to involuntary dystonic movements. Yet, there is a lack of *in vivo* studies that dissect activity and ensemble dynamics of D1 or D2 MSNs in dystonia. **Methods:** DYT-TOR1AΔGAG knock-in mice and wild-type mice (WT) expressing Cre recombinase under the control of the dopamine D1 or A2A receptors (for D2 populations). Using *in vivo* calcium imaging, MSNs activity was recorded in freely moving animals while behavior was assessed by video and head-mounted accelerometers. Assessments were performed before and weekly after a standardized sciatic nerve crush lesion (SNCL) – a procedure known to induce dystonic-like movement in genetically-predisposed animals. **Results:** No significant differences were found in calcium transients rate or amplitude between DYT1-Tor1a and WT mice in both D1 and D2 MSNs. However, activity of movement-modulated D1 MSNs significantly increased while activity of D2 MSNs decreased, as dystonic-like movements developed in DYT1-Tor1a mice. Our observations shed light into the pathophysiology of DYT-TOR1A dystonia by revealing an imbalance between the D1 and D2 pathways at movement onset, compatible with a focused selection and inhibition model of the basal ganglia.

Conservation of locomotion-induced oculomotor activity through evolution in mammals.
Efference copies are neural replicas of motor outputs used to anticipate the sensory consequences of a self-generated motor action or to coordinate neural networks involved in distinct motor behaviors. An established example of this motor-to-motor coupling is the efference copy of the propulsive motor command, which supplements classical visuo-vestibular reflexes to ensure gaze stabilization during amphibian larval locomotion. Such feedforward replica of spinal pattern-generating circuits produces a spino-extraocular motor coupled activity that evokes eye movements, spatiotemporally coordinated to tail undulation independently of any sensory signal. Exploiting the developmental stages of the frog, studies in metamorphing Xenopus demonstrated the persistence of this spino-extraocular motor command in adults and its developmental adaptation to tetrapodal locomotion. Here, we demonstrate for the first time the existence of a comparable locomotor-to-ocular motor coupling in the mouse. In neonates, ex vivo nerve recordings of brainstem-spinal cord preparations reveal a spino-extraocular motor coupled activity similar to the one described in Xenopus. In adult mice, trans-synaptic rabies virus injections in lateral rectus eye muscle label cervical spinal cord neurons closely connected to abducens motor neurons. Finally, treadmill-elicited locomotion in decerebrated preparations evokes rhythmic eye movements in synchrony with the limb gait pattern. Overall, our data are evidence for the conservation of locomotor-induced eye movements in vertebrate lineages. Thus, in mammals as in amphibians, CPG-efference copy feedforward signals might interact with sensory feedback to ensure efficient gaze control during locomotion.

Long term visuo-vestibular mismatch in freely behaving mice differentially affects gaze stabilizing reflexes.
The vestibulo-ocular reflex (VOR) and the optokinetic reflex (OKR) work synergistically to stabilize gaze in response to head

movements. We previously demonstrated that a 14-day visuo-vestibular mismatch (VVM) protocol applied in freely behaving mice decreased the VOR gain. Here, we show for the first time that the OKR gain is also reduced and report on the recovery dynamics of both VOR and OKR after the end of the VVM protocol. Using sinusoidally-modulated stimulations, the decreases in VOR and OKR were found to be frequency-selective with larger reductions for frequencies < 0.5 Hz. Constant-velocity OKR stimulation tests demonstrated that the persistent components of the OKR were not modified while the transient, initial responses were. To identify the signals driving VOR and OKR reductions, we compared the responses of mice exposed to a high-contrast and no-contrast VVM. Despite being more robust in the high-contrast conditions, reductions were largely comparable and recovered with a similar time course. An analysis that directly compared VOR and OKR responses revealed that, alterations in the VOR were of significantly larger amplitude with significantly slower dynamics of recovery. Our findings are evidence for a frequency-selective influence of visual signals in the tuning of gaze stabilizing reflexes in normal mice.

Long-term Sensory Conflict in Freely Behaving Mice.
Long-term sensory conflict protocols are a valuable means of studying motor learning. The presented protocol produces a persistent sensory conflict for experiments aimed at studying long-term learning in mice. By permanently wearing a device fixed on their heads, mice are continuously exposed to a sensory mismatch between visual and vestibular inputs while freely moving in home cages. Therefore, this protocol readily enables the study of the visual system and multisensory interactions over an extended timeframe that would not be accessible otherwise. In addition to lowering the experimental costs of long-term sensory learning in naturally behaving mice, this approach accommodates the combination of in vivo and in vitro experiments. In the reported example, video-oculography is performed to quantify the vestibulo-ocular reflex (VOR) and optokinetic reflex (OKR) before and after learning. Mice exposed to this long-term sensory conflict between visual and vestibular inputs presented a strong VOR gain decrease but exhibited few OKR changes. Detailed steps of device assembly, animal care, and reflex measurements are hereby reported.

Local gene therapy durably restores vestibular function in a mouse model of Usher syndrome type 1G.
Our understanding of the mechanisms underlying inherited forms of inner ear deficits has considerably improved during the past 20 y, but we are still far from curative treatments. We investigated gene replacement as a strategy for restoring inner ear functions in a mouse model of Usher syndrome type 1G, characterized by congenital profound deafness and balance disorders. These mice lack the scaffold protein sans, which is involved both in the morphogenesis of the stereociliary bundle, the sensory antenna of inner ear hair cells, and in the mechanoelectrical transduction process. We show that a single delivery of the sans cDNA by the adenoassociated virus 8 to the inner ear of newborn mutant mice reestablishes the expression and targeting of the protein to the tips of stereocilia. The therapeutic gene restores the architecture and mechanosensitivity of stereociliary bundles, improves hearing thresholds, and durably rescues these mice from the balance defects. Our results open up new perspectives for efficient gene therapy of cochlear and vestibular disorders by showing that even severe dysmorphogenesis of stereociliary bundles can be corrected.

Long-Lasting Visuo-Vestibular Mismatch in Freely-Behaving Mice Reduces the Vestibulo-Ocular Reflex and Leads to Neural Changes in the Direct Vestibular Pathway.
Calibration of the vestibulo-ocular reflex (VOR) depends on the presence of visual feedback. However, the cellular mechanisms associated with VOR modifications at the level of the brainstem remain largely unknown. A new protocol was designed to expose freely behaving mice to a visuo-vestibular mismatch during a 2-week period. This protocol induced a 50% reduction of the VOR. pharmacological experiments demonstrated that the VOR reduction depends on changes located outside the flocculus/paraflocculus complex. The cellular mechanisms associated with the VOR reduction were then studied on brainstem slices through a combination of vestibular afferent stimulation and patch-clamp recordings of central vestibular neurons. The evoked synaptic activity demonstrated that the efficacy of the synapses between vestibular afferents and central vestibular neurons was decreased. In addition, a long-term depression protocol failed to further decrease the synapse efficacy, suggesting that the VOR reduction might have occurred through depression-like mechanisms. Analysis of the intrinsic membrane properties of central vestibular neurons revealed that the synaptic changes were supplemented by a decrease in the spontaneous discharge and excitability of a subpopulation of neurons. Our results provide evidence that a long-lasting visuo-vestibular mismatch leads to changes in synaptic transmission and intrinsic properties of central vestibular neurons in the direct VOR pathway. Overall, these results open new avenues for future studies on visual and vestibular

interactions conducted and .

FURTHER CHARACTERISATION OF THE RAT MODEL OF TOURETTE-RELATED STRIATAL DISINHIBITION: IN VIVO ELECTROPHYSIOLOGICAL AND BEHAVIOURAL STUDIES

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Joanna Loayza, Charlotte Taylor, Jacco Renstrom, Rachel Grasmeder Allen, Stephen Jackson, Tobias Bast
University of Nottingham, School Of Psychology, Nottingham, United Kingdom

Tourette's syndrome, characterised by tics, has been linked to reduced GABAergic inhibition, so-called neural disinhibition, in the striatum (Jackson et al.,2015,*Trends CognSci*). Dorsal striatal microinfusion of GABA-A antagonists like picrotoxin produces tic-like movements in rodents and primates (Bronfeld et al.,2013,*FrontSystNeurosci*; Klaus&Plenz,2016,*PLoSBiol*.) Here, we infused young adult male Lister hooded rats unilaterally with picrotoxin (300ng/0.5ul) or saline (0.5ul) into the anterior dorsal striatum and recorded electrophysiological and behavioural measurements to characterise further the neuro-behavioural impact of striatal disinhibition. Electrophysiological recordings under isoflurane in the striatum showed that picrotoxin disinhibition, apart from evoking large LFP spike-wave discharges, with sharp multi-unit bursts during the negative spike, markedly enhanced burst firing, similar to findings in prefrontal cortex and hippocampus (Bast et al.,2017,*BrJPharamcol*). In freely moving rats, striatal picrotoxin reliably induced tic-like contralateral forelimb movements. Automated photobeam measurements revealed that striatal disinhibition increased locomotor activity and fine motor counts. Fine motor counts showed a similar time course to tic-like movements, suggesting an automated method to quantify these movements. Prepulse inhibition (PPI) of acoustic startle depends on the striatum and is disrupted in Tourette's (Swerdlow,2013,*NeurosciBiobehavRev*). Striatal disinhibition in rats did not affect PPI, but tended to reduce startle during the first test block, before habituation led to similarly low startle responses in both infusion conditions (infusion-X-block: $F(2,26)=3.2$, $p=0.058$). Our findings confirm that striatal disinhibition causes marked spike-wave discharges in striatum and tic-like movements. In addition, such disinhibition markedly enhances striatal burst firing and increases locomotor activity, but does not reproduce PPI deficits seen in Tourette's.

The role of the insula in the generation of motor tics and the experience of the premonitory urge-to-tic in Tourette syndrome.
Tourette syndrome (TS) is a neurological disorder of childhood onset that is characterised by the occurrence of motor and vocal tics. TS is associated with cortical-striatal-thalamic-cortical circuit [CSTC] dysfunction and hyper-excitability of cortical limbic and motor regions that are thought to lead to the occurrence of tics. Importantly, individuals with TS often report that their tics are preceded by 'premonitory sensory/urge phenomena' (PU) that are described as uncomfortable bodily sensations that precede the execution of a tic and are experienced as a strong urge for motor discharge. While the precise role played by PU in the occurrence of tics is largely unknown, they are nonetheless of considerable theoretical and clinical importance, not least because they form the core component in many behavioural therapies used in the treatment of tic disorders. Several lines of evidence indicate that the insular cortex may play a particularly important role in the generation of PU in TS and 'urges-for-action' more generally. In the current study we utilised voxel-based morphometry techniques together with 'seed-to-voxel' structural covariance network (SCN) mapping to investigate the putative role played by the right insular cortex in the generation of motor tics and the experience of PU in a relatively large group of young people TS. We demonstrate that clinical measures of motor tic severity and PU are uncorrelated with one another, that motor tic severity and PU scores are associated with separate regions of the insular cortex, and that the insula is associated with different structural covariance networks in individuals with TS compared to a matched group of typically developing individuals.

Hippocampal Disinhibition Reduces Contextual and Elemental Fear Conditioning While Sparing the Acquisition of Latent Inhibition.
Hippocampal neural disinhibition, i.e., reduced GABAergic inhibition, is a key feature of schizophrenia pathophysiology. The hippocampus is an important part of the neural circuitry that controls fear conditioning and can also modulate prefrontal and striatal mechanisms, including dopamine signaling, which play a role in salience modulation. Consequently, hippocampal

neural disinhibition may contribute to impairments in fear conditioning and salience modulation reported in schizophrenia. Therefore, we examined the effect of ventral hippocampus (VH) disinhibition in male rats on fear conditioning and salience modulation, as reflected by latent inhibition (LI), in a conditioned emotional response (CER) procedure. A flashing light was used as the conditioned stimulus (CS), and conditioned suppression was used to index conditioned fear. In experiment 1, VH disinhibition via infusion of the GABA-A receptor antagonist picrotoxin before CS pre-exposure and conditioning markedly reduced fear conditioning to both the CS and context; LI was evident in saline-infused controls but could not be detected in picrotoxin-infused rats because of the low level of fear conditioning to the CS. In experiment 2, VH picrotoxin infusions only before CS pre-exposure did not affect the acquisition of fear conditioning or LI. Together, these findings indicate that VH neural disinhibition disrupts contextual and elemental fear conditioning, without affecting the acquisition of LI. The disruption of fear conditioning resembles aversive conditioning deficits reported in schizophrenia and may reflect a disruption of neural processing both within the hippocampus and in projection sites of the hippocampus.

RESTORATION OF DOPAMINE D2 RECEPTORS IN THE SENSORIMOTOR STRIATUM OF D2R KNOCKDOWN MICE SELECTIVELY AMELIORATES DEFICITS IN MOTOR SKILL LEARNING

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Rudolf Faust[1], Jared Hinkle[2], Jeff Beeler[1], Xiaoxi Zhuang[3]
[1]Queens College, Psychology, Flushing, United States of America, [2]Johns Hopkins University, Medical Scientist Training Program, Baltimore, United States of America, [3]University of Chicago, Neurobiology, Chicago, United States of America

Dopamine D2 receptors (D2Rs) are necessary for normal voluntary movement, but the behavior-specific contributions of D2R function in different striatal territories and cell types remain incompetely understood. We sought to define the subpopulations of striatal neurons in which restoration of D2R signaling rescues specific behavioral deficits induced by global knockdown of D2R expression (D2R-KD). Therefore, we characterized a D2R-KD mouse line in which a transcriptional STOP cassette that could be excised by Cre recombinase had been inserted between the D2 promoter and the coding sequence of the D2R gene. In this D2-KD mouse line, expression of D2R mRNA was greatly reduced and could be rescued in indirect pathway medium spiny neurons by local transduction with an adeno-associated viral vector encoding Cre recombinase driven by the enkephalin promoter. D2-KD mice exhibited severe impairments on the rotarod and in a self-paced action sequence task. Although they executed the action sequence in the correct order, they displayed impaired movement initiation and a phenotype that appears similar to the “freezing” observed in Parkinson’s disease patients. To elucidate the minimal neural substrates in which D2R signaling can ameliorate deficits induced by global D2R knockdown, we restored D2R expression in indirect pathway medium spiny neurons (iMSNs) of the dorsolateral striatum (DLS). Restoration of D2R signaling to DLS iMSNs ameliorated performance deficits on the accelerating rotarod, but not in our operant action sequence task. We conclude that D2R signaling in the aDLS is partially sufficient to support the learning and/or performance of motor skills.

CELL-TYPE SPECIFIC RESPONSES TO ASSOCIATIVE LEARNING IN THE PRIMARY MOTOR CORTEX

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Candice Lee, Emerson Harkin, Xuming Yin, Richard Naud, Simon Chen
University of Ottawa, Cellular And Molecular Medicine, Ottawa, Canada

The primary motor cortex (M1) is a critical site for both movement initiation and motor learning. Intriguingly, neurons in M1 have also been shown to have reward-related activity, possibly to facilitate reward-based learning of new movements. However, whether reward-related signals are represented among different cell types in M1, and whether their response properties change after cue-reward conditioning remains unclear. Here, we performed longitudinal *in vivo* two-photon Ca^{2+} imaging to monitor the activity of different neuronal cell types in M1 of adult mice engaged in a classical conditioning task. Our findings reveal that most of the major neuronal cell types in M1 show robust but differential responses to both cue and reward stimuli, and their response properties undergo cell-type specific modifications following associative learning. PV inhibitory neuron responses became more reliable to the cue stimulus, while VIP inhibitory neuron responses became more reliable to the reward. Moreover, we did not observe these changes in PV or VIP inhibitory neuron responses when the cue and reward were randomly timed and not paired together. These observations demonstrate that cue- and reward-related signals are represented among different neuronal cell types in M1, and these responses undergo distinct modifications during associative learning.

Neural activity in a hippocampus-like region of the teleost pallium is associated with active sensing and navigation.
Most vertebrates use active sensing strategies for perception, cognition and control of motor activity. These strategies include directed body/sensor movements or increases in discrete sensory sampling events. The weakly electric fish, , uses its active electric sense during navigation in the dark. Electric organ discharge rate undergoes transient increases during navigation to increase electrosensory sampling. also use stereotyped backward swimming as an important form of active sensing that brings objects toward the electroreceptor dense fovea-like head region. We wirelessly recorded neural activity from the pallium of freely swimming . Spiking activity was sparse and occurred only during swimming. Notably, most units tended to fire during backward swims and their activity was on average coupled to increases in sensory sampling. Our results provide the first characterization of neural activity in a hippocampal (CA3)-like region of a teleost fish brain and connects it to active sensing of spatial environmental features.

Light Up the Brain: The Application of Optogenetics in Cell-Type Specific Dissection of Mouse Brain Circuits.
The exquisite intricacies of neural circuits are fundamental to an animal's diverse and complex repertoire of sensory and motor functions. The ability to precisely map neural circuits and to selectively manipulate neural activity is critical to understanding brain function and has, therefore been a long-standing goal for neuroscientists. The recent development of optogenetic tools, combined with transgenic mouse lines, has endowed us with unprecedented spatiotemporal precision in circuit analysis. These advances greatly expand the scope of tractable experimental investigations. Here, in the first half of the review, we will present applications of optogenetics in identifying connectivity between different local neuronal cell types and of long-range projections with both and methods. We will then discuss how these tools can be used to reveal the functional roles of these cell-type specific connections in governing sensory information processing, and learning and memory in the visual cortex, somatosensory cortex, and motor cortex. Finally, we will discuss the prospect of new optogenetic tools and how their application can further advance modern neuroscience. In summary, this review serves as a primer to exemplify how optogenetics can be used in sophisticated modern circuit analyses at the levels of synapses, cells, network connectivity and behaviors.

Cell-type-specific responses to associative learning in the primary motor cortex.

FENS Forum 2022
9-13 July 2022 | Paris, France

The primary motor cortex (M1) is known to be a critical site for movement initiation and motor learning. Surprisingly, it has also been shown to possess reward-related activity, presumably to facilitate reward-based learning of new movements. However, whether reward-related signals are represented among different cell types in M1, and whether their response properties change after cue-reward conditioning remains unclear. Here, we performed longitudinal in vivo two-photon Ca imaging to monitor the activity of different neuronal cell types in M1 while mice engaged in a classical conditioning task. Our results demonstrate that most of the major neuronal cell types in M1 showed robust but differential responses to both the conditioned cue stimulus (CS) and reward, and their response properties undergo cell-type-specific modifications after associative learning. PV-INs' responses became more reliable to the CS, while VIP-INs' responses became more reliable to reward. Pyramidal neurons only showed robust responses to novel reward, and they habituated to it after associative learning. Lastly, SOM-INs' responses emerged and became more reliable to both the CS and reward after conditioning. These observations suggest that cue- and reward-related signals are preferentially represented among different neuronal cell types in M1, and the distinct modifications they undergo during associative learning could be essential in triggering different aspects of local circuit reorganization in M1 during reward-based motor skill learning.

CELL-CLASS-SPECIFIC OPTOGENETIC STIMULATION REVEALS SEGREGATED MOTOR MAPS IN MOUSE DORSAL CORTEX

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Keita Tamura, Pol Bech, Hidenobu Mizuno, Yanqi Liu, Hugo Thiallier, Lea Veaute, Sylvain Crochet, Carl Petersen

Functional localization is a fundamental organizing principle of the cerebral cortex. Direct cortical stimulation can be used to define cortical motor maps, i.e. maps of cortical regions which causally induce movements of a specific body part. But how different classes of neurons constitute a motor map is unknown. Here, we started to address this question by optogenetic stimulation mapping in transgenic mice expressing channelrhodopsin-2 (ChR2) in different genetically-defined classes of cortical neurons. We systematically delivered focal blue laser stimuli across dorsal cortex of awake head-restrained mice, and quantified stimulation-evoked jaw movements by high-speed video analysis. Mice expressing ChR2 in all excitatory neurons showed oscillatory opening and closing movements of the jaw evoked by optogenetic stimulation within a large elliptical area covering orofacial cortex, while mice expressing ChR2 in all inhibitory neurons did not show evoked movements. Next, we stimulated layer-specific and projection-specific excitatory neurons in different mouse lines. Surprisingly, we found that each class of excitatory neurons has its most effective cortical site in different coordinates from each other, just to cover the overall effective area defined by motor-mapping in mice expressing ChR2 in all excitatory neurons. This result suggests that a cortical motor map is organized by spatially segregated elemental maps, each of which is contributed by different classes of neurons. To reveal the circuits connecting the segregated maps, we have begun to combine optogenetic motor mapping with wide-field calcium imaging. A further important future goal is to investigate context- and learning-dependent features of these cell-class-specific motor maps.

MULTIPLE CORTICOSPINAL MODULES FOR COMMAND FUNCTIONS

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Alexandra Battaglia-Mayer[1], Rory Bufacchi[2], Giandomenico Iannetti[2], Roberto Caminiti[2]
[1]Sapienza University of Rome, Department Of Physiology And Pharmacology, Rome, Italy, [2]Italian Institute of Technology, Neuroscience And Behaviour, Rome, Italy

Classical neurology and neurophysiology have assigned to motor cortex (MI) and its cortico-spinal tract an exclusive role in action control. A different perspective, highlighting the modular nature of command functions, results from multiple observations. *(i)* The statistics of cortical connectivity of the parieto-frontal system suggest the existence of multiple functionally-connected cortical clusters in premotor, cingulate and parietal areas. *(ii)* The recruitment timing of these clusters is task-dependent; therefore, different areas can be activated selectively, bypassing the cortical hierarchy leading to MI. *(iii)* Multiple corticospinal systems stem from different premotor, cingulate, and parietal areas. *(iv)* Each corticospinal system has a different mean conduction velocity; thus, descending pathways can be selected in a task-dependent manner. *(v)* Within each corticospinal system, axons calibers differ, leading to temporal smearing of information. The metabolic costs associated with integrating this temporal information after an obligatory transfer through long oligosynaptic corticocortical paths toward MI are higher than those incurred by sending information directly through separate corticospinal pathways. *(vi*) Certain consequences of lesioning the parieto-frontal system do not occur when lesioning MI (e.g. different forms of apraxia, optic ataxia, etc.). Examples of different corticospinal modules beyond that stemming from MI are: the parieto-spinal module for the control of reaching, object manipulation, and visuomotor adaptations; the dorsal premotor-spinal module for storing memory traces of learned associations; the ventral premotor-spinal system for defensive actions. Local availability of both information and outflow paths therefore seem to be a prerequisite for command functions, and probably a major achievement of cortical evolution.

THE PREDICTIVE BRAIN: LINKING MOTOR AND SENSORY ATTENUATION USING COMBINED TMS-EEG

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Dominic Tran[1], Nicolas Mcnair[1], Alexis Whitton[2], Thomas Whitford[3], Evan Livesey[1]
[1]The University of Sydney, School Of Psychology, Sydney, Australia, [2]UNSW Sydney, Black Dog Institute, Randwick, Australia, [3]UNSW Sydney, School Of Psychology, Randwick, Australia

When sensory inputs can be predicted by an organism's own actions or external environmental cues, neural activity is downweighted compared to sensory inputs that are unpredictable. We have recently demonstrated that this downweighting to predictable inputs is also observed when stimulating the motor system with transcranial magnetic stimulation (TMS). Akin to sensory attenuation, predictable TMS excites the motor system less effectively than unpredicted TMS. Using a combined TMS-EEG setup, we measured corticospinal attenuation to motor cortex stimulation using motor-evoked potentials (MEP), and simultaneously measured sensory attenuation to the sound of TMS (a coil "click") using event-related potentials (ERP). We found that both ERPs and MEPs were downweighted to predictable TMS compared to unpredictable TMS. Critically, the magnitude of ERP suppression predicted the magnitude of MEP suppression. Our results reveal a close correspondence between attenuation of the sensory and motor systems. The findings provide compelling evidence that predictive coding is governed by domain-general properties across distinct neural systems and has shared mechanisms responsible for all forms of predictive learning.

MODULAR REPRESENTATION OF REACHING ENDPOINTS IN MOUSE MOTOR CORTEX

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Gregorio Galinanes, Daniel Huber
University of Geneva, Department Of Basic Neuroscience, Geneva, Switzerland

Motor cortex controls voluntary movements through descending commands via the brainstem and spinal cord. To better understand the cortical role in motor control, we studied the activity of motor cortex neurons of mice performing a multi-directional water-reaching task. We found that task-related neurons became sequentially active at different phases of the task, from target presentation to reaching and water consumption. Interestingly, while all task-related neurons displayed strong selectivity for the location of the reaching target, few were modulated by the arm's actual trajectory. This suggests that task-related neurons encode spatial information of reaching endpoint instead of kinematic parameters. We analyzed the spatial representation and found that neurons could be clustered into three roughly segregated groups representing reaching targets located to the left, center or right of the animal's snout, conforming a coarse reaching endpoint map. As a whole, subsets of layer 2/3 neurons represent specific combinations of spatial and temporal aspects of the task. We speculated that these subsets of neurons form functional modules which are dynamically recruited during task execution. To evaluate this possibility, we analyzed the neuronal activity while the reaching target was suddenly moved from one to another location during an ongoing reach. According to our speculation, activity of the neuronal modules was consistently updated to match the novel target location and the upcoming phases of the task. In summary, our data suggests that mouse motor cortex activity does not solely represent motor commands, but broader spatio-temporal information relevant to the task phase and reaching target location.

Temporal controls over inter-areal cortical projection neuron fate diversity.
Interconnectivity between neocortical areas is critical for sensory integration and sensorimotor transformations. These functions are mediated by heterogeneous inter-areal cortical projection neurons (ICPN), which send axon branches across cortical areas as well as to subcortical targets. Although ICPN are anatomically diverse, they are molecularly homogeneous, and how the diversity of their anatomical and functional features emerge during development remains largely unknown. Here we address this question by linking the connectome and transcriptome in developing single ICPN of the mouse neocortex using a combination of multiplexed analysis of projections by sequencing (MAPseq, to identify single-neuron axonal projections) and single-cell RNA sequencing (to identify corresponding gene expression). Focusing on neurons of the primary somatosensory cortex (S1), we reveal a protracted unfolding of the molecular and functional differentiation of motor cortex-projecting ([Formula: see text]) ICPN compared with secondary somatosensory cortex-projecting ([Formula: see text]) ICPN. We identify SOX11 as a temporally differentially expressed transcription factor in [Formula: see text] versus [Formula: see text] ICPN. Postnatal manipulation of SOX11 expression in S1 impaired sensorimotor connectivity and disrupted selective exploratory behaviours in mice. Together, our results reveal that within a single cortical area, different subtypes of ICPN have distinct postnatal paces of molecular differentiation, which are subsequently reflected in distinct circuit connectivities and functions. Dynamic differences in the expression levels of a largely generic set of genes, rather than fundamental differences in the identity of developmental genetic programs, may thus account for the emergence of intra-type diversity in cortical neurons.

Directional Reaching for Water as a Cortex-Dependent Behavioral Framework for Mice.
Optogenetic tools and imaging methods for recording and manipulating brain activity have boosted the field of neuroscience in unprecedented ways. However, behavioral paradigms for mice lag behind those of primates, limiting the full potential of such tools. Here, we present an innovative behavioral framework in which head-fixed mice directionally reach for water droplets, similar to the primate "center-out" reaching task. Mice rapidly engaged in the task, performed hundreds of trials, and reached in multiple directions when droplets were presented at different locations. Surprisingly, mice used chemosensation to determine the presence of water droplets. Optogenetic inactivation of the motor cortex halted the initiation and rapidly diverted the trajectory of ongoing movements. Layer 2/3 two-photon imaging revealed robust direction selectivity in most reach-related neurons. Finally, mice performed directional reaching instructed by vibratotactile stimuli, demonstrating the potential of this framework for studying, in addition to motor control, sensory processing, and decision making.

Properties of the corticostriatal long term depression induced by medial prefrontal cortex high frequency stimulation in vivo.
Repetitive stimulation of cognitive forebrain circuits at frequencies capable of inducing corticostriatal long term plasticity is increasingly being used with therapeutic purposes in patients with neuropsychiatric disorders. However, corticostriatal plasticity is rarely studied in the intact brain. Our aim was to study the mechanisms of corticostriatal long term depression (LTD) induced by high frequency stimulation (HFS) of the medial prefrontal cortex in vivo. Our main finding is that the LTD induced in the dorsomedial striatum by medial prefrontal cortex HFS in vivo (prefrontostriatal LTD) is not affected by manipulations that block or reduce the LTD induced in the dorsolateral striatum by motor cortex HFS in brain slices, including pharmacological dopamine receptor and CB1 receptor blockade, chronic nigrostriatal dopamine depletion, CB1 receptor genetic deletion and selective striatal cholinergic interneuron (SCIN) ablation. Conversely, like in the hippocampus and other brain areas, prefrontostriatal LTD is NMDA receptor dependent. Thus, we describe a novel form of corticostriatal LTD that operates in brain circuits involved in reward and cognition and could be relevant for understanding the therapeutic effects of deep brain stimulation.

Rapid Integration of Artificial Sensory Feedback during Operant Conditioning of Motor Cortex Neurons.
Neuronal motor commands, whether generating real or neuroprosthetic movements, are shaped by ongoing sensory feedback from the displacement being produced. Here we asked if cortical stimulation could provide artificial feedback during operant conditioning of cortical neurons. Simultaneous two-photon imaging and real-time optogenetic stimulation were used to train mice to activate a single neuron in motor cortex (M1), while continuous feedback of its activity level was provided by proportionally stimulating somatosensory cortex. This artificial signal was necessary to rapidly learn to increase the conditioned activity, detect correct performance, and maintain the learned behavior. Population imaging in M1 revealed that learning-related activity changes are observed in the conditioned cell only, which highlights the functional potential of individual neurons in the neocortex. Our findings demonstrate the capacity of animals to use an artificially induced cortical channel in a behaviorally relevant way and reveal the remarkable speed and specificity at which this can occur.

Altered Corticostriatal Connectivity and Exploration/Exploitation Imbalance Emerge as Intermediate Phenotypes for a Neonatal Dopamine Dysfunction.
Findings showing that neonatal lesions of the forebrain dopaminergic system in rodents lead to juvenile locomotor hyperactivity and learning deficits have been taken as evidence of face validity for the attention deficit hyperactivity disorder. However, the core cognitive and physiological intermediate phenotypes underlying this rodent syndrome remain unknown. Here we show that early postnatal dopaminergic lesions cause long-lasting deficits in exploitation of shelter, social and nutritional resources, and an imbalanced exploratory behavior, where nondirected local exploration is exacerbated, whereas sophisticated search behaviors involving sequences of goal directed actions are degraded. Importantly, some behavioral deficits do not diminish after adolescence but instead worsen or mutate, particularly those related to the exploration of wide and spatially complex environments. The in vivo electrophysiological recordings and morphological reconstructions of striatal medium spiny neurons reveal corticostriatal alterations associated to the behavioral phenotype. More specifically, an attenuation of corticostriatal functional connectivity, affecting medial prefrontal inputs more markedly than cingulate and motor inputs, is accompanied by a contraction of the dendritic arbor of striatal projection neurons in this animal model. Thus, dopaminergic neurons are essential during postnatal development for the functional and structural maturation of corticostriatal connections. From a bottom-up viewpoint, our findings suggest that neuropsychiatric conditions presumably linked to developmental alterations of the dopaminergic system should be evaluated for deficits in foraging decision making,

alterations in the recruitment of corticostriatal circuits during foraging tasks, and structural disorganization of the frontostriatal connections.

Origin and properties of striatal local field potential responses to cortical stimulation: temporal regulation by fast inhibitory connections.
Evoked striatal field potentials are seldom used to study corticostriatal communication in vivo because little is known about their origin and significance. Here we show that striatal field responses evoked by stimulating the prelimbic cortex in mice are reduced by more than 90% after infusing the AMPA receptor antagonist CNQX close to the recording electrode. Moreover, the amplitude of local field responses and dPSPs recorded in striatal medium spiny neurons increase in parallel with increasing stimulating current intensity. Finally, the evoked striatal fields show several of the basic known properties of corticostriatal transmission, including paired pulse facilitation and topographical organization. As a case study, we characterized the effect of local GABA(A) receptor blockade on striatal field and multiunitary action potential responses to prelimbic cortex stimulation. Striatal activity was recorded through a 24 channel silicon probe at about 600 µm from a microdialysis probe. Intrastriatal administration of the GABA(A) receptor antagonist bicuculline increased by 65±7% the duration of the evoked field responses. Moreover, the associated action potential responses were markedly enhanced during bicuculline infusion. Bicuculline enhancement took place at all the striatal sites that showed a response to cortical stimulation before drug infusion, but sites showing no field response before bicuculline remained unresponsive during GABA(A) receptor blockade. Thus, the data demonstrate that fast inhibitory connections exert a marked temporal regulation of input-output transformations within spatially delimited striatal networks responding to a cortical input. Overall, we propose that evoked striatal fields may be a useful tool to study corticostriatal synaptic connectivity in relation to behavior.

Striatal gating through up states and oscillations in the basal ganglia: Implications for Parkinson's disease.
Up states are a hallmark of striatal physiology. Spontaneous activity in the thalamo-cortical network drives robust plateau depolarizations in the medium spiny projection neurons of the striatum. Medium spiny neuron firing is only possible during up states and is very tightly regulated by dopamine and NMDA receptors. In a rat model of Parkinson's disease the medium spiny neurons projecting to the globus pallidus (indirect pathway) show more depolarized up states and increased firing. This is translated into abnormal patterns of synchronization between the globus pallidus and frontal cortex, which are believed to underlie the symptoms of Parkinson's disease. Here we review our work in the field and propose a mechanism through which the lack of D2 receptor stimulation in the striatum allows the establishment of fixed routes of information flow in the cortico-striato-pallidal network.

Dopamine-dependent periadolescent maturation of corticostriatal functional connectivity in mouse.
Altered corticostriatal information processing associated with early dopamine systems dysfunction may contribute to attention deficit/hyperactivity disorder (ADHD). Mice with neonatal dopamine-depleting lesions exhibit hyperactivity that wanes after puberty and is reduced by psychostimulants, reminiscent of some aspects of ADHD. To assess whether the maturation of corticostriatal functional connectivity is altered by early dopamine depletion, we examined preadolescent and postadolescent urethane-anesthetized mice with or without dopamine-depleting lesions. Specifically, we assessed (1) synchronization between striatal neuron discharges and oscillations in frontal cortex field potentials and (2) striatal neuron responses to frontal cortex stimulation. In adult control mice striatal neurons were less spontaneously active, less responsive to cortical stimulation, and more temporally tuned to cortical rhythms than in infants. Striatal neurons from hyperlocomotor mice required more current to respond to cortical input and were less phase locked to ongoing oscillations, resulting in fewer neurons responding to refined cortical commands. By adulthood some electrophysiological deficits waned together with hyperlocomotion, but striatal spontaneous activity remained substantially elevated. Moreover, dopamine-depleted animals

showing normal locomotor scores exhibited normal corticostriatal synchronization, suggesting that the lesion allows, but is not sufficient, for the emergence of corticostriatal changes and hyperactivity. Although amphetamine normalized corticostriatal tuning in hyperlocomotor mice, it reduced horizontal activity in dopamine-depleted animals regardless of their locomotor phenotype, suggesting that amphetamine modified locomotion through a parallel mechanism, rather than that modified by dopamine depletion. In summary, functional maturation of striatal activity continues after infancy, and early dopamine depletion delays the maturation of core functional capacities of the corticostriatal system.

MOTOR CORTEX AREA-SPECIFIC PATTERNS OF CONVERGENT THALAMIC INPUTS IN THE MOUSE

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Carmen Alonso Martinez, Cesar Porrero, Francisco Clascá
Autonoma de Madrid University, Department Of Anatomy, Histology And Neuroscience, Madrid, Spain

A large region of the mouse dorsal and medial frontal isocortex is commonly labelled ‘motor’. However, the published histological and electrophysiological data in rodents provide ambiguous and often conflicting evidence for delineation of individual areas. Since multiple thalamic nuclei innervate the motor cortex, fine quantitative differences between mouse motor cortex regions in the thalamocortical input composition and/or intracortical distribution could provide an independent and consistent reference for area delineation, as well as for cross-species comparisons. To map and quantify thalamus neurons innervating different motor cortex regions in the adult C57BL/6 mouse, we microinject in cortex retrograde tracers and calculate the percentage of labelled cells in each nucleus within all labelled cells in each case and compare then between cases. We are currently using anterograde labelling to analyze the laminar convergence of this pathways. Our preliminary data show that, the most numerous source of thalamic innervation comes from VM (ventromedial nuclei) and VAL (ventral anterior-lateral nuclei), to a lesser extend from the posterior, intralaminar and the midline nuclei. It also reveals a remarkable heterogeneity in the set of nuclei whose projections converge at different points in the cortex, and a complex topography within each nucleus. This supports the idea that this approach can provide valuable data for the consistent delineation of functional domains in the motor cortex of the mouse. AN ALTERNATIVE CORTICO-SUBCORTICAL LOOP INVOLVING THE THALAMUS FOR LOCOMOTION

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Emília Bősz[1,2], Viktor Plattner[3], Marco Diana[4], László Acsády[2]
[1]Semmelweis Univ, Neurosciences ("jÁnos SzentÁgothai"), Budapest, Hungary, [2]Institute of Experimental Medicine, Budapest, Hungary, Laboratory Of Thalamus Research, Budapest, Hungary, [3]Sainsbury Wellcome Ctr., Akrami Lab, London, United Kingdom, [4]Pierre et Marie Curie Univ, Neuronal Networks And Physiopathological Rhythms, Paris, France

The cortico-basal ganglia-thalamocortical loop has been known to be involved in locomotor behavior. Disturbance of the basal ganglia activity results in characteristic, unilateral rotation. Similar to basal ganglia the pontine reticular formation (PRF) also sends inhibitory terminals to the intralaminar thalamus (IL). Activation of the PRF-IL pathway interference induces a strong phenotype, a complete behavioral arrest. In this study, we outline a new motor-related cortico-subcortico-thalamocortical loop by examining the impact of cortical inputs on the PRF inhibitory cells (PRF/GlyT2+) and testing the effect of photoactivation of PRF/GlyT2+ neurons on locomotor behavior. AAV-ChR2 injections into the frontal cortex (M2 and cingulate) of RBP4-Cre/Glyt2-eGFP transgenic mice revealed that mid-caliber dendrites and spines of the PRF/GlyT2+ cells receive L5 inputs. In *in vitro* slice preparation, the photoactivation of the L5 fibers reliably produced purely glutamatergic synaptic responses on PRF/GlyT2+ cells. Juxtacellular recording *in vivo* showed that photoactivation of L5 neurons evoked short-latency APs in the PRF/GlyT2+ cells with a high probability. Spontaneous rhythmic activity of PRF/Glyt2+ neurons was strongly linked to the slow cortical oscillation. Photoactivation of PRF/Glyt2+ cells resulted in unilateral rotation and significantly decreased firing rate of the IL cells. We conclude that synchronous frontal cortical activity may convey behavioral signals to PRF and this can reliably activate PRF/GlyT2+ neurons. PRF/GlyT2+ cells transfer cortical input as inhibitory signals to the IL before they return to the cortex via the thalamocortical pathway. Both the concept of network organization and the evoked behavioral response are reminiscent of the cortico-basal ganglia loop.

Sudden and surprising sensory events often signal environmental threats, triggering a cascade of neural mechanisms aimed to adapt behavior accordingly. To study the phylogenetic origin of these mechanisms, we trained two rhesus monkeys (*macaca mulatta*) to exert force on an isometric joystick and thereby keep the position of a cursor inside a visual target. Fast-rising and task-irrelevant auditory stimuli were occasionally presented. We examined the effect of such unexpected stimuli on both isometric force and electroencephalographic (EEG) activity recorded using 29 active scalp electrodes. Auditory stimuli elicited a consistent biphasic modulation of isometric force, consisting of an initial transient decrease (d1, moving the cursor away from the target center) followed by a tonic increase (i2, bringing to cursor back to its original position). The same stimuli also elicited an EEG potential dominated by two large negative-positive waves (N70 and P130) maximal at the scalp vertex, homologous of the human 'vertex potential'. A trial-by-trial correlation analysis between force and EEG revealed that the amplitude of the vertex potential positivity (P130) predicted the magnitude of the following force increase (i2). This correlation was maximal on EEG electrodes contralateral to the limb exerting force, suggesting a direct effect of the vertex potential on cortical motor regions. Together, these results disclose a cortico-motor mechanism supporting adaptive behavior in response to salient sensory events. The striking similarity between these results and those previously reported in humans indicates that this mechanism is well conserved in human and non-human primates.

CORTICAL PYRAMIDAL CELLS EXPRESS THYROID HORMONE TRANSPORTERS MCT8 AND OATP1C1 IN HUMAN AND MONKEY BRAIN.

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Yu Wang[1,2,3], Ting Wang[1,2,3,4], Lucía Prensa[1], Ana Guadaño[3], Estrella Rausell[1]
[1]School of Medicine. Autonomous University of Madrid (UAM), Department Of Anatomy, Histology And Neuroscience, Madrid, Spain, [2]PhD Program in Neuroscience, UAM, Dept Of Anatomy, Histology & Neuroscience, Madrid, Spain, [3]The Instituto de Investigaciones Biomédicas "Alberto Sols" (IIBM), Department Of Pathophysiology Endocrine And Nervous System, Madrid, Spain, [4]Lintong Shiyoucheng, General Clinic, Xi'an, China

Monocarboxylate transporter 8 (MCT8) and organic anion-transporting polypeptide 1C1 (OATP1C1) are thyroid hormone (TH) transmembrane transporters that play a crucial role in the availability of systemic THs for neural cells allowing their appropriate development and function. This study aims to analyze the presence of these two proteins at the cellular level in the monkey and human cerebral cortex by means of immunohistochemistry and double labeling immunofluorescence. OATP1C1 is expressed in pyramidal neurons in layers II, III, V, and VI in both monkey and human motor cortex, as evidenced by its colocalization with RC3/Neurogranin and SMI-32. MCT8 distribution is similar to OATP1C1, although the intensity of its signal is lower.Interestingly, Cajal-Retzius like cells expressing OATP1C1 are observed in layer I. Double labeling immunofluorescence for OATP1C1 or MCT8 and several cortical interneuron markers was negative, confirming the presence of those TH transporters mostly in projection pyramidal neurons. OATP1C1 and MCT8 immunostained cells with small soma and large processes compatible with astrocyte morphology were found in the subcortical white matter in close relation to vessels. MCT8 is also expressed in the endothelial cells of different size vessels and capillaries throughout the monkey and human cortex, while OATP1C1 is occasionally observed in the endothelium of large and medium-sized vessels. Our results demonstrate the presence of MCT8 and OATP1C1 TH transporters in long and short projection pyramidal cortical neurons in adult human and non-human primates and their abundance in the astrocyte-vessel complexes, which suggest their critical position in the efferent cortical motor system.

CHARACTERIZING PATTERNS OF DENDRITIC ACTIVITY IN AWAKE BEHAVING MICE USING ARBOREAL SCANNING, A MULTISCALE 3D IMAGING APPROACH.

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Antoine Valera[1], Thomas Younts[2], Victoria Griffiths[2], Diccon Coyle[2], R. Angus Silver[2]
[1]CNRS, Institut Des Neurosciences Cellulaires Et Integratives (inci), Strasbourg, France, [2]University College London, Department Of Neuroscience, Physiology And Pharmacology, London, United Kingdom

Understanding brain function requires to identify how information is represented by single neurons and how it is transformed as it flows through microcircuits. Deciphering when and where synaptic inputs are integrated across 3D dendritic trees requires recordings of patterns of activity across many dendritic branches. Non-linear acousto-optic lens (nAOL) 2-photon microscope enables this through fast focusing and selective imaging of regions of interest distributed within the imaging volume. Non-linear AOL functionality enables the selective imaging of dendritic arbors in any arbitrary X-Y-Z direction, a method we named arboreal scanning. Combining this with our recently developed real-time 3D movement correction and semi-automated 3D dendritic tracing has enabled imaging of a large fraction of the dendritic tree in vivo. We carried out arboreal scans on layer II, III, and V pyramidal cells expressing GCaMP6f in motor cortex in head-fixed mice as they rested or ran on a treadmill, during air puff-evoked startles, and during whisker stimulation. Our results indicate that layer II, III, and V cells exhibit mostly global, multi-branch activation that is strongly coupled to the soma but present a large heterogeneity on how these events are modulated. We used an unsupervised dimensionality reduction approach to identify regions that were comodulated and studied their relationship to spine activity patterns and behavioral variables. Our results should extend our understanding of dendritic integration in pyramidal cells in motor cortex during behaviour.

EXPERIENCE WITH TOOL USE MODULATES VISUOMOTOR NEURONAL RESPONSE TO TOOL ACTION OBSERVATION IN MONKEY MOTOR AND PREMOTOR CORTEX

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Coudé, Kirchherr, Bonaiuto, Baldi, Pier Francesco Ferrari
CNRS, Institut Des Sciences Cognitives, Bron, France

Neurophysiological experiments on tool use in macaque monkeys have shown that visual exposure to tools and sensorimotor training aimed at using tools are linked with changes in the visual responses of neurons in premotor cortex. However, it is not clear to what extent these changes are a consequence of visual exposure or motor learning. In this study, we assessed the changes in the visual discharge of primary and premotor neurons following visual exposure to actions made with a tool, and following a specific sensorimotor training where the monkeys gradually learned to use a tool. We recorded from microelectrode arrays chronically implanted in the hand sectors of the ventral premotor and primary cortices. In the first weeks or recordings, the monkeys had to observe the experimenter using the rake, but never experienced using it themselves. Later, in separate sessions, the monkeys were trained to use the rake. Our preliminary results show systematic changes in neuronal activity over the weeks of training to use a rake. In some recorded channels, the time-locked multi-unit activity evoked by the observation of the rake retrieving the object increased over the weeks as the monkey became better at using the tool. Interestingly, the bulk of these changes seems to appear when the monkey had reached a proficient level of tool use. These preliminary findings suggest that motor experience, as opposed to mere visual familiarization, plays an important role in scaffolding the neuronal changes necessary to form new motor representations that can be activated during action observation.

SIMULTANEOUS YET SEPARABLE POPULATION ENCODING OF ARM MOVEMENT DIRECTION AND KINEMATICS IN MOTOR CORTEX

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Andrea Colins[1], Mark Humphries[1,2]
[1]University of Nottingham, School Of Psychology, Nottingham, United Kingdom, [2]University of Nottingham, School Of Psychology, RD, United Kingdom

Motor cortex has been proposed to control multiple features of movement. However, the encoding of movement features has been commonly studied by analysing one feature at a time. Little is known about if and how multiple features of movement are simultaneously encoded at a population level. Using neural activity from dorsal premotor cortex (PMd) and motor cortex (M1) as monkeys performed a sequential arm movement task, here we report that the direction and kinematics of arm movements are simultaneously but separably encoded in the low-dimensional trajectories of population activity [1]. We found that strongly stereotyped, rotational trajectories of population activity encoded movement direction, such that trajectories separate from each other in proportion to the angle difference between the movements they evoked. By contrast, trajectories from arm movements in the same direction were temporally scaled to produce different movement kinematics. Consistent with this separability into geometry and speed of population activity, we could well decode the direction and duration of arm movement independently from the same trajectory of population activity. A recurrent neural network (RNN) model of our results replicated this separable encoding of direction and duration, and suggested the two could be independently controlled by respectively rotating the inputs to motor cortex and scaling the effective neuron time constant within motor cortex. Our results propose a mechanism for motor cortex to latently encode multiple arm movement features simultaneously. Decoding motor intentions for performing desired movements and increasing the sense of embodiment of an artificial effector is one of the main challenges of neuroprosthesis design. Here, we aimed to decode a broad range of motor actions from intracortical signals recorded from chronic multielectrode arrays implanted in the monkey ventral premotor cortex. Two monkeys (*Macaca mulatta*) were filmed while performing different reaching-grasping and mouth actions. Ethological scoring of the videos was performed to obtain the timestamps of behavioural events. We adopted a novel decoding algorithm, based on - *The selection of the most informative minimal set of neurons*. Different approaches to determine the set were considered, from simple inter-group comparison to feature selection algorithms; - *A support vector machine analysis of the temporal evolution* of the activity of the selected population. For each neuronal unit we took into account the firing activity over several temporally overlapping windows. The proposed approach was able to decode 6 different behaviors – performance was improved grouping them in classes: grasping, food touching the mouth, and baseline, in which no movements are performed. According to offline tests, the decoding algorithm successfully classifies the planning phase of the mentioned classes 100-200ms in advance. Additionally, the use of different feature selection techniques does not affect the decoder performance in terms of accuracy. Ultimately, the decoding algorithm predicts monkeys' movements in restrained laboratory conditions and constitutes a promising approach for real time use in detecting motor intentions of freely-moving animals, a crucial step for future neuroprosthetic applications.

EXAMINATION OF BRAINSTEM V2A NEURONS' DIVERSITY IN MOTOR CONTROL

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Edwin Gatier, Giovanni Usseglio, Séverine Diem, Julien Bouvier
Université Paris Saclay, Neuropsi, Cnrs, Saclay, France

Adaptive control of locomotion requires that information from multiple integrative brain centers are relayed to the executory circuits of the spinal cord. One of these relays are reticulospinal (RS) neurons, a highly intermingled population of the reticular formation whose axons project along the spinal cord. We previously showed that the V2a subpopulation of glutamatergic RS neurons relay orienting commands from the Superior Colliculus (SC) and comprise distinct subsets specialized by their projection to a specific spinal segment (Usseglio et al. 2020). Retrograde trans-synaptic tracings however showed that V2a RS neurons receive inputs from multiple brain areas aside the SC, including the deep cerebellar nuclei (DCN). This i) raises the possibility that V2a RS may also relay signals related to posture and/or motor learning; and ii) prompts investigating whether different upstream modalities target the same, or distinct, V2a populations. To answer these questions we are implementing a combination of viral tracings, activity interferences and imaging strategies. We first characterized the identity and spatial organization of DCN neurons upstream the V2a RS neurons. Furthermore, we now aim at manipulating V2a RS neurons defined by the origin of their inputs using retrograde and anterograde trans-synaptic viral vectors. Interestingly, we observe divergent functional outcomes when manipulating V2a neurons that receive inputs from the DCN or the SC. This suggests a possible participation of V2a RS neurons in a cerebello-reticulo-spinal pathway, and argues for the existence of parallel V2a descending tracts for relaying modality-specific signals to the spinal cord.

ANATOMICAL AND MOLECULAR ORGANIZATION OF THE SUBTHALAMIC AREA, INCLUDING THE SUBTHALAMIC AND PARA-SUBTHALAMIC NUCLEI (STN AND PSTN), IN RODENTS AND PRIMATES

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Åsa Wallén-Mackenzie[1], Carine Karachi[2], Sylvie Dumas[3]
[1]Uppsala University, Department Of Organismal Biology, Uppsala, Sweden, [2]AP-HP, Hôpital Pitié-Salpêtrière, Dmu Neurosciences 6, Service De Neurologie, Paris, France, [3]Oramacell, Oramacell, PARIS, France

Aims: The subthalamic nucleus (STN) is crucial for normal motor, limbic and associative function. STN dysregulation has long been correlated with Parkinson´s disease, and an increasing number of brain disorders also show dysregulation of the STN. Consequently, high-frequency stimulation of the STN is increasing as therapy. However, the anatomical-functional organization of the STN and surrounding structures remains to solve, both to understand symptoms and results of treatment. The aim of our study is to use recent molecular data from mouse-based experiments of the STN and neighboring areas (including the para-STN (PSTN)) for assessment of the spatial organization within the same structures in the primate brain. Mouse, macaque and human subthalamic areas were compared. **Methods:** We recently implemented single-nuclei RNA sequencing (snRNASeq) of the mouse STN followed through with histological analysis of several cluster genes of interest. This led us to identify four distinct spatio-molecularly defined domains within the mouse STN. Further, molecular profiles that dissociated the STN from the adjoining PSTN were identified. Here, we took advantage of this recent knowledge from the mouse to address if the same spatio-molecular profiles and domains can be identified in the macaque and human STN area. Fluorescent *in situ* hybridization was implemented. **Results:** Preliminary data support the presence of three to four molecularly distinct domains within the primate STN and unique molecular profiles also within adjoining structures. **Conclusions:** Comparative anatomical and molecular mapping will enable deeper insight into the complex STN area.

COMPLEMENTARY CODING OF MOVEMENT, REWARD EXPECTATION AND OUTCOME IN THE CEREBELLUM AND BASAL GANGLIA

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Noga Larry, Gil Zur, Mati Joshua
The Hebrew University of Jerusalem, Edmond And Lily Safra Center For Brain Sciences, Jerusalem, Israel

Recent findings of reward signals in the cerebellum challenge the view that the cerebellum performs error-based learning whereas the basal ganglia (BG) are involved in reward-based learning. While cerebellar reward signals are similar to those in the BG, the comparison is problematic as prior studies probed activity in areas that control different behaviors and in different animals. Thus, we aimed to compare directly the coding of motor and reward signals in both areas. We recorded from eye-movements related areas in the BG and cerebellum of the same monkeys while manipulating eye-movements parameters and reward. We partitioned single neurons activity into reward, movement, and temporal components. We found that before reward delivery, the BG coded the expectation of reward, while the reward signals in the cerebellum were relatively small. In contrast during reward delivery, reward signals were more pronounced in the cerebellum than in the BG. We additionally compared the BG input structure (caudate) and output structure (SNpr). Reward expectation, time, and movement signals were sharper in the SNpr than in caudate. Conversely, cerebellar cortex local and output populations coded of these variables similarly and less than the SNpr. Our results suggest a division of labor: coding of reward expectation in the BG and reward outcome in the cerebellum. Additionally, we find that movement and reward expectation information is most prominent in the SNpr. This result is facilitated by the sharpening of information between local and output neurons in the BG and not the cerebellum.

Cerebellar climbing fibers encode expected reward size.
Climbing fiber inputs to the cerebellum encode error signals that instruct learning. Recently, evidence has accumulated to suggest that the cerebellum is also involved in the processing of reward. To study how rewarding events are encoded, we recorded the activity of climbing fibers when monkeys were engaged in an eye movement task. At the beginning of each trial, the monkeys were cued to the size of the reward that would be delivered upon successful completion of the trial. Climbing fiber activity increased when the monkeys were presented with a cue indicating a large reward, but not a small reward. Reward size did not modulate activity at reward delivery or during eye movements. Comparison between climbing fiber and simple spike activity indicated different interactions for coding of movement and reward. These results indicate that climbing fibers encode the expected reward size and suggest a general role of the cerebellum in associative learning beyond error correction.

COMPLEX DYNAMICAL CODING OF SIMPLE MOVEMENTS IN THE OUTPUT OF THE BASAL GANGLIA

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Gil Zur[1], Noga Larry[2], Mati Joshua[1]
[1]Hebrew University, Elsc, Jerusalem, Israel, [2]The Hebrew University of Jerusalem, Edmond And Lily Safra Center For Brain Sciences, Jerusalem, Israel

The Substantia Nigra pars Reticulata (SNr), an output structure of the basal ganglia, is known to play a role in pursuit and saccadic eye movements. Previous studies have reported that neurons in the SNr are active tonically and show either a pause or increase during eye movements, consistent with the gating role of the basal ganglia output. These studies have mostly focused on probing SNr activity in a narrow behavioral regime. We recorded activity in the SNr of monkeys while they performed a broad regime of behavioral eye movement tasks including saccade and pursuit eye movements, with multiple directions and reward conditions. This diverse set of tasks was designed to provide a better understanding of the output of the basal ganglia. We found complex dynamical coding in SNr neurons during smooth pursuit eye movements. These neurons exhibited a highly complex reaction pattern during pursuit, including frequent increases and decreases in the firing rate during the trial, uncorrelated responses in different directions and high variance in reaction times and reaction durations. We also compared these results to other brain regions in the eye movement pathway. The results suggest that SNr neurons have a specific high-dimensional dynamic which differentiates them from other regions in the eye movement pathway. Previous research has suggested that the output of the basal ganglia presents a simple mapping to behavior. Our results strongly hint at a dynamical and complex mapping between sensorimotor parameters and activity, akin to intermediate levels in artificial neural networks.

Efficient every day skills rely on automatized behaviours. As behaviours are learnt and repeated, the link between the action and its context incrementally increases until automaticity. Key players involved in this process of learning and consolidation of an action are cortico-basal ganglia loops (CBGs). CBGs are topographically organized into limbic, associative and sensorimotor loops coursing through the ventral, dorsomedial, and dorsolateral striatum, respectively. These circuits are recruited to different extents during learning; however, the dynamics of the region-specific molecular events have never been assessed during learning and consolidation of a skill. **Aims:** Detection of region-specific striatal molecular key players of skill learning and consolidation. **Methods:** We have developed a binary visual discrimination task in fully automated operant conditioning chambers. At different learning stages (naïve , early, intermediate, and over-trained), we collected brain samples from the ventral, dorsomedial, and dorsolateral striatum of wild-type mice, and performed bulk RNA-sequencing using the SCRB-seq protocol. **Results:** Molecular changes of early learning distinguish themselves from changes characteristic for learning consolidation or automatization. While gene categories involved in early learning include brain plasticity and development, those of later learning stages appear more related to long-term plastic changes including long-term synaptic potentiation and dendritic spine maintenance. Throughout learning, we could also find differentially expressed genes related to dopamine signaling and synthesis of different types of neurotransmitters, among others. **Conclusions:** Striatal molecular signatures of early learning and automatization are complementary and changes in expression patterns align with expected early or long-term plastic changes, respectively.

INPUTS GOVERNING THE RESPONSES TO SENSORY STIMULATION IN THE EXTERNAL GLOBUS PALLIDUS

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Maya Ketzef
Karolinska Institutet, Department Of Neuroscience, Stockholm, Sweden

The external globus pallidus (GPe) is a central nucleus in the basal ganglia (BG) integrating information from the direct, the indirect and the hyperdirect BG pathways. The GPe is composed of two main cell populations, the prototypic and arkypallidal cells, which differ in their membrane properties, developmental origin, molecular markers, and axonal projections. The inputs to these two GPe subpopulations have recently been described using optogenetic manipulations, however, how they are integrated in a physiological process has not been fully addressed. Both GPe subpopulations respond to whisker deflection with a triphasic response pattern, suggesting the involvement of multiple synaptic inputs. Here, I used in vivo whole cell patch clamp recordings in the GPe combined with optogenetic silencing to dissect the different inputs underlying sensory responses in prototypic and arkypallidal cells. My results show that sensory responses in prototypic cells are controlled by the subthalamic nucleus (STN) and indirect pathway medium spiny neurons (MSNs), while responses in arkypallidal cells are shaped by direct pathway MSNs, and to a lesser extent by the STN and neighbouring prototypic cells. These results suggest that the responses to whisker stimulation in the GPe subpopulations are shaped by different synaptic inputs, affecting their outputs to downstream as well as upstream BG targets.

WHAT DO MC4R-EXPRESSING NEURONS IN THE LATERAL STRIPE OF THE STRIATUM ENCODE?

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Gisela Lazzarino, Johan Sköld, Joost Wiskerke, David Engblom
Center for Social and Affective Neuroscience (CSAN), Department Of Biomedical And Clinical Sciences (bkv), Linköping, Sweden

Emerging evidence has implicated melanocortin 4 receptors (MC4R) in the attribution of motivational valence to salient stimuli. Our group has shown that striatal MC4Rs under normal conditions hinder aversive signals from getting access to dopaminergic reward circuits, and that mice with deletion of MC4Rs consequently perceive aversive stimuli as rewarding. The Lateral Stripe of the Striatum (LSS) is an area in the ventral striatum that presents a high expression of MC4Rs, but the function of the receptor in this region remains unknown. Our objective was to characterize the MC4R-expressing neurons in the LSS, to elucidate if their activation is rewarding or aversive, and to analyze their activity during aversive events. This was done by using MC4R-cre mice, optogenetic stimulation, fiber photometry, and several behavioral paradigms. Using immunofluorescence, we found that MC4R expressing neurons are mostly medium spiny neurons that co-express the dopamine D1 receptor. Optogenetic activation of MC4R expressing neurons in the the LSS enhanced motivational drive and induced robust place preference, as well as increased the locomotion. Conversely, in vivo calcium imaging revealed that MC4R-expressing neurons in the LSS increased their firing when the animals were exposed to electric foot shock, indicating that these neurons are activated by aversive stimuli. Collectively, our findings indicate that MC4R-expressing neurons in the LSS are involved in both reward-related and aversive signaling.

Temporary effects of neonatal overfeeding on homeostatic control of food intake involve alterations in POMC promoter methylation in male rats.
A small litter (SL) model was used to determine how neonatal overfeeding affects the homeostatic control of food intake in male rats at weaning and postnatal day (PND) 90. At PND4, litters were reduced to small (4 pups/dam) or normal (10 pups/dam) litters. At weaning, SL rats showed higher body weight and characteristic features of the metabolic syndrome. Gene expression of pro-opiomelanocortin (POMC), cocaine and amphetamine regulated transcript, neuropeptide Y (NPY) and leptin and ghrelin (GHSR) receptors were increased and POMC promoter was hypomethylated in arcuate nucleus, indicating that the early development of obesity may involve the GHSR/NPY system and changes in POMC methylation state. At PND90, body weight, metabolic parameters and gene expression were restored; however, POMC methylation state remained altered. This work provides insight into the effects of neonatal overfeeding, showing the importance of developmental plasticity in restoring early changes in central pathways involved in metabolic programming.

IL-6R expressed on CNS vascular endothelial cells contributes to the development of experimental autoimmune encephalomyelitis in mice.
Experimental autoimmune encephalomyelitis (EAE) is the most common model for studying the molecular mechanisms of multiple sclerosis (MS). Here, we examined the CNS-restricted effects of classical interleukin (IL)-6 signaling on the development of EAE, using mice with cell-type specific deletion of the IL-6 receptor (IL-6R). We found that IL-6R deletion in CNS vascular endothelial cells, but not in microglia, ameliorated symptoms of EAE. The milder clinical symptoms in the gene-deleted mice were associated with less demyelination and immune cell infiltration/activation, and lower mRNA levels of the cytokines IL-17 and IL-1β, as well as the cell adhesion molecules VCAM-1, ICAM-1 and ICAM-2 than what was seen in WT mice. These findings demonstrate that classical IL-6 signaling via endothelial cells of the CNS contributes substantially to the development of MS-like pathology, which should be taken into consideration when conceptualizing future therapeutic approaches.

Epigenetic Dysregulation of Dopaminergic System by Maternal Cafeteria Diet During Early Postnatal Development.
Dopamine is a neurotransmitter crucial for motor, motivational, and reward-related functions. Our aim was to determine the effect of a palatable maternal diet on the transcriptional regulation of dopaminergic-related genes during perinatal development of rat offspring. For that, female offspring from dams fed with a control (CON) or a cafeteria (CAF) diet were sacrificed on embryonic day 21 (E21) and postnatal day 10 (PND10). Using micropunch techniques, ventral tegmental area (VTA) and nucleus accumbens (NAc) were isolated from brain's offspring. Bioinformatic analysis of the promoter regions, mRNA quantification and methylation studies were done. The increase in tyroxine hidroxylase (TH), dopamine receptor (DRD) 1 and ghrelin receptor (GHSR) expression in VTA and NAc from E21 to PND10 was correlated with changes in DNA methylation of their promoter regions. Maternal diet did not affect the expressionpatternsin E21. At PND10, maternal CAF diet decreased the transcription of TH, GHSR, DRD2 and dopamine transporter (DAT) in VTA. Interestingly, the changes in TH, DRD2 and DAT expression were related to the methylation status of their promoters. In NAc, maternal CAF diet reduced DRD1, DRD2 and DAT expression in the offspring at PND10, although alternations in the methylation patterns were only detected in DAT promoter. These results show the importance of maternal nutrition and provide novel insights into the mechanisms through which maternal junk-food feeding can affect reward system during development and early postnatal life. Particularly important is the expression decline of DRD2 given its physiological implication in obesity and addiction.

Cafeteria diet induces progressive changes in hypothalamic mechanisms involved in food intake control at different feeding periods in female rats.
We studied the effects of cafeteria diet (CAF) intake from weaning on mRNA levels and DNA methylation state of feeding-related neuropeptides and hormone receptors in individual hypothalamic nuclei at different feeding periods. Four weeks of CAF (short-term) increased energy intake and adiposity, without affecting neuropeptides' expression. Eleven weeks of CAF (medium-term) increased energy intake, adiposity, leptinemia, and body weight, with an orexigenic response of the lateral hypothalamus, paraventricular and ventromedial nuclei, given by upregulation of Orexins, AgRP, and NPY opposed by an anorectic signal of the arcuate nucleus, which displayed a higher POMC expression. The changes in neuropeptidic mRNA levels were related to epigenetic modifications in their promoter regions. Metabolic and molecular changes were intensified after 20 weeks of diet (long-term). The alterations in these hypothalamic brain nuclei could add information about their differential role in food intake control, and how their action is disrupted during the development of obesity.

The impact of sensory and motor enrichment on the epigenetic control of steroidogenic-related genes in rat hippocampus.
In the present study, we analyzed the effects of a short-term environmental enrichment on the mRNA expression and DNA methylation of steroidogenic enzymes in the hippocampus. Thus, young adult (80-day-old) and middle-aged (350-day-old) Wistar female rats were exposed to sensory (SE) or motor (ME) enrichment during 10 days and compared to animals housed under standard conditions. SE was provided by an assortment of objects that included plastic tubes and toys; for ME, rodent wheels were provided. In young adult animals, SE and ME increased the mRNA expression of cytochrome P450 17α-hydroxylase/c17,20-lyase, steroid 5α-reductase type 1 (5αR-1) and 3α-hydroxysteroid dehydrogenase and decreased the methylation levels of 5αR-1 gene. In middle-aged rats, ME and SE upregulated the gene expression of aldosterone synthase and decreased the methylation state of its promoter. These results propose that SE and ME differentially regulate the transcription of neurosteroidogenic enzymes through epigenetic mechanisms in young and aged rats.

Induction of uterine hyperplasia after cafeteria diet exposure.
Our aim was to evaluate whether chronic administration of CAF affects the uterus and induces the morphological and molecular changes associated with endometrial hyperplasia. Female Wistar rats exposed to CAF from weaning for 20 weeks displayed increased energy intake, body weight and fat depots, but did not develop metabolic syndrome. The adult uteri showed an increase in glandular volume fraction and stromal area. The epithelial proliferation rate and protein expression of oestrogen receptor alpha (ERα) were also increased. The CAF diet enhanced leptin serum levels and the long form of leptin receptor (Ob-Rb) mRNA expression in the uterus. No changes were detected in either insulin serum levels or those of insulin growth factor I (IGF-I) mRNA expression. However the levels of IGF-I receptor (IGF-IR) mRNA were lower in CAF-fed animals. Overall, the results indicate that our rat model of the CAF diet produces morphological and molecular changes associated with uterine hyperplasia and could predispose to endometrial carcinogenesis.
Mol Cell Endocrinol, 2018; 477

Cafeteria diet differentially alters the expression of feeding-related genes through DNA methylation mechanisms in individual hypothalamic nuclei.
We evaluated the effect of cafeteria diet (CAF) on the mRNA levels and DNA methylation state of feeding-related neuropeptides, and neurosteroidogenic enzymes in discrete hypothalamic nuclei. Besides, the expression of steroid hormone receptors was analyzed. Female rats fed with CAF from weaning increased their energy intake, body weight, and fat depots, but did not develop metabolic syndrome. The increase in energy intake was related to an orexigenic signal of paraventricular (PVN) and ventromedial (VMN) nuclei, given principally by upregulation of AgRP and NPY. This was mildly counteracted by the arcuate nucleus, with decreased AgRP expression and increased POMC and kisspeptin expression. CAF altered the transcription of neurosteroidogenic enzymes in PVN and VMN, and epigenetic mechanisms associated with differential promoter methylation were involved. The changes observed in the hypothalamic nuclei studied could add information about their differential role in food intake control and how their action is disrupted in obesity.

27040308: Rossetti MF, Varayoud J, Lazzarino GP, Luque EH, Ramos JG
Pregnancy and lactation differentially modify the transcriptional regulation of steroidogenic enzymes through DNA methylation mechanisms in the hippocampus of aged rats.
In the present study, we examined the mRNA expression and DNA methylation state of steroidogenic enzymes in the hippocampus of young adult (90-days-old) and middle-aged (450-days-old) nulliparous rats, and middle-aged multiparous rats subjected to three pregnancies with and without lactation. Aging decreased the mRNA levels of steroidogenic-related genes, while pregnancy and lactation significantly reduced the effect of aging, maintaining high expression levels of cytochrome P450 side-chain cleavage (P450scc), steroid 5α-reductase-1 (5αR-1), cytochrome P450arom (P450arom) and aldosterone synthase (P450(11β)-2). In addition, pregnancy and lactation diminished the methylation state of the 5αR-1 promoter and increased the transcription of brain-derived neurotrophic factor, synaptophysin and spinophilin. Pregnancy without lactation increased P450scc and 5αR-1 gene expression and decreased the methylation of their promoters. We concluded that the age-related decrease in the mRNA expression of steroidogenic enzymes is differentially attenuated by pregnancy and lactation in the rat hippocampus and that differential methylation mechanisms could be involved.

Dietary whey reduces energy intake and alters hypothalamic gene expression in obese phyto-oestrogen-deprived male rats.
Removing dietary phyto-oestrogens in adult male rats causes obesity and diabetes. As whey proteins have been reported to reduce food intake and improve glucose homoeostasis, we investigated whether they could attenuate susceptibility to obesity and diabetes due to phyto-oestrogen deprivation. To this end, thirty male Wistar rats were fed a high-phyto-oestrogen (HP) or a phyto-oestrogen-free (PF) diet for 10 weeks; six rats from each group were killed. The remaining HP animals (six animals) continued receiving the HP diet for 6 weeks. The remaining PF rats (twelve rats) were divided in two groups: one was given the PF diet and the other a variation of the PF diet plus whey protein (PF-W). Body weight, food intake and adipose tissue weights were recorded. Hypothalamic mRNA expressions of orexigenic (neuropeptide Y, agouti-related protein (AgRP)) and anorexigenic (pro-opiomelanocortin (POMC), cocaine-amphetamine-related transcript (CART)) neuropeptides were quantified by real-time PCR. Serum glucose, insulin and total thyroxine (T4), thyroid-stimulating hormone, testosterone and oestradiol were assessed. After 10 weeks of PF diet, increased body weight, adiposity and energy intake, with up-regulation of AgRP and down-regulation of POMC', were observed. Longer treatment exacerbated these results, increased total T4 levels, reduced oestradiol levels and impaired glucose homoeostasis. PF-W reduced energy intake and increased POMC expression; however, body weight and adiposity remained unchanged. PF-W could not prevent the hormonal changes or the high circulating glucose levels induced by phyto-oestrogen deprivation, but reduced fasting insulin. These data demonstrate that, although 6 weeks of whey administration could not prevent obesity in phyto-oestrogen-deprived rats, the reduction in energy intake and circulating insulin could be beneficial with longer treatments.
Br J Nutr, 2016; 116

Dietary withdrawal of phytoestrogens resulted in higher gene expression of 3-beta-HSD and ARO but lower 5-alpha-R-1 in male rats.
Removing dietary phytoestrogens causes obesity and diabetes in adult male rats. Based on the facts that hypothalamic food intake control is disrupted in phytoestrogen-deprived animals and that several steroids affect food intake, we hypothesized that phytoestrogen withdrawal alters the expression of hypothalamic steroidogenic enzymes. Male Wistar rats fed with a high-phytoestrogen diet from conception to adulthood were subjected to phytoestrogen withdrawal by feeding them a low-phytoestrogen diet or a high-phytoestrogen, high-fat diet. Withdrawal of dietary phytoestrogens increased 3β-hydroxysteroid dehydrogenase and P450 aromatase gene expression and decreased those of 5α-reductase-1. This is a direct effect of the lack of dietary phytoestrogens and not a consequence of obesity, as it was not observed in high-fat-fed rats. Phytoestrogen

withdrawal and high-fat diet intake reduced hypothalamic expression of estrogen receptor (ER)α correlated with low levels of ERα-O, ERα-OS, and ERα-OT transcripts. Variations in gene expression of steroidogenic enzymes may affect the content of neurosteroids. As neurosteroids are related to food intake control, the changes observed may be a novel mechanism in the regulation of energy balance in obese phytoestrogen-deprived animals. In rats, steroidogenesis and ER signaling appear to be altered by phytoestrogen withdrawal in the rat. The ubiquity of phytoestrogens in the diet and changing intakes or withdrawal suggest that aspects of human health could be affected based on the rat and warrant further research.

ZINC MODULATES FRONTO-STRIATAL GLUTAMATERGIC TRANSMISSION AND IMPLEMENTATION OF PROACTIVE INHIBITORY CONTROL THROUGH HIGH-AFFINITY BINDING AT NMDA RECEPTOR GLUN2A SUBUNIT

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Abdel Ouagazzal[1], Joanna Sikora[1], Juliette Lhost[1], Brigitte Kieffer[2], Pierre Paoletti[3], Paolo Gubellini[4]
[1]Aix Marseille Univ, CNRS,, Lnc (umr 729), Marseille, France, [2]Institut national de la Santé et de la Recherche Médicale, Centre De Recherche Biomédicale De Strasbourg, U1114, Université De Strasbourg, Strasbourg, France, [3]Ecole normale supérieure, Institut De Biologie, Paris, France, [4]Aix Marseille University, Ibdm Cnrs Umr 7288, Marseille, France

Fronto-striatal system mediates various aspects of executive functions that support implementation of adaptive goal-directed behaviors. Striatum receives dense zinc-containing glutamatergic projections from prefrontal cortex, but the contribution of synaptic Zn^{2+} to behavioral functions subserved by fronto-striatal system remains elusive. We used knock-in (KI) mice lacking a high-affinity Zn^{2+} inhibition of GluN2A containing NMDA receptors (GluN2A-NMDARs) to examine whether Zn^{2+} modulation of goal-directed learning and inhibitory control processes involves glutamatergic mechanisms. Electrophysiological recording performed in the nucleus accumbens, the striatal region containing the highest synaptic zinc density, revealed enhanced NMDAR-mediated synaptic transmission in KI mice upon stimulation of prefrontal cortex inputs. When tested in simple appetitive operant learning tasks, KI mice and wild type (WT) littermates performed similarly. In a more demanding task designed for assessing proactive inhibitory control, KI mice acquired the new rules quicker than WT mice and displayed improved motor readiness, reflected by a faster reaction time upon the offset of the inhibitory cue. Short-term spatial memory assessed in the Y-maze task was also improved in KI mice compared to WT animals indicating that ablation of GluN2A zinc binding site improves mnemonic functions. Collectively, these findings show that synaptic Zn^{2+} acts as an endogenous modulator of fronto-striatal glutamatergic transmission and provide *in vivo* evidence that this cation negatively regulates mnemonic processing and goal-directed control by dampening GluN2A-NMDAR activity.

LINE-1 LONG NON-CODING RNAS AT STRIATAL CIRCUITS CONTRIBUTE TO THE TRANSITION FROM FLEXIBLE TO INFLEXIBLE BEHAVIORAL CONTROL

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Alessandra Longaretti[1], Damiano Mangoni[2], Vincent Paget-Blanc[1], Arjen Boender[1], Yann Pelloux[1], Pierre Lau[2], Gian Gaetano Tartaglia[2], Stefano Gustincich[2], Raffaella Tonini[1]

The ability to adapt behavior to an ever-changing environment requires flexible control of behavior, which depends on the causal relationship between an action and its outcome (A-O). With repetition, behavior becomes inflexible; actions are no longer sensitive to changes in A-O associations and are primarily elicited by retrospective events. The epigenetic modification of chromatin offers a mechanistic link between the genome and environmental experience, including the transition from flexible to inflexible behavioral control. In particular, epigenetic modifications can unsilence the expression of transposable elements, which in turn can act as a key factor for post-transcriptional regulation of gene expression. In this study, we demonstrated that task overtraining is associated with the increase of RNA levels of Long Interspersed Nuclear Elements -1 (L1), specifically in the dorsolateral striatum (DLS). Upregulation of L1 RNAs expression occurs in parallel to decreased methylation of L1 promoters and reduced expression of the DNA methyltransferase 3b. Finally, viral-mediated silencing of L1 transcripts in the DLS preserves behavioral flexibility, thus establishing a direct role of L1 upregulation in behavioral control. We are currently investigating mechanisms by which L1 RNAs interfere with bioavailability of key mRNA targets involved in synaptic processes that subserve the updating of behavioral strategy during the presentation of a new A-O contingency. Our findings support the role of (epi)genomic plasticity in instrumental behavior. This study reveals molecular substrates that might be relevant for the numerous neuropsychiatric conditions that are characterized by a loss in behavioral flexibility and striatal circuit dysfunction.

PHOSPHODIESTERASES AS INTEGRATORS OF THE DOPAMINE SIGNAL IN THE STRIATUM

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Pierre Vincent, Liliana Castro, Ségolène Bompierre, Elia Mota
Sorbonne University, Institut De Biologie Paris Seine, PARIS, France

Aims – The cAMP/PKA signaling pathway plays a critical role in the integration of dopaminergic signals in the striatum. Phosphodiesterases degrade cAMP, and medium-sized spiny neurons express PDE1B, activated by calcium-calmodulin, PDE2A, activated by cGMP, PDE4 and PDE10A. We wanted to determine the functional contribution of each of these phosphodiesterase in the integration of dopamine signals at the level of cAMP.
Methods – Genetically-encoded FRET biosensors were used to monitor the dynamics of cAMP/PKA signaling in MSNs in striatal brain slices from young mice: Epac-SH150 for cAMP, and AKAR4 for PKA-dependent phosphorylation. Highly selective inhibitors were used to acutely suppress the activity of each phosphodiesterase type.
Results – After a positive cAMP signal, PDE10A appears as the only PDE able to decrease cAMP concentration below micromolar level, and its activity is therefore required to deactivate PKA. PDE2A and PDE4 operate on cAMP concentration above micromolar, thus regulating the peak of dopamine D1 response, or the steady-state adenosine A2A response. PDE2A activity is increased by cGMP. PDE1B also controls high cAMP levels, and is active only after intracellular calcium has been increased.
Conclusion – PDE action is thus functionally defined by a cAMP concentration range on which it operates, with PDE10A characterized by its action on low cAMP levels. In addition, PDE1B and PDE2A allow cross-talks with other signaling pathways such as calcium and NO-cGMP. This mechanistic understanding helps define the potential of each phosphodiesterase as a potential therapeutic target.

AN ATTEMPT TO ENHANCE FINE MOTOR PERFORMANCE: INVESTIGATING IMMEDIATE AND DELAYED EFFECTS OF NEUROFEEDBACK TRAINING AND MOTOR IMAGERY TRAINING ON SEQUENTIAL FINGER TAPPING TASK

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Mira Hanna[1], Rose Mery Bou Merhi[2], Rami Abed El Malak[1], Gemma Gebrayel Matta[2], Joseph Maarrawi[3], Sandra Kobaïter Maarrawi[1]
[1]Saint Joseph University of Beirut, Laboratory Of Research In Neuroscience, Faculty Of Medicine, Beirut, Lebanon, [2]Saint Joseph University, Institute Of Psychomotor Therapy, Faculty Of Medicine, Beirut, Lebanon, [3]Hotel Dieu de France Hospital, Neurosurgery Department, Beirut, Lebanon

Background Various training approaches are being proposed to enhance motor performance with debatable results. It has been established that Motor Imagery (MI) generates activation of motor cortical areas (MA) with proven beneficial effects on motor performance. It has also been shown possible to self-modulate neural activity in MA through non-invasive EEG-NeuroFeedback (NF), but it remains unclear whether increase in cortical activation of MA via Event-Related Desynchronization (ERD) of sensorimotor rhythm brainwave would have beneficial motor outcomes. **Aim** Investigate immediate and delayed effects of a single NF training session on motor performance in comparison to MI and to MI+NF trainings. **Methods** Sixty-eight right-handed healthy adults were randomly assigned to one of four groups (a)NF (n=17), (b)MI (n=17), (c)NF+MI (n=18) and (d)Control (n=16). Participants performed a sequential finger tapping task (SFTT) before and after (immediately, 20-min and 24hr) a single 30-minute training session. Movement accuracy, speed and ERD data were analyzed. **Preliminary Results** Current data reveal beneficial effects of NF, MI and NF+MI trainings on accuracy ($p=0.02$) and speed accuracy trade-off ($p=0.02$) only when participants showed good baseline SFTT performance level. MI training effects were observed at all re-test phases, while NF and NF+MI trainings were only beneficial at 24-hr ($p<0.05$), with potential benefits after 20-min. ERD data are under analysis. **Conclusions** Data herein suggest that NF training (alone or combined to MI) can have delayed benefits on movement performance. Such protocols can contribute to the development of more effective methods for enhancing motor performance with applications in therapy and sports.

INHIBITION AND GAIT INITIATION IN HEALTHY SUBJECTS : AN EEG STUDY

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Déborah Ziri[1], Laurent Hugueville[1], Claire Olivier[1], Carine Karachi[1,2], Marie-Laure Welter[1,3], Nathalie George[1]
[1]Sorbonne Université, Institut du Cerveau - Paris Brain Institut, ICM, Inserm U 1127, Cnrs Umr 7225, Paris, France, [2]AP-HP, Hôpital Pitié-Salpêtrière, Dmu Neurosciences 6, Service De Neurologie, Paris, France, [3]CHU ROUEN, Service De Neurophysiologie, Rouen, France

Inhibition is the capacity to suppress one or several possible responses in order to produce adapted behavior. We distinguish reactive inhibition, which is triggered by a stimulus, and proactive inhibition, which consists in an anticipatory inhibitory state prior to any stimulus. Here, we study how those inhibitions are engaged during gait initiation in a Go-NoGo task, i.e. initiate gait or not depending a visual signal, but modified and including an additional Go-certain condition, where subject initiates gait at each trial. Here, we aim to assess the existence of such inhibitory processes for gait initiation, with longer reaction times (RT) during Go-Uncertain vs Go-Certain blocks with releasing of proactive inhibition for Go-Certain blocks, and its relationship with cortical EEG activity using high-density EEG recordings. Gait initiation parameters and cortical activity were recorded in 23 healthy subjects, using a force platform AMTI and an EEG-ActiCHamp 128 active electrode system. We found increased RT for gait initiation during uncertain relative to certain Go trials ($p < 10^{-4}$). We found also different cortical activities with modulations within the N2-P3 complex, an ERP previously considered as a reflect of inhibitory processes, and within the alpha (8-12Hz) and beta (13-30Hz) band activities, mainly in the fronto-central areas. These data suggest a proactive inhibition of gait initiation in human, in uncertain environmental context. The next step would be to examine this in pathological condition such as Parkinson's disease where patients present an inability to initiate gait that could reflect increased proactive inhibition.

NEURONAL REPRESENTATIONS OF SELF AND OTHER IN THE BASAL GANGLIA

POSTER SESSION 07 - SECTION: BASAL GANGLIA & MOTOR CONTROL

Cristina Rotunno, Monica Maranesi, Carolina Ferroni, Matteo Di Volo, Matilde Reni, Luca Bonini
University of Parma, Department Of Medicine And Surgery, Parma, Italy

It is widely accepted that an extended cortical action observation network (AON) underlying the coding of other's actions largely overlaps with areas devoted to action planning and execution. Recent anatomical data demonstrated that most of the cortical areas belonging to the AON send convergent projection to overlapping territories of the putamen nucleus in the basal ganglia, suggesting that it may play a role in others' action processing. To address this issue, we recorded neuronal activity from the putamen nucleus of the macaque during a reaching-grasping task in which the animal and an experimenter, facing each other and taking turns based on contextual cues, grasped (or observed the other grasping) a multi-affordance object in a shared space. Most of the recorded neurons were modulated either only during action execution (self type, 20%) or observation (other type, 9%), or during both (self-other type, 49%), whereas others (22%) did not show any action-related modulation. Among self-other type neurons showing Facilitated (F) or Suppressed (S) discharge during action execution and observation, 41% could be classified as FF type, 19% as FS type, 11% as SF and 29% as SS type. Overall, facilitatory modulations prevailed during task execution, whereas they were balanced by suppressive modulatory influences during task observation. Our findings demonstrate the existence of neurons modulated by others' observed action in the putamen. These findings support the involvement of the putamen in the AON, and indicate the need to investigate its overall modulatory impact on the functioning of the AON cortical nodes.

Aims: To identify the genetic aetiology and understand disease mechanisms in patients with undiagnosed complex hyperkinetic movement disorders **Methods:** Singleton and triome whole-genome sequencing and analysis was undertaken using the Illumina NovaSeq 6000 platform, Qiagen QCI Interpret Translational and Sanger sequencing. Site-directed mutagenesis was utilised to generate mutant constructs for overexpression in HEK293T cells. Gene and protein expression, localisation and function were assessed using qPCR, Western blotting, biotinylation, immunofluorescence and cyclic adenosine monophosphate (cAMP) assays. **Results:** In 5 patients, pathogenic monoallelic and biallelic variants were identified in three dopamine receptor genes: c.110C>A (p.Thr37Lys), homozygous in *DRD1*; c.1121 T > G (p.Met374Arg), heterozygous in *DRD2*; c.340G>A (p.Asp114Asn) and c.463C>T (p.Arg155Cys), heterozygous in *DRD5.* None of these variants impacted gene and protein expression or subcellular localisation. All mutant proteins however led to altered cAMP levels in response to dopaminergic agonists. For DRD1, p.Thr37Lys resulted in a significant reduction in cAMP levels ($p<0.0001$), indicating loss of function. In contrast, p.Met374Arg in DRD2 resulted in gain of function, with a significant decrease in cAMP ($p<0.01$). p.Arg155Cys and p.Asp114Asn in DRD5 also resulted in a significant increase in cAMP indicating gain of function ($p<0.001$). **Conclusion:** Our study identifies *DRD1* and *DRD5* as novel Mendelian disease-associated genes. Pathogenic variants in *DRD1, DRD2* and *DRD5* all result in aberrant protein function; the observed disruption of downstream cAMP signalling is likely to affect key corticostriatal neuronal networks involved in motor control. Better understanding of the underlying biochemical mechanisms may facilitate future development of targeted precision therapies.

[1]Nencki Institute, Polish Academy of Sciences, Center Of Excellence For Neural Plasticity And Brain Disorders: Braincity, A Nencki-embl Partnership, Warsaw, Poland, [2]KU Leuven, Haesler Lab, Neuroelectronics Research Flanders, Leuven, Belgium, [3]Warsaw University of Technology, Faculty Of Electronics And Information Technology, Warsaw, Poland, [4]Nencki Institute of Experimental Biology, Laboratory Of Neuroinformatics, Warsaw, Poland, [5]University of Warsaw, Institute Of Theoretical Physics, Faculty Of Physics, Warsaw, Poland

Until recently laboratory behavioral tasks were conducted without much consideration for the environmental or social context. Unfortunately, such an approach allows for researching neither voluntary responses nor individual differences. Importantly for neuroscience studies, the neural background underlying unnatural, artificial behavior is highly variable and hard to predict. Thus, to develop valid models of human disorders and resulting targeted, individualized therapies we need to test spontaneous behaviors consistently engaging well-defined, evolutionarily-conserved neuronal circuits. The presented field studies were performed in the field Eco-HAB, an ecologically relevant habitat located in the wild, however, spatially constrained environment. It consisted of 8 subterritories of differing survival values and resources. The subterritories were connected via underground corridors equipped with RFID antennas, allowing for the continuous, non-invasive recording of the social behavior in groups of mice over the 10-day-period. We show how testing animals in a complex, naturalistic habitat allows for measuring aspects of social behavior inaccessible under laboratory conditions. We examine the social interactions of mice and their stability over time, as well as the dispersal of the individuals within the habitat with high ecological accuracy. Moreover, the obtained data enables us to assess individual territoriality and social status, as measured by the access to high-value resources. We also present the data on social networks formed by the animals over time, as they explored the novel and challenging territory. The proposed approach allows for combining neuroscience research with field studies, enabling testing behavioral patterns truly relevant for surviving and thriving under varying environmental conditions.

CRYPTOGRAPHIC-LIKE HIPPOCAMPAL MECHANISM UNDERLIES HIDING AND RETRIEVAL BEHAVIORS IN ANIMALS

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Oren Forkosh
Hebrew University, Cognition And Brain Sciences, Jerusalem, Israel

The brain's extraordinary abilities are often associated with its ability to learn and to adapt. But memory has its limitations, especially when faced with the task of retrieving tens or even hundreds of thousands of cached food items annually - such as in the case of scatter-hoarding animals. Here, we present a brain mechanism that works by utilizing cryptographic principles in lieu of plasticity. Rather than memorizing their cache locations as previously suggested, we propose that cache-hoarding animals use a single cryptographic-like mechanism during both caching and retrieval. The model we developed is similar to hippocampal spatial cells, which respond to an animal's positional attention, such as when the animal enters a specific region (place-cells) or gazes at a particular location (spatial-view-cells). We know that the region that activates each spatial cell remains consistent across subsequent visits to the same area but not between areas. This remapping, combined with the uniqueness of cognitive maps, produces a persistent crypto-hash function for both food caching and retrieval. We further show that the model can maintain temporal information that might help animals prioritize food items that are perishable or according to their nutritional value. This behavior, which we refer to as crypto-taxis, can also explain how animals of the same species might find each other in order to mate or for other social purposes.

Objective: Aphasia syndromes have been mostly reported as a result of stroke syndromes. Often the assessment of language ability, plays a central role in the clinical evaluation of patients with suspected dementia. Its most relevant contribution are: the diagnosis of cognitive impairment, the differential diagnosis among different causes of dementia and a classification in the variety of APP which may have a probabilistic relation ship with different pathological substrate. The present case study analyses the cognitive impairment due to a acute AVC T- P sin. in a 54 year old right- handed patient with higher formal education. **Method:** The patient was tested on a broad range of cognitive abilities , including language, memory, praxis, number processing and calculation, visual spatial abilities, executive functions. **Results:** On neuropsychological examination, he presented a moderate verbal apraxia, noted by word rate not often running , essentially on not frequent words with lexical production rate and phonological/articulatory phonemic errors neither phonetic nor disarthric, accompanied with others clinical manifestations like: spatial acalculia, and moderate anarithmetic. However, not suspicion for a APP not trouble, not decrease of syntaxic formes or a DPD not anomie, neither pause nor low voice. **Conclusions** The present case study highlights the diversity of clinical manifestation of speech disorders. Additional observations of this syndrome being needed to appreciate the full spectrum of impairments in patients with neurodegenerative brain disease , including those often considered as “movements disorders” PNFA or Logopenic aphasia typically due to AD pathology or patients with DPD.

THE ROLE OF THE LATERAL PERIAQUEDUCTAL GRAY IN FEMALE MATING BEHAVIOR

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Baylor Brangers[1], Susana Q Lima[2]
[1]Champalimaud Center for the Unknown, Neuroscience, Lisbon, Portugal, [2]Champalimaud Foundation, Champalimaud Research, Lisbon, Portugal

The periaqueductal gray (PAG) controls key aspects of female social behavior, from sex to maternity. Early work on the PAG showed that its lateral and ventrolateral subdivisions are involved in female sexual receptivity, especially in the control of lordosis, the receptive behavior fundamental for successful copulation in rodents. Female sexual behavior depends on the integration of several processes, changes in movement and the execution of lordosis. In mice, lordosis occurs only when females are in the fertile phase of the reproductive cycle. In addition, it requires male-derived stimulation of the female's flanks. Until now, it was not known if the two PAG subdivisions worked in concert or separately to control different aspects of sexual behavior.
Taking advantage of the Fos-TRAP mouse line, we specifically tested the involvement of the lateral PAG in female sexual behavior. Inhibiting (DREADDS and optogenetics) the activity of lateral PAG neurons lead to specific disruptions in the execution of the lordosis posture, but receptivity was largely unaffected, as females still perceived the flank stimulation and remained immobile next to the male. Therefore, our results suggest that different elements of female receptivity are controlled by distinct PAG subdivisions, with the lateral PAG primarily involved in execution of lordosis.
These findings agree with recent studies characterizing the involvement of the PAG in other complex behaviors, such as fear-induced immobility. This suggests that PAG-controlled behaviors are accomplished via the coordinated action of distinct subdivisions controlling specific elements, which collectively output a behavior that reflects the animal's internal state.

Neural Representations of Unconditioned Stimuli in Basolateral Amygdala Mediate Innate and Learned Responses.
Stimuli that possess inherently rewarding or aversive qualities elicit emotional responses and also induce learning by imparting valence upon neutral sensory cues. Evidence has accumulated implicating the amygdala as a critical structure in mediating these processes. We have developed a genetic strategy to identify the representations of rewarding and aversive unconditioned stimuli (USs) in the basolateral amygdala (BLA) and have examined their role in innate and learned responses. Activation of an ensemble of US-responsive cells in the BLA elicits innate physiological and behavioral responses of different valence. Activation of this US ensemble can also reinforce appetitive and aversive learning when paired with differing neutral stimuli. Moreover, we establish that the activation of US-responsive cells in the BLA is necessary for the expression of a conditioned response. Neural representations of conditioned and unconditioned stimuli therefore ultimately connect to US-responsive cells in the BLA to elicit both innate and learned responses.

SMAD2 and the relationship of colorectal cancer to inflammatory bowel disease.
Inflammatory bowel diseases (IBDs) affecting the colon [Crohn's disease (CD) and ulcerative colitis (UC)] are associated with an increased risk of colorectal cancer (CRC). Our previous work using oligonucleotide array data indicated that SMAD2 was significantly underexpressed in UC dysplastic tissue compared to benign UC. The aim of this current study was to determine whether single nucleotide polymorphisms (SNPs) within the SMAD2 gene are associated with IBD dysplasia/cancer. We performed an SNP haplotype-based case-control association study. Leukocyte DNA was obtained from 489 unrelated

Caucasians (158 UC, 175 CD, 71 CRC, 85 controls). Eleven SNPs were genotyped. All 11 SNPs were in Hardy-Weinberg equilibrium in the control population. Strong linkage disequilibrium was observed among nearly all SMAD2 SNPs. There were no significant associations between SMAD2 allele or haplotype frequencies. Power calculations indicated good power for single-marker analysis (>0.8) and reasonably good power against effects of 0.1-0.15 for haplotype analysis. SMAD2 SNPs were not associated with the development of IBD dysplasia/cancer. This incongruity between our previous microarray data and the findings from this genotype study may be attributed to mechanisms such as alternative splicing of pre-mRNA SMAD2 and/or cross talk with other cellular pathways.

Human speech and birdsong both critically rely on the processing of the auditory feedback provided by the perception of one own's vocalizations. Whether and how non-auditory modalities can drive vocal motor plasticity remains poorly understood. Yet, it was recently shown that deafened adult male zebra finches are able to modify their song when a transient flash of light is delivered contingent on the pitch of a song syllable (Zai et al, 2020, Nat. Commun.). Here, we sought to determine whether a visual area is engaged during this learning. We focused on the Wulst, a visual area receiving inputs from different sensory modalities. Anatomical studies revealed that this area projects to the songbird primary auditory area (Field L), which we confirmed by electrophysiological recordings. We subsequently deafened birds and performed either bilateral Wulst or Sham lesions. A third group of birds were only deafened. All the birds were involved in the behavioral task in which a light flash is provided contingent on the pitch of a song syllable. Despite the Wulst lesion, behavioral evidence demonstrates that the birds were not blind. Yet, they were not able to modify their song. It was previously shown that the basal ganglia (Area X) were involved in this task. Since Area X receives indirect afferents from the Field L and the Wulst projects to this auditory area, our results suggest that this pathway (Wulst-Field L-Area X) conveys visual information which eventually reaches the network of brain nuclei involved in song learning, variability and control.

INTEGRATION OF INTERNAL BRAIN DYNAMICS AND CHANGING ENVIRONMENTAL RESOURCES DURING ZEBRAFISH FORAGING

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Lílian De Sardenberg Schmid, Drew Robson, Jennifer Li
Max Planck Institute for Biological Cybernetics, Systems Neuroscience And Neuroengineering, Tuebingen, Germany

Foraging represents an ideal paradigm to study decision making as it is universal and subject to high selective pressure. While foraging, animals have to decide between staying local and depleting known food sources and exploring for distant sources in order to replenish them. This so-called exploitation-exploration dilemma also encompasses a trade-off in allocation of attentional, sensory and motor resources. In constant environments a wide range of species exhibit spontaneous fluctuations in exploitation or exploration states (Flavell et al., 2013; Martin, Ernst, & Heisenberg, 1999, Marques et al., 2020). To better understand the effect of environmental sensory stimuli on the neural dynamics that underly exploitation-exploration transitions, we developed a microfluidic system for freely behaving zebrafish larvae that allows for 1) temporally precise control of prey density, 2) large field of view behavioral imaging with high spatial and temporal resolution, and 3) whole-brain cellular resolution neural imaging. We observe that changes in environmental prey density alter the balance between exploitation and exploration states, overriding intrinsic oscillations in internal brain state. This may represent a mechanism to optimize foraging in the face of changing environments.

NUMERICAL DISCRIMINATION IN DROSOPHILA MELANOGASTER

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Mercedes Bengochea
Paris Brain Institute, Brain Development Team - Hassan Lab, Paris, France

Sensitivity to numbers is a crucial cognitive ability that is widespread across the animal kingdom. The lack of experimental models amenable to systematic genetic and neural manipulation has precluded discovering neural circuits required for numerical cognition. Here, we demonstrate that, when provided with a choice, *Drosophila* flies spontaneously prefer sets containing larger numbers of objects. This preference is determined by the ratio between the two numerical quantities tested, a characteristic signature of numerical cognition across species. Individual flies maintained their numerical choice over consecutive days. Using a numerical visual conditioning paradigm, we found that flies are capable of associating sucrose with numerical quantities and can be trained to reverse their spontaneous preference for large quantities. Finally, we show that silencing LC11 neurons reduces the preference for more objects, thus identifying a neuronal substrate for numerical cognition in invertebrates. This discovery paves the way for the systematic analysis of the behavioral and neural mechanisms underlying the evolutionary conserved sensitivity to numerosity.

NEURAL CORRELATES OF NATURAL SOCIAL BEHAVIOR IN FREELY-MOVING MACAQUES

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Camille Testard[1], Sebastien Tremblay[2], Ronald Ditullio[1], Felipe Parodi[2], Michael Platt[1]
[1]University of Pennsylvania, Neuroscience, PHILADELPHIA, United States of America, [2]University of Pennsylvania, Neuroscience, Philadelphia, United States of America

Current understanding of the neural mechanisms underlying primate social behavior derives almost exclusively from highly-constrained and scripted laboratory tasks. Precisely how the primate brain dynamically navigates species-typical social interactions, in all their richness and complexity, remains unknown. Here we leverage new technology to investigate the neural correlates of an unprecedentedly diverse array of species-typical behaviors in freely-moving, socially-interacting rhesus macaques. We recorded single neurons from the inferior temporal area TEO and prefrontal area 45 in two male macaques (n=6,129 units, 20 sessions) while they interacted with their female partner, and varied the identity of neighboring monkeys. Monkeys exhibited a rich behavioral repertoire of up to 27 different behaviors also observed in the wild, including grooming, foraging, aggression, and mating. The behaviors of the recorded monkeys were reliably decoded on a second-by-second basis from a few hundred neurons (>70% accuracy) –even during behaviors extending over many minutes where the sensorimotor environment changed considerably. Remarkably, neurons encoded the context of affiliative interactions: whether grooming was reciprocated or initiated, whether it occurred after a threatening event and the identity of neighboring monkeys. Moreover, neural activity was also modulated by the actions of the partner, providing parallel representations of the behavior of both self and other. Surprisingly, decoding performance was similar across brain areas, with important implications for theories of social information processing. These preliminary results demonstrate that neural ensembles in the prefrontal and inferior temporal cortices of macaques carry information about species-typical social stimuli, behavior, and contexts required for success in the wild.

SOCIAL INTERACTION SHAPES SELECTIVE MEMORY IN THE HIGHER AUDITORY AREA THROUGH THE NEURONAL ACTIVITIES OF LOCUS COERULEUS

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Jelena Katic, Yuichi Morohashi, Yoko Yazaki-Sugiyama
Okinawa Institute of Science and Technology, Neuronal Mechanism For Critical Period Unit, Onna, Japan

Juvenile zebra finches learn to sing by engaging in social communications with their tutors. Social exposure to a tutor singing is crucial for successful learning. Here we show, by recording extracellular single-unit activities in free-moving juvenile zebra finches, that neurons in the locus coeruleus (LC), an attention control area, responded stronger to live tutor singing (LIVE TUT) than to playback of pre-recorded tutor songs (TUT playback). The LC neurons sent axons to the zebra finch higher auditory cortex, the caudomedial nidopallium (NCM), where early tutor song memories form. Previously we showed that a fraction of broad-spiking NCM neurons responded selectively to TUT playback (TUT-selective neurons) upon LIVE TUT. To ask whether LC neurons directly influence song perception in the NCM, we optogenecially blocked LC terminal activities in the NCM every time juveniles heard LIVE TUT and recorded NCM neuronal activities. Around 30% of broad-spiking NCM neurons, which responded to TUT playbacks, showed reduced responses to LIVE TUT when paired with LC terminal inhibition and did not develop selectivity to the TUT playback. Those neurons showed a reduced response to TUT playback hours after LC terminal inhibition but showed no response reduction to playbacks of other song stimuli. Finally, juveniles, which heard LIVE TUT for three days with LC terminal inhibition failed to copy tutor songs, while control juveniles learned tutor songs well. Taken together, our data suggest that social vocal communication with a tutor modulates song perception in the auditory cortex and shapes selective auditory memories through LC inputs.

Humans and animals possess remarkable abilities to negotiate challenging terrains during walking. Discovering the organisational principles of motor systems that facilitate such efficient and adaptive walking can provide insights to designing artificial robotic controllers for dynamic locomotion in diverse environments. One challenge is that flat and variable terrains pose conflicting requirements for motor circuits. While flat terrains favour centralised, feedforward architectures that autonomously generate efficient gaits variable terrains demand flexible adjustments to gaits, a property of feedback-based architectures. We studied this dichotomy in Drosophila melanogaster using a combination of behavioural analysis, sensory silencing and data-driven mathematical modelling. First, we designed a climbing assay and a computational pipeline using deep learning-based monocular pose estimation to obtain for the first time 3D limb kinematics during repeatable behaviours in untethered flies. On flat terrain, both wild-type and sensory silenced flies predominantly used the tripod gait, corroborating previous findings. However, obstacles caused gait perturbations, which in wild-type animals resulted either in the recovery of the tripod gait, or gait adaptation, depending on the inter-obstacle distance. We then identified sensory neuron classes whose silencing allowed gait recovery, albeit slower, but suppressed gait adaptation, suggesting that flies switch from feedforward to feedback-based circuits on rough terrains. To unravel parsimonious circuit topologies, we developed a data-driven modelling framework using variational autoencoders and symbolic regression. The distribution of network topologies revealed distinct structural classes, favouring decentralised architectures in challenging terrains. Our work provides insight into how freely behaving animals tune their motor circuits for efficient locomotion.

OXYTOCIN MODULATION OF SOCIALLY DRIVEN ADULT NEUROGENESIS IN ZEBRAFISH

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Bianca Fusani[1,2], Magda Teles[1], Rui Oliveira[1,2]
[1]Instituto Gulbenkian de Ciência, Integrative Behavioural Biology, Oeiras, Portugal, [2]ISPA - Instituto Universitário de Ciências Psicológicas, Sociais e da Vida, Ispa, Lisboa, Portugal

Adult neurogenesis, the formation of new neurons from precursors cells, is regulated by both intrinsic and extrinsic factors. The social context is a key environmental factor that can modulate positively or negatively the formation of new neurons. Preliminary work from our lab shows that social isolation has a negative impact on cell proliferation in zebrafish, which can be rescued by the exposure to a social stimulus (a sex-mixed shoal). Moreover, in rats, adult neurogenesis can be modulated by the action of oxytocin receptors present in the hippocampus, an area belonging to the social decision-making network (SDMN). The SDMN is a network that regulates social behaviour and is influenced by the action of hormones and neuromodulators, like oxytocin. Here, we used a zebrafish mutant line for oxytocin receptor, to test if oxytocin mediates the effects of the social environment on adult neurogenesis in the brain nuclei belonging to the SDMN. The results indicate an effect of oxytocin on brain cell proliferation in Dm, Vc, PPa, PPp, Vd and the pretectum. Thus, this study can be considered a steppingstone to clarify the role of oxytocin on the social modulation of adult neurogenesis in vertebrates.

DEVELOPMENT OF A HPLC-UV-FLD METHOD FOR MONOAMINE DETERMINATION IN LIZARD BRAIN TISSUE SAMPLES

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Dunja Šikić[1], Matea Matković[1], Tomislav Gojak[1], Olga Malev[2], Sofia Blažević[1]
[1]Faculty of Science, Department Of Animal Physiology, Division Of Biology, Zagreb, Croatia, [2]Ruđer Bošković Institute, Division For Marine And Environmental Research, Zagreb, Croatia

Lizards have simpler brains than mammals yet share common neural circuits in the brainstem responsible for motivational behavior including aggression. This simpler brain is favorable for studying mechanisms of behavioral control which could be translated to other species to clarify the axis that links aggressive behavior with the regulation of neurotransmitter levels. The aim of this study was to develop and validate a rapid HPLC method with UV and fluorescence detection for monoamine neurotransmitters, precursors and metabolites in lizard brain tissue. Samples of the left hemisphere were collected and homogenized in deproteinization solution, centrifuged and injected into the HPLC-UV. The RP-HPLC gradient method was modified in various ways: duration (20-45 min), flow (0.45-1 mL/min), proportion of organic phase (0-30%), pH of the aqueous phase (2-3) and injection volume (10-90 µL). We changed the composition of the mobile phase - organic phase (acetonitrile, methanol) and aqueous phase (formic acid, phosphoric acid). In the process, we changed three columns - two with C18 and one with phenyl as a stationary phase. A mix of known concentrations of 12 compounds - serotonin, dopamine hydrochloride, L-3,4-dihydroxyphenylalanine, norepinephrine hydrochloride, epinephrine bitartrate, L-Tryptophan, L-Tyrosine hydrochloride, 5-Hydroxytryptophan, 5-hydroxyindole-3-acetic acid, vanillylmandelic acid, homovanilic acid and octopamine hydrochloride was used for identification of peaks in samples and for daily calibration curves. The peaks were identified by an UV detector (280 nm) and a fluorescence detector (270/320 nm). Monoamine levels in the brains of 200 coexisting lizard species (female and male of *Podarcis siculus* and *Podarcis melisellensis*) are presented.

Potential radioprotective properties of arbutin against ionising radiation on human leukocytes in vitro.
Arbutin is a simple phenolic glucoside biosynthesised in many plant families. Some of the everyday foods that contain arbutin are species of the genus Origanum, peaches, cereal products, coffee and tea and Arctostaphyllos uva ursi L. leaves. Arbutin possesses various beneficial effects in the organism, and was confirmed effective in the treatment of urinary tract infections as well as in preventing skin hyperpigmentation. It shows antioxidant and anti-inflammatory properties, and antitumor activity. The aim of this study was to explore potential radioprotective properties of arbutin in concentrations of 11.4 µg/mL, 57 µg/mL, 200 µg/mL and 400 µg/mL administered as a pre-treatment for one hour before exposing human leukocytes to ionising radiation at a therapeutic dose of 2 Gy. The alkaline comet assay was used to establish the levels of primary DNA damage, and cytokinesis-block micronucleus (CBMN) cytome assay to determine the level of cytogenetic damage. None of the tested concentrations of single arbutin showed genotoxic and cytotoxic effects. Even at the lowest tested concentration, 11.4 µg/mL, arbutin demonstrated remarkable potential for radioprotection in vitro, observed both at the level of primary DNA damage, and using CBMN cytome assay. The best dose reduction compared with amifostine was observed after pre-treatment with the highest concentration of arbutin, corresponding to 400 µg/mL. Promising results obtained on the leukocyte model speak in favour of extending similar experiments on other cell and animal models.

A NEURONAL SUBSTRATE FOR TRANSLATING RESOURCE DENSITY ESTIMATIONS INTO FORAGING DECISIONS

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Dennis Goldschmidt[1], Ibrahim Tastekin[1], Daniel Münch[1], Hannah Haberkern[2], Lúcia Serra[1], Celia Baltazar[1], Ann Hermundstad[2], Vivek Jayaraman[2], Gerald Rubin[2], Carlos Ribeiro[1]

Foraging animals must balance the costs of exploring their surroundings with the potential benefits of finding nutritional resources. Upon finding a food source, they have to make the central decision of whether to stop and initiate feeding or to continue searching for potentially better options. Foraging theory predicts that this decision should be dependent on an estimate of the density of available resources in the environment. How this complex computation is algorithmically implemented in the brain remains poorly explored. Here, we use video-based tracking to show that *Drosophila melanogaster* regulates the decision to stop at food spots based on the density of food patches in the environment. To answer how underlying neuronal circuits may implement this computation algorithmically, we performed a large-scale neurogenetic silencing screen of more than 400 different genetic driver lines with sparse expression patterns in the brain. We identified a population of neurons in the fly central brain that acts as a key regulator of the decision to stop. Specifically, we show that manipulating activity in these neurons increases not only the probability of stopping at food spots, but also alters their ability to adjust this foraging variable to the estimated resource density. Our results reveal a neuronal substrate involved in modulating ethologically relevant foraging decisions, a key step towards a mechanistic explanation of cognitive functions required to solve complex cost-benefit trade-offs.

optoPAD, a closed-loop optogenetics system to study the circuit basis of feeding behaviors.
The regulation of feeding plays a key role in determining the fitness of animals through its impact on nutrition. Elucidating the circuit basis of feeding and related behaviors is an important goal in neuroscience. We recently used a system for closed-loop optogenetic manipulation of neurons contingent on the feeding behavior of to dissect the impact of a specific subset of taste neurons on yeast feeding. Here, we describe the development and validation of this system, which we term the optoPAD. We use the optoPAD to induce appetitive and aversive effects on feeding by activating or inhibiting gustatory neurons in closed-loop - effectively creating virtual taste realities. The use of optogenetics allowed us to vary the dynamics and probability of stimulation in single flies and assess the impact on feeding behavior quantitatively and with high throughput. These data demonstrate that the optoPAD is a powerful tool to dissect the circuit basis of feeding behavior, allowing the efficient implementation of sophisticated behavioral paradigms to study the mechanistic basis of animals' adaptation to dynamic environments.

Craving for the future: the brain as a nutritional prediction system.
In the last decades, predictive coding has emerged as an important framework for understanding how the brain processes information. It states that the brain is constantly inferring and predicting sensory data from statistical regularities in its environment. While this framework has been largely applied to sensory processing and motor control, we argue here that it could also serve as framework for a better understanding of how animals regulate nutrient homeostasis. Mechanisms that underlie nutrient homeostasis are commonly described in terms of negative feedback control, which compares current states with a reference point, called setpoint, and counteracts any mismatches. Using concepts from control theory, we explain shortcomings of negative feedback as a purely reactive controller, and how feed-forward mechanisms could be incorporated into feedback control to improve the performance of the control system. We then provide numerous examples to show that many insects, as well as mammals, make use of feed-forward, anticipatory mechanisms that go beyond the prevailing view of homeostasis being achieved through reactive negative feedback. The emerging picture is that the brain incorporates predictive signals as well as negative feedback to regulate nutrient homeostasis.

A Neurocomputational Model of Goal-Directed Navigation in Insect-Inspired Artificial Agents.
Despite their small size, insect brains are able to produce robust and efficient navigation in complex environments. Specifically in social insects, such as ants and bees, these navigational capabilities are guided by orientation directing vectors generated by a process called path integration. During this process, they integrate compass and odometric cues to estimate their current location as a vector, called the home vector for guiding them back home on a straight path. They further acquire and retrieve path integration-based vector memories globally to the nest or based on visual landmarks. Although existing computational models reproduced similar behaviors, a neurocomputational model of vector navigation including the acquisition of vector representations has not been described before. Here we present a model of neural mechanisms in a modular closed-loop control-enabling vector navigation in artificial agents. The model consists of a path integration mechanism, reward-modulated global learning, random search, and action selection. The path integration mechanism integrates compass and odometric cues to compute a vectorial representation of the agent's current location as neural activity patterns in circular arrays. A reward-modulated learning rule enables the acquisition of vector memories by associating the local food reward with the path integration state. A motor output is computed based on the combination of vector memories and random exploration. In simulation, we show that the neural mechanisms enable robust homing and localization, even in the presence of external sensory noise. The proposed learning rules lead to goal-directed navigation and route formation performed under realistic conditions. Consequently, we provide a novel approach for vector learning and navigation in a simulated, situated agent linking behavioral observations to their possible underlying neural substrates.

Distributed recurrent neural forward models with synaptic adaptation and CPG-based control for complex behaviors of walking robots.
Walking animals, like stick insects, cockroaches or ants, demonstrate a fascinating range of locomotive abilities and complex behaviors. The locomotive behaviors can consist of a variety of walking patterns along with adaptation that allow the animals to deal with changes in environmental conditions, like uneven terrains, gaps, obstacles etc. Biological study has revealed that such complex behaviors are a result of a combination of biomechanics and neural mechanism thus representing the true nature of embodied interactions. While the biomechanics helps maintain flexibility and sustain a variety of movements, the neural mechanisms generate movements while making appropriate predictions crucial for achieving adaptation. Such predictions or planning ahead can be achieved by way of internal models that are grounded in the overall behavior of the animal. Inspired by these findings, we present here, an artificial bio-inspired walking system which effectively combines biomechanics (in terms of the body and leg structures) with the underlying neural mechanisms. The neural mechanisms consist of (1) central pattern generator based control for generating basic rhythmic patterns and coordinated movements, (2) distributed (at each leg) recurrent neural network based adaptive forward models with efference copies as internal models for sensory predictions and instantaneous state estimations, and (3) searching and elevation control for adapting the movement of an individual leg to deal with different environmental conditions. Using simulations we show that this bio-inspired approach with adaptive internal models allows the walking robot to perform complex locomotive behaviors as observed in insects, including walking on undulated terrains, crossing large gaps, leg damage adaptations, as well as climbing over high obstacles. Furthermore, we demonstrate that the newly developed recurrent network based approach to online forward models outperforms the adaptive neuron forward models, which have hitherto been the state of the art, to model a subset of similar walking behaviors in walking robots.

24523694: Goldschmidt D, Wörgötter F, Manoonpong P
Biologically-inspired adaptive obstacle negotiation behavior of hexapod robots.
Neurobiological studies have shown that insects are able to adapt leg movements and posture for obstacle negotiation in changing environments. Moreover, the distance to an obstacle where an insect begins to climb is found to be a major parameter for successful obstacle negotiation. Inspired by these findings, we present an adaptive neural control mechanism for obstacle negotiation behavior in hexapod robots. It combines locomotion control, backbone joint control, local leg reflexes, and neural learning. While the first three components generate locomotion including walking and climbing, the neural learning mechanism allows the robot to adapt its behavior for obstacle negotiation with respect to changing conditions, e.g., variable obstacle heights and different walking gaits. By successfully learning the association of an early, predictive signal (conditioned stimulus, CS) and a late, reflex signal (unconditioned stimulus, UCS), both provided by ultrasonic sensors at the front of the robot, the robot can autonomously find an appropriate distance from an obstacle to initiate climbing. The adaptive neural control was developed and tested first on a physical robot simulation, and was then successfully transferred to a real hexapod robot, called AMOS II. The results show that the robot can efficiently negotiate obstacles with a height up to 85% of

the robot's leg length in simulation and 75% in a real environment.

DATA-DRIVEN DISCOVERY OF LONG TIMESCALE BEHAVIORAL STRATEGIES DURING SENSORY EVOKED NAVIGATION

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Gautam Sridhar[1], Antonio Costa[2], Massimo Vergassola[2], Claire Wyart[1]
[1]Paris Brain Institute, Icm, Inserm U 1127, Cnrs Umr 7725, Sorbonne Université, Paris, France, [2]Laboratoire de Physique de l'Ecole normale supérieure, Ens, Université Psl, Cnrs, Sorbonne Université, Université De Paris, Paris, France

Survival requires flexible and adaptive behavioral mechanisms on multiple timescales. Bridging between short-time behaviors and long timescale strategies can help identify the internal states that modulate behavior across scales. We leverage high-resolution, high throughput recordings of the freely swimming behavior of larval zebrafish to find such strategies from their constituent short timescale burst-like movements called bouts. We reconstruct a maximally predictive behavioral state by stacking consecutive bouts, and study the time evolution of state-space densities through transfer operators. Their spectral decomposition allows us to identify slowly decaying modes corresponding to stereotyped long timescale behavioral strategies. During exploratory behavior in arenas of diverse shapes, we find two main strategies lasting from tens to hundreds of seconds – a "roaming" strategy where turn bouts in similar directions cause large changes in orientation, and a "cruising" strategy where forward bouts with smaller changes in orientation persist. Closed loop visual gradients trigger switches between such long timescale behaviors, while more natural stimuli like prey or aversive cues can cause finer scale modulations of each strategy. Furthermore, mesoscopic stimulus responses such as a sequence of bouts underlying prey capture are nested into one of the strategies, suggesting a hierarchical organization of behavior. The presence of two behavioral strategies irrespective of the sensory landscape point towards a homeostatic mechanism regulating behavior across scales.

HYPOTHALAMIC CIRCUITS FOR FEMALE SOCIAL BEHAVIOUR: INVESTIGATING THE ROLE OF PMV-DAT NEURONS

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Antonio Dias, Susana Lima
Champalimaud Foundation, Champalimaud Neuroscience Programme, Algés, Portugal

In rodents, the hypothalamus has been extensively implicated in the control of sociosexual behaviours. Here we characterize the activity of dopamine active transporter-expressing neurons within the ventral premammillary nucleus (PMv-DAT) of female mice. Using fiber photometry, we show that female PMv-DAT neurons are strongly activated by contact-dependent male cues, but not by female ones. We also show that the male-driven activity of PMv-DAT neurons is highly modulated during sexual behaviour. To test the importance of this population in female sexual behaviour we used optogenetics to increase the activity of PMv-DAT neurons in fertile females. Our results show that activation of female PMv-DAT neurons led to a significant decrease in the rate of female-led investigations, suggesting a role of the PMv-DAT population in the maintenance of investigatory behaviour. Lastly, the PMv has also been implicated in the control of aggressive behaviours, namely maternal aggression. Here, we performed photometric recordings of PMv-DAT neuronal activity during distinct epochs of the peri-and postpartum period in female mice. We show that the activity of PMv-DAT neurons is elevated in the presence of an intruder mouse, independently if the female engages in aggressive or just investigatory behaviour with the male. In contrast, activity towards the father of the pups, to whom the female is not aggressive, is highly decreased when compared to the activity elicited towards conspecific males in virgin females. We propose that, when investigating a male, female PMv-DAT neurons relay male-conspecific cues to its downstream targets to elicit appropriate male-directed behaviours.

Drosophila melanogaster larvae make nutritional choices that minimize developmental time.
Organisms from slime moulds to humans carefully regulate their macronutrient intake to optimize a wide range of life history characters including survival, stress resistance, and reproductive success. However, life history characters often differ in their response to nutrition, forcing organisms to make foraging decisions while balancing the trade-offs between these effects. To date, we have a limited understanding of how the nutritional environment shapes the relationship between life history characters and foraging decisions. To gain insight into the problem, we used a geometric framework for nutrition to assess how the protein and carbohydrate content of the larval diet affected key life history traits in the fruit fly, Drosophila melanogaster. In no-choice assays, survival from egg to pupae, female and male body size, and ovariole number - a proxy for female fecundity - were maximized at the highest protein to carbohydrate (P:C) ratio (1.5:1). In contrast, development time was minimized at intermediate P:C ratios, around 1:2. Next, we subjected larvae to two-choice tests to determine how they regulated their protein and carbohydrate intake in relation to these life history traits. Our results show that larvae targeted their consumption to P:C ratios that minimized development time. Finally, we examined whether adult females also chose to lay their eggs in the P:C ratios that minimized developmental time. Using a three-choice assay, we found that adult females preferentially laid their eggs in food P:C ratios that were suboptimal for all larval life history traits. Our results demonstrate that D. melanogaster larvae make foraging decisions that trade-off developmental time with body size, ovariole number, and survival. In addition, adult females make oviposition decisions that do not appear to benefit the larvae. We propose that these decisions may reflect the living nature of the larval nutritional environment in rotting fruit. These studies illustrate the interaction between the nutritional environment, life history traits, and foraging choices in D. melanogaster, and lend insight into the ecology of their foraging decisions.

Aims. The Life MILCH Project is a longitudinal pilot study that aims to determine the association between levels of maternal milk contamination/exposure to Endocrine Disrupting Chemicals (EDCs) and infants' growth, development and neurobehavioral health in the first year of life. **Methods.** 250 pregnant women in the third trimester of gestation with no gestational or fetal pathologies were enrolled at Parma Hospital. At recruitment, women's lifestyle and nutritional habits were recorded through two questionaries and maternal urine and plasma samples were collected for assessing EDCs exposure. At parturition, cord blood sample, newborns' growth parameters and urine were collected and assessed. Mother-infant dyads are recalled 1, 3, 6 and 12 months after delivery for assessing EDC exposure by biological samples (breast-milk, maternal and infant urine), infants' growth and neurodevelopment through Visual Preference Paradigm (at 1 month), Face-to-Face-Still-Face (at 3 months), Fagan test (at 6 months), Barrier task (at 12 months) and the Bayley III scale for infant neurodevelopment (at 6 and 12 months). **Results.** This is an ongoing study and analysis of results are not completed yet. Maternal lifestyle, nutritional and clinical information before and after pregnancy will be correlated with EDCs levels in biological samples, infants' growth, perceptive, socioemotional, cognitive, and behavioral developmental areas and infant neurodevelopment. **Conclusions.** Perceptive, socioemotional, cognitive, behavioral and reproductive development are susceptible to developmental EDCs exposure. Maternal exposure to EDCs results in fetal and neonatal exposure via utero and breast milk and can affect infants'growth and neuro behavioral development during the first year of life.

Sex-biased impact of endocrine disrupting chemicals on behavioral development and vulnerability to disease: Of mice and children.
Sex is a fundamental biological characteristic that influences many aspects of an organism's phenotype, including neurobiological functions and behavior as a result of species-specific evolutionary pressures. Sex differences have strong implications for vulnerability to disease and susceptibility to environmental perturbations. Endocrine disrupting chemicals (EDCs) have the potential to interfere with sex hormones functioning and influence development in a sex specific manner. Here we present an updated descriptive review of findings from animal models and human studies regarding the current evidence for altered sex-differences in behavioral development in response to early exposure to EDCs, with a focus on bisphenol A and phthalates. Overall, we show that animal and human studies have a good degree of consistency and that there is strong evidence demonstrating that EDCs exposure during critical periods of development affect sex differences in emotional and cognitive behaviors. Results are more heterogeneous when social, sexual and parental behaviors are considered. In order to pinpoint sex differences in environmentally-driven disease vulnerabilities, researchers need to consider sex-biased developmental effects of EDCs.

TO REJECT OR TO MATE? INSIGHTS FROM A NOVEL HYPOTHALAMIC SUBREGION INVOLVED IN FEMALE SEXUAL BEHAVIOUR

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Basma Husain, Nicolas Gutierrez-Castellanos, Inês Dias, Margarida Duarte, Susana Lima
Champalimaud Foundation, Champalimaud Research, Lisbon, Portugal

Whether a female accepts or rejects the sexual advances of a male depends on her reproductive state as well as male-derived sensory stimuli received during the interaction. The ventrolateral part of the ventromedial hypothalamus (VMHvl) is hypothesized to integrate these internal and external cues to influence female socio-sexual behaviour. To elucidate mechanisms by which the VMHvl performs this function, we studied the progesterone receptor-expressing (PR+) cell population in the VMHvl, as progesterone is a key hormone in regulating the reproductive cycle. We first characterized the electrophysiological properties of PR+ cells in the VMHvl and found that they exhibit cyclical changes in their excitation/inhibition (E/I) balance across the reproductive cycle. This cyclical plasticity is more pronounced in the anterior VMHvl (aVMHvl), with the E/I ratio being higher in neurons originating from non-fertile females as compared to fertile ones. Furthermore, we observed that the interaction with a male leads to higher cFos expression in the aVMHvl of non-fertile females that display rejection behaviour compared with fertile females that mate with the male. These results led us to hypothesize that the aVMHvl.PR+ population might be involved in rejection behavior in non-fertile females. To test this we used optogenetics to artificially excite aVMHvl.PR+ neurons in fertile females and, as expected, our manipulation led to increased rejection behaviours in fertile females and to a reduction in the total number of females that mated with the male. Overall, our study highlights the role of aVMHvl.PR+ neurons in female rejection and mating behaviour.

Hippocampal transcriptional and neurogenic changes evoked by combination yohimbine and imipramine treatment.
Adjunct α2-adrenoceptor antagonism is a potential strategy to accelerate the behavioral effects of antidepressants. Co-administration of the α2-adrenoceptor antagonist yohimbine hastens the behavioral and neurogenic effects of the antidepressant imipramine. We examined the transcriptional targets of short duration (7days), combination treatment of yohimbine and imipramine (Y+I) within the adult rat hippocampus. Using microarray and qPCR analysis we observed functional enrichment of genes involved in intracellular signaling cascades, plasma membrane, cellular metal ion homeostasis, multicellular stress responses and neuropeptide signaling pathways in the Y+I transcriptome. We noted reduced expression of the α2A-adrenoceptor (Adra2a), serotonin 5HT2C receptor (Htr2c) and the somatostatin receptor 1 (Sstr1), which modulate antidepressant action. Further, we noted a regulation of signaling pathway genes like inositol monophosphatase 2 (Impa2), iodothyronine deiodinase 3 (Dio3), regulator of G-protein signaling 4 (Rgs4), alkaline ceramidase 2 (Acer2), doublecortin-like kinase 2 (Dclk2), nuclear factor of kappa light polypeptide gene enhancer in B-cells inhibitor, alpha (Nfkbia) and serum/glucocorticoid-regulated kinase 1 (Sgk1), several of which are implicated in the pathophysiology of mood disorders. Comparative analysis revealed an overlap in the hippocampal regulation of Acer2, Nfkbia, Sgk1 and Impa2 between Y+I treatment, the fast-acting electroconvulsive seizure (ECS) paradigm, and the slow-onset chronic (21days) imipramine treatment. Further, Y+I treatment enhanced the quiescent neural progenitor pool in the hippocampal neurogenic niche similar to ECS, and distinct from chronic imipramine treatment. Taken together, our results provide insight into the molecular and cellular targets of short duration Y+I treatment, and identify potential leads for the development of rapid-action antidepressants.

Acute and Chronic Electroconvulsive Seizures (ECS) Differentially Regulate the Expression of Epigenetic Machinery in the Adult Rat Hippocampus.
Electroconvulsive seizure treatment is a fast-acting antidepressant therapy that evokes rapid transcriptional, neurogenic, and behavioral changes. Epigenetic mechanisms contribute to altered gene regulation, which underlies the neurogenic and behavioral effects of electroconvulsive seizure. We hypothesized that electroconvulsive seizure may modulate the expression

of epigenetic machinery, thus establishing potential alterations in the epigenetic landscape.

ON THE ROLE OF SINGING FOR SONG PLASTICITY

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Anja Zai[1], Anna Stepien[1], Nicolas Giret[2,3], Richard Hahnloser[1]
[1]ETH Zurich, Institute Of Neuroinformatics, University Of Zurich, Zurich, Switzerland, [2]Chargé de Recherche CNRS, Institut Des Neurosciences Paris-saclay, Saclay, France, [3]Institut des Neurosciences Paris Saclay, Cnrs, Université Paris Saclay, Saclay, France

Songbirds' vocal mastery is impressive, but to what extent is it a result of practice? Young birds undoubtedly need practice to imitate a vocal target, but can adult birds, similar to humans, make targeted changes to their song in a practice-free manner without intermittently singing? In principle, such ability can arise if the brain stores distinct motor memories of multiple song variants or if the brain's internal models of the sensorimotor system allow immediate translation of a desired sensory target into the appropriate motor command for imitating that target. To explore these ideas, we test whether adult zebra finches subjected to pitch reinforcement can instantaneously retrieve a previous song variant. First, we drive one syllable of their song away from its crystallized (baseline) variant acquired from a tutor, then we withdraw reinforcement and subsequently mute or deafen the birds to deprive them of song experience. In this deprived state, birds barely change their songs and do not show the typical rapid recovery of baseline song, revealing a requirement of song practice for full song recovery. Nevertheless, in this deprived state, birds seem capable of making small but directed song changes (on the order of a daily standard deviation), not necessarily towards the original target, but towards song variants with higher expected reward. Thus, our work reveals vocal plasticity in songbirds independent of sensory experience but suggests a limit to internally guided vocal flexibility.

A COMPARATIVE APPROACH IN VERTEBRATE NEUROSCIENCE: THE ZEBRAFISH (DANIO RERIO) AND GIANT DANIO (DEVARIO AEQUIPINNATUS)

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Pedro Tomás Silva[1], Aaron Ostrovsky[1], Sabine Renninger[1], Adrien Jouary[1], Ruth Diez Del Corral[1], João Marques[1], Edite Figueiras[1], Alexandre Laborde[1], Mariana Sampaio[1], Adriana Correia[2], Michael Orger[1]

In behavioral neuroscience a comparative approach can help us to distinguish general organizing principles in the brain from specialized adaptations to a particular ecological niche, and to link neurological differences to behavioral phenotypes and ecological variation on an evolutionary timescale. To address this idea, we studied the swimming behavior of the larvae of two closely related species of Danioninae: *Danio rerio* and *Devario aequipinnatus*. Although these species share similar anatomy at the larval stage, they have different developmental rate and locomotor styles. We measured the locomotion of a cohort of larvae from each species in freely swimming behavior and in a set of automated assays with optomotor response and social behavior. Compared to Zebrafish, the Devario larvae show more rapid development of behavioral responses, in particular showing clear social attraction in the first week of life. They also show increased maneuverability and performance in the optomotor response, with shorter intervals between tail movements. Currently we are investigating how this increased maneuverability impacts their prey capture behavior. Seeing the differences in the level of behavior, we compared basic neural anatomy and started building an expression atlas for the Devario larva using antibody labelings for neuromodulators and dextran-dye back-fills of reticulospinal neurons for the descending motor system. Comparing the anatomy of the descending motor system across the two species shows a high degree of conservation, although with some small differences in dendritic projection patterns. Lastly, we are making Devario GCaMP lines to see if there are differences in brain-wide activity during behavior.

DYNAMIC INTEGRATION OF SPACE AND SOCIAL STATUS IN THE MAMMALIAN HYPOTHALAMUS

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Dorian Battivelli
EMBL, Lazio, Monterotondo, Italy

The hypothalamus is an evolutionarily ancient brain region that controls innate behaviors associated with reproduction, defense, and ingestion. Work has shown that the ventrolateral part of the ventromedial hypothalamus (VMHvl) encodes a generalized state of social threat and is necessary and sufficient for producing both social aggression and avoidance. However, it remains unclear how social experience contributes to the selection of each of these specific defensive behaviors. Recent work in the lab has shown that neurons that fire in the context of social defeats are reactivated when the animal explores the location where the defeat occurred, even in absence of the aggressor. Also, at the neural population level, VMHvl firing becomes tuned to the location where the animal is, discriminating between the safe home cage and the chamber where the aggression took place. Based on these data, my project aims to test the hypothesis that neuroplastic changes in the VMH might occur in a territorial context to encode a functional map of social space that guide instinctive behaviors. To this end, we developed an experimental apparatus that allows the study of territorial behavior in semi-natural conditions. Our protocol allows for the identification of robust and reproducible territorial behaviors in laboratory mice, and the development of a new urine marking protocol to enrich our understanding of territorial dynamics. Finally, we demonstrate the compatibility of our apparatus with imaging and manipulating neural tools, thus allowing for new insight regarding how VMHvl encodes territorial cues that shape defensive behaviors.

COMPARATIVE BRAIN MORPHOLOGY OF THREE SPECIMENS WITH DIFFERENT ADAPTATIVE BEHAVIORS: THE BONGO, THE JAVA DEER MOUSE AND THE MAKI CATTA

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Elodie Chaillou[1], Scott Love[1], Najoua Arroub[1], Marine Siwiaszczyk[1], Mélody Morisse[1], Quentin Derian[1], Baptiste Mulot[2], Christophe Destrieux[3], Raïssa Yebga Hot[4], Cyril Poupon[4], Frédéric Andersson[5]
[1]INRAE, Umr Prc, Nouzilly, France, [2]Beauval Nature, Zooparc De Beauval, Saint-Aignan-sur-Cher, France, [3]Faculté de Médecine, Laboratoire D'anatomie, Tours, France, [4]CEA/Joliot/NeuroSpin, Unirs, Gif-sur-Yvette, France, [5]INSERM, Ibrain, Tours, France

One aim of comparative neuroanatomy is to better understand brain function among species. It is tempting to try and explain brain differences throughout the animal kingdom by differences in adaptive behaviors as well as ecological factors. Based on this idea, we explored, with MRI, the brain morphology of three species with different sociality and predator avoidance (Bongo, Java deer mouse and Maki Catta). Brains were collected after death of natural causes and MR-imaged. Brain and body weights were collected, and volumes of brain were estimated after MRI segmentation. The brain-to-body weight ratio was close to 1 for the Java deer mouse (1.04%) and the maki catta (1.05%) but only 0.26% for the bongo. Encephalization quotients (EQ) were calculated using formulas defined for human (hEQ, constants 0.12 and 2/3; Cairó 2011, doi:10.3389/fnhum.2011.00108) and for dog (dEQ, constants 0.14 and 0.528; Saganuwan 2021, doi:10.1186/s13104-021-05638-0). Whatever the method, the Java deer mouse EQs were the smallest (hEQ=0.98; dEQ=0.88). The maki catta had a higher hEQ (1.23) than the bongo (1.14) whereas the order was reversed for the dEQ (maki catta dEQ=1.21; bongo dEQ=1.96). These values are coherent with the idea that EQ is higher in prey species using active predator avoidance (bongo) and in social species (bongo and maki catta).

MATERNAL DEPRIVATION AND MILK REPLACEMENT AFFECT THE INTEGRITY OF GRAY AND WHITE MATTER IN THE DEVELOPING LAMB BRAIN

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Scott Love[1], Emmanuelle Haslin[1], Manon Bellardie[1], Frédéric Andersson[2], Laurent Barantin[2], Isabelle Filipiak[2], Hans Adriaensen[1], Csilla Lea Fazekas[3], Laurène Leroy[1], Dóra Zelena[4], Mélody Morisse[1], Frédéric Elleboudt[1], Christian Moussu[1], Frédéric Lévy[1], Raymond Nowak[1], Elodie Chaillou[1]
[1]INRAE, Umr Physiologie De La Reproduction Et Des Comportements, Nouzilly, France, [2]INSERM, Ibrain, Tours, France, [3]University of Pécs Medical School, Centre for Neuroscience, Szentágothai Research Centre, Institute Of Physiology, Pécs, Hungary, [4]University of Pécs, Medical School, Centre for Neuroscience, Szentágothai Research Centre, Institute Of Physiology, Pécs, Hungary

The psychoendocrine evaluation of lamb development has demonstrated that maternal deprivation and milk replacement alters health, behavior and endocrine profiles. While lambs are able to discriminate familiar and non-familiar conspecifics (mother or lamb), only lambs reared with their mother develop such clear social discrimination or preference. Lambs reared without mother display no preference for a specific lamb from its own group. Differences in exploratory and emotional behaviours between mother-reared and mother deprived lambs have also been reported. As these behavioural abilities are supported by the brain, we hypothesize that rearing with maternal deprivation and milk replacement leads to altered brain development and maturation. To test this hypothesis, we examined brain morphometric and microstructural variables extracted from *in-vivo* T1-weighted and diffusion-weighted magnetic resonance images acquired longitudinally (1 week, 1.5 months and 4.5 months of age) in mother-reared and mother-deprived lambs. From the morphometric variables the caudate nuclei volume was found to be smaller for mother-deprived than for mother-reared lambs. T1-weighted signal intensity and radial diffusivity were higher for mother-deprived than for mother-reared lambs in both the white and gray matters. The fractional anisotropy of the white matter was lower for mother-deprived than for mother-reared lambs. Based on these morphometric and microstructural characteristics we conclude that maternal deprivation delays and affects lamb brain growth and maturation.

"THIS IS MY SPOT!": SOCIAL DETERMINANTS REGULATE SPACE UTILIZATION IN MACAQUES.

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Sylvia Wirth[1], Tadeusz Kononowicz[2], Felipe Rolando[1], Lucas Maigre[1], Jean-René Duhamel[1], Sebastien Ballestra[3], Angela Sirigu[1]
[1]ISC Marc Jeannerod, UMR5229, Cnrs, Bron, France, [2]Polish Academy of Sciences, Institute Of Psychology, Warszawa, Poland, [3]university of strabsourg, Centre De Pimatologie, Strasbourg, France

Space can be a limited resource. Many species including humans, evolved a compromised sharing of space based on social determinants. For example, students in a classroom sit close to their friends, keeping the same spots across days, revealing the social structure in the classroom. This suggests that factors such as social hierarchy and affiliation can shape space utilization; contrasting with classical random walk models of agents moving at random in any given direction. Here, we asked whether spatial occupancy of macaques (*Macaca fascicularis* and *M. mulatta*) within a unisex group, reveals a structured space utilization beyond simple spatial affordance of the finite space. To this end, in two groups of four animals, we analyzed the simultaneously recorded positions of each individual while the group roamed in an enclosure. (1) The identity of each animal could be decoded from its individual pattern of spatial occupancy, revealing that each animal sustained its spatial footprint across days. (2) Average distance between monkeys was a proxy of their social hierarchy. (3) Alternating the social context by removing one of the monkeys revealed that social context influences occupancy. (4) Finally, the distribution of distance between pairs of monkeys was bimodal and was modeled using random walk approach with an additional parameter reflecting propensity to stay in close proximity, which was again related to dominance hierarchy. These analyses reveal the hidden structured nature of space utilization as a function of social determinants in macaques and simple modeling approach to further study group organization in neuro-ethological settings.

WHAT IS THE ETHOLOGICAL ROLE OF THE ZEBRAFISH PALLIUM - THE EVOLUTIONARY ANCESTOR OF THE MAMMALIAN CORTEX?

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Thomas Ryan, Elena Dreosti
University College London, Wolfson Institute For Biomedical Research, London, United Kingdom

In humans, the cortex takes a commanding role in sensory perception and exerts ultimate control over almost all aspects of behaviour. However, a clear role is less apparent in lower order mammals and vertebrates. In rats, it was recently reported that cortical lesions have few effects on the animal's behaviour, except for a specific deficit in rapid motor adaptation to a sudden change in a learned environment. The zebrafish pallium is the ancestral homolog of the cortex, sharing molecular markers as well as developmental and functional similarities. A high level of activity is consistently observed across the whole pallium in behaving animals, but with little clear association to any sensory input or behaviour. What is the role of this primordial cortex? Moreover, what advantage does having a pallium give a zebrafish? To investigate this, we surgically remove dorsal telencephalon from 24 hour old zebrafish embryos and study their free-swimming behaviour at larval and juvenile stages in the presence of naturalistic challenges such as obstacles, paramecia and simulated predators. Interestingly, zebrafish lacking pallium show no dramatic disturbance of free-swimming bout rates, turn frequency or kinematic parameters. Similarly, stereotyped ballistic escape responses to looming stimuli seem to be unaffected, with subtle changes to sustained escape trajectories observed. Preliminary analysis using neural networks to predict behaviour also suggest changes to exploration strategies and bout sequencing. This is in line with the hypothesis that pallium plays a subtle modulatory role in behaviour, perhaps providing variability to facilitate flexible, adaptive behaviour.

BEHAVIORAL DIVERSITY ACROSS ZEBRAFISH STRAINS OCCURS AT THE LEVEL OF SWIM SEQUENCES.

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

João Marques[1], Gautam Sridhar[2], Rita Felix[1], Claire Wyart[3], Michael Orger[1]
[1]Champalimaud Research, Neuroscience, Lisbon, Portugal, [2]ICM- Paris Brain Institute, Spinal Sensory Signalling, Wyart Lab, Paris, France, [3]Sorbonne Université, Paris Brain Institute (icm), Paris, France

To survive in ever-changing environments, animals evolved a panoply of behaviors that allow them to avoid predation, explore the world, and exploit resources. A core concept in ethology is that behaviors are constructed from a repertoire of basic movements that are assembled into sequences to permit goals at longer timescales, creating nested behavioral hierarchies. Closely related strains of animals show behavioral diversity that allow them to thrive over distinct environments. It is unclear at what level of the behavioral hierarchy this diversity is produced. Is behavioral diversity produced at the lowest level of the hierarchy, having each strain its own movement repertoire, or do they share a common movement repertoire, and diversity is generated at the sequence level? To tackle this question, we turned to the zebrafish larvae because their body plan is simple. It is possible, using a high-speed camera, to automatically track all of its body parts and, contrary to most animals, larvae move discontinuously, swimming in short bursts of movement called “swim bouts”. Thus, larval behavior is naturally segmented in time. We performed behavioral recordings for 6 zebrafish strains, creating a data set with millions of swims over 10 distinct behaviors. After, using an unsupervised classification method (clusterdv), we discovered that these strains share a common swim repertoire. We also observed that for long timescale behaviors they chain their swims in sequences that are specific for each strain. We discuss the idea that sequence diversity is a mechanism to produce behavioral diversity where evolution acts on.

Early-Life Social Experience Shapes Social Avoidance Reactions in Larval Zebrafish.
Social experiences greatly define subsequent social behavior. Lack of such experiences, especially during critical phases of development, can severely impede the ability to behave adequately in social contexts. To date, it is not well characterized how early-life social isolation leads to social deficits and impacts development. In many model species, it is challenging to fully control social experiences, because they depend on parental care. Moreover, complex social behaviors involve multiple sensory modalities, contexts, and actions. Hence, when studying social isolation effects, it is important to parse apart social deficits from general developmental effects, such as abnormal motor learning. Here, we characterized how social experiences during early development of zebrafish larvae modulate their social behavior at 1 week of age, when social avoidance reactions can be measured as discrete swim events. We show that raising larvae in social isolation leads to enhanced social avoidance, in terms of the distance at which larvae react to one another and the strength of swim movement they use. Specifically, larvae raised in isolation use a high-acceleration escape swim, the short latency C-start, more frequently during social interactions. These behavioral differences are absent in non-social contexts. By ablating the lateral line and presenting the fish with local water vibrations, we show that lateral line inputs are both necessary and sufficient to drive enhanced social avoidance reactions. Taken together, our results show that social experience during development is a critical factor in shaping mechanosensory avoidance reactions in larval zebrafish.

Internal state dynamics shape brainwide activity and foraging behaviour.
The brain has persistent internal states that can modulate every aspect of an animal's mental experience. In complex tasks such as foraging, the internal state is dynamic. Caenorhabditis elegans alternate between local search and global dispersal. Rodents and primates exhibit trade-offs between exploitation and exploration. However, fundamental questions remain about how persistent states are maintained in the brain, which upstream networks drive state transitions and how state-encoding neurons exert neuromodulatory effects on sensory perception and decision-making to govern appropriate behaviour. Here, using tracking microscopy to monitor whole-brain neuronal activity at cellular resolution in freely moving zebrafish larvae, we show that zebrafish spontaneously alternate between two persistent internal states during foraging for live prey (Paramecia).

In the exploitation state, the animal inhibits locomotion and promotes hunting, generating small, localized trajectories. In the exploration state, the animal promotes locomotion and suppresses hunting, generating long-ranging trajectories that enhance spatial dispersion. We uncover a dorsal raphe subpopulation with persistent activity that robustly encodes the exploitation state. The exploitation-state-encoding neurons, together with a multimodal trigger network that is associated with state transitions, form a stochastically activated nonlinear dynamical system. The activity of this oscillatory network correlates with a global retuning of sensorimotor transformations during foraging that leads to marked changes in both the motivation to hunt for prey and the accuracy of motor sequences during hunting. This work reveals an important hidden variable that shapes the temporal structure of motivation and decision-making.

Clusterdv: a simple density-based clustering method that is robust, general and automatic.
How to partition a dataset into a set of distinct clusters is a ubiquitous and challenging problem. The fact that data vary widely in features such as cluster shape, cluster number, density distribution, background noise, outliers and degree of overlap, makes it difficult to find a single algorithm that can be broadly applied. One recent method, clusterdp, based on search of density peaks, can be applied successfully to cluster many kinds of data, but it is not fully automatic, and fails on some simple data distributions.
Bioinformatics, 2019; 35

Structure of the Zebrafish Locomotor Repertoire Revealed with Unsupervised Behavioral Clustering.
An important concept in ethology is that complex behaviors can be constructed from a set of basic motor patterns. Identifying the set of patterns available to an animal is key to making quantitative descriptions of behavior that reflect the underlying motor system organization. We addressed these questions in zebrafish larvae, which swim in bouts that are naturally segmented in time. We developed a robust and general purpose clustering method (clusterdv) to ensure accurate identification of movement clusters and applied it to a dataset consisting of millions of swim bouts, captured at high temporal resolution from a comprehensive set of behavioral contexts. We identified a set of thirteen basic swimming patterns that are used flexibly in various combinations across different behavioral contexts and show that this classification can be used to dissect the sensorimotor transformations underlying larval social behavior and hunting. Furthermore, using the same approach at different levels in the behavioral hierarchy, we show that the set of swim bouts are themselves constructed from a basic set of tail movements and that bouts are executed in sequences specific to different behaviors.

Pan-neuronal calcium imaging with cellular resolution in freely swimming zebrafish.
Calcium imaging with cellular resolution typically requires an animal to be tethered under a microscope, which substantially restricts the range of behaviors that can be studied. To expand the behavioral repertoire amenable to imaging, we have developed a tracking microscope that enables whole-brain calcium imaging with cellular resolution in freely swimming larval zebrafish. This microscope uses infrared imaging to track a target animal in a behavior arena. On the basis of the predicted trajectory of the animal, we applied optimal control theory to a motorized stage system to cancel brain motion in three dimensions. We combined this motion-cancellation system with differential illumination focal filtering, a variant of HiLo microscopy, which enabled us to image the brain of a freely swimming larval zebrafish for more than an hour. This work expands the repertoire of natural behaviors that can be studied with cellular-resolution calcium imaging to potentially include spatial navigation, social behavior, feeding and reward.

LsrF, a coenzyme A-dependent thiolase, catalyzes the terminal step in processing the quorum sensing signal autoinducer-2.
The quorum sensing signal autoinducer-2 (AI-2) regulates important bacterial behaviors, including biofilm formation and the production of virulence factors. Some bacteria, such as Escherichia coli, can quench the AI-2 signal produced by a variety of species present in the environment, and thus can influence AI-2-dependent bacterial behaviors. This process involves uptake of AI-2 via the Lsr transporter, followed by phosphorylation and consequent intracellular sequestration. Here we determine the metabolic fate of intracellular AI-2 by characterizing LsrF, the terminal protein in the Lsr AI-2 processing pathway. We identify the substrates of LsrF as 3-hydroxy-2,4-pentadione-5-phosphate (P-HPD, an isomer of AI-2-phosphate) and coenzyme A, determine the crystal structure of an LsrF catalytic mutant bound to P-HPD, and identify the reaction products. We show that LsrF catalyzes the transfer of an acetyl group from P-HPD to coenzyme A yielding dihydroxyacetone phosphate and acetyl-CoA, two key central metabolites. We further propose that LsrF, despite strong structural homology to aldolases, acts as a thiolase, an activity previously undescribed for this family of enzymes. With this work, we have fully characterized the biological pathway for AI-2 processing in E. coli, a pathway that can be used to quench AI-2 and control

quorum-sensing-regulated bacterial behaviors.

25066084: Severi KE, Portugues R, Marques JC, O'Malley DM, Orger MB, Engert F
Neural control and modulation of swimming speed in the larval zebrafish.
Vertebrate locomotion at different speeds is driven by descending excitatory connections to central pattern generators in the spinal cord. To investigate how these inputs determine locomotor kinematics, we used whole-field visual motion to drive zebrafish to swim at different speeds. Larvae match the stimulus speed by utilizing more locomotor events, or modifying kinematic parameters such as the duration and speed of swimming bouts, the tail-beat frequency, and the choice of gait. We used laser ablations, electrical stimulation, and activity recordings in descending neurons of the nucleus of the medial longitudinal fasciculus (nMLF) to dissect their contribution to controlling forward movement. We found that the activity of single identified neurons within the nMLF is correlated with locomotor kinematics, and modulates both the duration and oscillation frequency of tail movements. By identifying the contribution of individual supraspinal circuit elements to locomotion kinematics, we build a better understanding of how the brain controls movement.

Phosphoenolpyruvate phosphotransferase system regulates detection and processing of the quorum sensing signal autoinducer-2.
Autoinducer-2 (AI-2) a signal produced by a range of phylogenetically distant microorganisms, enables inter-species cell-cell communication and regulates many bacterial phenotypes. Certain bacteria can interfere with AI-2-regulated behaviours of neighbouring species by internalizing AI-2 using the Lsr transport system (encoded by the lsr operon). AI-2 imported by the Lsr is phosphorylated by the LsrK kinase and AI-2-phosphate is the inducer of the lsr operon. Here we show that in Escherichia coli the phosphoenolpyruvate phosphotransferase system (PTS) is required for Lsr activation and is essential for AI-2 internalization. Although the phosphorylation state of Enzyme I of PTS is important for this regulation, LsrK is necessary for the phosphorylation of AI-2, indicating that AI-2 is not phosphorylated by PTS. Our results suggest that AI-2 internalization is initiated by a PTS-dependent mechanism, which provides sufficient intracellular AI-2 to relieve repression of the lsr operon and, thus induce depletion of AI-2 from the extracellular environment. The fact that AI-2 internalization is not only controlled by the community-dependent accumulation of AI-2, but also depends on the phosphorylation state of PTS suggests that E. coli can integrate information on the availability of substrates with external communal information to control quorum sensing and its interference.

Stereochemical diversity of AI-2 analogs modulates quorum sensing in Vibrio harveyi and Escherichia coli.
Bacteria coordinate population-dependent behaviors such as virulence by intra- and inter-species communication (quorum sensing). Autoinducer-2 (AI-2) regulates inter-species quorum sensing. AI-2 derives from the spontaneous cyclisation of linear (S)-4,5-dihydroxypentanedione (DPD) into two isomeric forms in dynamic equilibrium. Different species of bacteria have different classes of AI-2 receptors (LsrB and LuxP) which bind to different cyclic forms. In the present work, DPD analogs with a new stereocenter at C-5 (4,5-dihydroxyhexanediones (DHDs)) have been synthesized and their biological activity tested in two bacteria. (4S,5R)-DHD is a synergistic agonist in Escherichia coli (which contains the LsrB receptor), while it is an agonist in Vibrio harveyi (LuxP), displaying the strongest agonistic activity reported so far (EC(50)=0.65μM) in this organism. Thus, modification at C-5 opens the way to novel methods to manipulate quorum sensing as a method for controlling bacteria.

Processing the interspecies quorum-sensing signal autoinducer-2 (AI-2): characterization of phospho-(S)-4,5-dihydroxy-2,3-pentanedione isomerization by LsrG protein.
The molecule (S)-4,5-dihydroxy-2,3-pentanedione (DPD) is produced by many different species of bacteria and is the precursor of the signal molecule autoinducer-2 (AI-2). AI-2 mediates interspecies communication and facilitates regulation of bacterial behaviors such as biofilm formation and virulence. A variety of bacterial species have the ability to sequester and process the AI-2 present in their environment, thereby interfering with the cell-cell communication of other bacteria. This process involves the AI-2-regulated lsr operon, comprised of the Lsr transport system that facilitates uptake of the signal, a kinase that phosphorylates the signal to phospho-DPD (P-DPD), and enzymes (like LsrG) that are responsible for processing the phosphorylated signal. Because P-DPD is the intracellular inducer of the lsr operon, enzymes involved in P-DPD processing impact the levels of Lsr expression. Here we show that LsrG catalyzes isomerization of P-DPD into 3,4,4-trihydroxy-2-pentanone-5-phosphate. We present the crystal structure of LsrG, identify potential catalytic residues, and determine which of these residues affects P-DPD processing in vivo and in vitro. We also show that an lsrG deletion mutant

accumulates at least 10 times more P-DPD than wild type cells. Consistent with this result, we find that the lsrG mutant has increased expression of the lsr operon and an altered profile of AI-2 accumulation and removal. Understanding of the biochemical mechanisms employed by bacteria to quench signaling of other species can be of great utility in the development of therapies to control bacterial behavior.

EFFECTS OF EARLY SOCIAL ENVIRONMENT ON ADULT ZEBRAFISH BEHAVIOUR – A NEURONAL AND TRANSCRIPTOMIC APPROACH

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Magda Teles[1], Miguel Correia[1], Rita Gageiro[1], Rui Oliveira[1,2]
[1]Instituto Gulbenkian de Ciência, Integrative Behavioural Biology, Oeiras, Portugal, [2]ISPA - Instituto Universitário de Ciências Psicológicas, Sociais e da Vida, Ispa, Lisboa, Portugal

The social environment of an animal can have a profound and determining effect on its behaviour. During development, variations in the social structure provide inadvertent information that influences many aspects of individual development on a wide range of physiological and cognitive traits. In the present work, we studied the influence of environmental complexity in the development of different adult social phenotypes at three levels: behavioural, neuronal, and genetic. Therefore, zebrafish were raised in different social environmental complexities, by varying group size and group stability, until adulthood and then tested in different behavioural contexts. Our results indicate that distinct aspects of social complexity (i.e. group size and group stability) influence differentially adult social behaviour; for instance, group cohesion is influenced by group size, while the preference for conspecifics changes depending on group stability. At the neuronal level, animals raised in less complex social environments experience changes in neuronal densities, a significant reduction in brain size, in specific regions related to social information processing, and changes in gene expression patterns. These results indicate that variations in the social environmental complexity during development can profoundly impact an individual throughout their lifetime.

ROLE OF ENVIRONMENT AND EXPERIMENTER IN REPRODUCIBILITY OF BEHAVIORAL STUDIES WITH LABORATORY MICE

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Martina Nigri[1,2], Johanna Åhlgren[3], David P. Wolfer[1,2], Vootele Voikar[3,4]
[1]University of Zürich, Faculty of Medicine, Institute Of Anatomy, Zürich, Switzerland, [2]Department of Health Sciences and Technology, Eth, Zürich, Switzerland, [3]Laboratory Animal Center, Hilife, University Of Helsinki, Helsinki, Finland, [4]Neuroscience Center, Hilife, University Of Helsinki, Helsinki, Finland

Behavioral phenotyping of mice has received a great deal of attention during the past three decades. However, there is still a pressing need to understand the variability caused by environmental and biological factors, human interference, and poorly standardized experimental protocols. The inconsistency of results is often attributed to the inter-individual difference between the experimenters and environmental conditions. The present work aims to dissect the combined influence of the experimenter and the environment on the detection of behavioral traits in two inbred strains most commonly used in behavioral genetics due to their contrasting phenotypes, the C57BL/6J and DBA/2J mice. To this purpose, the elevated O-maze, the open field with object, the accelerating rotarod and the Barnes maze tests were performed by two experimenters in two diverse laboratory environments. Our findings confirm the well-characterized behavioral differences between these strains in exploratory behavior, motor performance, learning and memory. Moreover, the results demonstrate how the experimenter and the environment influence the behavioral tests with a variable-dependent effect, often with mutually exclusive contributions. In this context, our study highlights how both the experimenter and the environment can have an impact on the strain effect size without altering the direction of the conclusions. Importantly, the general agreement on the results is reached by converging evidence from multiple measures addressing the same trait. In conclusion, the present work elucidates the contribution of both the experimenter and the laboratory environment in the intricate field of reproducibility in mouse behavioral phenotyping.

NOISE-INDUCED ALTERATIONS IN THE BEHAVIOR OF THE CARIBBEAN HERMIT CRAB (COENOBITA CLYPEATUS) DURING THE SHELL SELECTION TEST

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

María De Jesús-Burgos, Paola Negrón-Moreno, Francisco Torres-Torres, Ana González-Colón, María González-De Jesús, Yeritmary Rodríguez-Delgado, Gabriel Rivera-Rodríguez, Camila Ortíz-Méndez, Araceli Francisco
University of Puerto Rico in Cayey, Biology, Cayey, Puerto Rico

The littoral ecosystems and the animals inhabiting them are particularly impacted by noise pollution. Coenobita clypeatus (C. clypeatus) is a species abundant in the littoral zones that depends on basic behavioral patterns for survival. Although the detrimental effects of noise pollution on social- and threat-related behaviors are known, how noise affects C. clypeatus' ability to explore and choose its shells is uncertain. We aimed to test whether anthropogenic noise would impair C. clypeatus' investigative patterns and decision-making abilities during shell selection. To evaluate the effects of noise on C. clypeatus' behaviors, animals were subjected to either acute or chronic noise regimens. During the test, we assessed the investigation of three different shell resources (suboptimal-, optimal-, and supraoptimal-shells) and final shell selection. The results suggest that acute noise significantly alters the animal's exploration, increasing both locomotion and velocity, when compared to control- and chronically treated animals ($p<0.001$). Even though most animals, regardless of the noise conditions, opted for the optimal shell, only animals under chronic- and acute-noise regimens spent more time investigating and occupying the suboptimal shell ($p<0.05$). The observed noise-induced behavioral alterations may be modulated by an increase in the distraction and physiological stress of the animals. Therefore, these behavioral alterations may also impact the social-, defensive-, and reproductive behaviors of the animals inhabiting noise-polluted littoral areas. Future studies are necessary to understand the neural substrates underpinning noise-induced changes in C. clypeatus' behavioral responses.

TRANSIENT AND PERSISTENT FEAR STATES IN DROSOPHILA MELANOGASTER REVEALED BY A HIGH-THROUGHPUT BEHAVIORAL ASSAY

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Matheus Farias, Mirjam Heinemans, João Frazão, Marta Moita
Champalimaud Center for the Unknown, Champalimaud Research, Lisbon, Portugal

Different taxonomic groups exhibit very similar responses to immediate threats that have been grossly categorized into flight, freeze or fight. It is remarkable that animals with very distinct morphologies, occupying very different environmental niches, display one of the three universal defense modules in a context dependent manner. This convergence in defensive responses all across the animal kingdom appeals for its evolutionary value. Here we present a high-throughput behavioral assay (behavioral paradigm, experimental setup, fully-automated tracking and analysis pipeline) to study Drosophila melanogaster responses to repeated inescapable visual looming-stimulus mimicking a predator repeating its attack after a failed attempt at catching its prey. The rich repertoire of defensive behaviors, together with its arsenal of tools to dissect neuronal circuits, makes the fly a valuable model organism to tackle the behavioral and neuronal basis of defense responses. Using this assay, we can distinguish two phases of the defensive responses - a startle response that is aligned with the stimulus presentation and shows a transient profile, as well as defensive states that emerge following the startle response and can persist for longer periods of time, such as sustained freezing and escapes. Focusing on freezing responses we tested the role of different looming-responsive visual projection neurons and found that looming triggered freezing behavior relies on the activity of several visual projection neurons. Our findings suggest that freezing arises from the coordinated activity of different neural input pathways even when driven by the same stimulus.

EFFECT OF EMBRIONAL VALPROINIC ACID AND DELTAMETHRIN TREATMENT ON SOCIAL BEHAVIOR IN DOMESTIC CHICKS (GALLUS GALLUS)

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

David Barnabas Balazs, Gergely Zachar, Dorina Kiss
Semmelweis University, Department Of Anatomy, Histology And Embryology, Budapest, Hungary

Embryonic exposure to valproic acid (VPA) is known to produce sociability deficits, in several vertebrate species, resembling human autistic phenotypes. Chicks of Galliform birds, known to display early preference behaviours, have been used extensively for neurobehavioural studies. Our question was whether the investigated environmental contaminant, deltamethrin, can cause autism-specific behavioural abnormalities. The secondary goal was to create a potentially new pharmacological model of autism and compare it to the widely used model of valproic acid. Here, domestic chicken eggs were injected with sodium valproate (200 µl of 35 µmol/l solution) or with vehicle (distilled water) and deltamethrine (1.5mg/kg) on the 14th day of incubation. After hatching, the chicks were tested for sociability, and social memory before and after social isolation. Our findings confirm previous studies, reporting an adverse effect of VPA on embryonic development, including a tendency for aborted or delayed hatching and, occasionally, for locomotor disorders in a small percentage of birds. The most prominent finding was attenuation of sociability of VPA-exposed birds. Social memory of familiarized individuals is not yet formed in chicks at this age. Although deltamethrin treatment caused minor changes in behaviour, it did not cause a behaviour pattern similar to VPA, it was not associated with a decrease in sociability and vocalization. There is probably no direct association between deltamethrin and the incidence of autism. It seems that embryonic deltamethrin treatment is not an appropriate chemical model for autism.

TEMPORAL COORDINATION OF DANIONELLA C. VOCALISATIONS

POSTER SESSION 07 - SECTION: NEUROETHOLOGY AND EVOLUTION OF THE NERVOUS SYSTEM

Maximilian Hoffmann, Lukas Breitzler, Johannes Veith, Benjamin Judkewitz
Einstein Center for Neuroscience, NeuroCure Cluster of Excellence, Charité, Universitätsmedizin Berlin, Berlin, Germany

Danionella cerebrum is an emerging model organism for the neuroethology of acoustic communication. *Danionella c.* possesses the smallest known vertebrate brain and is sufficiently transparent to allow for non-invasive optical interrogation of the brain even in adult animals. Additionally, male *Danionella c.* are known to produce characteristic click bursts at 60 and 120 Hz. These bursts occur in various lengths, grouped into sequences and often in the context of agonistic behaviour. Here, using a sub-wavelength acoustic triangulation setup and identity tracking in video recordings, we present the first characterisation of the vocal repertoire of *Danionella c.* at the level of the individual. We describe the temporal coordination of vocal interaction, as well as its relationship to social hierarchy and investigate possible behavioural motifs that accompany vocalisation episodes

WAXHOLM SPACE ATLAS OF THE RAT BRAIN VERSION 4: A VOLUMETRIC ATLAS ENABLING DATA INTEGRATION AND ANALYSIS

POSTER SESSION 07 - SECTION: DATA SHARING IN NEUROSCIENCE

Heidi Kleven[1], Ingvild Elise Bjerke[1], Jala Imad[1], Francisco Clascá[2], Henk Groenewegen[3], Jan Bjaalie[1], Trygve Leergaard[1]
[1]University of Oslo, Department Of Molecular Medicine, Oslo, Norway, [2]School of Medicine. Autonomous University of Madrid, Department Of Anatomy And Neuroscience, Madrid, Spain, [3]Amsterdam University medical Center, Department Of Anatomy And Neuroscience, Amsterdam, Netherlands

Anatomical atlases for the murine brain are important reference resources used to define, analyze and communicate locations in experimental neuroscience research. The Waxholm Space atlas of the Sprague Dawley rat brain v3 (RRID: SCR_017124) is an open-source volumetric atlas featuring 118 anatomical delineations defined in a high-resolution magnetic resonance imaging (MRI) and diffusion tensor imaging (DTI) dataset acquired ex-vivo from an adult Sprague Dawley brain. The atlas provides a spatial framework for integration and analysis of multiscale and multimodal rat brain data. It is developed by the EU Human Brain Project and shared via the EBRAINS research infrastructure (https://ebrains.eu/service/rat-brain-atlas). However, interpretation and analysis of data registered to this atlas has so far been limited by the lack of detailed subdivision of several major brain regions. We have revised and upgraded the Waxholm Space rat brain atlas, based on expert interpretations of MRI/DTI contrast combined with spatially registered histological images and published reference resources. We here present version 4 of the Waxholm Space rat brain atlas with 222 structures and full brain coverage, including complete and revised subdivisions of the cerebral cortex, striatopallidal region, midbrain dopaminergic system and thalamus cell groups and main fiber tracts. The atlas has been integrated in several open-source tools and workflows. We demonstrate how use of the atlas improves interpretation, integration, analysis and dissemination of rat brain data. Funded from EU Horizon 2020, Specific Grant Agreement No. 945539 (Human Brain Project

SGA3).

MACBRAIN RESOURCE: ARCHIVED PROCESSED AND UNPROCESSED RHESUS MONKEY BRAIN TISSUE AVAILABLE FOR DE NOVO NEUROSCIENCE STUDIES

POSTER SESSION 07 - SECTION: DATA SHARING IN NEUROSCIENCE

Alvaro Duque
Yale University School of Medicine, Neuroscience, New Haven, United States of America

The MacBrain Resource Center (MBRC), in the Department of Neuroscience at Yale University, currently houses 7 different collections of macaque monkey brain tissue available to the research community at large (https://medicine.yale.edu/neuroscience/macbrain/). Among the available materials are Dr. Pasko Rakic's tritiated thymidine injections in pregnant monkeys to locate newly born neurons in the brains of the offspring (Collection 1). Materials produced in these pioneering studies of neurogenesis continue to be used today to address the basic tenets of neurodevelopment. Available in Collection 5 are thousands of plastic-embedded electron microscopy (EM) blocks of various brain areas including visual, sensorimotor, and prefrontal cortices from NHPs ranging in age from embryonic to postnatal. These EM blocks are available for analysis of synapses and other cellular components at the ultrastructural level. The growing Collection 6 houses the current histo- and immunohistochemical work of Dr. Alvaro Duque to identify the numbers and distributions of different cell types in male and female NHPs from newborn to elderly. At present, over 10,000 coronal sections, spanning rostral to caudal and organized in series by type of label and brain, are zoomable and publicly available. The Collections in the MBRC constitute the largest public and virtually accessible collection of NHP brain tissue in the world and a modern new tool for Neuroscience Research with transparent access to the raw data and super-efficient sharing of resources that contributes to lowering the need to sacrifice animals. Supported by NIH MH113257.

AVOIDING BIAS IN ESTIMATING PARTICLE SIZE AND DENSITY FROM 2D IMAGES WITH APPLICATION TO CELLS AND SYNAPTIC VESICLES

POSTER SESSION 07 - SECTION: DATA SHARING IN NEUROSCIENCE

Jason Rothman[1], Carolina Borges-Merjane[2], Peter Jonas[2], R. Angus Silver[1]
[1]University College London, Department Of Neuroscience, Physiology And Pharmacology, London, United Kingdom, [2]Institute of Science and Technology Austria, Cellular Neuroscience, Klosterneuburg, Austria

Estimating the 3D size and density of a distribution of particles from their 2D projection is a classic inverse problem of stereology. Here, we investigated the analytical solution for estimating particle size by Keiding et al. (1972) that accounts for missing profiles, i.e. 'lost caps', via a fixed cap-angle limit (ϕ). Using Monte Carlo simulations, we tested the Keiding model over a range of section thickness (T) and ϕ and found the model accurately estimated the 3D diameter distribution (F(d)) from the measured 2D diameter distribution (G(d)). However, the estimates were less accurate when true ϕ > 50° since G(d) ≈ F(d) under this condition and ϕ was indeterminable. To further validate the Keiding model, we estimated F(d) and ϕ from G(d) for synaptic vesicles in an electron-tomography z-stack and found excellent agreement with direct 3D measurements. To estimate the 3D particle density from the measured 2D density, we developed a correction formula that accounts for lost caps via ϕ. Analysis of this ϕ-correction method showed it was more accurate than using the minimum observed diameter or the widely used disector method; however, it required an accurate estimate of ϕ (i.e. a true ϕ < 50°). Finally, we applied these methods to estimating the size and density of cerebellar granule-cell somata and nuclei and mossy-fiber-terminal vesicles in rats and mice. Results showed planar sections (where T << particle size) were best for estimating both particle size and density.

[1]Heidelberg University, Institute Of Pharmacology, Heidelberg, Germany, [2]Heidelberg University, Institute For Anatomy And Cell Biology, Heidelberg, Germany, [3]University of Dundee, The Centre For Gene Regulation And Expression (gre), Dundee, United Kingdom

The rapid development of many multimodal microscopy techniques and image analysis tools for image visualization, preprocessing and quantification reinforces the need for a common research data management strategy for microscopy image metadata standardization. A large number of heterogeneous imaging file formats, high-quality analysis workflows, and software tools are being developed and utilized. The challenge lies in streamlining the way we organize, analyze, archive, and share the data and metadata of biological images. There is a strong emphasis on the significance of extensive metadata (experimental, acquisition, and analytical metadata) in ensuring image data quality, reproducibility, and scientific outcome. We aim to provide a strategy for the integration of bioimage data and metadata with electronic lab notebooks and repositories in the context of FAIR data principles. We are developing solutions to document and link the experimental metadata in an electronic lab notebook (eLabFTW) alongside microscope specifications, image acquisition settings, and analysis workflows in a standardized manner. This work will not only focus on optimizing the use of available solutions but will also encourage the development of a tool for interoperable exchange of data between services such as cloud storage, HPC clusters, and bioimaging software applications (ImageJ/Fiji, Galaxy, etc). This work will also highlight our aligned efforts with major international and national bioimaging community consortiums such as NFDI4BIOIMAGE. We acknowledge that a completely automated solution may not be fully achieved, nevertheless, implementation of such a strategy will enable seamless data integration and would support the bioimaging community in optimizing the entire scientific data flow.

Davison[1], Benjamin Weyers[4], Jan Gründling[4], Mathew Abrams[5], Tom Gillespie[6], Visakh Muraleedharan[5], Heidi Kleven[7], Ida Aasebø[2], Trygve Leergaard[7], Katrin Amunts[3], Jan Bjaalie[7], Timo Dickscheid[3,8], Oliver Schmid[9], Lyuba Zehl[3]
[1]Institut des Neurosciences Paris-Saclay, CNRS, Integrative & Computational Neuroscience, Saclay, France, [2]University of Oslo, Institute Of Basic Medical Sciences, Oslo, Norway, [3]Jülich Research Centre, Institute For Neuroscience And Medicine, Julich, Germany, [4]University of Trier, Human-computer Interaction, Trier, Germany, [5]Karolinska Institutet, Incf, Solna, Sweden, [6]INCF, Department Of Neurosciences, University Of California,, Los Angeles, United States of America, [7]Neural Systems Laboratory, Institute Of Basic Medical Sciences, University Of Oslo, Oslo, Norway, [8]Institute of Computer Science, Heinrich Heine University, Düsseldorf, Germany, [9]EBRAINS AISBL, Ebrains Aisbl, Watermael-Boitsfort, Belgium

Providing a framework for standardized metadata descriptions is particularly challenging in neuroscience due to the heterogeneity of data. The multimodal nature of neuroscientific data and the fact that they have a wide range in spatial and temporal scales is making the definition of an adequate set of metadata practically challenging and difficult. Hence, suitable metadata schemas for neuroscientific data should be flexible as well as restrictive enough to accommodate the inter-individuality of the data while keeping them overall comparable.
To achieve this goal, we launched the **open M**etadata **I**nitiative for **N**euroscience **D**ata **S**tructures (**openMINDS**). Powered by the Human Brain Project and EBRAINS, openMINDS develops and maintains interlinked metadata models composed of schemas that are tailored to describe neuroscience research products in graph databases, such as the EBRAINS Knowledge Graph.
openMINDS can handle a wide variety of research products (experimental/simulated data, computational models, software tools, metadata/data models, and brain atlases) as well as different granularity levels of provenance description (basic, advanced, in-depth). In addition, for better data integration, openMINDS maintains libraries of controlled metadata instances for general terms, licenses and content types that include links to external resources where applicable (e.g., InterLex Project, Knowledge Space, IANA.org). Here we present the infrastructure behind openMINDS and explain how we meet the challenge of creating a community-driven, flexible, but standardized metadata framework for sharing neuroscience data via graph databases.

Open access to data increases the exposure and impact of the research, and enables the reuse and reanalysis of shared data in new combinations. In neuroscience, the heterogeneous nature of the research data poses a substantial challenge to maximize the opportunities of data sharing. The EBRAINS Curation Services, developed by the Human Brain Project, meet these and other challenges of open data by providing the necessary data stewardship and workflows for sharing multimodal neuroscientific data. We have developed novel standards and tools to make data discoverable and comparable across modalities. Additionally, all these efforts aim to follow the FAIR guiding principles (*Wilkinson et al., Scientific Data 3:160018, 2016*) to make data Findable, Accessible, Interoperable and Reusable. These workflows and the underlying infrastructure is continually modified according to improvements in infrastructure and researcher needs. Here we present our most updated strategies to integrate heterogeneous neuroscientific data to the EBRAINS data sharing platform. We demonstrate how researchers can share experimental or computational data of all modalities, including models and software, and highlight the benefits of sharing data via EBRAINS for the individual researcher. This project has received funding from EU Horizon 2020, Specific Grant Agreement No. 945539 (Human Brain Project SGA3).

THE COLLECTION OF HUMAN BRAIN DEVELOPMENT IN THE RESEARCH INSTITUTE OF HUMAN MORPHOLOGY, MOSCOW

POSTER SESSION 07 - SECTION: DATA SHARING IN NEUROSCIENCE

Alexandra Proshchina, Anastasia Kharlamova, Dmitry Otlyga, Yuliya Krivova, Ekaterina Tsvetkova, Olga Junemann, Gleb Sonin, Sergey Saveliev
Petrovsky National Research Centre of Surgery, Research Institute Of Human Morphology, Moscow, Russian Federation

Laboratory of Nervous System Development of Research Institute of Human Morphology, Moscow possesses the unique Collection of prenatal human development, which was founded more than 40 years ago. Up-to-date, it consists of more than 200 human embryos and fetuses which staged from the second developmental week (2 pcw) until birth. The Collection is presented as wet material, also as histological, immunohistochemical and electron microscopic preparations, including serial sections of the developing human brain. This Collection could complement the world-famous Carnegie collection with wider samples and fetal cases. On our Laboratory of Nervous System Development website, a section exclusively devoted to the prenatal human brain development is presented https://brainmicroscopy.com/en/collection/homo/brain-development/. In 2021, our online project "The collection of human brain development of the Research Institute of Human Morphology, Moscow." has been selected for a grant of the FENS History Committee. We plan to expand the online content, gradually increasing the section image data with new samples from the Collection, creating articles, that complement images, detailed schemes and diagrams, which illustrate the prenatal developmental course and patterns of the human brain. In the frames of FENS History of Neuroscience online project, we would like to make the Collection more visible worldwide. Now, on the basis of our collection, we have launched human prenatal brain development Atlas that aims to create spatio-temporal reference maps of whole fetal brain on the various early ontogeny stages. This new project is supported by the Russian Science Foundation (RSF) grant 22-15-00172.

COMPARING THE ANATOMY OF THE ANTENNAL LOBE ACROSS BUMBLEBEE SPECIES

POSTER SESSION 07 - SECTION: DATA SHARING IN NEUROSCIENCE

Iman Muktar, Alexandra Baker, Olena Riabinina
Durham University, Bioscience Department, Durham, United Kingdom

Bumblebees play an important role as pollinators in natural and agricultural ecosystem. Bumblebees detect scents using olfactory sensory neurons located in the antennae; the olfactory signals are processed in the antennal lobe . *Bombus terrestris* are the most extensively studied and the only commercially available bumblebee species in the UK and in Europe. Other bumblebee species have so far received little attention in terms of the neuroethology and sensory neuroscience. The aim of this project was to study species-specific features of the olfactory anatomy of bumblebees. The project will provide important information for neuroethological studies of bumblebees, with possible insights into their olfactory preferences and the evolution of their olfactory systems. We focused on several species, local to Durham, UK. Worker and drone specimen collected in Durham in summer 2021 and DNA-barcoded via PCR amplification of CO1 and 16S rRNA mitochondrial genes to ascertain their species. Next, the brains of workers and drones were dissected, immunostained and imaged on a confocal microscopy. Finally, we created 3D model of the bee brains using the Amira software and measured the volume of the antennal lobe glomeruli in worker bees of *Bombus lapidarius*, *B.hypnorum* and *B.pascuorum*. From the data we have obtained we have not identified any particularly large glomeruli in workers in the studied species of bumblebees as there was no significant variabilities in glomeruli volume. Importantly the three-dimensional reconstruction, we have established will serve a tool to identify the respective target glomeruli with further physiological characterisation to reveal possible structure-function relationship.

[1]Paris Brain Institute (ICM), Movement Investigation And Therapeutics Team, Paris, France, [2]Sorbonne University, Brain Connectivity And Behaviour Laboratory, Paris, France, [3]Paris Brain Institute (ICM), Centre De Neuroimagerie De Recherche – Cenir, Paris, France, [4]Institut des Maladies Neurodégénératives-UMR 5293, Groupe D'imagerie Neurofonctionnelle, Bordeaux, France

Although very well adapted to brain study, Magnetic Resonance Imaging (MRI) remains limited by the facilities and capabilities required to acquire data, especially for non-human primates. Addressing the data gaps that result from these limitations requires making data more accessible and open access. Despite the regular use of the Squirrel monkey (Saïmiri sciureus) in neurosciences research, no in vivo diffusion dataset is yet openly available for this species. Here we propose a new anesthetized high-resolution diffusion dataset for Saïmiris sciureus to be shared on the PRIMatE Data Exchange (PRIME-DE) database.
We used an ultra-high-field (11.7 Tesla) MRI scanner to acquire multishell diffusion-weighted imaging data on six living squirrel monkeys. Subjects are all females aged from eight to ten years. Diffusion images were acquired with b-values of 2000, 1000 and 300s/mm² with 64, 29 and 7 directions, respectively.
We propose an overview of squirrel monkey brain connectivity based on this preliminary dataset. We investigated long-range connections using tractography analysis. We focused on brain microstructure with Neurite Orientation Dispersion and Density Imaging analysis (NODDI). Finally, we used the ActiveAx analysis technique to estimate axons diameter in the corpus callosum.
This dataset will help conduct and replicate studies on brain connectivity, microstructure or evolution through cross-species cross modalities comparisons.

INFLUENCE OF NEUROMODULATORY SYSTEMS IN THE HINDLIMB REPRESENTATION IN THE DEVELOPING SOMATOSENSORY CORTEX OF THE RAT

POSTER SESSION 07 - SECTION: DATA SHARING IN NEUROSCIENCE

Cristina Colangelo[1], Alberto Munoz[2], Alberto Antonietti[1], Armando Romani[1], Javier Defelipe[3], Henry Markram[1], Srikanth Ramaswamy[1]
[1]EPFL, Bbp, Geneva, Switzerland, [2]Complutense University of Madrid, Departamento De Biología Celular, Madrid, Spain, [3]Centro de Tecnología Biomédica, Universidad Politécnica de Madrid, Laboratorio Cajal Del Circuitos Corticales, Madrid, Spain

The vast majority of cortical synapses are found in the neuropil which is implicated in multiple and diverse functions underlying brain computation. Unraveling the organizing principles of the cortical neuropil requires an intricate characterization of synaptic connections established by excitatory and inhibitory axon terminals, of intrinsic and extrinsic origin and from ascending projections that govern the function of cortical microcircuits through the release of neuromodulators either through point-to-point chemical synapses or diffuse volume transmission. The hindlimb representation of the somatosensory cortex (HLS1) of two-week old Wistar rats has served as a model system to dissect the microcircuitry of neurons and their synaptic connections. In the present study, we quantified the fiber length per cortical volume and the density of varicosities for catecholaminergic, serotonergic and cholinergic neuromodulatory systems in the cortical neuropil using immunocytochemical staining and stereological techniques. Acquired data were integrated into a computational modeling framework to reconcile the specific modalities and predict the effects of neuromodulatory release in shaping neocortical network activity. We predict that ACh and DA and 5-HT desynchronize cortical activity by inhibiting slow oscillations (delta range), and that 5-HT triggers faster oscillations (theta). Moreover, we found that high levels (>30%) of neuromodulatory volumetric transmission (VT) are sufficient to induce network desynchronization, but also that combining volume release with synaptic inputs leads to more robust and stable effects, and lower levels of VT are needed to achieve the same outcome (10%).

FLATTENING OF ENHANCED CORTICAL ATLASES OPENS UP NEW POSSIBILITIES FOR DATA-DRIVEN MODELING AND DATA VISUALIZATION

POSTER SESSION 07 - SECTION: DATA SHARING IN NEUROSCIENCE

Sirio Bolaños-Puchet, Michael Reimann
École polytechnique fédérale de Lausanne, Blue Brain Project, Geneva, Switzerland

Digital brain atlases define a hierarchy of brain regions and their locations in three-dimensional space. They provide a standard coordinate system in which diverse datasets can be integrated for visualization and analysis, and they enable building of data-driven computational models of brain regions. For atlases of the cerebral cortex, additional information is required to work effectively with its particular, layered architecture and curved geometry. Although some approaches have been employed in the literature, no usable method to produce such information has been made openly available. To fill this gap, we describe here methods to enhance a cortical atlas with three auxiliary, voxel-wise datasets: first, a field of cortical depth; second, a field of local orientations towards the cortical surface; and third, a *flat map* of the cortical volume: a two-dimensional representation with the property that each pixel maps to a sub-volume in which the layer structure is preserved, akin to a cortical column. We apply these methods to a digitized version of Paxinos & Watson's atlas for rat somatosensory cortex and to the isocortex region of the Allen Mouse CCFv3, and define metrics to assess the quality of our results. Among the many applications of the resulting flat maps to computational modeling, we show their usefulness for: decomposing the cortical volume into columns, positioning and orienting input fibers, defining a topographic mapping for white-matter connections between sub-regions, and visualizing connectivity tracing and simulated neuronal activity. We provide an open source implementation of our methods for the benefit of the community.

THE WIENER DECONVOLUTION TOOLS: A NOVEL SOFTWARE FOR DECONVOLVING LIGHT SHEET AND CONFOCAL MICROSCOPY DATA.

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Klaus Becker[1,2], Saiedeh Saghafi[2], Hans-Ulrich Dodt[1,2]
[1]Center for Brain Research, Section Bioelectronics, Vienna, Austria, [2]Technical University Vienna, Department Of Solid State Electronics, Vienna, Austria

We developed a novel deconvolution software that stunningly increases the visibility of minute details in light sheet microscopy and confocal microscopy recordings. Prior to deconvolution the software can optionally apply adaptive background subtraction by rolling ball filtering along the three principal axes . As demonstrated by the presented 3D-reconstructions this approach stunningly increases the level of detail in data sets depicting small structures (as e.g. dendrites or nerve fibers) located on a inhomogeneous, diffuse background. By automatic block-wise processing the *Wiener Deconvolution Tools* can process image stacks of virtually unlimited size even on small computers with only 8 or 16 GB RAM. Via consequent usage of parallelization as well as optional GPU-acceleration the software works with high speed: On a PC equipped with a state of the art NVIDIA graphic board a stack containing about 1 billion voxels can be deconvolved in less than 10 minutes. Our deconvolution algorithm uses flux-preserving regularization that does not modify the photogrammetry of the image data. To our knowledge, this regularization approach has not been used for deconvolving microscopy data before. Preservation of photogrammetry is especially helpful for performing quantitative comparisons of signal intensities between different images or regions. For non-commercial use a fully functional command line version of the *Wiener Deconvolution Tools* can be downloaded as free software. An additional graphical user interface (GUI) providing further features as batch processing, destriping of light sheet microscopy data by directional frequency filtering and basic 3D visualization is commercially available from the Technical University of Vienna.

SEARCHLIGHT ANALYSIS FOR INTRACRANIAL EEG RECORDINGS

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Cristian Donos[1], Bogdan Blidarescu[1], Constantin Pistol[1], Irina Oane[1], Ioana Mindruta[2], Andrei Barborica[1]
[1]University Of Bucharest, Physics Department, Magurele, Romania, [2]Emergency University Hospital Bucharest, Neurology Department, Bucharest, Romania

Aims: Searchlight analysis (SLA) is a multivariate pattern analysis (MVPA) method for identifying locally informative areas. Here we investigate SLA's performance in highlighting contrasts of cognitive task conditions using intracranial EEG (iEEG) data, and we benchmark the results against a permutation cluster test (PCT). **Methods:** Ten subjects implanted with depth electrodes performed a facial emotion discrimination task. We used iEEG recorded during the task, to contrast activations produced by happy and angry faces, using PCT and SLA. The iEEG data was cleaned of artifacts and epileptic spikes, resampled to 256Hz, baseline corrected, and filtered in the 55-145 Hz high gamma band. The searchlight radius was defined as a sphere of 25mm radius centered on each electrode. For each electrode, we trained MVPA models using all electrodes located within the searchlight radius, with 10-fold cross-validation, and we assessed significance above the random chance level. The Jaccard index was used to compare the result of PCT and SLA, at the group level. **Results:** The Jaccard coefficient was 0.24 and 0.35 for the left (LH) and the right (RH) hemisphere structures. SLA highlighted up smaller effects within the same number of trials and discriminates task conditions in more brain structures than PCT (SLA: 17 LH and 12 RH, $p<0.01$; PCT: 9 LH and 15 RH, $p<0.05$). **Conclusions:** SLA identified an extended brain network involved in emotion processing, supporting the hypothesis of different emotions being processed by distributed activation patterns, rather than locally, in a few specialized locations of the brain.

Understanding how neurons encode, transmit, and process information is fundamental for uncovering the working principles of neural systems. Information theory provides a principled framework to shed light on such questions. Its application to the analysis of neural data is especially advantageous, allowing to uncover non-linear interactions of any order in a model-free way. However, the quantification of information from neural data is affected by major practical difficulties. This is especially true for two-photon calcium imaging data, characterized by low signal-to-noise ratio and temporal resolution. Here, we present Neuroscience Information Toolbox (NIT), a toolbox for the accurate information theoretical analysis of neural data. NIT features statistical estimators of Mutual Information including both discrete and continuous estimators, the analysis of directed information transmission among neurons, and the calculation of information quantities based on Partial Information Decompositions (e.g., Intersection Information). A selection of sampling bias corrections is available, together with routines for dimensionality reduction and neural decoding. Through simulations of biophysically plausible fluorescence emission in pyramidal neurons, we investigated how to best apply NIT to recover neural spike rate information from calcium data over a wide range of experimental (e.g. indicator, signal-to-noise ratio), biophysical (e.g. firing rate), and computational (e.g. discrete vs continuous estimators) conditions. NIT enabled us to retrieve up to > 90% of the information in spike rates from fluorescent transients only. Our conclusions were backed up by validation against experimental data. Altogether, our work demonstrates that NIT can be successfully used to analyse two-photon calcium imaging recordings.

RELATIONSHIP BETWEEN TONIC DOPAMINE LEVEL AND APERIODIC COMPONENT FROM LOCAL FIELD POTENTIALS OF THE SUBTHALAMIC NUCLEUS IN HEMIPARKINSONIAN RATS

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Jinmo Kim, Seongtak Kang, Ji-Woong Choi
Daegu Gyeongbuk Institute of Science and Technology, Information And Communication Engineering, Daegu, Korea, Republic of

Electrophysiological biomarkers provide useful information to gain an etiological understanding of Parkinson's disease (PD). However, there are limited studies to simultaneously investigate electrophysiological biomarkers and dopamine tone with invasive recordings. We recorded dopamine levels in the striatum of hemiparkinsonian rats using fast-scan cyclic voltammetry (FSCV). We simultaneously recorded local field potentials (LFP) in the subthalamic nucleus (STN). During the recordings, we acutely modulated dopamine levels with an intraperitoneal injection of levodopa. In the post-analysis, LFP was separated into the parameterized periodic and aperiodic components from the fitting oscillations and one-over-f (FOOOF) algorithm, which has recently been developed by Voytek and colleagues. Recorded currents from the FSCV were processed to extract both phasic and postulated tonic dopamine information by using our novel mathematical method. We confirmed the feasibility of the method for correcting drift effects due to capacitive currents over time in saline. Using the novel method, we successfully eliminated drift effects in vivo recordings. We investigated the correlations between various properties of beta band oscillations (e.g., power, frequency, bandwidth, and non-sinusoidal shape), aperiodic parameters (i.e., aperiodic offset and exponent), and phasic/tonic dopamine level. Finally, we performed machine learning-based prediction of phasic/tonic dopamine levels to find the best feature reflecting pathological information. Two methods, support vector machine (SVM) and deep neural networks (DNN), were chosen in this study. We suggest that aperiodic parameters change according to the dopamine level, and the aperiodic component has synergistic effects with the oscillatory properties resulting in the effective prediction of the dopamine level.

ANALYSIS OF NEURONAL ACTIVITY IN 3D VOLUME OF TISSUE-CLEARED MOUSE BRAIN: CHALLENGES AND ADVANCES

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Margaryta Tevosian[1,2], Stefan Pastore[3], Stanislav Sys[3], Irina Kovlyagina[1], Monika Chongtham[4], Susanne Gerber[3], Beat Lutz[1,2]
[1]University Medical Center of the Johannes Gutenberg University, Institute Of Physiological Chemistry, Mainz, Germany, [2]Leibniz-Institut für Resilienzforschung (LIR) gGmbH, Research Group Prof. Beat Lutz, Mainz, Germany, [3]Institute of Human Genetics, Computational Systems Genomics Group, Mainz, Germany, [4]Leibniz-Institut für Resilienzforschung (LIR) gGmbH, Research Group Prof. Susann Schweiger, Mainz, Germany

Aims: Reporter mouse lines are used to study responses of defined neuronal populations in the brain, by using activity-dependent regulator elements as drivers for Cre-induced recombination and cell tagging, allowing to trace labelled cells. We used reporter mice to map neuronal activity in response to aversive stimuli. **Methods:** Labelled neurons are spread throughout the brain. A common practice for their detection is immunohistology on sections, possibly resulting in bias. To overcome these limitations, tissue clearing (TC) techniques have emerged. The main principle of TC is the matching of the refractive index (RI) of the sample to the RI of the imaging media. The tissue is subjected to fixation, delipidation, depigmentation, and dehydration steps, followed by RI-matching, which renders it transparent. The need for fast imaging of large samples led to the development of light-sheet microscopes, enabling the investigation of labelled cells in an intact volume of an organ in an unbiased and high throughput manner. **Results:** Using commercial software packages, we established a pipeline of data pre-processing and stitching, focussing on overcoming the artefacts resulting from sample preparation and imaging. Further computationally intensive steps are required to align labelled cells to the common coordinate system of a reference atlas and perform group comparison. **Conclusions:** Although TC has become more widespread, the data analysis remains a challenge. Commercial software lacks necessary functionality to perform brain-wide signal annotation and alignment, whereas open-source software is not easy to use. In this study, we combined and optimized existing tools to achieve this goal.

USER FRIENDLY ANALYSIS TOOLBOX FOR THREE-DIMENSIONAL LIGHT-SHEET MICROSCOPY DATA IN HEMISPHERIC AND WHOLE MOUSE BRAIN SAMPLES

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Stefan Pastore[1], Margaryta Tevosian[2,3], Stanislav Sys[1], Nils Molnar[1], Irina Kovlyagina[2], Monika Chongtham[4], Beat Lutz[2,3], Susanne Gerber[1]
[1]Institute of Human Genetics, Computational Systems Genomics Group, Mainz, Germany, [2]University Medical Center of the Johannes Gutenberg University Mainz, Institute Of Physiological Chemistry, Mainz, Germany, [3]Leibniz-Institut für Resilienzforschung (LIR) gGmbH, Research Group Prof. Beat Lutz, Mainz, Germany, [4]Leibniz-Institut für Resilienzforschung (LIR) gGmbH, Research Group Prof. Susann Schweiger, Mainz, Germany

Aims: Currently, only a few analysis tools for mapping neuronal activity in three-dimensional light-sheet microscopy data are available. These tools mainly enable the annotation of fluorescent cell signals to a reference brain atlas but lack sufficient statistical analysis. Furthermore, the available tools are somewhat complicated to use for researchers without a computational background. Here we introduce a user-friendly graphical user interface (GUI) driven toolbox, that enables researchers to investigate hemispheric and whole brain tissue on a different level. The toolbox also includes various automated statistical analysis options for comparative studies of brain region activity. **Methods:** The toolbox integrates ClearMap2 (Kirst et al., 2020) and CellFinder (Tyson et al., 2021) in a PyQt5 based graphical user interface. The deployment as a docker container allows an easy and fast installation. Cell annotation results are visualized with napari. Furthermore, the toolbox enables comparative differential gene abundance analysis between conditions on custom selectable phylogenetic levels based on the Allan Brain Atlas ontology. It performs abundancy analysis on a relational and a density-based level. **Results:** We established a toolbox to comparatively analyse hemispheric and whole brain light-sheet microscopy data. The toolbox is designed to allow also inexperienced users a fast and reliable analysis. **Conclusion:** Analysis of whole brain tissue has high potential for investigating neuronal brain activity but requires novel computational approaches to be utilized. Our toolbox includes first attempts to automatize whole brain tissue analysis. New approaches and ideas will expand the range of possibilities and tools for mapping whole brain neuronal activity.

AUTOMATED QUANTIFICATION AND 3D COLOCALIZATION ANALYSIS OF FLUORESCENT NUCLEAR MARKERS WITH AN IMAGEJ MACRO: EXAMPLE OF A REPRODUCIBLE, TRACEABLE AND ACCESSIBLE WORKFLOW FOR BIOLOGISTS

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Melodie Ambroset[1,2], Jean-Luc Morel[1,2], Bruno Bontempi[1,2]
[1]CNRS, Institut De Neurosciences Cognitives Et Intégratives D'aquitaine, Umr5287, Bordeaux, France, [2]Université de Bordeaux, Institut De Neurosciences Cognitives Et Intégratives D'aquitaine, Umr5287, Bordeaux, France

Aims: While extremely common in life sciences, analysis of microscopy images is often insufficiently described in research articles, rendering workflows impossible to replicate and potential image mishandlings difficult to appreciate. We sought to develop an efficient and reproducible method to quantify and study the colocalization of two fluorescent nuclear markers revealed by immunohistochemistry on rat brain slices. Methods: Using a spinning disk confocal microscope, we acquired more than 150 multichannel z-stack tiled images spanning the anterior cingulate or parietal cortices and tracked the fluorescent expression of the proliferation marker 5-ethynyl-2'-deoxyuridine (EdU) and the endothelial cell-specific marker ERG in these two regions of interest (ROIs). Image analysis was achieved in Fiji using a semi-automated macro approach. After testing a subset of images to select appropriate filtering and thresholding parameters, ROIs were drawn and images were batch-processed automatically (filtering, segmentation, quantification and 3D colocalization). Finally, macro-generated binary segmentation and colocalization masks enabled to locate and review each colocalization event and to perform and document corrections if needed, such as ROI adjustment or exclusion of out of focus stack extremities. Results: With this approach requiring no extensive programming knowledge, we achieved appropriate processing of the majority of our images, saving precious time and limiting biases, while recording all quantitative results, parameters used and post-processing corrections performed. Conclusions: In the context of rising awareness regarding the need for reproducibility in microscopy image analysis, we provide an example of a reproducible and reliable workflow that may be applied to similar tasks.

A PYTHON HANDS-ON TUTORIAL ON NETWORK AND TOPOLOGICAL NEUROSCIENCE

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Eduarda Centeno[1], Giulia Moreni[2], Chris Vriend[3], Linda Douw[2], Fernando Antônio Santos[2]
[1]Université de Bordeaux, Institut Des Maladies Neurodégénératives De Bordeaux, Bordeaux, France, [2]Amsterdam UMC, Anatomy And Neurosciences, Amsterdam, Netherlands, [3]Amsterdam UMC, Psychiatry, Amsterdam, Netherlands

Network neuroscience aims to uncover brain functioning through the prism of connectivity. Graph theory (GT) and topological data analysis (TDA) are two frameworks that can be used to study brain connectivity. However, the mathematical abstractions of each of these frameworks can be daunting to inexperienced researchers. In this project, our goal was to provide an easy-to-grasp theoretical and computational tutorial to explore neuroimaging data using GT and TDA, therefore facilitating the accessibility, data visualization, and comprehension for newcomers to the field. Our tutorial focuses on resting-state functional magnetic resonance imaging (rsfMRI) data; however, the main concepts and tools discussed in this paper can be extrapolated to other imaging modalities. We used different Open Science-related tools, including GitHub, Jupyter Notebooks, Python, Binder, Zenodo, and an open-access dataset (rsfMRI dataset – 1000 functional connectomes project). Our work resulted in a manuscript covering the theoretical overview of the two frameworks and a set of Jupyter Notebooks that explain how to compute the different GT and TDA metrics in Python. In addition, we developed a high-order 3-D brain network visualization tool (example in Figure 1), a novelty to the field. All the material can be found at https://github.com/multinetlab-amsterdam/network_TDA_tutorial. We hope to have facilitated the comprehension of some aspects of the computation and visualization of network and topological neuroscience.

EBRAINS LIVE PAPERS - INTERACTIVE RESOURCES AND SUPPLEMENTARY MATERIALS FOR NEUROSCIENCE

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Shailesh Appukuttan[1], Luca L. Bologna[2], Felix Schürmann[3], Michele Migliore[2], Andrew P. Davison[1]
[1]Institut des Neurosciences Paris-Saclay, CNRS, Integrative & Computational Neuroscience, Saclay, France, [2]National Research Council, Institute Of Biophysics, Palermo, Italy, [3]École polytechnique fédérale de Lausanne, Blue Brain Project, Geneva, Switzerland

Introduction:
Computational neurosciences lacks an established system for distributing code, data and other related resources. This significantly diminishes the utility of scientific outputs and hinders reproducibility. The EBRAINS Live Papers is an online platform that holds promise to help address these shortcomings. **Methods:**
All data is stored in the EBRAINS Knowledge Graph. Being a graph-based database, it interlinks all data units thereby offering a high degree of data provenance. The integrated Live Paper Builder tool allows for creation of rich, interactive web pages without requiring any web development skills. It allows for easy linking to resources in community databases, thereby acting as an integrator of scientific resources spanning diverse data types. Live papers can also be password-protected to enable restricted access while under review. Additionally, the EBRAINS platform issues DOIs for published Live Papers. **Results:**
EBRAINS Live Papers are interactive web pages bringing together code, models, and data. They complement published scientific articles by providing access to the underlying models, data or analyses. Interactivity is a prominent feature with several integrated tools and services that allow users to download, visualize or simulate. There are already over 20 published live papers with interactive supplementary material associated with corresponding journal publications. **Conclusions:**
Live Papers are intended at making neuroscience publications more valuable to the scientific community by offering a holistic view of the various digital components of a publication. It promises to incentivise researchers to publish and share such resources, while ensuring that they are duly acknowledged when these resources are utilized.

MACHINE LEARNING-BASED DENDRITIC SPINE SEGMENTATION AND QUANTIFICATION_

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Lina Saveikytė[1], Kristina Jevdokimenko[1], Simona Skiotytė[2], Ilja Karanin[3], Urte Neniskyte[1,4]
[1]Vilnius University, Department Of Neurobiology And Biophysics, Vilnius, Lithuania, [2]Karolinska Institutet, -, Solna, Sweden, [3]Carl Zeiss Microscopy GmbH, Product Center Light Microscopy, Jena, Germany, [4]Vilnius University, Vu-embl Partnership Institute, Life Sciences Center, Vilnius, Lithuania

Aims: Dendritic spine plasticity includes the changes of spine number and morphology and has central role in brain development, physiology and pathology. Thus, the quantification and classification of spines in microscopy images is used to gain insights into neuronal function. Unfortunately, current tools for automated spine segmentation and evaluation still underperform manual analysis, while manual measurements of individual spines are time consuming and subjective. Therefore, we aimed to develop new automated tool for precise dendritic spine segmentation and quantification.
Methods: *Thy1::*EGFP mice brain sections were imaged with confocal laser scanning microscope. Images were pre-processed with FIJI software and used as a data set for training and segmentation in *Zeiss* APEER platform. Model was trained for semantic segmentation using deep learning U-net architecture. FIJI software was used for quantification of segmented spines and for the evaluation of the model.
Results: We used image pre-processing plugins to facilitate the same class object recognition in images acquired under different sample preparation or imaging conditions. We developed and evaluated APEER model for dendritic spine segmentation and showed that our tool can be applied to measure dendritic spine density in pyramidal neurons from mouse hippocampus.
Conclusions: Our method proposed fast and simple tool to detect and segment dendritic spines in two-dimensional maximum-intensity projections from confocal fluorescent images. For successful spine detection, our model required very small data set and showed high spine detection performance comparing to other described methods. This tool can facilitate future studies of brain development, plasticity and disease.

BOARD NUMBER: S07-404

SIGNAL-BASED ADAPTIVE THRESHOLDING FOR NEURONAL ACTION POTENTIAL SPIKE DETECTION

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Jarno Tanskanen, Jari Hyttinen
Tampere University, Faculty Of Medicine And Health Technology, Tampere, Finland

Neuronal action potential spike detection is usually required to analyze electrophysiological measurements and is often accomplished by thresholding at an amplitude level set a priori. However, action potential spikes higher in amplitude than the background noise are sparse in time compared to signal sampling rate; thus, spikes and noise are often separable in amplitude histograms. Here, we present the new full-featured Matlab implementation [1] of our signal amplitude histogram analysis-based method to find threshold amplitudes objectively. To find positive and negative thresholds, first, a spike count histogram is formed by thresholding at, e.g., 500 amplitudes equispaced between the minimum and maximum of the signal. The gradient of the histogram is calculated, smoothed, and analyzed for shoulder-like features, which for many signal types appear near the noise envelope amplitudes. In addition to the basic automatic thresholding functionality, the algorithm now includes detection and alleviation of baseline wander and 50/60 Hz line noise, and automatic continuously or segment-wise adaptive thresholding for cases where the standard deviation of the signal varies in time. If no automatic thresholding can be obtained from the signal at hand, the algorithm falls back to thresholding at a preset level. The method is demonstrated with simulations and neuronal in vitro and in vivo microelectrode array measurements. Our method produces objective spike detection thresholds agreeable by an electrophysiology expert. Acknowledgement: The project has received funding from the European Union’s Horizon 2020 research and innovation programme, grant agreement No. 824164. COMPARISON OF MOTION CORRECTION STRATEGIES FOR TASK-FMRI STUDIES IN MULTIPLE SCLEROSIS

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Júlia Soares[1], Rodolfo Abreu[1], Ana Lima[2], Lívia Sousa[2,3], Sónia Batista[2,3], Miguel Castelo-Branco[1,3], João Valente Duarte[1,3]
[1]University of Coimbra, Cibit - Coimbra Institute For Biomedical Imaging And Translational Research, Coimbra, Portugal, [2]Centro Hospitalar e Universitário de Coimbra, Neurology Department, Coimbra, Portugal, [3]University of Coimbra, Faculty Of Medicine, Coimbra, Portugal

Functional magnetic resonance imaging (fMRI) signal is highly corrupted by head motion, particularly in clinical populations prone to characterize by higher motion such as Multiple Sclerosis (MS). Despite several approaches have been proposed to compensate, there are still controversies regarding the best strategy. In this study our aim is to perform a systematic comparison of the most used motion correction strategies within a task-based design in MS. We included 11 early MS patients and 8 healthy controls (HC) and characterized motion in both groups during performance of a visual task. We then compared task-activation Z-scores obtained with: models without motion correction, models containing 6 or 24 motion parameters (MPs) as nuisance regressors, models containing 6 or 24 MPs and motion outliers detected with Framewise Displacement (FD) or Derivative or root mean square VARiance over voxelS (DVARS) as nuisance regressors (scrubbing), and models with 6 or 24 MPs with volume interpolation for motion outliers. In general, models with 6MPs present higher Z-scores than models with 24MPs. Models with 6MPs and outliers' volume interpolation or scrubbing with FD presented higher Z-scores in the MS group, while models with 6MPs and scrubbing with DVARS or volume interpolation were the best combinations for the HC group. Differences between groups draw attention to the intrinsic impact of MS on fMRI analyses, which should be carefully addressed. Finding an optimal motion correction strategy is required to improve the accuracy of fMRI analyses, crucially in clinical studies in MS and other patient populations.

Optimizing EEG Source Reconstruction with Concurrent fMRI-Derived Spatial Priors.
Reconstructing EEG sources involves a complex pipeline, with the inverse problem being the most challenging. Multiple inversion algorithms are being continuously developed, aiming to tackle the non-uniqueness of this problem, which has been shown to be partially circumvented by including prior information in the inverse models. Despite a few efforts, there are still current and persistent controversies regarding the inversion algorithm of choice and the optimal set of spatial priors to be included in the inversion models. The use of simultaneous EEG-fMRI data is one approach to tackle this problem. The spatial resolution of fMRI makes fMRI derived spatial priors very convenient for EEG reconstruction, however, only task activation maps and resting-state networks (RSNs) have been explored so far, overlooking the recent, but already accepted, notion that brain networks exhibit dynamic functional connectivity fluctuations. The lack of a systematic comparison between different source reconstruction algorithms, considering potentially more brain-informative priors such as fMRI, motivates the search for better reconstruction models. Using simultaneous EEG-fMRI data, here we compared four different inversion algorithms (minimum norm, MN; low resolution electromagnetic tomography, LORETA; empirical Bayes beamformer, EBB; and multiple sparse priors, MSP) under a Bayesian framework (as implemented in SPM), each with three different sets of priors consisting of: (1) those specific to the algorithm; (2) those specific to the algorithm plus fMRI task activation maps and RSNs; and (3) those specific to the algorithm plus fMRI task activation maps and RSNs and network modules of task-related dFC states estimated from the dFC fluctuations. The quality of the reconstructed EEG sources was quantified in terms of model-based metrics, namely the expectation of the posterior probability P(model|data) and variance explained of the inversion models, and the overlap/proportion of brain regions known to be involved in the visual perception tasks that the participants were submitted to, and RSN templates, with/within EEG source components. Model-based metrics suggested that model parsimony is preferred, with the combination MSP and priors specific to this algorithm exhibiting the best performance. However, optimal overlap/proportion values were found using EBB and priors specific to this algorithm and fMRI task activation maps and RSNs or MSP and considering all the priors (algorithm priors, fMRI task activation maps and RSNs and dFC state modules), respectively, indicating that fMRI spatial priors, including dFC state modules, might contain useful information to recover EEG source components reflecting neuronal activity of interest. Our main results show that providing

fMRI spatial derived priors that reflect the dynamics of the brain might be useful to map neuronal activity more accurately from EEG-fMRI. Furthermore, this work paves the way towards a more informative selection of the optimal EEG source reconstruction approach, which may be critical in future studies.

ELUCIDATING THE ROLES OF OPTIC ATROPHY 1 IN THE REGULATION OF MITOCHONDRIAL CRISTAE STRUCTURE BY DEEP LEARNING-BASED ULTRASTRUCTURAL ANALYSIS

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Shogo Suga[1], Koki Nakamura[1], Bruno Humbel[2], Hiroki Kawai[1], Yusuke Hirabayashi[1]
[1]The University of Tokyo, School of Engineering, Chemistry And Biotechnology, Bunkyo-ku, Tokyo, Japan, [2]Okinawa Institute of Science and Technology, The Imaging Section, Onna-son, Kunigami-gun, Okinawa, Japan

Optic Atrophy 1(OPA1) is originally identified as a protein related to Autosomal Dominant Optic Atrophy (ADOA). Although it has been revealed that OPA1 regulates the inner mitochondrial membrane structure, the precise roles of OPA1 are still elusive. With the recent development of genetic modification technology, the analysis of phenotypes caused by genetic mutations in cells has become high-throughput. Also, the contribution of those mutations to the determination of organelle structure at the nanometer level has also been revealed using electron microscopy (EM). However, because EM image analysis is labor-intensive and time-consuming, quantitative and three-dimensional analysis have been often insufficient. Therefore, in this study, I aimed to construct a high-throughput workflow using deep learning to analyze organelle structures from thousands of continuous tomographic images. For this purpose, I developed a platform called "Python-based platform for human-in-the-loop workflow (PHILOW)" that implements three-axis prediction (TAP) and human-in-the-loop (HITL) training data generation. Equipped with these techniques, we have succeeded in reconstructing serial sectioned EM images obtained by focused-ion-beam scanning EM (FIB-SEM). Based on the reconstruction from the control and OPA1 knock-down mouse fibroblasts, we analyzed the structure of mitochondrial outer and inner membranes in three-dimension, quantitatively (Figure). We also applied these techniques for reconstructing the neuronal intracellular structure.

INVESTIGATING ELECTRICALLY EVOKED RESPONSES OF PATTERNED NEURAL NETWORKS ON HD-MEAS

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Benedikt Maurer, Jens Duru, Stephan Ihle, Joël Küchler, Robert John, János Vörös
ETH Zürich, Laboratory Of Biosensors And Bioelectronics, Institute For Biomedical Engineering, Zürich, Switzerland

How the brain processes information to learn and form memories is still an unanswered question. To gain insights, neurons are studied under great effort *in vivo*. However, the applied methods often only enable monitoring subsets of neurons embedded in a complex network or lack the spatiotemporal resolution for analysis on a single-cell level. To overcome such limitations, we are following the approach of bottom-up neuroscience, in which small engineered neural networks are studied *in vitro*. To reduce the complexity of the network architecture, rat primary cortical neurons are seeded into polydimethylsiloxane (PDMS) microstructures to spatially confine the location of their soma and guide neurite growth[1]. Using these microstructures on high-density multi-electrode arrays (HD-MEAs) enables communicating with the network by stimulation and recording with high spatiotemporal resolution[2]. Repetitive stimulation of these networks yields stable and reproducible responses over several hours, which improves reproducibility in network studies[3]. We analyse and track response traces evoked by stimulating every network electrode individually depending on stimulation site. Further experiments include sensitivity assays with varying stimulus parameters and the combination of different stimulation sites. Combining microstructures with HD-MEAs enables comparison of network responses with respect to stimulus location. With these tools we aim to describe the complex input-output relationship of small neural networks which could validate fundamental neuroscience postulates and aid the design of more realistic *in silico* models. AUTOMATIC POST-PROCESSING AND MERGING OF MULTIPLE SPIKE-SORTING ANALYSES WITH LUSSAC

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Victor Llobet, Aurélien Wyngaard, Boris Barbour
Ecole Normale Supérieure, Ibens, PARIS, France

The increasing site counts of multielectrodes used in extracellular recording preclude traditional manual spike sorting and have led to the development of several new software suites with increased automation. It remains difficult, however, to find parameters enabling optimal processing of signals from all neuronal types. Here, we describe a procedure for automatic post-processing and merging the outputs of multiple spike-sorting analyses, enabling the accumulation of results optimised for different activity features. This approach was motivated by and first applied to the analysis of cerebellar activity, in which the complex spikes challenge standard analyses. The core of our modular procedure involves the identification of cluster-fusion candidates and assurance that only fusions that increase a clearly defined cluster-quality metric are performed; important subsidiary steps that have also been automated include spike alignment and duplicate removal. The procedure was validated by recovery of injected spike waveforms. In tests combining analyses from Kilosort and MountainSort, our procedure yielded a 50 % increase in the detected number of Purkinje cell clusters with both simple and complex spikes. A further validation used the synthetic ‘SpikeForest’ dataset approximating neocortical activity, in which our package also improved performance. Combining multiple analyses therefore offers a general method for improving spike-sorting.

MULTIPLANE MICROSCOPIC ATLAS OF RAT BRAIN ZINCERGIC TERMINAL FIELDS AND METAL-CONTAINING GLIA STAINED WITH TIMM'S SULPHIDE SILVER METHOD

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Camilla Blixhavn, Finn-Mogens Haug, Heidi Kleven, Maja Puchades, Jan Bjaalie, Trygve Leergaard
Neural Systems Laboratory, Institute Of Basic Medical Sciences, University Of Oslo, Oslo, Norway

The ability of Timm's sulphide silver method to stain zincergic terminal fields has made it a useful neuromorphological marker. Beyond its roles in zinc-signaling and neuromodulation, zinc is involved in the pathophysiology of ischemic stroke, traumatic brain injury, epilepsy, degenerative diseases and neuropsychiatric conditions. To provide a reference for planning and interpretation of experimental investigations of zinc-related phenomena in rat brains, we established a comprehensive repository of serial microscopic images from a historical collection of coronally, horizontally and sagittally oriented rat brain sections stained with Timm's method. Section images were acquired with a Zeiss Axioscan slide scanner and registered to the Waxholm Space rat brain atlas (RRID: SCR_017124) using the QuickNII (RRID:SCR_016854) and VisuAlign (RRID:SCR_017978) tools provided by the EBRAINS research infrastructure (https://ebrains.eu/services/atlases). The customized atlas overlays accompanied by adjacent Nissl-stained sections provides spatial reference and guidance in identifying anatomical boundaries. The image repository includes microscopic images from five adult albino (Wistar) rats. The collection of high resolution images will be shared via the EBRAINS Data and Knowledge services (https://ebrains.eu/services/data-and-knowledge), with web-microscopy viewer links for each subject, allowing interactive inspection of the spatial distribution and density of zincergic terminal fields across the entire brain in three planes of view.
This project/research has received funding from the European Union's Horizon 2020 Framework Programme for Research and Innovation under the Specific Grant Agreement No. 945539 (Human Brain Project SGA3).

MOUSE REACH: AUTOMATED BEHAVIORAL READOUTS IN MOTOR RECOVERY AFTER STROKE

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Matej Skrobot, Christoph Harms, Nikolaus Wenger
Charité – Universitätsmedizin Berlin, Experimental Neurology, Berlin, Germany

Despite best medical care, motor recovery after stroke is often incomplete. Basic research in young adult mice has shown that substantial degrees of spontaneous recovery after cortical stroke rely on the rewiring of spinal circuits, that attract new synaptic innervation from multiple supraspinal brain areas. Post-stroke motor decline as well as the subsequent improvement in paw reaching ability visibly illustrate a steady substitution of the damaged corticobulbospinal connections. The corresponding changes in mouse paw kinematics are an important parameter providing spatiotemporal information on fine motor control and paw grip recovery that offers an additional translational perspective pertaining to hand functionality of stroke-affected patients. At the present time, most animal motor assessments are still based on scoring schemes and exclude much information on paw kinematics, making them difficult to compare with clinical evidence. Here, we have developed a state-of-the-art deep learning-based pipeline that processes reaching video data and enables the user to carry out a detailed evaluation of graphical behavioral readouts obtained with the Staircase test. Our analysis framework results in significantly faster computing times compared to a human rater and allows for a more extensive extraction of movement data including features that have until now been unattainable through classical approaches.

CITE-ON: CELL IDENTIFICATION AND TRACE EXTRACTION ONLINE IN FUNCTIONAL TWO-PHOTON CALCIUM IMAGING

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Luca Sità[1], Marco Brondi[1], Pedro Lagomarsino[1,2], Sebastiano Curreli[1], Mariangela Paniello[1], Dania Vecchia[1], Tommaso Fellin[1]
[1]Istituto Italiano di Tecnologia, Optical Approaches To Brain Function, Genova, Italy, [2]Università di Genova, Neuroscienze, Genova, Italy

Two-photon (2P) microscopy in combination with genetically encoded calcium indicators (GECIs) is a powerful tool for the functional investigation of the intact brain. However, processing 2P recordings is computationally intensive, making it challenging to perform online frame-by-frame analysis. For example, identifying and locating imaged neurons in a field-of-view (FOV) is a crucial but time consuming step, and its outcome strictly depends on the experimental conditions (e.g., GECI of choice and image signal-to-noise ratio). Here, we develop CITE-On (Cell Identification and Trace Extraction Online), a deep learning-based algorithm for fast automatic cell identification, dynamic segmentation, identity tracking, and trace extraction in mouse 2P calcium imaging data. CITE-On identifies thousands of cells, and extracts their functional traces in real-time, including during large-FOV mesoscopic 2P imaging. CITE-On is based on a publicly available object detector trained on neuronal morphological features extracted from a dedicated imaging dataset obtained in different mouse brain regions under varied experimental conditions. Applied offline to publicly available datasets, CITE-On achieves a performance similar to state-of-the-art methods, it maintains a low computational cost, and generalizes well across GECIs, brain regions, and acquisition parameters in both anesthetized and awake head-fixed mice. The online pipeline takes advantage of GPU accelerated computing and efficient memory management, and provides real-time identity tracking and functional trace extraction for most neurons in a FOV with high accuracy. CITE-On is a potent tool to speed up 2P calcium imaging analysis and, therefore, it facilitates closed-loop approaches, for example in all-optical experiments combining neuronal imaging and manipulation.

PREDICTION OF IMPEDANCE BEHAVIOR OF NEURAL INTERFACE USING DEEP LEARNING

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Ebrahim Ismaiel, Anita Zatonyi, Zoltan Fekete
Pázmány Péter Catholic University, Research Group For Implantable Microsystems, Faculty Of Information Technology & Bionics, Budapest, Hungary

Background and aims: To ensure the long-term reliability of the neural implants or any bionics system with electrodes, it is important to examine the major modes of failure during long-term implantation by conducting pre-in-vitro experiments. Electrochemical impedance spectroscopy (EIS) describes electrode behavior, stability and long-term durability to a specific range of frequency. Impedance measurements during In Vivo and clinical applications are used also to examine a feedback-based electrode rehydration for long-term bio-potential measurements. This research aims to provide a novel approach to predict impedance changes using deep learning. **Methods**: A novel approach of impedance prediction is presented to convert EIS features during many days of an experiment into a one-dimensional sequence of values using a novel formula called Day Factor that makes us able to predict the behaviour of neural implant using long short-term memory (LSTM) network. Four neural interfaces of various material compositions with long-term in vitro ageing tests are used to validate the proposed approach. **Results and conclusions**: Day Factor formula with primitive trails show a satisfying conversion tool of multi-dimensional values of impedance in a one-dimension signal. Day factor signal was able to detect the big difference between normal impedance behaviour and sudden high impedance increasing during ageing tests. Using LSTM network and day factor signal as forecasting method to predict the impedance behaviour is a viable approach that helps to prepare for potential device failure in bionics systems.

CELL ASSEMBLY DETECTION THROUGH THE ITERATIVE SEARCH FOR RECURRENT SYNCHRONY

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Gabriel Makdah[1,2], Ralitsa Todorova[1], Michaël Zugaro[1], Sidney Wiener[1], Marco Pompili[1]
[1]Collège de France, CNRS, INSERM, Université PSL, Centre Interdisciplinaire De Recherche En Biologie (cirb), Paris, France, [2]GHU Paris Psychiatrie & Neurosciences, Hopital Sainte Anne, Paris, France

Higher brain functions involve the cooperation and interaction of large numbers of neurons. Cell assemblies, groups of neurons active synchronously in time, are thought to mediate these interactions. Technological advances permit the simultaneous recording of large neuronal populations, upholding the need for tools that detect cell assemblies within such datasets. Existing algorithms use proxy measures to estimate global cellular co-activations and cell membership within patterns. This leads to the detection of patterns of cell assembly amalgams that do not reflect the underlying neuronal dynamics. Here we present a novel computational framework for the direct detection of cell assemblies through a rigorous search for neuronal co-activations. Activation patterns are progressively constructed by adding new cells that fire together above chance levels as determined through two complementary measures that ensure the internal coherence of a detected pattern and its independence from population dynamics. Here we test the performance of our computational framework in a wide range of simulated datasets while comparing its performance to the seven other most used algorithms within the scientific literature. Low level computational optimizations enable our algorithm to run up to one hundred times faster than another comparable algorithm. We show its results and applications in experimentally recorded datasets in the rat hippocampus and prefrontal cortex, such as the detection of cell assembly formation and the organization of neuronal activity within assemblies into sequences after a behavioral task.

HERBS: A TOOLKIT FOR HISTOLOGICAL E-DATA REGISTRATION IN RAT BRAIN SPACES

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Pearl Saldanha, Jingyi Fuglstad, Jacopo Paglia, Jonathan Whitlock
Kavli Institute for Systems Neuroscience, Faculty Of Health And Medicine, Trondheim, Norway

Recent recording technologies allow users to sample thousands of neurons from multiple brain regions at a time, which has driven a great need for anatomical registration and visualization tools. Most existing toolkits, however, were developed using mouse atlases, leaving few options for rat users. We therefore developed a graphical user interface specifically for rats, HERBS. Which allows users to reconstruct recording electrode trajectories (e.g. Neuropixels, tetrodes), insertion angles, and to estimate which electrodes sampled which brain regions. Regional delineations in HERBS are based on annotated 3D volumes from the Waxholm Space rat brain atlas. In addition, users can obtain cell counts and delineate expression of multiple virus injections across tissue sections. HERBS also fully supports free-transformation from tissue sections to atlas slices and can therefore be used for brain atlasing or generating coordinates for targeting brain regions prior to surgery. Furthermore, HERBS allows anatomists to reconstruct a 3D brain mesh with tissue from individual animals, and interactive 3D visualizations are provided after desired processes. Finally, HERBS can triangulate the distance of individual neurons from the recording electrode using waveforms from multiple recordings sites. HERBS is available openly on GitHub and is compatible with Windows, macOS and Linux operating systems. Figure: Face of HERBS

SYNTALOS - A SOFTWARE FOR SIMULTANEOUS ACQUISITION OF HETEROGENEOUS NEUROPHYSIOLOGICAL DATA AND FOR CLOSED-LOOP INTERVENTION PROTOCOLS

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Matthias Klumpp, Lee Embray, Andreas Draguhn, Martin Both
Heidelberg University, Institute Of Physiology And Pathophysiology, Heidelberg, Germany

Many experiments rely on the acquisition of heterogeneous data from a variety of different sources, making accurately aligned timestamps a key requirement. In addition, it is often necessary to manipulate experimental settings on the fly, especially *in vivo* where interventions depend on the animal's state or behavior. Finally, acquired data should be stored in a standardized format to simplify subsequent analysis. Software packages supporting these requirements should be readily available, easy to handle and versatile enough to allow setting up new data acquisition pipelines without much effort. To address these requirements, we developed a new, integrated software solution capable of simultaneous acquisition of data from an arbitrary amount of sources of different kinds, e.g. multi-channel electrophysiological recordings, conventional video images, high-speed camera data, serial interfaces or Miniscopes. The software, called Syntalos, ensures aligned timestamps for all inputs, and makes use of the parallel-processing capabilities of modern CPUs to effectively run many tasks simultaneously. New data sources can be integrated and adjusted with minimal programming skills. For more advanced applications, the modular software design facilitates extension with new modules written in either C/C++ or Python. All data generated from a given experiment is stored in a well-defined, comprehensive structure, making it easy to compare, pool or share data between experimentalists with different research questions. With these abilities, Syntalos enables reliable closed-loop experiments for many different (neuro)scientific questions. Tests with diverse research questions, experimental setups and laboratories show the good performance and easy-to-learn structure of the program.

SCICLOUD: A WEB-BASED TOOL TO REPRESENT AND MEASURE MEDICAL SCIENCE OUTPUT.

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Quentin Lo Giudice[1], Moein Sarhadi[1], Denis Jabaudon[2]
[1]University of Geneva, Centre medical universitaire, Department Of Basic Neurosciences, Geneva, Switzerland, [2]University of Geneva, Centre Medical universitaire, Department Of Basic Neurosciences, Geneva, Switzerland

The number of scientific publications is continuously expanding and provides a tremendous metadata source to identify and predict scientific trends. Most biomedical articles are referenced in Pubmed, a publicly available database that allows systematic retrieval of metadata such as type of publication, date of submission, author credentials, and scientific content (abstract).
To take advantage of these resources, we developed Scicloud, a webpage-based tool that analyzes and represents how researchers publish worldwide and sheds light on a neglected domain of science: the representation of science itself.We built Scicloud in four steps: (1) parsing and text-mining of the Pubmed public database, (2) inference and integration of geographic information for each entry and each author, (3) indexing and interrogation of the generated knowledge by a search engine strategy and (4) display through an interactive world map web page.We expect that the implementation of this tool will provide opportunities for scientists of all levels of training and for various stakeholders such as private and national funding agencies, editors, and the public at large.

MOTILA – AN OPEN-SOURCE TOOL FOR AUTOMATIZED AND STANDARDIZED MICROGLIA PROCESS MOTILITY ANALYSIS

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Fabrizio Musacchio, Sophie Crux, Felix Nebeling, Manuel Mittag, Falko Fuhrmann, Eleonora Ambrad, Andrea Baral, Julia Steffen, Stefanie Poll, Martin Fuhrmann
German Center for Neurodegenerative Diseases (DZNE), Neuroimmunology And Imaging, Bonn, Germany

Fluorescence microscopy in combination with implanting a chronic window enables the consecutive *in-vivo* monitoring of cellular activity in the brain over long time periods. To handle both, the standardized and reproduceable analysis of microglia process motility and the resulting large amount of data, we present the open-source pipeline *MotilA*. *MotilA* provides fully automatic processing of multiple time-lapse image stacks. After pre-processing the data including registration, denoising, histogram equalization, image projection and binarization, *MotilA* calculates the motility of microglia processes or other cells by assessing the pixel variation between the individual time points, i.e., by calculating and comparing stable, gained and lost pixels. *MotilA* is able to process both, single- and multi-channel image stacks, including optional spectral unmixing. Batch processing image stacks of an entire microscopy campaign, the *MotilA* post-hoc analysis presents the resulting cellular motility over time and groups. To benchmark the performance of *MotilA* we compare our results with the manually assessed motility of a set of hippocampal microglial cells in the mouse brain. We demonstrate that *MotilA* reproduces the human detected motility in significant shorter time, ruling out any human bias and increasing the reliability of the results due to the standardization of the analysis.

CDEEP3M - DEEP LEARNING FOR IMAGE SEGMENTATION

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Matthias Haberl[1], Daniela Boassa[2], Mark Ellisman[2]
[1]Charite, Neuroscience Research Center, Berlin, Germany, [2]University of California, San Diego, School Of Medicine, San Diego, United States of America

Analysis of large-scale images is a major bottleneck in new discoveries, from the ever-increasing throughput of modern microscopy techniques. Deep neural networks outperform humans in speed and precision in image analysis tasks. We developed *CDeep3M*, an end-to-end analysis pipeline to identify cellular organelles (Mitochondria, Nuclei, Membranes, Vesicles, ER) in very large 3D electron microscopy datasets. To democratize access of the community to deep learning for image segmentation we have implemented a set of free complementary tools around CDeep3M. To minimize the end-user effort to take advantage of our new developments and use the software: (1) a CDeep3M web interface: allowing to run segmentations, quickly generate training data, or re-train a model all for free online, backed by a decentralized GPU cluster (2) CDeep3M cloud applications (Google Colab and AWS) (3) CDeep3M containerized installations (Docker and Singularity), to facilitate usage on local, remote and supercomputer infrastructure (4) The CDeep3M modelzoo, which is an organized and searchable database with many pre-trained deep neural networks for image segmentation, in which each trained model is indexed with unique DOIs. We co-host the modelzoo of trained deep neural networks with a database of microscopy images. This strategy will in the future help to enhance the utility of both, allowing the community to more easily re-analyze microscopy data and evaluate pre-trained models on different datasets.

AUTOMATIC CELL COUNTING WITH DEEP LEARNING

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Julien Clauzel[1], Nina Colitti[1], Carla Cirillo[1], Wafae Labriji[1], Lorenne Robert[1], Franck Desmoulin[1,2], Isabelle Loubinoux[1]
[1]INSERM, Tonic, Toulouse, France, [2]INSERM, Crefre, Toulouse, France

Aims When analyzing histology results, counting cells can quickly become a daunting task, with thousand cells in a single slice. Hence, we decided to automate the process of counting human cells in rat brain slices. They are visually characterized by mitochondrias on the edge of the cell-nucleus, and we were not able to count them with classical methods. The deep learning methods we found relied on segmentation, which requires a long annotation process. We thus designed our own neural network. **Methods** We mixed two well-known architectures: UNet and ResNet. The annotation was a single dot in the middle of each cell. Each dot was then transformed into a gaussian kernel of the size of the cells, and the resulting heatmap was used for training. We limited the amount of annotated data required with data augmentation. We then alternated training-annotation until the results were sufficiently good for our need. **Results** Above 80% of the cells were correctly detected. Mistakes mainly concern ambiguous cases, so it is actually hard to assess an objective rate of success. We found that evaluating the algorithm performances on a test dataset based on a single indicator was not practical and the real work was done looking directly at the data. **Conclusion** The deep learning architecture we used was fairly simple, and yet worked surprisingly well, given that the task is not straightforward for a human. We also found that the classical deep learning methodology, originating from the industry, did not seem to fit with our task.

A SIMPLE TO USE GRAPHICAL INTERFACE FOR THE ANALYSIS OF WHOLE BRAIN OPTICAL IMAGES WITH CLEARMAP2

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Charly Rousseau[1], Sophie Skriabine[1], Christoph Kirst[2], Nicolas Renier[3]
[1]Paris Brain Institute, Laboratory Of Structural Plasticity, Paris, France, [2]University of California, San Francisco, Kavli Institute For Fundamental Neuroscience And Anatomy Department, San Francisco, United States of America, [3]Institut du Cerveau et de la Moelle Epinière., Laboratory Of Structural Plasticity, Paris, France

Whole-brain optical-imaging techniques, using either serial tomography or tissue clearing combined with lightsheet microscopy, have paved the way for neuroanatomical studies of the entire central nervous system with single cell resolution. With the underpinning of a range of molecular techniques like clearing combined with immunolabellings, immediate early genes expression or viral tracing, these microscopy advancements have enabled a wide array of experiments. These range from the probing of neuronal activity, through to investigations of connectivity and analysis of the whole brain vasculature. Although several companies now supply the hardware required for these experiments, the analysis of the substantial dataset generated still often requires specialised pipelines designed for experts.
Here, we present a straightforward and documented graphical user interface to the established tools of the ClearMap2 pipeline that allows experimenters to easily process and analyse their own datasets. This open source software allows the users to reconstruct, analyse and visualise cell labellings or vascular graphs vetted with the help of artificial neural networks.

A PRACTICAL GUIDE TO USING THE EBRAINS KNOWLEDGE GRAPH IN (YOUR) RESEARCH

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Maaike Van Swieten[1], Oliver Schmid[2], Gilles Dénervaud[2], Ioannis Tsanaktsidis[2], Benjamin Weyers[3], Andrew Davison[4], Lyuba Zehl[5], Ida Aasebø[1], Jan Bjaalie[1]
[1]University of Oslo, Institute Of Basic Medical Sciences, Oslo, Norway, [2]EBRAINS AISBL, Glaverbel Building, Brussels, Belgium, [3]University of Trier, Human-computer Interaction, Trier, Germany, [4]Institut des Neurosciences Paris-Saclay, Department For Integrative And Computational Neuroscience (icn), Gif-sur-Yvette Cedex, France, [5]Jülich Research Centre, Institute For Neuroscience And Medicine, Julich, Germany

Scientific articles are mostly published as text files containing unstructured and semi-structured information. Consequently, important information is typically deeply hidden in documents which severely limits the possibilities to automatically process and reuse scholarly knowledge. One approach to make information explicit and directly usable is to transform this into a standardised format and store it in a knowledge graph. This allows scholarly knowledge to be represented in a structured, machine-actionable, interlinked and semantically rich manner. The EBRAINS Knowledge Graph was developed to facilitate the search and information exchange in research, so that research results across different domains become directly comparable and easier to retrieve and reuse. Here, we provide a practical guide to extracting information from the EBRAINS Knowledge graph using a user-friendly interface as well as a more advanced programmatic route via an Application Programming Interface (API). We also provide concrete examples on how the extracted information can be leveraged in order to develop new research objectives as well as validate ongoing research. The EBRAINS Knowledge Graph is integrated in the wider EBRAINS research infrastructure as a part of the EBRAINS Data and Knowledge services for sharing and finding research data and models. Data found through these services can be directly used and analysed via the various integrated tools and analysis workflows. The EBRAINS Knowledge Graph is a valuable machine-actionable and FAIR (**F**indable, **A**ccessible, **I**nteroperable and **R**eusable) resource for discovery-based and hypothesis-driven research as it already contains a wide variety of neuroscience data types, models and software.

BRAINSTEM: A COLLABORATIVE ELECTRONIC LAB NOTEBOOK FOR EXPERIMENTAL NEUROSCIENCE

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Peter C. Petersen[1], Rodrigo Amaducci[1], György Buzsáki[2], Alisa Surkis[1]
[1]New York University, Neuroscience Institute, New York, United States of America, [2]NYU Langone Health, Neuroscience Institute, New York, United States of America

Research data from published papers on large-scale single neuron research is rarely shared. This data often has considerable potential for reuse and reinterpretation in different studies and provides transparency and reproducibility to already-published studies. Further, data shared on public repositories is often difficult to discover, lacking standardized metadata, limiting its degree of reusability. To address these current shortcomings, this group is building BrainSTEM. BrainSTEM is a collaborative electronic lab notebook that is tailored to experimental neuroscience, with a focus on large-scale single-cell neurophysiology as captured using intracellular, extracellular, and two-photon recording techniques. It allows for the organization of experiments, in a format that is easily interpretable by other researchers and discoverable by machines. BrainSTEM has two entry points, a web interface that allows for fast data entry using user-friendly forms, and a REST API for programmable access. BrainSTEM's metadata model is built on a standardized yet flexible language, promoting detailed interpretable notes. Granular access control enables private collaboration within and across labs, and public sharing of projects and datasets is only a click away, lowering the data sharing entry barrier substantially. BrainSTEM has the potential to become the standard metadata model within neurophysiology, make data FAIR, promote standardization, data sharing, and provide better integration across datasets, both within and across collaborative labs and for published

datasets.

THE DEEPLABCUT MODEL ZOO: DEVELOPMENT OF PRETRAINED ANIMAL POSE ESTIMATION MODELS FOR NEUROSCIENCE

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Shaokai Ye, Maxime Vidal, Steffen Schneider, Tian Qiu, Jessy Lauer, Alexander Mathis, Mackenzie Mathis
Swiss Federal Institute of Technology (EPFL), Center For Neuroprosthetics, Geneve, Switzerland

In recent years, markless animal pose estimation has become an important tool for studying animal behavior. Deep learning typically excels by, in part, leveraging large datasets. Yet, large datasets for animal pose estimation do not exist yet. One reason for this lack of data is that most labs define keypoints differently to fit their research needs and because due to transfer learning, for specific contexts relatively little labeled data is required. As a consequence, there exist sets of disjoint data for the same type of animals, but being able to combine across labs could provide highly powerful networks. Yet, how to combine different keypoints across animals has not been shown. To tackle this, we propose a simple and effective way to merge datasets for model pre-training and corresponding protocols for fine-tuning. We show that our approach is effective for both state of the art bottom up and top down methods for pose estimation and we are able to obtain powerful pre-training models that have decent zero-shot performance. After fine-tuning, such models largely outperform models that use ImageNet pre-trained weights. This sets the stage of providing the community plug-and-play solutions for animal pose estimation for the first time. We also will showcase the DeepLabCut Model Zoo, which contains models for various model systems from mice, to dogs and primates.

AN OPEN-SOURCE R SCRIPT FOR MEA DATA ANALYSIS AND VISUALISATION

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Carine Dalle, Nelson Rebola, Lars Jorgensen, François-Xavier Lejeune
ICM - Institut du Cerveau | Paris Brain Institute, Sorbonne Université - Cnrs - Inserm, Paris, France

Aims Microelectrode array (MEA) system are increasingly used as technical approach too monitor activity of neuronal networks *in vitro.* Such a method allows to simultaneous record extracellular voltage signals from multiple electrodes. At the same time, commercial and open-source solutions have been developed to analyze and visualize MEA data. Here we present a new open-source R-based script for analyzing activity of neuronal networks recorded with MED64 (AlphaMed Scientific). **Methods** The script was programmed in RStudio and its performance was demonstrated using recordings from 2D and 3D cultures of iPSC-derived neurons with a 64 channels array. Spikes were recorded and extracted using Mobius software which produces data files in csv format. These files are loaded by the script to extract various features of neuronal activity. **Results**. The script developed in-house contains an automatic analysis of several raw source files based on an analytical guideline. This guideline allows to define the electrodes and the period to be analyzed. Firstly, our script allows the overlap display of spikes for each electrode, enabling the user to efficiently handle signal artefacts. Secondly, spike raster plot and heat maps with number of spike or frequency are generated for advanced data visualization. Finally, the script contains several burst analysis methods based on previous publications. **Conclusions** This new tool allows the unbiased and timely analyze of large datasets and complements the applications already available for MEA analysis. A community of MEA users has been created in order to detect limitations and continuously improve pipeline. We also wish to develop an interface for users not familiar with R.

XNEURO: UNIFIED NEURAL DATA INTERFACE FOR SCALABLE MODEL INFERENCE

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Baihan Lin
Columbia University, Zuckerman Mind Brain Behavior Institute, New York, United States of America

With increasing complexity and magnitude of neural data arising from recent high-throughput multi-channel neurophysiology and neuroimaging techniques, the standardization of data storage and processing is an important element to promote reproducibility and collaboration in neuroscience. Although projects like Neurodata-Without-Borders initiative has made a long way along the data standardization in neuroscience, there are still several outstanding challenges: (1) efficient storage and fast retrieval are at an increasingly irreconcilable tradeoff given the increasingly combinatorial numbers of meta information; (2) high-dimensionality of spatial and temporal resolutions from single cell and multi-channel techniques prevents a workable analytical pipeline in local machines and hard disks; (3) analytical pipelines are adopting resource-heavy models like deep learning which pose additional bandwidth and computational constraints. This is especially the case in cognitive neuroscience, where the recordings of neural responses often accompany high-dimensional stimulus inputs, hierarchical meta information and delicate cognitive model architectures for neurobiological inference. In this work, we propose a new data format that tackles all three challenges and provide an opensourced Python toolbox, called Xneuro, as a unified neural data interface to facilitate scalable data import, standardization, search and retrieval. We benchmark Xneuro across several high-throughput datasets, collected each in different modalities under various stimulus types and behavioral tasks, where traditional analytic pipelines find difficult to collate. We demonstrate the effectiveness and scalability of our framework by comparing these datasets to a series of cognitive models in a fast and scalable fashion, the first time neural model inference of this scale can be performed.

Regularity Normalization: Neuroscience-Inspired Unsupervised Attention across Neural Network Layers.
Inspired by the adaptation phenomenon of neuronal firing, we propose the regularity normalization (RN) as an unsupervised attention mechanism (UAM) which computes the statistical regularity in the implicit space of neural networks under the Minimum Description Length (MDL) principle. Treating the neural network optimization process as a partially observable model selection problem, the regularity normalization constrains the implicit space by a normalization factor, the universal code length. We compute this universal code incrementally across neural network layers and demonstrate the flexibility to include data priors such as top-down attention and other oracle information. Empirically, our approach outperforms existing normalization methods in tackling limited, imbalanced and non-stationary input distribution in image classification, classic control, procedurally-generated reinforcement learning, generative modeling, handwriting generation and question answering tasks with various neural network architectures. Lastly, the unsupervised attention mechanisms is a useful probing tool for neural networks by tracking the dependency and critical learning stages across layers and recurrent time steps of deep networks.

Influence of ocular dominance columns and patchy callosal connections on binocularity in lateral striate cortex: Long Evans versus albino rats.
In albino rats, it has been reported that lateral striate cortex (V1) is highly binocular, and that input from the ipsilateral eye to this region comes through the callosum. In contrast, in Long Evans rats, this region is nearly exclusively dominated by the contralateral eye even though it is richly innervated by the callosum (Laing, Turecek, Takahata, & Olavarria, 2015). We hypothesized that the inability of callosal connections to relay ipsilateral eye input to lateral V1 in Long Evans rats is a consequence of the existence of ocular dominance columns (ODCs), and of callosal patches in register with ipsilateral ODCs in the binocular region of V1 (Laing et al., 2015). We therefore predicted that in albino rats input from both eyes intermix in the binocular region, without segregating into ODCs, and that callosal connections are not patchy. Confirming our predictions, we found that inputs from both eyes, studied with the transneuronal tracer WGA-HRP, are intermixed in the binocular zone of

albinos, without segregating into ODCs. Similarly, we found that callosal connections in albino rats are not patchy but instead are distributed homogeneously throughout the callosal region in V1. We propose that these changes allow the transcallosal passage of ipsilateral eye input to lateral striate cortex, increasing its binocularity. Thus, the binocular region in V1 of albino rats includes lateral striate cortex, being therefore about 25% larger in area than the binocular region in Long Evans rats. Our findings provide insight on the role of callosal connections in generating binocular cells.

Self-Assembling 2D Arrays with de Novo Protein Building Blocks.
Modular self-assembly of biomolecules in two dimensions (2D) is straightforward with DNA but has been difficult to realize with proteins, due to the lack of modular specificity similar to Watson-Crick base pairing. Here we describe a general approach to design 2D arrays using de novo designed pseudosymmetric protein building blocks. A homodimeric helical bundle was reconnected into a monomeric building block, and the surface was redesigned in Rosetta to enable self-assembly into a 2D array in the C12 layer symmetry group. Two out of ten designed arrays assembled to micrometer scale under negative stain electron microscopy, and displayed the designed lattice geometry with assembly size up to 100 nm under atomic force microscopy. The design of 2D arrays with pseudosymmetric building blocks is an important step toward the design of programmable protein self-assembly via pseudosymmetric patterning of orthogonal binding interfaces.

An Integrative Analysis Reveals a Central Role of P53 Activation via MDM2 in Zika Virus Infection Induced Cell Death.
(ZIKV) infection is an emerging global threat that is suspected to be associated with fetal microcephaly. However, the molecular mechanisms underlying ZIKV disease pathogenesis in humans remain elusive. Here, we investigated the human protein interaction network associated with ZIKV infection using a systemic virology approach, and reconstructed the transcriptional regulatory network to analyze the mechanisms underlying ZIKV-elicited microcephaly pathogenesis. The bioinformatics findings in this study show that P53 is the hub of the genetic regulatory network for ZIKV-related and microcephaly-associated proteins. Importantly, these results imply that the ZIKV capsid protein interacts with mouse double-minute-2 homolog (MDM2), which is involved in the P53-mediated apoptosis pathway, activating the death of infected neural cells. We also found that synthetic mimics of the ZIKV capsid protein induced cell death and . This study provides important insight into the relationship between ZIKV infection and brain diseases.

Model-informed risk assessment for Zika virus outbreaks in the Asia-Pacific regions.
Recently, Zika virus (ZIKV) has been recognized as a significant threat to global public health. The disease was present in large parts of the Americas, the Caribbean, and also the western Pacific area with southern Asia during 2015 and 2016. However, little is known about the factors affecting the transmission of ZIKV. We used Gradient Boosted Regression Tree models to investigate the effects of various potential explanatory variables on the spread of ZIKV, and used current with historical information from a range of sources to assess the risks of future ZIKV outbreaks. Our results indicated that the probability of ZIKV outbreaks increases with vapor pressure, the occurrence of Dengue virus, and population density but decreases as health expenditure, GDP, and numbers of travelers. The predictive results revealed the potential risk countries of ZIKV infection in the Asia-Pacific regions between October 2016 and January 2017. We believe that the high-risk conditions would continue in South Asia and Australia over this period. By integrating information on eco-environmental, social-economical, and ZIKV-related niche factors, this study estimated the probability for locally acquired mosquito-borne ZIKV infections in the Asia-Pacific region and improves the ability to forecast, and possibly even prevent, future outbreaks of ZIKV.

Dynamic Forecasting of Zika Epidemics Using Google Trends.
We developed a dynamic forecasting model for Zika virus (ZIKV), based on real-time online search data from Google Trends (GTs). It was designed to provide Zika virus disease (ZVD) surveillance and detection for Health Departments, and predictive numbers of infection cases, which would allow them sufficient time to implement interventions. In this study, we found a strong correlation between Zika-related GTs and the cumulative numbers of reported cases (confirmed, suspected and total cases; $p<0.001$). Then, we used the correlation data from Zika-related online search in GTs and ZIKV epidemics between 12 February and 20 October 2016 to construct an autoregressive integrated moving average (ARIMA) model (0, 1, 3) for the dynamic estimation of ZIKV outbreaks. The forecasting results indicated that the predicted data by ARIMA model, which used the online search data as the external regressor to enhance the forecasting model and assist the historical epidemic data in improving the quality of the predictions, are quite similar to the actual data during ZIKV epidemic early November 2016.

Integer-valued autoregression provides a useful base predictive model for ZVD cases. This is enhanced by the incorporation of GTs data, confirming the prognostic utility of search query based surveillance. This accessible and flexible dynamic forecast model could be used in the monitoring of ZVD to provide advanced warning of future ZIKV outbreaks.

Systematic Genome-wide Screening and Prediction of microRNAs in EBOV During the 2014 Ebolavirus Outbreak.
Recently, several thousand people have been killed by the Ebolavirus disease (EVD) in West Africa, yet no current antiviral medications and treatments are available. Systematic investigation of ebolavirus whole genomes during the 2014 outbreak may shed light on the underlying mechanisms of EVD development. Here, using the genome-wide screening in ebolavirus genome sequences, we predicted four putative viral microRNA precursors (pre-miRNAs) and seven putative mature microRNAs (miRNAs). Combing bioinformatics analysis and prediction of the potential ebolavirus miRNA target genes, we suggest that two ebolavirus coding possible miRNAs may be silence and down-regulate the target genes NFKBIE and RIPK1, which are the central mediator of the pathways related with host cell defense mechanism. Additionally, the ebolavirus exploits the miRNAs to inhibit the NF-kB and TNF factors to evade the host defense mechanisms that limit replication by killing infected cells, or to conversely trigger apoptosis as a mechanism to increase virus spreading. This is the first study to use the genome-wide scanning to predict microRNAs in the 2014 outbreak EVD and then to apply systematic bioinformatics to analyze their target genes. We revealed a potential mechanism of miRNAs in ebolavirus infection and possible therapeutic targets for Ebola viral infection treatment.

DATA WORKFLOW FOR MULTI-ANIMAL VIDEO-LOCAL FIELD POTENTIAL ACQUISITION AND SEIZURE ANALYSIS USING OPEN EPHYS AND BONSAI.

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Gergely Tarcsay, Brittney Boublil, Laura Ewell
University of California – Irvine, Anatomy & Neurobiology, Irvine, United States of America

Chronic local field potential (LFP) and video monitoring is a common technique in neuroscience which often requires purchase of expensive hardware systems that are only suitable for low channel count, low sampling rate recordings. We aimed to develop a low-cost platform that could later be repurposed for other electrophysiological applications such as high-density single unit recording. The major challenges of chronic video-LFP acquisition are synchronization between distinct data streams and handling of large data files. Moreover, preprocessing and analyzing several days of video-LFP data is time consuming. Therefore, we developed a data workflow using the open-source Bonsai visual programming software to 1) acquire data from an Open Ephys acquisition board (LFP) and from a web-camera (video) 2) synchronize the video-LFP data 3) save data regularly to avoid potential data loss during chronic recordings and limit file sizes to facilitate later processing. Our workflow was successfully applied during 48-hour video-LFP recordings of epileptic mice (n=8 mice, two groups of four simultaneously recorded mice). In order to analyze seizure activity and to assign the behavioral state, a graphical user interface (GUI) was written in MATLAB. The GUI provides a user-friendly solution for 4) organization of the recorded video-LFP data 5) automatized seizure detection 6) convenient behavior analysis during seizure activity. In conclusion, our pipeline serves as a straightforward and easy way for chronic recordings and analysis of multi-site video-LFP data in epileptic mice. We present a low cost solution that utilizes a hardware platform that can be applied to other experimental needs.

Small Size of Recorded Neuronal Structures Confines the Accuracy in Direct Axonal Voltage Measurements.
Patch-clamp instruments including amplifier circuits and pipettes affect the recorded voltage signals. We hypothesized that realistic and complete representation of recording instruments together with detailed morphology and biophysics of small recorded structures will reveal signal distortions and provide a tool that predicts native, instrument-free electrical signals from distorted voltage recordings. Therefore, we built a model that was verified by small axonal recordings. The model accurately recreated actual action potential (AP) measurements with typical recording artefacts and predicted the native electrical behavior. The simulations verified that recording instruments substantially filter voltage recordings. Moreover, we revealed that instrumentation directly interferes with local signal generation depending on the size of the recorded structures, which complicates the interpretation of recordings from smaller structures, such as axons. However, our model offers a straightforward approach that predicts the native waveforms of fast voltage signals and the underlying conductances even from the smallest neuronal structures.

EBRAINS TOOLS FOR RODENT BRAIN ATLASING

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Maja Puchades, Sharon Yates, Nicolaas Groeneboom, Gergely Csúcs, Dmitri Darine, Harry Carey, Trygve Leergaard, Jan Bjaalie
Neural Systems Laboratory, Institute Of Basic Medical Sciences, University Of Oslo, Oslo, Norway

Research in small animals depends on comparisons of cellular and molecular measures in large groups, requiring efficient and reproducible methods for registration of data to brain atlases followed by quantitative analysis. While numerous methodologies and increasing amounts of data are available, they are difficult to combine into coherent and reproducible workflows suitable for large-scale analyses. The EBRAINS research infrastructure enables neuroscientists to conduct their mouse and rat brain data analyses in an open, robust and user-friendly environment. It provides tools and workflows for viewing images; automatic and user guided registration of brain sections image data to a volumetric atlas; feature extraction with machine learning; whole brain distribution analysis, and metadata management according to the FAIR principles. We present examples of typical use cases, illustrating how the available suite of tools can be used and the results obtained, with an emphasis on the reproducibility of the methods applied and the sharing of the data and metadata. The tools are part of the EBRAINS Atlases services (https://ebrains.eu/services/atlases) and offer comprehensive solutions for organizing, analyzing and sharing brain research data. These and other EBRAINS research infrastructure tools and workflows are developed in close interaction with users in the neuroscience community. EMPLOYING MASSIVE PARALLEL COMPUTING POWER TO UNCOVER THE MYSTERIES OF SINGLE-CHANNEL GATING

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Efthymios Oikonomou[1], Thomas Gruber[2], Achanta Ravi Chandra[1], Gerhard Wellein[2], Tobias Huth[1]
[1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Institut Für Physiologie Und Pathophysiologie, Erlangen, Germany, [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Erlangen National High Performance Computing Center, Erlangen, Germany

The importance of single-channel recordings is widely known among ion channel enthusiasts. The method allows observing the function of a single protein in real time. Therefore, the analysis of single-channel recordings is essential for estimating the gating kinetics of ion channels. A widely employed method to model single-channel gating is with Hidden Markov Models (HMM). Among different algorithms for single-channel current analysis, arguably, the Two-Dimensional-Dwell-Time Fit (2D-Fit) has proven the most powerful thus far. The algorithm compares Two-Dimensional-Dwell-Time histograms derived from a recorded time series with simulated ones. It iteratively optimizes the parameters of the kinetic model until one of the simulated time series is as close as possible to the recorded one. Estimating the HMM of an ion channel in this way comes with exceptional computational demands. Using the parallel computing power of a High Performance Computing (HPC) cluster the algorithm can converge in a reasonable amount of time. The increased computing power also enables the computation of an ensemble of solutions, which can be ranked according to the computed loss, revealing the best solutions. Thus, statistics can be obtained further optimizing the 2D-Fit algorithm while also estimating the limits of its capabilities. This makes it possible to statistically compare results and pave the way for a realizable topology estimation, which relies on an exhaustive search over relevant models. Making use of HPC, the power of 2D-Dwell-Time analysis can be used to its fullest, possibly gaining an edge over other methods employed so far.

DEEPSLICE RAT: A DEEP NEURAL NETWORK FOR AUTOMATIC REGISTRATION OF RAT BRAIN IMAGES TO THE WAXHOLM SPACE ATLAS OF THE RAT BRAIN

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Harry Carey[1], Gergely Csúcs[1], Simon Mcmullan[2], Maja Puchades[1], Jan Bjaalie[1]
[1]Neural Systems Laboratory, Institute Of Basic Medical Sciences, University Of Oslo, Oslo, Norway, [2]Macquarie University, Faculty Of Medicine, Health And Human Sciences, Sydney, Australia

The rat is widely used in experimental neuroscience and with the increasing availability of many genetic tools in rat, its popularity in neuroscientific research is likely to increase. In order to properly leverage the magnitude of rat data that the neuroscientific community generates, brain derived data must be mapped to a common spatial reference space. To this end, the Waxholm Space atlas of the rat brain (RRID:SCR_017124) has been created. While there exist tools to register rat brain data to the Waxholm Space, including the QuickNII (RRID:SCR_016854) and VisuAlign (RRID:SCR_017978) tools provided by the EBRAINS research infrastructure (https://ebrains.eu/services/atlases), these tools are relatively demanding of time and expertise, often requiring hours per whole brain. If we are to comprehensively map the massive amount of brain data currently being generated, we will require automated methods capable of registering data to a common reference space. Here we present DeepSlice Rat, a deep neural network for the automated registration of rat brain images to the Waxholm Space atlas of the rat brain. We show that DeepSlice Rat is equal in performance to an expert neuroanatomist whilst being thousands of times faster. DeepSlice Rat can be used in combination with QuickNII for verification of the registration, and VisuAlign for non-linear adjustments, creating an AI assisted workflow that will greatly enhance productivity. DeepSlice Rat will be freely available on EBRAINS (alongside a mouse implementation) as both a Python package and web-application.

Sign tracking predicts cue-induced but not drug-primed reinstatement to methamphetamine seeking in rats: Effects of oxytocin treatment.
The incentive sensitisation theory of addiction posits that drug-associated stimuli become imbued with incentive motivational properties, driving pathological drug seeking. However, pre-existing variability in the incentive salience to non-drug reward cues ('sign trackers' (STs); 'goal trackers' (GTs)) is also predictive of the desire for and relapse to cocaine and opioids. Here, we asked whether variation in propensity to attribute incentive salience to a food cue is predictive of reinstatement to the highly addictive psychostimulant methamphetamine (METH), and whether treatment with the promising anti-addiction therapy oxytocin differentially reduces METH behaviour between STs and GTs.

A NEW FREE SOFTWARE FOR 3D DENDRITIC SPINE DETECTION AND MORPHOLOGICAL ANALYSIS

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Nicolas Heck[1], Jean-François Gilles[2], Philippe Mailly[3], Thomas Boudier[4]
[1]Sorbonne Université, Neuroscience Paris Seine, Paris, France, [2]Institut de Biologie Paris Seine, Imaging Facility, PARIS, France, [3]Center for Interdisciplinary Research in Biology (CIRB), College de France, CNRS Unité Mixte de Recherche 724, INSERM Unité 1050, Orion Imaging Facility, Paris, France, [4]Sorbonne Université, Su, paris, France

Dendritic spines are indicative of the density of connections in the neural network, and their morphology corresponds to properties of synaptic integration. Dendrites and spines can be labeled with various techniques and imaged in 3D from confocal or two-photon image stacks. Several softwares are available for spine detection and morphological analysis, but their efficiency varies depending on labeling method and image type. We introduce a new freely available plugin for ImageJ/FIJI. The plugin operates in 3D to detect dendritic spines along a traced dendrite, segment the spine head and trace the spine neck. Spine density, spine head volumes and surfaces, neck length are computed. Importantly, the user can at each step and for each spine edit the result of the automated process. As compared to a fully automated procedure, that would not be applicable to many images, the possibility for the user to edit the result make our tool more versatile.

DOMEVR: A SETUP FOR EXPERIMENTAL CONTROL OF AN IMMERSIVE DOME VIRTUAL ENVIRONMENT FOR NON-HUMAN AND HUMAN BEHAVIOR CREATED WITH UNREAL ENGINE 4

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Katharine Shapcott[1], Marvin Weigand[1], Iuliia Glukhova[1], Martha Havenith[1], Marieke Schölvinck[2]
[1]Ernst Strüngmann Institut, Havenith & Schölvinck, Frankfurt am Main, Germany, [2]Ernst Strüngmann Institute, Havenith & Schölvinck Lab, Frankfurt, Germany

Creating immersive and realistic virtual reality (VR) environments for different species is a goal of many neuroscientific groups. Unfortunately, designing and implementing behavioural tasks in such environments is often complicated. To tackle this challenge we created DomeVR, an immersive virtual reality dome environment built using Unreal Engine 4 (UE4). UE4 is a powerful game engine with photo-realistic graphics containing a visual scripting language designed for use by non-programmers, meaning behavioural task design and level creation are simply performed using drag-and-drop elements. DomeVR introduces features to UE4 that are necessary for neuroscience experiments. This includes a logging and synchronization system to solve the timing uncertainties inherent in UE4, both key for the analysis of neuroscientific data; parameterizable stimuli, an interactive GUI for scientists to observe subjects during experiments and adjust task parameters on the fly, and a dome projection system for broad visual coverage (250 degree visual angle). These features are modular and can be easily added into other UE4 projects. Here we present the design of the DomeVR system together with proof-of-principle data from three different species; human, macaque and mouse.

Predictive coding of natural images by V1 firing rates and rhythmic synchronization.
Predictive coding is an important candidate theory of self-supervised learning in the brain. Its central idea is that sensory responses result from comparisons between bottom-up inputs and contextual predictions, a process in which rates and synchronization may play distinct roles. We recorded from awake macaque V1 and developed a technique to quantify stimulus predictability for natural images based on self-supervised, generative neural networks. We find that neuronal firing rates were mainly modulated by the contextual predictability of higher-order image features, which correlated strongly with human perceptual similarity judgments. By contrast, V1 gamma (γ)-synchronization increased monotonically with the contextual predictability of low-level image features and emerged exclusively for larger stimuli. Consequently, γ-synchronization was induced by natural images that are highly compressible and low-dimensional. Natural stimuli with low predictability induced prominent, late-onset beta (β)-synchronization, likely reflecting cortical feedback. Our findings reveal distinct roles of synchronization and firing rates in the predictive coding of natural images.
Neuron, 2022; 110

Stimulus-specific plasticity of macaque V1 spike rates and gamma.
When a visual stimulus is repeated, average neuronal responses typically decrease, yet they might maintain or even increase their impact through increased synchronization. Previous work has found that many repetitions of a grating lead to increasing gamma-band synchronization. Here, we show in awake macaque area V1 that both repetition-related reductions in firing rate and increases in gamma are specific to the repeated stimulus. These effects show some persistence on the timescale of minutes. Gamma increases are specific to the presented stimulus location. Further, repetition effects on gamma and on firing rates generalize to images of natural objects. These findings support the notion that gamma-band synchronization subserves the adaptive processing of repeated stimulus encounters.
Cell Rep, 2021; 37
32350517: Shapcott KA, Schmiedt JT, Kouroupaki K, Kienitz R, Lazar A, Singer W, Schmid MC
Reward-Related Suppression of Neural Activity in Macaque Visual Area V4.
In order for organisms to survive, they need to detect rewarding stimuli, for example, food or a mate, in a complex environment with many competing stimuli. These rewarding stimuli should be detected even if they are nonsalient or

irrelevant to the current goal. The value-driven theory of attentional selection proposes that this detection takes place through reward-associated stimuli automatically engaging attentional mechanisms. But how this is achieved in the brain is not very well understood. Here, we investigate the effect of differential reward on the multiunit activity in visual area V4 of monkeys performing a perceptual judgment task. Surprisingly, instead of finding reward-related increases in neural responses to the perceptual target, we observed a large suppression at the onset of the reward indicating cues. Therefore, while previous research showed that reward increases neural activity, here we report a decrease. More suppression was caused by cues associated with higher reward than with lower reward, although neither cue was informative about the perceptually correct choice. This finding of reward-associated neural suppression further highlights normalization as a general cortical mechanism and is consistent with predictions of the value-driven attention theory.

High-density electrophysiological recordings in macaque using a chronically implanted 128-channel passive silicon probe.
The analysis of interactions among local populations of neurons in the cerebral cortex (e.g. within cortical microcolumns) requires high resolution and high channel count recordings from chronically implanted laminar microelectrode arrays. The request for high-density recordings of a large number of recording sites can presently only be accomplished by probes realized using complementary metal-oxide-semiconductor (CMOS) technology. In preparation for their use in non-human primates, we aimed for neural probe validation in a head-fixed approach analyzing the long-term recording capability.

Theta Rhythmic Neuronal Activity and Reaction Times Arising from Cortical Receptive Field Interactions during Distributed Attention.
Growing evidence suggests that distributed spatial attention may invoke theta (3-9 Hz) rhythmic sampling processes. The neuronal basis of such attentional sampling is, however, not fully understood. Here we show using array recordings in visual cortical area V4 of two awake macaques that presenting separate visual stimuli to the excitatory center and suppressive surround of neuronal receptive fields (RFs) elicits rhythmic multi-unit activity (MUA) at 3-6 Hz. This neuronal rhythm did not depend on small fixational eye movements. In the context of a distributed spatial attention task, during which the monkeys detected a spatially and temporally uncertain target, reaction times (RTs) exhibited similar rhythmic fluctuations. RTs were fast or slow depending on the target occurrence during high or low MUA, resulting in rhythmic MUA-RT cross-correlations at theta frequencies. These findings show that theta rhythmic neuronal activity can arise from competitive RF interactions and that this rhythm may result in rhythmic RTs potentially subserving attentional sampling.

The Influence of Endogenous and Exogenous Spatial Attention on Decision Confidence.
Spatial attention allows us to make more accurate decisions about events in our environment. Decision confidence is thought to be intimately linked to the decision making process as confidence ratings are tightly coupled to decision accuracy. While both spatial attention and decision confidence have been subjected to extensive research, surprisingly little is known about the interaction between these two processes. Since attention increases performance it might be expected that confidence would also increase. However, two studies investigating the effects of endogenous attention on decision confidence found contradictory results. Here we investigated the effects of two distinct forms of spatial attention on decision confidence; endogenous attention and exogenous attention. We used an orientation-matching task, comparing the two attention conditions (endogenous and exogenous) to a control condition without directed attention. Participants performed better under both attention conditions than in the control condition. Higher confidence ratings than the control condition were found under endogenous attention but not under exogenous attention. This finding suggests that while attention can increase confidence ratings, it must be voluntarily deployed for this increase to take place. We discuss possible implications of this relative overconfidence found only during endogenous attention with respect to the theoretical background of decision confidence.

Correlated activity of cortical neurons survives extensive removal of feedforward sensory input.
A fundamental property of brain function is that the spiking activity of cortical neurons is variable and that some of this variability is correlated between neurons. Correlated activity not due to the stimulus arises from shared input but the neuronal circuit mechanisms that result in these noise correlations are not fully understood. Here we tested in the visual system if correlated variability in mid-level area V4 of visual cortex is altered following extensive lesions of primary visual cortex (V1). To this end we recorded longitudinally the neuronal correlations in area V4 of two behaving macaque monkeys before and after a V1 lesion while the monkeys fixated a grey screen. We found that the correlations of neuronal activity survived the

lesions in both monkeys. In one monkey, the correlation of multi-unit spiking signals was strongly increased in the first week post-lesion, while in the second monkey, correlated activity was slightly increased, but not greater than some week-by-week fluctuations observed. The typical drop-off of inter-neuronal correlations with cortical distance was preserved after the lesion. Therefore, as V4 noise correlations remain without feedforward input from V1, these results suggest instead that local and/or feedback input seem to be necessary for correlated activity.

Cell-Targeted Optogenetics and Electrical Microstimulation Reveal the Primate Koniocellular Projection to Supra-granular Visual Cortex.
Electrical microstimulation and more recently optogenetics are widely used to map large-scale brain circuits. However, the neuronal specificity achieved with both methods is not well understood. Here we compare cell-targeted optogenetics and electrical microstimulation in the macaque monkey brain to functionally map the koniocellular lateral geniculate nucleus (LGN) projection to primary visual cortex (V1). Selective activation of the LGN konio neurons with CamK-specific optogenetics caused selective electrical current inflow in the supra-granular layers of V1. Electrical microstimulation targeted at LGN konio layers revealed the same supra-granular V1 activation pattern as the one elicited by optogenetics. Taken together, these findings establish a selective koniocellular LGN influence on V1 supra-granular layers, and they indicate comparable capacities of both stimulation methods to isolate thalamo-cortical circuits in the primate brain.

SCALE SPACE METHODS FOR THE GEOMETRIC ANALYSIS OF NEURITE TRACES

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Minh Son Phan[1], Katherine Matho[2], Emmanuel Beaurepaire[3], Jean Livet[4], Anatole Chessel[5]
[1]Institut Pasteur, Image Analysis Hub, Paris, France, [2]Cold Spring Harbor Laboratory, -, Cold Spring Harbor, United States of America, [3]Ecole Polytechnique, Laboratory For Optics And Biosciences, Paris, France, [4]Sorbonne Université, Institut De La Vision, Paris, France, [5]Ecole Polytechnique - Institut Polytechnique de Paris, Laboratory Of Optics And Biosciences, Palaiseau, France

Large scale imaging and automated tracing are yielding many single cell neuronal reconstructions, and analysis methods able to probe the local geometry of the traces are needed to fully exploit them. Scale space methods are classical tools in signal processing, where a signal is computed at diverse scales, from that of the original signal down to a very smoothed out, coarse, one providing only the largest trend. They allow to study how features vary through scales, or spot the most important ones from noise. Here, we applied this approach/strategy on neurite traces, seen as 3D space curves, via gaussian smoothing of the coordinates. We extracted the curves' that way 'principal turns', i.e. their major changes in direction. We also defined a new algorithm, termed *nAdde*r, which computes a 'local 3D scale' measuring a curve's local geometric complexity, i.e. how much it is in 3D vs confined to a plane or a line.. We applied this algorithm on published neuron traces, including a whole zebrafish larva brain atlas, showing that it is a meaningful and significant metric enabling to analyze datasets in ways previously unavailable, shedding new light on the stereotypical nature of neurites' local geometry . These new methods, available in the open source python library GeNePy3D, provide innovative and easy to use ways to process the flood of geometric data produced by large-scale connectomics efforts.

A SEMI-AUTOMATIC PREPROCESSING TOOLBOX FOR BELT-RECORDED RESPIRATION SIGNAL

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Camille Straboni[1], Clara Dargent[1], Tahnée Engelen[2], Catherine Tallon-Baudry[2]
[1]Ecole normale supérieure, Department Of Cognitive Studies, Paris, France, [2]Laboratoire de Neurosciences Cognitives et Computationelles, Inserm, Ecole Normale Supérieure, Université Psl, Paris, France

Respiration is a semi-automatic process centrally generated by intricated microcircuits integrating behavior and physiological information. Perceptual, cognitive, emotional and motor processes have been shown both to modulate respiration and to be influenced by respiration. Respiration is thus becoming an important measure of interest in neuroscience. In humans, breathing at rest should not be considered as a simple periodical signal. Respiratory traces reveal a wide range of respiratory events. Sighs, amplitude or phase variability of breathing cycles and pauses are sporadically embedded in the breathing pattern. Here, we present a semi-automatic toolbox in order to preprocess breath traces recorded using easy to use and non-intrusive respiratory belts. The toolbox builds on previous work from different groups and non-oscillatory methods. It allows to identify inspiration and expiration onsets, to extract the respiration phase and identify respiratory events such as sighs or short breathing interruption. Furthermore, concurrent behavior of interest such as voluntary action, eye movements, cardiac or gastric events can be visualized within the respiration phase.

Aims: Behaviors are encoded by neural circuits that are widespread within the brain and change with age and experience. Immunodetection of the immediate early gene c-fos has been successfully used for decades to reveal neural circuits active during specific tasks or conditions. Our aims here is to develop a workflow that circumvents classical temporal and spatial limitations associated to c-fos quantifications. Method: We used a new genetic TRAP method combining Cre-dependent tdTomato expression under c-fos promoter with Fos immunohistochemistry, allowing visualization and direct comparison of neural circuits activated at different times or during different tasks. We established a workflow that optimize and automate cell detection, cell classification (e.g. Fos *vs*. Fos/tdTomato) and whole brain registration. Results: We demonstrate that this workflow allows accurate cell number quantification with minimal interindividual variability. Further, interrogation of brain atlases at different scales (from simplified to detailed) was achieved allowing gradually zooming on brain regions to explore spatial distribution of activated cells. Finally, we illustrate the potential of this approach by comparing patterns of neuronal activation in various contexts (e. g. different vigilance states, complex behavioral tasks …). Conclusion: Altogether, this automated workflow allows a fast and accurate analysis of whole brain activity pattern at the cellular level, in various contexts.

Markerless pose estimation has become a powerful tool in neuroscience for digitizing video data. DeepLabCut is a software package for animal pose estimation that achieves state of the art performance on challenging animal datasets. Here, we introduce two novel tools that directly build and integrate with DeepLabCut: DLC2Kinematics and DLC2Action, that respectively allow users to compute kinematic features and perform action segmentation on the outputs of DeepLabCut. Specifically, DLC2Kinematics leverages machine learning and classical motion analysis and makes them available with a simple user interface. DLC2Action allows for user-defined behavior recognition. DLC2Action shows state of the art performance on CalMS21 (an animal behavior challenge from CVPR 2021).

POST-ACTIVATION CONFORMATIONAL CHANGES IN PIGEON CRYPTOCHROME

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Fabian Schuhmann[1], Daniel Kattnig[2], Ilia Solov'Yov[1]
[1]Carl-von-Ossietzky University Oldenburg, Institute Of Physics, Oldenburg, Germany, [2]University of Exeter, Living Systems Institute And Department Of Physics, Exeter, United Kingdom

A wide-spread hypothesis ascribes the ability of migratory birds to navigate over large distances to an inclination compass realized by the protein cryptochrome in the birds' retinae. Cryptochromes are activated by blue light, which triggers a radical pair that could be sensitive to the Earth's magnetic field. This magnetic information might be communicated to downstream processes through conformational changes eventually reaching the bird's brain and therefore allowing magnetoreception. Starting from the ClCry4 crystal structure [1], we employ extensive all-atom MD simulations for three pairs of replicas for a total time of 6 µs utilizing the Scandinavian Online Kit For Nanoscale Modeling (VIKING) [2], in which we simulate the ground state and the activated state of the protein structure. Employing an evaluation of inter-residue distance changes, we found clear indications of conformational changes that arise upon protein activation. Specifically, we have identified two versatile regions whose motion can be directly attributed to the protein's activation. Our results show that cryptochrome's conformational dynamics involve the so-called phosphate-binding loop, which opens like a gate, creating a passage to the active site of the protein [3]. THE BRAINGLOBE INITIATIVE: AN OPEN SOURCE NEUROANATOMY PLATFORM FOR THE 21ST CENTURY

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Adam Tyson[1,2], Federico Claudi[2], Luigi Petrucco[3,4], Ruben Portugues[3], Tiago Branco[2], Troy Margrie[2]
[1]University College London, Gatsby Computational Neuroscience Unit, London, United Kingdom, [2]University College London, Sainsbury Wellcome Centre, London, United Kingdom, [3]Technical University of Munich, Institute Of Neuroscience, Munich, Germany, [4]Istituto Italiano di Tecnologia, Center For Neuroscience And Cognitive Systems, Rovereto, Italy

Neuroanatomy is key for understanding the brain, but software to analyse the data are often single purpose, for one model species and suffer from lack of support following publication. We have established the BrainGlobe Initiative (BGI) - an international, distributed team of users and developers working towards the goal of creating open-source, interoperable and easy to use tools for the analysis of all types of neuroanatomical data. To analyze data from many samples, it is critical to map individual datasets onto a standard anatomical reference atlas, but neuroscience relies on many animal model species. The BrainGlobe toolkit is therefore not built around a specific brain atlas but rather a generalised atlas framework (the BrainGlobe Atlas API) which is regularly updated with new brain atlases from multiple species. We have initially focussed on the analysis of whole-brain microscopy data (e.g. from tissue clearing or blockface methods). The BGI software suite includes brainreg, a 3D registration tool for mapping data to an atlas space. Novel tools have also been developed to map specific structures or objects within the brain, such as the volume and location of virus-labelled cells and the location of implanted devices such as recording electrodes. Lastly, brainrender can be used for the visualisation of any data registered to the reference atlas. This includes all data from BGI software, but importantly, data from other software packages and from large-scale efforts such as the Allen Brain Institute.

Ultrafast ultrasound is an emerging imaging modality derived from standard medical ultrasound. It allows for high spatiotemporal resolution with techniques such as ultrafast Doppler used for functional ultrasound (fUS). In neurosciences fUS imaging is limited by the difficulty to identify cerebral structures in Doppler images. Thus, localization algorithms were developed to align volumetric Doppler images. In practice those algorithms are very sensitive to the initial misalignment between volumes and often require manual pre-registration. Yet, this first step is operator dependent and challenging especially with pathological data. Here we propose a deep learning approach to the 3D Doppler image registration task, utilizing vascular landmark detection in volumetric Doppler images of mouse brains. 150 volumetric images were obtained by mouse brain angiographic scan, normalized and placed in a 12.8x12.8x6.4mm field of view with a 100µm isotropic resolution. First, we manually annotated these images with 9 landmarks corresponding to prominent vascular clues. Then, a 3D convolutional neural network was implemented and trained to identify those landmarks. Our network is consistent at identifying the landmarks granting a Dice score of 0.68±0.09 on test samples. It also produces a small localization error of 130±40µm. After automatic localization, landmark point clouds were used to perform rigid vascular 3D registration, for both intra and inter animal studies, with large initial misalignments and pathological vascular deformations induced by stroke events.

Aims Functional MRI studies about the central control of breathing play a crucial role in unravelling the physiopathology of several autonomic diseases. In this context, the main challenge is represented by the entanglement between non-specific BOLD effects, e.g., due to vasoreaction and physiological noise, and specific ones. We propose an analysis pipeline for the characterization of nonlinearities in the BOLD response to CO_2 challenges. This might provide insight on nonlinearity as discriminative criterion for specific effects. **Methods** Three runs of fMRI images are acquired on six subjects at increasing inhaled CO_2 concentrations (0, 3 and 7%). Group-ICA is implemented with the Matlab toolbox GIFT. We select components by considering their correlation with end-tidal $PETCO_2$ and their power spectral distribution. By using GICA3 algorithm, subject-level reconstructions preserve information on percentage signal change. Triplets of spatially similar components across CO_2 levels are defined. We fitted voxel-by-voxel a linear and a quadratic model on percent signal change. The R^2 indicated the degree of nonlinearity expressed by the BOLD response to CO_2 across the brain. **Results** We were able to highlight brain regions that presented highly-nonlinear BOLD signal increases with increasing CO_2 concentrations. Hotspots are present in regions involved in the central control of breathing, as the brainstem, as well as in the thalamus, hypothalamus and basal ganglia (Fig1). **Conclusions** Our new pipeline suggests that group-ICA in association with polynomial regression analysis might provide information of interest for the definition of the specificity of BOLD fluctuations in

CO_2 studies.

DEEPRSLICE: AUTOMATED RODENT BRAIN EXTRACTION USING DEEP LEARNING

POSTER SESSION 07 - SECTION: SOFTWARE TOOLS FOR BRAIN IMAGING

Amr Eed, Ravi Menon
University of Western Ontario, Medical Biophysics, London, Canada

Removing the skull from brain images is usually the first step in most of the magnetic resonance imaging (MRI) processing pipelines, as it affects all the subsequent steps including registration and tissue segmentation. While multiple tools can automatically perform this task in human data, the same cannot be said for rodent MRI images, where the process is often error-prone and requires manual intervention. In this line of work, we present a convolutional neural network capable of performing brain extraction across different modalities and species. Aims: leveraging the power of deep learning to create a global apt tool for rodent brain extraction, regardless of contrast, resolution, or species. Methods: a dataset consisting of 68 manually segmented mice images aging between 8-12 weeks were used for the training. The images were converted to 2D slices before feeding them to the network. The 2D images were augmented by scaling, rotation, shearing, and cropping. Various 2D U-Net architectures were examined and the best performing architecture was compared to popular tools from MRI packages such as FSL's BET and ANTS' antsBrainExtraction. Results: The best performing network achieved an intersection over union (iou) score of 0.9223 on the test set surpassing the other tools included in the comparison. Conclusions: In the present work, we showed and evaluated a robust skull-stripping U-Net-based tool surpassing the performance of the traditional approaches commonly used in the field. Using such tools can significantly decrease processing times in preclinical imaging settings by eliminating arduous manual steps such as brain extraction.

FOLATE RECEPTOR α POSITIVE HYBRIDOSOMES AS VEHICLES FOR NON-INVASIVE BRAIN-TARGETED GENE THERAPY

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Andreas Stäuble[1,2], Cristina Bellotti[1,2], Robert Steinfeld[1,2]
[1]University of Zurich, Faculty Of Medicine, Zurich, Switzerland, [2]Children's Hospital Zurich, Neurology, Zurich, Switzerland

Current gene therapies are mainly performed with viral vectors. The disadvantages of viral vectors include cell-type-nonspecific transduction and high immunogenicity. Lipid nanoparticles (LNPs) carrying nucleotides provide an alternative to viral gene therapy and vaccines, since many individuals have already received LNP-based vaccination. Here, we exploit this method for cerebral targeted gene therapy. We optimized a formulation with nanoplasmids for stable transfection. Further, we generated hybridosomes by enveloping LNPs with cell derived plasma membranes. Specific membrane anchored receptors expressed by those cells enable our hybridosomes to target and pass barriers in a tissue- and cell-type-specific manner. One such protective brain barrier is the blood-cerebrospinal fluid-brain barrier (BCSFB). Previously, we had demonstrated the transport of folate receptor α positive (FRα+) extracellular vesicles (EVs) across the BCSFB. Therefore, we disguise our FRα+ hybridosomes as EVs allowing the transport of our gene of interest across the BCSFB. So far, we have achieved high encapsulation efficiency and transfection rates in our *in vitro* studies in HEK293 and neuronal cells. Our next steps will include *in vivo* experiments in a reporter mouse line. Because of FRα and its ability to cross the BCSFB barrier, we can apply our hybridosomes non-invasively by intranasal inhalation and follow target cell expression over time. Compared to viral vectors, our hybridosomes can be used for tissue-specific transduction with low immunogenicity. This will enable novel vesicle-based gene therapies for neurodegenerative diseases.

Phylogeny and expression of canonical transient receptor potential (TRPC) genes in developing zebrafish.
Canonical transient receptor potential (TRPC) channels are nonselective, calcium-permeable cation channels that are expressed in a great variety of organisms, tissues, and cell types. TRPC channels are known to be involved in the transduction of polymodal sensory input. Additionally, they are implicated in a variety of developmental processes. Distinct gating mechanisms have been elucidated so far, but their exact functional role in vertebrate organisms still needs to be resolved.

Functional Imaging of Dentate Granule Cells in the Adult Mouse Hippocampus.
The hippocampal dentate gyrus is critically involved in learning and memory. However, methods for imaging the activity of its principal neurons, the dentate gyrus granule cells, are missing. Here we demonstrate chronic two-photon imaging of granule cell population activity in awake mice using a cortical window implant that leaves the hippocampal formation intact and does not lead to obvious alteration of animal behavior. Using virus delivery, we targeted expression of genetically encoded calcium indicators specifically to dentate gyrus granule cells. Calcium imaging of granule cell activity 600-800 µm below the hippocampal surface was facilitated by using 1040 nm excitation of the red indicator R-CaMP1.07, but was also achieved using the green indicator GCaMP6s. We found that the rate of calcium transients was increased during wakefulness relative to an extremely low rate during anesthesia; however, activity still remained sparse with, on average, approximately one event per 2-5 min per cell across the granule cell population. Comparing periods of running on a ladder wheel and periods of resting, we furthermore identified state-dependent differences in the active granule cell population, with some cells displaying highest activity level during running and others during resting. Typically, cells did not maintain a clear state preference in their activity pattern across days. Our approach opens new avenues to elucidate granule cell function, plasticity mechanisms, and network computation in the adult dentate gyrus.

Layer-specific integration of locomotion and sensory information in mouse barrel cortex.

FENS Forum 2022
9-13 July 2022 | Paris, France

During navigation, rodents continually sample the environment with their whiskers. How locomotion modulates neuronal activity in somatosensory cortex, and how it is integrated with whisker-touch remains unclear. Here, we compared neuronal activity in layer 2/3 (L2/3) and L5 of barrel cortex using calcium imaging in mice running in a tactile virtual reality. Both layers increase their activity during running and concomitant whisking, in the absence of touch. Fewer neurons are modulated by whisking alone. Whereas L5 neurons respond transiently to wall-touch during running, L2/3 neurons show sustained activity. Consistently, neurons encoding running-with-touch are more abundant in L2/3 and they encode the run-speed better during touch. Few neurons across layers were also sensitive to abrupt perturbations of tactile flow during running. In summary, locomotion significantly enhances barrel cortex activity across layers with L5 neurons mainly reporting changes in touch conditions and L2/3 neurons continually integrating tactile stimuli with running.

Amyotrophic Lateral Sclerosis (ALS) is caused by a number of mutations, with C9orf72 repeat expansions being the most common genetic cause. Due to the limitations of current pharmacological therapies, there is a strong need to develop innovative approaches. The goal of this study is the development of genome editing approaches aimed at reducing neurodegenerative aspects in ALS. The genomic engineering strategy adopted is a CRISPR-Cas9-based genome editing technology that allows the introduction of point mutations in the DNA without generating DSBs, using recently developed, highly precise enzymes: cytidine base editors (CBEs) and adenine base editors (ABEs) allowing C>T and A>G conversions, respectively. Several single-guide RNAs (sgRNA) were designed to target C9orf72 within the region containing the repeat expansions with the aim of boosting C9orf72 expression to counteract C9orf72 haploinsufficiency. This strategy was validated in the K562 cell line. In particular, at least three optimal sgRNA candidates resulted in up to 52%±5 base editing efficiency, that consequently resulted in 2-fold change increase of the C9orf72 transcripts levels. This strategy is currently being validated in induced pluripotent stem cell line (iPSCs) derived from ALS patients and differentiated to motor neurons in order to determine whether increasing the expression of C9orf72 will lead to amelioration of several cellular phenotypes in motor neuron cultures. We will also carry out proteomics and metabolomics analyses to define molecular pathways and targets in vitro that are altered upon increased expression of C9orf72 to further establish the potential of genome editing as a therapeutic strategy for ALS patients.

CREATING CHOLINERGIC NEURON SPECIFIC KNOCK-OUT MICE BY COMBINING THREE (CRISPR-CAS9, CRE/LOXP AND AAV) GENOME EDITING TECHNOLOGIES

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Tamás Kovács[1], Szidónia Farkas[2]
[1]University of Pécs Medical School, Centre for Neuroscience, Szentágothai Research Centre, Institute Of Physiology, Pécs, Hungary, [2]University of Pécs, Medical School, Institute Of Physiology, Pécs, Hungary

Aim: The aim of our experiment was to create a genetically modified mouse strain in which we knock-out the Estrogen Receptor alpha (ERα) (or any other receptor) specifically from cholinergic neurons, in any interested areas of the brain. **Material and methods:** First, two homozygous mouse strains were crossed. One contains a cholinergic neuron-specific Cre recombinase (choline acetyltransferase; ChAT-Cre), and the other contains the Cas9 enzyme, the transcription is blocked by two loxP cleavage sites (LoxP-STOP-LoxP-Cas9). All cholinergic (and not other types) neurons in double heterozygous animals, formed during crossing, will express the Cas9 enzyme. The next step was a stereotaxic injection of an adeno-associated virus vector (AAV) containing an ERα-specific guide-RNA into a specific area of the brain, in our case the nucleus basalis magnocellularis (NBM). The AAV virus was custom made in our laboratory. **Results:** In these animals, Cas9 is presented and active only in cholinergic cells. AAV viruses are active in the NBM (site of the AAV injection), because only here the CRISPR sequence required for its function appears. This specifically applies only to the ERα gene (see guide-RNA), which disappeared from these cells. **Conclusions:** The technology combining the CRISPR-Cas9, Cre/loxP and AAV virus systems is really promising to edit the genome in adult animals more selectively. Creating new genetically modified animals will help the better understanding of neurological diseases and improve research tools.

Alteration in the Wnt microenvironment directly regulates molecular events leading to pulmonary senescence.
In the aging lung, the lung capacity decreases even in the absence of diseases. The progenitor cells of the distal lung, the alveolar type II cells (ATII), are essential for the repair of the gas-exchange surface. Surfactant protein production and survival of ATII cells are supported by lipofibroblasts that are peroxisome proliferator-activated receptor gamma (PPARγ)-dependent special cell type of the pulmonary tissue. PPARγ levels are directly regulated by Wnt molecules; therefore, changes in the Wnt microenvironment have close control over maintenance of the distal lung. The pulmonary aging process is associated with airspace enlargement, decrease in the distal epithelial cell compartment and infiltration of inflammatory cells. qRT-PCR analysis of purified epithelial and nonepithelial cells revealed that lipofibroblast differentiation marker parathyroid hormone-related protein receptor (PTHrPR) and PPARγ are reduced and that PPARγ reduction is regulated by Wnt4 via a β-catenin-dependent mechanism. Using a human in vitro 3D lung tissue model, a link was established between increased PPARγ and pro-surfactant protein C (pro-SPC) expression in pulmonary epithelial cells. In the senile lung, both Wnt4 and Wnt5a levels increase and both Wnt-s increase myofibroblast-like differentiation. Alteration of the Wnt microenvironment plays a significant role in pulmonary aging. Diminished lipo- and increased myofibroblast-like differentiation are directly regulated by specific Wnt-s, which process also controls surfactant production and pulmonary repair mechanisms. Down-regulation of canonical and up-regulation of non-canonical Wnt signalling in the carcinogenic process of squamous cell lung carcinoma.
The majority of lung cancers (LC) belong to the non-small cell lung carcinoma (NSCLC) type. The two main NSCLC sub-types, namely adenocarcinoma (AC) and squamous cell carcinoma (SCC), respond differently to therapy. Whereas the link between cigarette smoke and lung cancer risk is well established, the relevance of non-canonical Wnt pathway up-regulation detected in SCC remains poorly understood. The present study was undertaken to investigate further the molecular events in canonical and non-canonical Wnt signalling during SCC development. A total of 20 SCC and AC samples with matched non-cancerous controls were obtained after surgery. TaqMan array analysis confirmed up-regulation of non-canonical Wnt5a and

Wnt11 and identified down-regulation of canonical Wnt signalling in SCC samples. The molecular changes were tested in primary small airway epithelial cells (SAEC) and various lung cancer cell lines (e.g. A549, H157, etc). Our studies identified Wnt11 and Wnt5a as regulators of cadherin expression and potentiated relocation of β-catenin to the nucleus as an important step in decreased cellular adhesion. The presented data identifies additional details in the regulation of SCC that can aid identification of therapeutic drug targets in the future.

Live-Cell Imaging of Single Neurotrophin Receptor Molecules on Human Neurons in Alzheimer's Disease.
Neurotrophin receptors such as the tropomyosin receptor kinase A receptor (TrkA) and the low-affinity binding p75 neurotrophin receptor p75 play a critical role in neuronal survival and their functions are altered in Alzheimer's disease (AD). Changes in the dynamics of receptors on the plasma membrane are essential to receptor function. However, whether receptor dynamics are affected in different pathophysiological conditions is unexplored. Using live-cell single-molecule imaging, we examined the surface trafficking of TrkA and p75 molecules on live neurons that were derived from human-induced pluripotent stem cells (hiPSCs) of mutant familial AD (fAD) patients and non-demented control subjects. Our results show that the surface movement of TrkA and p75 and the activation of TrkA- and p75-related phosphoinositide-3-kinase (PI3K)/serine/threonine-protein kinase (AKT) signaling pathways are altered in neurons that are derived from patients suffering from fAD compared to controls. These results provide evidence for altered surface movement of receptors in AD and highlight the importance of investigating receptor dynamics in disease conditions. Uncovering these mechanisms might enable novel therapies for AD.

Estradiol-Induced Epigenetically Mediated Mechanisms and Regulation of Gene Expression.
Gonadal hormone 17β-estradiol (E2) and its receptors are key regulators of gene transcription by binding to estrogen responsive elements in the genome. Besides the classical genomic action, E2 regulates gene transcription via the modification of epigenetic marks on DNA and histone proteins. Depending on the reaction partner, liganded estrogen receptor (ER) promotes DNA methylation at the promoter or enhancer regions. In addition, ERs are important regulators of passive and active DNA demethylation. Furthermore, ERs cooperating with different histone modifying enzymes and chromatin remodeling complexes alter gene transcription. In this review, we survey the basic mechanisms and interactions between estrogen receptors and DNA methylation, demethylation and histone modification processes as well as chromatin remodeling complexes. The particular relevance of these mechanisms to physiological processes in memory formation, embryonic development, spermatogenesis and aging as well as in pathophysiological changes in carcinogenesis is also discussed.

Increased poly-β-hydroxybutyrate production from carbon dioxide in randomly mutated cells of cyanobacterial strain Synechocystis sp. PCC 6714: Mutant generation and characterization.
Photosynthetic Poly-β-hydroxybutyrate (PHB) productivity in cyanobacteria needs to be increased to make cyanobacterial derived bioplastics economically feasible and competitive with petroleum-based plastics. In this study, high PHB yielding mutants of Synechocystis sp. PCC 6714 have been generated by random mutagenesis, using UV light as a mutagen. The selection of strains was based on PHB content induced by nitrogen and phosphorus starvation. The fast growing mutant MT_a24 exhibited more than 2.5-fold higher PHB productivity than that of the wild-type, attaining values of 37 ± 4% dry cell weight PHB. The MT_a24 was characterized for phenotypes, CO uptake rate and gene expression levels using quantitative PCR. Genome sequencing showed that UV mutagenesis treatment resulted in a point mutation in the ABC-transport complex, phosphate-specific transport system integral membrane protein A (PstA). The MT_a24 shows potential for industrial production of PHB and also for carbon capture from the atmosphere or point sources.

Single-Molecule Imaging Reveals Rapid Estradiol Action on the Surface Movement of AMPA Receptors in Live Neurons.
Gonadal steroid 17β-estradiol (E2) exerts rapid, non-genomic effects on neurons and strictly regulates learning and memory through altering glutamatergic neurotransmission and synaptic plasticity. However, its non-genomic effects on AMPARs are not well understood. Here, we analyzed the rapid effect of E2 on AMPARs using single-molecule tracking and super-resolution imaging techniques. We found that E2 rapidly decreased the surface movement of AMPAR via membrane G protein-coupled estrogen receptor 1 (GPER1) in neurites in a dose-dependent manner. The cortical actin network played a

pivotal role in the GPER1 mediated effects of E2 on the surface mobility of AMPAR. E2 also decreased the surface movement of AMPAR both in synaptic and extrasynaptic regions on neurites and increased the synaptic dwell time of AMPARs. Our results provide evidence for understanding E2 action on neuronal plasticity and glutamatergic neurotransmission at the molecular level.

Isolation and Characterization of a Murine Spontaneous High-Grade Follicular Lymphoma with Restricted In Vivo Spreading--a Model for Lymphatic Metastasis Via the Mesentery.
Spontaneous or induced malignant lymphomas in mice are valuable tools for studying human lymphoproliferative diseases, including the mechanism of migration between peripheral lymphoid organs and positioning within distinct tissue compartments. Here we report the isolation and characterization of a novel spontaneous lymphoma from BALB/c mice showing restricted tissue distribution and metastasis. The lymphoma cells display CD19, B220, MHC II, surface IgG2a/kappa chain with VH7183 rearrangement of the IgH gene, indicating their B-cell origin. Serial intraperitoneal injection of primary tumor into both BALB/c and RAG-1-deficient hosts led to the successful propagation of lymphoma. Despite the cytological characteristics of high-grade follicular B-cell lymphoma, the tumor cells (denoted as Bc-DLFL.1) showed significantly lesser spreading to extraabdominal locations upon intraperitoneal passage compared to splenic and mesenteric lymph node expansion. In mesenteric lymph nodes the high endothelial venules contained only few tumor cells, while the lymphatic vessels were almost completely filled with lymphoma cells. Similarly, the LYVE-1-positive lymphatic capillaries within the mesentery were packed with lymphoma cells. These findings suggest that Bc-DLFL.1 cells likely propagate primarily via the lymphatic circulation within the mesentery, therefore this tumor may offer an in vivo model to investigate the tumor cell migration via the lymphatic circulation from the peritoneal cavity.

A NOVEL MODULAR TOOLBOX FOR PRECISE NEURONAL EPIGENOME EDITING

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Marta Alaiz-Noya, Beatriz Del Blanco, Carina Racovac, Ángel Barco
Instituto de Neurociencias (CSIC-UMH), Molecular Neurobiology And Neuropathology, San Juan de Alicante, Spain

Among epigenome editing systems, the use of CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats) stands out for its versatility, ease of engineering, and cost-effectiveness. The chimeric fusion of the nuclease-deficient dCas9 with epigenetic enzymatic activities enables locus-specific rewriting of epigenetic information by guide RNAs. However, the resulting chimeric proteins are often large in size and beyond the packaging capacity of most common neurotropic vectors. To overcome this limitation, we have developed a novel, modular toolbox in which chimeric proteins are split into two smaller constructs taking advantage of nanobodies' ability to bind with high affinity to the recognized epitope. More precisely, the dCas9 protein has been linked to a nanobody that specifically recognizes GFP and GFP has been linked to the catalytic domain of different effector proteins. Results combining our tool with synthetic and epigenetic effector modules highlight the potential of this novel toolbox for precise neuronal epigenome editing *in vitro* and open new opportunities for the development of novel *in vivo* and *ex* vivo therapies to treat epigenome-associated diseases.

Transcriptome and epigenome analysis of engram cells: Next-generation sequencing technologies in memory research.
Transcription and epigenetic changes are integral components of the neuronal response to stimulation and have been postulated to be drivers or substrates for enduring changes in animal behavior, including learning and memory. Memories are thought to be deposited in neuronal assemblies called engrams, i.e., groups of cells that undergo persistent physical or chemical changes during learning and are selectively reactivated to retrieve the memory. Despite the research progress made in recent years, the identity of specific epigenetic changes, if any, that occur in these cells and subsequently contribute to the persistence of memory traces remains unknown. The analysis of these changes is challenging due to the difficulty of exploring molecular alterations that only occur in a relatively small percentage of cells embedded in a complex tissue. In this review, we discuss the recent advances in this field and the promise of next-generation sequencing (NGS) and epigenome editing methods for overcoming these challenges and address long-standing questions concerning the role of epigenetic mechanisms in memory encoding, maintenance and expression.

Characterization of an eutherian gene cluster generated after transposon domestication identifies Bex3 as relevant for advanced neurological functions.
One of the most unusual sources of phylogenetically restricted genes is the molecular domestication of transposable elements into a host genome as functional genes. Although these kinds of events are sometimes at the core of key macroevolutionary changes, their origin and organismal function are generally poorly understood.

Comprehensive expression analysis for the core cell cycle regulators in the chicken embryo reveals novel tissue-specific synexpression groups and similarities and differences with expression in mouse, frog and zebrafish.
The core cell cycle machinery is conserved from yeast to humans, and hence it is assumed that all vertebrates share the same set of players. Yet during vertebrate evolution, the genome was duplicated twice, followed by a further genome duplication in teleost fish. Thereafter, distinct genes were retained in different vertebrate lineages; some individual gene duplications also occurred. To which extent these diversifying tendencies were compensated by retaining the same expression patterns across homologous genes is not known. This study for the first time undertook a comprehensive expression analysis for the core cell cycle regulators in the chicken, focusing in on early neurula and pharyngula stages of

development, with the latter representing the vertebrate phylotypic stage. We also compared our data with published data for the mouse, Xenopus and zebrafish, the other established vertebrate models. Our work shows that, while many genes are expressed widely, some are upregulated or specifically expressed in defined tissues of the chicken embryo, forming novel synexpression groups with markers for distinct developmental pathways. Moreover, we found that in the neural tube and in the somite, mRNAs of some of the genes investigated accumulate in a specific subcellular localisation, pointing at a novel link between the site of mRNA translation, cell cycle control and interkinetic nuclear movements. Finally, we show that expression patterns of orthologous genes may differ in the four vertebrate models. Thus, for any study investigating cell proliferation, cell differentiation, tissue regeneration, stem cell behaviour and cancer/cancer therapy, it has to be carefully examined which of the observed effects are due to the specific model organism used, and which can be generalised.

DESIGNING VIRAL TOOLS TO CLASSIFY SUBPOPULATIONS OF TANYCYTES ALONG THE THIRD VENTRICLE

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Vanessa Neve[1], Helge Müller-Fielitz[1], Frauke Spieker[1], Anke Fähnrich[2], Ruben Nogueiras[3], Vincent Prevot[4], Markus Schwaninger[1]
[1]University of Lübeck, Institute Of Experimental And Clinical Pharmacology And Toxicology, Lübeck, Germany, [2]University of Lübeck, Group For Medical Systems Biology, Lübeck, Germany, [3]University of Santiago de Compostela, Center For Research In Molecular Medicine And Chronic Diseases, Santiago de Compostela, Spain, [4]University of Lille, Development & Plasticity Of The Neuroendocrine Brain, Lille Cedex, France

In the hypothalamus, the third ventricle is lined by specialised glia-like cells called tanycytes. Their projections reach into nuclei of the mediobasal hypothalamus and the median eminence (ME), which are responsible for energy homeostasis, food intake, hormone release and other functions. Historically, tanycytes were distinguished by their morphology and location along the ventricle. The classical beta-tanycytes, located in the ME and the lateral protrusions of the third ventricle, have projections into the arcuate nucleus (ARH) and the ME. They seem to be important for the transport of endogenous compounds between brain and periphery and regulating hormone release. On the other hand, the alpha-tanycytes extending from the ARH to the ventromedial- (VMH) as well as dorsomedial (DMH) nucleus regulate feeding behaviour. However, the classification according to localisation alone does not provide information about the function. To manipulate tanycytic subpopulations, we have modified an established adeno-associated virus (AAV)-based approach, with which we had only been able to target all tanycytes. We use small promotor fragments of different genes driving a Cre-recombinase combined with a fluorescent marker. The new AAV vectors were injected into the lateral ventricle of Ai14 reporter mice by stereotactic surgery. By immunofluorescence staining, we analysed the transduction pattern of 19 different promotor fragments. Using this approach, we were able to identify promoters that specifically target tanycytic subpopulations. The differential expression pattern of the AAV vectors provides evidence for the function heterogeneity of tanycytes. With these new vectors we are now able characterise the specific physiological functions of tanycyte subpopulations.

TARGETING NORADRENERGIC NEURONS OF THE LOCUS COERULEUS: A COMPARISON OF MODEL SYSTEMS AND STRATEGIES

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Alexander Dieter[1], Chantal Wissing[1], Maxime Maheu[1,2], J. Simon Wiegert[1]
[1]Universitätsklinikum Hamburg-Eppendorf, Center For Molecular Neurobiology (zmnh), Hamburg, Germany, [2]Universitätsklinikum Hamburg-Eppendorf, Section Computational Cognitive Neuroscience, Department Of Neurophysiology And Pathophysiology, Hamburg, Germany

The locus coeruleus (LC) noradrenergic system is involved in a plethora of physiological and pathophysiological processes. Refining our understanding of LC function largely relies on selective transgene expression in molecularly defined cells, enabling targeted manipulation and read-out of noradrenergic neurons. Here, we performed a side-by-side comparison of the most commonly used strategies and model systems enabling genetic access to the locus coeruleus. We report substantial differences among them both in terms of transgene expression efficacy, and in their molecular specificity. These findings are of critical importance for interpreting the results obtained from past experiments using the respective targeting strategies, as well as for the design of future studies.

Optogenetic stimulation of cochlear neurons activates the auditory pathway and restores auditory-driven behavior in deaf adult gerbils.
Cochlear implants partially restore hearing via direct electrical stimulation of spiral ganglion neurons (SGNs). However, spread of excitation from each electrode limits spectral coding. We explored the use of optogenetics to deliver spatially restricted and cell-specific excitation in the cochlea of adult Mongolian gerbils. Adeno-associated virus carrying the gene encoding the light-sensitive calcium translocating channelrhodopsin (CatCh) was injected into the cochlea of adult gerbils. SGNs in all cochlea turns showed stable and long-lasting CatCh expression, and electrophysiological recording from single SGNs showed that light stimulation up to few hundred Hertz induced neuronal firing. We characterized the light-induced activity in the auditory pathway by electrophysiological and behavioral analysis. Light- and sound-induced auditory brainstem responses showed similar kinetics and amplitude. In normal hearing adult gerbils, optical cochlear implants elicited stable optical auditory brainstem responses over a period of weeks. In normal hearing animals, light stimulation cued avoidance behavior that could be reproduced by subsequent acoustic stimulation, suggesting similar perception of light and acoustic stimuli. Neurons of the primary auditory cortex of normal hearing adult gerbils responded with changes in firing rates with increasing light intensity. In deaf adult gerbils, light stimulation generated auditory responses and cued avoidance behavior indicating partial restoration of auditory function. Our data show that optogenetic cochlear stimulation achieved good temporal fidelity with low light intensities in an adult rodent model, suggesting that optogenetics might be used to develop cochlear implants with improved restorative capabilities.

Near physiological spectral selectivity of cochlear optogenetics.
Cochlear implants (CIs) electrically stimulate spiral ganglion neurons (SGNs) and partially restore hearing to half a million CI users. However, wide current spread from intracochlear electrodes limits spatial selectivity (i.e. spectral resolution) of electrical CIs. Optogenetic stimulation might become an alternative, since light can be confined in space, promising artificial sound encoding with increased spectral selectivity. Here we compare spectral selectivity of optogenetic, electric, and acoustic stimulation by multi-channel recordings in the inferior colliculus (IC) of gerbils. When projecting light onto tonotopically distinct SGNs, we observe corresponding tonotopically ordered IC activity. An activity-based comparison reveals that spectral selectivity of optogenetic stimulation is indistinguishable from acoustic stimulation for modest intensities. Moreover, optogenetic stimulation outperforms bipolar electric stimulation at medium and high intensities and monopolar electric stimulation at all intensities. In conclusion, we demonstrate better spectral selectivity of optogenetic over electric SGN stimulation, suggesting the potential for improved hearing restoration by optical CIs.

μLED-based optical cochlear implants for spectrally selective activation of the auditory nerve.
Electrical cochlear implants (eCIs) partially restore hearing and enable speech comprehension to more than half a million users, thereby re-connecting deaf patients to the auditory scene surrounding them. Yet, eCIs suffer from limited spectral selectivity, resulting from current spread around each electrode contact and causing poor speech recognition in the presence of background noise. Optogenetic stimulation of the auditory nerve might overcome this limitation as light can be conveniently confined in space. Here, we combined virus-mediated optogenetic manipulation of cochlear spiral ganglion neurons (SGNs) and microsystems engineering to establish acute multi-channel optical cochlear implant (oCI) stimulation in adult Mongolian gerbils. oCIs based on 16 microscale thin-film light-emitting diodes (μLEDs) evoked tonotopic activation of the auditory pathway with high spectral selectivity and modest power requirements in hearing and deaf gerbils. These results prove the feasibility of μLED-based oCIs for spectrally selective activation of the auditory nerve.

32718992: Keppeler D, Schwaerzle M, Harczos T, Jablonski L, Dieter A, Wolf B, Ayub S, Vogl C, Wrobel C, Hoch G, Abdellatif K, Jeschke M, Rankovic V, Paul O, Ruther P, Moser T
Multichannel optogenetic stimulation of the auditory pathway using microfabricated LED cochlear implants in rodents.
When hearing fails, electrical cochlear implants (eCIs) provide the brain with auditory information. One important bottleneck of CIs is the poor spectral selectivity that results from the wide current spread from each of the electrode contacts. Optical CIs (oCIs) promise to make better use of the tonotopic order of spiral ganglion neurons (SGNs) inside the cochlea by spatially confined stimulation. Here, we established multichannel oCIs based on light-emitting diode (LED) arrays and used them for optical stimulation of channelrhodopsin (ChR)-expressing SGNs in rodents. Power-efficient blue LED chips were integrated onto microfabricated 15-μm-thin polyimide-based carriers comprising interconnecting lines to address individual LEDs by a stationary or mobile driver circuitry. We extensively characterized the optoelectronic, thermal, and mechanical properties of the oCIs and demonstrated stability over weeks in vitro. We then implanted the oCIs into ChR-expressing rats and gerbils, and characterized multichannel optogenetic SGN stimulation by electrophysiological and behavioral experiments. Improved spectral selectivity was directly demonstrated by recordings from the auditory midbrain. Long-term experiments in deafened ChR-expressing rats and in nontreated control animals demonstrated specificity of optogenetic stimulation. Behavioral studies on animals carrying a wireless oCI sound processor revealed auditory percepts. This study demonstrates hearing restoration with improved spectral selectivity by an LED-based multichannel oCI system.

Towards the optical cochlear implant: optogenetic approaches for hearing restoration.
Cochlear implants (CIs) are considered the most successful neuroprosthesis as they enable speech comprehension in the majority of half a million CI users suffering from sensorineural hearing loss. By electrically stimulating the auditory nerve, CIs constitute an interface re-connecting the brain and the auditory scene, providing the patient with information regarding the latter. However, since electric current is hard to focus in conductive environments such as the cochlea, the precision of electrical sound encoding-and thus quality of artificial hearing-is limited. Recently, optogenetic stimulation of the cochlea has been suggested as an alternative approach for hearing restoration. Cochlear optogenetics promises increased spectral selectivity of artificial sound encoding, hence improved hearing, as light can conveniently be confined in space to activate the auditory nerve within smaller tonotopic ranges. In this review, we discuss the latest experimental and technological developments of cochlear optogenetics and outline the remaining challenges on the way to clinical translation.
EMBO Mol Med, 2020; 12
32033755: Moser T, Dieter A
Towards optogenetic approaches for hearing restoration.
Hearing impairment (HI) is the most frequent sensory deficit in humans. As yet there is no causal therapy for sensorineural HI - the most common form - that results from cochlear dysfunction. Hearing aids and electrical cochlear implants (eCIs) remain the key options for hearing rehabilitation. The eCI, used by more than 0.7 Mio people with profound HI or deafness, is considered the most successful neuroprosthesis as it typically enables open speech comprehension in quiet. By electrically stimulating the auditory nerve, eCIs constitute a brain-machine interface re-connecting the patient with the auditory scene. Nonetheless, there are short-comings resulting from the wide spread of electric current inside the cochlea which limit the quality of artificial hearing. Since light can be better confined in space than electric current, optogenetic stimulation of the auditory nerve has been suggested as an alternative approach for hearing restoration, enabling higher resolution of artificial sound encoding. Future optical CIs (oCIS) promise increased spectral selectivity of artificial sound encoding, and hence might improve speech recognition in background noise as well as processing of music.

Anesthetics fragment hippocampal network activity, alter spine dynamics, and affect memory consolidation.
General anesthesia is characterized by reversible loss of consciousness accompanied by transient amnesia. Yet, long-term memory impairment is an undesirable side effect. How different types of general anesthetics (GAs) affect the hippocampus, a brain region central to memory formation and consolidation, is poorly understood. Using extracellular recordings, chronic 2-photon imaging, and behavioral analysis, we monitor the effects of isoflurane (Iso), medetomidine/midazolam/fentanyl (MMF), and ketamine/xylazine (Keta/Xyl) on network activity and structural spine dynamics in the hippocampal CA1 area of adult mice. GAs robustly reduced spiking activity, decorrelated cellular ensembles, albeit with distinct activity signatures, and altered spine dynamics. CA1 network activity under all 3 anesthetics was different to natural sleep. Iso anesthesia most closely resembled unperturbed activity during wakefulness and sleep, and network alterations recovered more readily than with Keta/Xyl and MMF. Correspondingly, memory consolidation was impaired after exposure to Keta/Xyl and MMF, but not Iso. Thus, different anesthetics distinctly alter hippocampal network dynamics, synaptic connectivity, and memory consolidation, with implications for GA strategy appraisal in animal research and clinical settings.

BiPOLES is an optogenetic tool developed for bidirectional dual-color control of neurons.
Optogenetic manipulation of neuronal activity through excitatory and inhibitory opsins has become an indispensable experimental strategy in neuroscience research. For many applications bidirectional control of neuronal activity allowing both excitation and inhibition of the same neurons in a single experiment is desired. This requires low spectral overlap between the excitatory and inhibitory opsin, matched photocurrent amplitudes and a fixed expression ratio. Moreover, independent activation of two distinct neuronal populations with different optogenetic actuators is still challenging due to blue-light sensitivity of all opsins. Here we report BiPOLES, an optogenetic tool for potent neuronal excitation and inhibition with light of two different wavelengths. BiPOLES enables sensitive, reliable dual-color neuronal spiking and silencing with single- or two-photon excitation, optical tuning of the membrane voltage, and independent optogenetic control of two neuronal populations using a second, blue-light sensitive opsin. The utility of BiPOLES is demonstrated in worms, flies, mice and ferrets.

Metachromatic leukodystrophy (MLD) is a rare, autosomal recessive disease caused by deficient activity of the lysosomal enzyme arylsulfatase A (ARSA), resulting in sulfatide accumulation and subsequent demyelination and neuronal loss within the central and peripheral nervous systems. Three clinical forms of MLD have been described, based on the age of symptom onset. Among them, early-onset forms comprise a continuum between late infantile MLD (most frequent accounting for 50-60% of MLD patients) and early juvenile MLD. In these early-onset forms, first symptoms typically develop between 1 and 4 years of age and progress rapidly towards severe motor and cognitive regression and premature death. There are currently no approved therapies for early onset MLD once patients are symptomatic. It is crucial to develop new approaches to treat symptomatic patients. Here we proposed a gene therapy approach based on intravenous delivery of an AAVPHP.eB encoding the human ARSA gene with a HA tag. ARSA KO animals were treated at 6 months with two different doses or 9 months of age and therapeutic efficacy has been evaluated at 12 months of age (ie 3 or 6 months after treatment). We demonstrated a broad transduction of brain and spinal cord leading to a complete correction of sulfatide storage both in brain and spinal cord in symptomatic animals as well as a significant improvement of neuroinflammation in mouse model of the disease. Our approach to treat symptomatic patient seem to be efficient in mouse model of the disease.

WHY NEURON-SPECIFIC STAINING AFTER INTRACEREBRAL INJECTION OF A VIRAL CONSTRUCT?

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Elodie Panzer, Laurine Boch, Brigitte Cosquer, Charleen Dias, Anne Pereira De Vasconcelos, Jean-Christophe Cassel, Aline Stephan
Université de Strasbourg, Cnrs Umr 7364 Lnca, Strasbourg, France

Viruses are precious, widely used technological tools in neuroscience research. For example, recombinant adeno-associated viruses (AAV) allow the expression of a gene of interest under the control of a specific promoter. After intracerebral injection of a virus, a DAPI or Hoechst nuclear staining is usually performed to verify the absence of target tissue alterations. We employed a pair of recombinant AAVs, one carrying a caspase gene and another, retrograde, carrying the Cre-recombinase gene in order to specifically disconnect two brain structures. We tested two retrograde viruses: an AAV-Cre-GFP (AAVrg.hSyn.HI.eGFP-Cre.WPRE.SV40, Addgene, MA, USA, 3.5 x 10^{12} particles/mL) carrying both the Cre-recombinase and the GFP fused genes under the hSyn promoter, and an AAV-Cre-mCh (AAVrg-EF1a-mCherry-IRES-Cre, Addgene, MA, USA, 1.2 x10^{12} particles/mL) carrying the Cre-recombinase and the mCherry genes (not fused) under the EF1a promoter. We injected 2 x 1µL of the virus into the midline thalamic reuniens and rhomboid nuclei (ReRh) of rats. After various post-injection delays, the infected region was immunostained using neuronal and glial markers (NeuN, Iba1 and GFAP) and a DAPI staining. We found that the ReRh infection by the AAV-Cre-GFP virus, not the AAV-Cre-mCh, produced massive neuronal loss 5 and 10 weeks after intracerebral injection, coinciding with a glial scar and microglial activation. This glial reaction prevented detection of cellular damage with the DAPI staining. We suggest that after intraparenchymal injection of AAVs, a neuron-specific labelling (e.g., NeuN) is essential to establish that the infection did not non-specifically alter the cellular composition of the target structure.

GENERATION OF CELL TYPE SPECIFIC VIRAL TOOLS FOR THE ANALYSIS OF NEURAL CIRCUITS IN THE HIPPOCAMPAL FORMATION

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Maria Letizia Potenza[1], Stefan Blankvoort[1], Valentina Di Maria[1], Markus Flatset[1], Menno Witter[2], Clifford Kentros[2]
[1]Kavli Institute for Systems Neuroscience, Centre For Neural Computation, Trondheim, Norway, [2]Norwegian University for Science and technology, Kavli Institute For Systems Neuroscience Faculty Of Medicine And Health Sciences, Trondheim, Norway

The human brain contains about one hundred billion electrically-active neurons, each establishing several thousand synaptic connections enabling their specific functional characteristics. The brain's anatomical and functional organization can therefore be thought of as an extremely complex set of neural circuits, which can best be studied by recording the effects of manipulating particular circuit elements, i.e. neuronal cell types. Despite the advent of opto- and chemogenetic tools that allow the manipulation of neural circuits, the ability to deliver them with the required anatomical specificity remains quite limited because the vast majority of promoters express in many different cell types. To address this issue our lab has developed an approach to generating celltype-specific tools known as “Enhancer-Driven Gene Expression” (EDGE) in which enhancers uniquely active in particular brain regions are combined with a heterologous minimal promoter. This allows for the generation of molecular genetic tools much more specific than native promoters in both transgenic animals and recombinant adeno-associated viral vectors (rAAVs), allowing one to specifically manipulate particular neuronal celltypes in any species. We applied this technology and screened the hippocampal formation on 21 putative enhancers by injection of rAAvs with these enhancers into the hippocampus of wild type animals for anatomical characterization of transgene expression. One of these viral constructs specifically labels dentate gyrus granule neurons when injected into the hippocampus. We present work characterizing the expression of this and other EDGE rAAVs with both local as well as systemic administration.

Calcium imaging using genetically encoded Ca2+ indicators (GECIs) is a widely adopted method to measure neural activity in modern neuroscience. Here, we explore the use of systemically administered viral vectors for brain-wide expression of GECIs, and adapt novel GECIs to optimize signal-to-noise. We show that systemic injections of PHP.eB or CAP-B10 serotype AAVs to express GECIs, especially jGCaMP8, is a highly promising technique for imaging neural activity and circumvents the need for transgenic GECI-expressing mouse lines. We also establish the use of soma-targeted GECI constructs where we combine the most popular soma-targeting peptides with the recently developed jGCaMP8 GECIs, providing unparalleled signal to noise ratios paired with the fastest GECI kinetics.

ANTEROGRADE TRANSNEURONAL TRANSFER OF RABIES VIA NOVEL PSEUDOTYPING WITH HSV-1 GLYCOPROTEINS GE, GI AND US9

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Simon Thompson[1], Andrew Murray[2]
[1]University College London, Sainsbury Wellcome Centre, London, United Kingdom, [2]UCL, Sainsbury Wellcome Centre, London, United Kingdom

Transsynaptic tracing methods have proved incredibly useful in furthering our understanding of brain-wide connectivity. In particular, rabies virus (RABV) has proven to be a highly useful retrograde tracer due to the ability to restrict transsynaptic transfer to one synapse. However, an equivalent monosynaptic anterograde tracer is not yet available. Here we attempt to produce an anterograde transsynaptic RABV by pseudotyping the virus with herpes simplex virus-1 (HSV-1) glycoproteins gE, gI and US9, which are known to facilitate anterograde spread. We first validated whether pseudotyping of RABV with HSV-1 glycoproteins would produce functional virions in vitro. Next, we developed a range of adeno-associated virus (AAV) complementation strategies to facilitate in vivo testing of multiple neural circuits in mice. Firstly, in wildtype mice RABV positive cells in the lateral vestibular nucleus were complemented with three AAVs, each expressing an individual glycoprotein, to test for anterograde spread to motor neurons within the spinal cord. Secondly, RABV positive Purkinje cells in TU/L7-Cre mice were complemented with two high expressing AAVs, one containing the receptor TVA and gE, another containing gI and US9, to test for anterograde transsynaptic spread to cells within the deep cerebellar nuclei. In both cases, a small number of RABV labelled cells were found in each downstream area with no corresponding retrogradely labelled cells visible. This outcome demonstrates the potential viability of this novel pseudotyping approach though presently the efficiency remains low and further optimisation is ongoing.

AUTOLOGOUS HAEMATOPOIETIC STEM CELL GENE THERAPY FOR PEOPLE WITH FRIEDREICH'S ATAXIA

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Nikoletta Jastrzebowska, Sian Baker, Chloe Moutin, Helen Scott, Neil Scolding, Oscar Cordero-Llana, James Uney, Kevin Kemp
University of Bristol, Bristol Medical School, Bristol, United Kingdom

Aims: Friedreich's ataxia (FA) is a neurodegenerative disease currently lacking any proven treatment. We propose to investigate whether autologous transplantation of genetically modified haematopoietic stem cells (HSCs), carrying a functional frataxin [*FXN*] transgene, is of therapeutic benefit. The aim of this study was therefore to develop a lentiviral-mediated transduction protocol for efficient and stable *FXN* delivery to isolated murine FA HSCs. **Methods:** Lineage^{-}, Sca-1^{+}, c-Kit^{+} haematopoietic stem cells (LSKs) were isolated from the bone marrow of FA transgenic mice (Fxn^{null}::YG8s(GAA)$_{>800}$) and transduced with a third-generation lentiviral vector carrying *FXN* and *EGFP* reporter (*lenti*-FXN.EGFP). Transduction efficiency and vector copy number (VCN) were assessed. Functional gene replacement was determined through analysis of frataxin protein levels, cell proliferation and differentiation, and mitochondrial function. **Results:** Using *lenti*-FXN.EGFP, a LSK transduction efficiency of 88% was achieved with an average VCN of 6 copies per cell. LSK cultures demonstrated a 12-fold increase in human frataxin protein expression following transduction, which was accompanied by a significant elevation in succinate dehydrogenase activity. *In vitro* quantification of LSK proliferation and differentiation showed no detrimental effects caused by lentiviral transduction on cell function. **Conclusions:** Our results demonstrate that lentiviral vector-mediated genome editing can provide an effective method for *FXN* gene correction and FA phenotype rescue in isolated HSCs. Further *in vivo* studies assessing transplantation of autologous *FXN*-corrected HSCs are warranted to demonstrate the therapeutic potential of our approach. Future translation into clinical trials may offer the development of a disease-modifying treatment for people with FA.

RT-QPCR-BASED ASSAY FOR MRNA INTEGRITY EVALUATION IN MOUSE AND HUMAN BRAIN TISSUE AND SYNAPTOSOMAL PREPARATIONS

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Daina Pamedytytė[1], Urte Neniskyte[2]
[1]Vilnius University, Life Sciences Center, Vilnius, Lithuania, [2]Vilnius University, Vu-embl Partnership Institute, Life Sciences Center, Vilnius, Lithuania

Aims: Subcellular compartments such as synaptosomes have very little ribosomal RNA (rRNA) on which traditional RNA integrity evaluation is based on. Also, rRNA integrity evaluation might not reflect the state of the mRNA pool correctly. Therefore, our aim was to adapt RT-qPCR-based 3′:5′ assay for mRNA integrity evaluation in RNA samples from mouse and human brain and their synaptosomal preparations. Methods: The 3′:5′ assay is based on using two sets of primers in qPCR to measure the relative expression of two amplicons located on the 3′ and 5′ regions of a gene of choice. All transcripts with poly(A) tail were reverse transcribed using only oligo-dT primers. cDNA obtained from a partly degraded mRNA sample was shorter and led to reduced amount of 5' end qPCR product and thus higher 3′:5′ ratio. Results: The 3′ and 5′ mouse and human *Pgk1* primer pairs were selected and validated for 3':5' mRNA integrity assay. The RNA integrity in heat-degraded RNA samples from mouse and human cortex was evaluated by 3':5' assay and the results were compared to the RIN values (Agilent Bioanalyzer). With prolonged heat treatment, 3':5' ratios gradually increased while RIN values gradually decreased. Regression analysis revealed significant association between 3':5' ratios and RIN values in the same sample. The application of 3′:5′ assay was further extended to mouse and human synaptosomal preparations. Conclusions: The 3′:5′ assay can be used as reliable alternative method to evaluate mRNA integrity in mouse and human brain tissue and synaptosomal preparations.

Different stability of miRNAs and endogenous control genes in archival specimens of papillary thyroid carcinoma.
The most popular miRNA quantitation technique is RQ-PCR with relative gene expression method that requires an endogenous control (EC) gene for data normalization. However, there are insufficient data and selection criteria on the most suitable ECs for miRNA expression studies in many cancer types including papillary thyroid carcinoma (PTC). Therefore, in this study we evaluated the impact of chosen EC and archival formalin-fixed, paraffin-embedded (FFPE) PTC tissue age on estimated target miRNA expression.

Association of MicroRNA Expression and BRAF Mutation with Recurrence of Thyroid Cancer.
Many miRNAs and cancer-related mutations have been proposed as promising molecular markers of papillary thyroid carcinoma (PTC). However, there are limited data on the correlation between miRNA expression, BRAF mutation, and PTC recurrence. Therefore, to evaluate the potential of BRAF mutation and five selected miRNAs (-146b, -222, -21, -221, -181b) in predicting PTC recurrence, these molecular markers were analyzed in 400 formalin-fixed, paraffin-embedded PTC tissue specimens. The expression levels of miRNAs were measured using qRT-PCR. It was demonstrated that expression levels of all analyzed miRNAs are significantly higher in recurrent PTC than in non-recurrent PTC (< 0.05). Moreover, higher expression levels of miR-146b, miR-222, miR-21, and miR-221 were associated with other clinicopathologic features of PTC, such as tumor size and lymph node metastases at initial surgery (< 0.05). No significant differences in the frequency of BRAF mutation in recurrent PTC and non-recurrent PTC were determined. Our results suggest that miRNA expression profile differs in PTC that is prone to recurrence when compared to PTC that does not reoccur after the initial surgery while BRAF mutation frequency does not reflect the PTC recurrence status. However, the prognostic value of the analyzed miRNAs is rather limited in individual cases as the pattern of miRNA expression is highly overlapping between recurrent and non-recurrent PTC.

Background: Synaptic heterogeneity is widely observed in mammalian systems and is potentially linked to differences in protein architecture of connections within specific neuronal ensembles relevant for cognition. In turn, this heterogeneity may influence the capacity of different synapse types to process information and adjust transmission in a plastic manner. So far, the identification of synaptic proteomes has been limited to global analysis of many synapses in one. This prevents the identification of cell-type and circuit-specific synaptosomes that underlie different brain functions such as learning and memory. This project aims to develop technology to label, isolate, and harvest specific synaptic populations to identify protein expression signatures of connections within ensembles implicated in memory formation and its persistence over time. **Methods and Results:** We utilize Fluorescence-Activated Synapse Sorting (FASS) to harvest fluorescently tagged hippocampal synapses from a mixed population. Using high-resolution microscopy, we show that these tagged and sorted synapses remain structurally intact, containing both pre-and post-synaptic compartments. Finally, using Mass Spectrometry (LC-MS/MS), we demonstrate that protein composition of sorted synapses yields a similar coverage across pre-and post-synaptic compartments as their pre/unsorted counterparts. **Conclusions:** Our technical toolbox enables molecular characterization of cell/ensemble-specific synaptic populations relevant for cognition and experience-dependent circuit use. **Keywords:** Synapse, Sorting, Proteomics, Plasticity, Memory **E-mail address:** b.moharana@vu.nl

Autophagy is a conserved degradative pathway with a crucial role in neuronal proteostasis. In humans, mutations in core autophagy genes lead to congenital disorders of the central nervous system, and impaired autophagy is also linked to late-onset neurodegeneration. However, the autophagic degradome in the brain remains only partially characterized. To overcome previous limitations, here we use a two-step protocol to purify LC3-positive autophagic vesicles (AVs) from the mouse brain and profile their content by quantitative proteomics. In addition to highlighting that aggrephagy, mitophagy and ER-phagy occur constitutively in the brain, we also reveal a significant synaptic content. To define the brain autophagic degradome, we proteomically analyze the accumulation of content proteins under genetic and pharmacological autophagy impairment. Lastly, we quantitatively compare the AV content and degradome during adolescence and aging, where autophagy impairment is causally linked to disease, and reveal dynamic and progressive changes in the nature and abundance of the autophagic protein cargo. Taken together, our findings form a basis for better understanding the contribution of macroautophagy to brain proteostasis under physiological conditions. They also provide novel insight as to how autophagy impairment may contribute to diseases, through the aberrant homeostasis of specific, age-relevant, protein cargo.

Aims: The neuronal ceroid lipofuscinoses (NCLs) are a group of rare life-limiting neurodegenerative disorders affecting children and adults with several clinical features including epilepsy, psychomotor decline, blindness, and early death. Mounting evidence points to bioenergetic and autophagic dysfunction as underlying conditions for disease progression founded altered also in other late-onset neurodegenerative and aging-related disorders. Multi-omic approaches represent promising tools for the identification of meaningful pathways as well as valid biomarkers for early diagnosis and disease progression in NCLs and possibly translational to other forms of dementia. **Methods:** 64 omic datasets from human and mouse samples have been bioinformatically integrated using pathway enrichment, biological network, or empirical correlation analyses. The comprehensive interpretation of experimental results has been assisted by the combination and integration of several sources of content/databases. **Results:** Our analyses evidenced an altered metabolic status across NCLs forms, both in human and mice. An altered synaptogenesis signalling pathway, autophagy, and neuroinflammation signs have been also recognized. Analyses in human datasets, highlighted candidate biomarkers of disease status and progression. Among these APP and CLU are implicated in beta-amyloid regulation and neurodegenerative process, indicating a further possible connection with Alzheimer's disease. From murine datasets we recognized several molecules directly related to AD and Parkinson's disease (as APOE, GFAP or SNCA), whereas CTSD and CLU were proposed as common interspecies biomarkers. **Conclusions:** Our multi-omic approach offers a better understanding on the molecular landscape across the NCL forms, also offering new points of contact with the more common forms of dementias.

[1]Jena University Hospital, Hans-berger-department Of Neurology, Jena, Germany, [2]Jena University Hospital, Izkf Of The Medical Faculty Jena, Jena, Germany, [3]Jena University Hospital, Jena Center For Healthy Aging, Jena, Germany, [4]Leibniz Institute on Aging, Aging Research Center Jena, Jena, Germany, [5]Jena University Hospital, Institute Of Human Genetics, Jena, Germany, [6]Jena University Hospital, Department Of Neurology, Biomagnetic Center, Jena, Germany, [7]Jena University Hospital, Brain Imaging Center Jena, Jena, Germany

Aim: Astrocytes are key regulators of brain neuronal network function, but their role at the molecular level is still largely unknown. Ribosomal tagging (Ribotag) is a powerful tool for cell type-specific extraction of mRNA, which in astrocytes is predominantly translocated in their thousands of fine distal processes for local translation. Here we aim to adopt the original protocol proposed by Sanz et al. (2009) to extract the whole astrocytic translatome in good quality from small tissue samples. **Method:** Floxed RPL22tm1.1Psam reporter mice were crossed with Aldh1l1-cre/ERT2 driver mice. In 6-week-old double heterozygote offspring, the expression of HA-tagged ribosomes was induced in astrocytes by peritoneal injection of tamoxifen. After two weeks of recombination, brain tissue was processed for affinity purification of the HA-tagged ribosomes. Various modifications were introduced to the initial protocol to optimize the yield and the quality of the final extracted ribosome-associated mRNA. The modifications were verified by microscopy, western blot, qPCR and the Agilent 2100 Bioanalyzer. **Results**: Our experiments indicate that tissue size (ranging from 60 to 5mg), tissue homogenization method (douncing vs grinding), HA-antibody type and concentration for affinity purification, as well as the mRNA extraction method (elution vs precipitation) specifically influence final mRNA quality and yield. **Conclusion:** There are multiple possible adaptations to the initial protocol to successfully extract the astrocytic translatome from small brain tissue samples.

THE BENEFICIAL ROLE OF EXERCISE-INDUCED NEURONAL DNA DAMAGE

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Natalie Ricciardi[1,2], Caroline Borja[3], Claude-Henry Volmar[2,4], Claes Wahlestedt[2,4]
[1]University of Miami, Department Of Biochemistry And Molecular Biology, Miami, United States of America, [2]University of Miami, Center For Therapeutic Innovation, Miami, United States of America, [3]University of Miami, Department Of Biology, Coral Gables, United States of America, [4]University of Miami, Department Of Psychiatry And Behavioral Sciences, Miami, United States of America

Background: DNA damage accumulation is a pathological feature that all chronic diseases of aging share, including neurodegenerative diseases. Interestingly, aerobic exercise induces DNA damage in peripheral tissues but there is little research investigating the relationship between exercise-induced DNA damage and the brain. Specifically, it is unknown how DNA damage and the concomitant DNA damage repair (DDR) response relate to neuroprotective gene expression or how physical activity primes against the neuronal DNA damage that accumulates with age. **Method:** Hippocampi from C57Bl/6J mice (n=8) were assessed for changes in gene expression, protein expression, DNA single-strand breaks, and DNA methylation. Two groups of mice were evaluated: (1) 6-month-old mice after a single bout of acute aerobic exercise and (2) 18-month-old mice after 6 months of regular aerobic exercise. After treadmill exercise, cognitive ability was assessed by novel object location, novel object recognition, and Barnes maze tests before tissue collection. **Result:** Upregulation of DDR enzymes Ape1, Ogg1, Parp1, and Parp2 was observed after both acute and chronic exercise protocols. These changes in gene expression coincided with upregulation of well-validated neurotrophic genes Bdnf and Creb1 and improved sub-threshold memory in the exercise groups. Unique patterns of DNA demethylation and single-strand DNA breaks occurred around active regulatory regions of neurotrophic genes. **Conclusion:** DNA damage and repair mechanisms are recruited during and after exercise that coincide with neurotrophic gene expression and memory function. Future research will evaluate the role of single-stranded DNA damage repair enzymes in the post-exercise neurotrophic response via genetic and pharmacological manipulation.

A novel knockout mouse model of the noncoding antisense () gene displays increased endogenous Bdnf protein and improved memory function following exercise.
) expression is tightly controlled at the transcriptional and post-transcriptional levels. Previously, we showed that inhibition of noncoding antisense (-AS) RNA upregulates Bdnf protein. Here, we generated a -antisense knockout (AS KO) mouse model by deleting 6 kilobases upstream of -AS. After verifying suppression of AS, baseline behavioral tests indicated no significant difference in knockout and wild type mice, except for enhanced cognitive function in the knockout mice in the Y-maze. Following acute involuntary exercise, -AS KO mice were re-assessed and a significant increase in mRNA and protein were observed. Following long-term involuntary exercise, we observed a significant increase in nonspatial and spatial memory in novel object recognition and Barnes maze tests in young and aged AS KO mice. Our data provides evidence for the beneficial effects of endogenous upregulation and the synergistic effect of -AS knockout on exercise and memory retention. Heliyon, 2021; 7

Emerging Technologies for Genome-Wide Profiling of DNA Breakage.
Genome instability is associated with myriad human diseases and is a well-known feature of both cancer and neurodegenerative disease. Until recently, the ability to assess DNA damage-the principal driver of genome instability-was limited to relatively imprecise methods or restricted to studying predefined genomic regions. Recently, new techniques for detecting DNA double strand breaks (DSBs) and single strand breaks (SSBs) with next-generation sequencing on a genome-wide scale with single nucleotide resolution have emerged. With these new tools, efforts are underway to define the "breakome" in normal aging and disease. Here, we compare the relative strengths and weaknesses of these technologies and their potential application to studying neurodegenerative diseases.

Sexual Dimorphism in the 3xTg-AD Mouse Model and Its Impact on Pre-Clinical Research.
Female sex is a leading risk factor for developing Alzheimer's disease (AD). Sexual dimorphism in AD is gaining attention as clinical data show that women are not only more likely to develop AD but also to experience worse pathology and faster cognitive decline. Pre-clinical AD research in animal models often neglects to address sexual dimorphism in evaluation of behavioral or molecular characteristics and outcomes. This can compromise its translation to a clinical setting. The triple-transgenic AD mouse model (3xTg-AD) is a commonly used but unique AD model because it exhibits both amyloid and tau pathology, essential features of the human AD phenotype. Mounting evidence has revealed important sexually dimorphic characteristics of this animal model that have yet to be reviewed and thus, are often overlooked in studies using the 3xTg-AD model. In this review we conduct a thorough analysis of reports of sexual dimorphism in the 3xTg-AD model including findings of molecular, behavioral, and longevity-related sex differences in original research articles through August 2020. Importantly, we find results to be inconsistent, and that strain source and differing methodologies are major contributors to lack of consensus regarding traits of each sex. We first touch on the nature of sexual dimorphism in clinical AD, followed by a brief summary of sexual dimorphism in other major AD murine models before discussing the 3xTg-AD model in depth. We conclude by offering four suggestions to help unify pre-clinical mouse model AD research inspired by the NIH expectations for considering sex as a biological variable.

Novel approach reveals genomic landscapes of single-strand DNA breaks with nucleotide resolution in human cells.
Single-strand breaks (SSBs) represent the major form of DNA damage, yet techniques to map these lesions genome-wide with nucleotide-level precision are limited. Here, we present a method, termed SSiNGLe, and demonstrate its utility to explore the distribution and dynamic changes in genome-wide SSBs in response to different biological and environmental stimuli. We validate SSiNGLe using two very distinct sequencing techniques and apply it to derive global profiles of SSBs in different biological states. Strikingly, we show that patterns of SSBs in the genome are non-random, specific to different biological states, enriched in regulatory elements, exons, introns, specific types of repeats and exhibit differential preference for the template strand between exons and introns. Furthermore, we show that breaks likely contribute to naturally occurring sequence variants. Finally, we demonstrate strong links between SSB patterns and age. Overall, SSiNGLe provides access to unexplored realms of cellular biology, not obtainable with current approaches.

Inhibition of HDAC3 reverses Alzheimer's disease-related pathologies in vitro and in the 3xTg-AD mouse model.
Alzheimer's disease (AD) is the leading cause of age-related dementia. Neuropathological hallmarks of AD include brain deposition of β-amyloid (Aβ) plaques and accumulation of both hyperphosphorylated and acetylated tau. RGFP-966, a brain-penetrant and selective HDAC3 inhibitor, or HDAC3 silencing, increases BDNF expression, increases histone H3 and H4 acetylation, decreases tau phosphorylation and tau acetylation at disease-associated sites, reduces β-secretase cleavage of the amyloid precursor protein (APP), and decreases Aβ accumulation in HEK-293 cells overexpressing APP with the double Swedish mutation (HEK/APP). In the triple transgenic AD mouse model (3xTg-AD), repeated administration of 3 and 10 mg/kg of RGFP-966 reverses pathological tau phosphorylation at Thr, Ser, and Ser, increases levels of the Aβ degrading enzyme Neprilysin in plasma, decreases Aβ protein levels in the brain and periphery, and improves spatial learning and memory. Finally, we show that RGFP-966 decreases Aβ accumulation and both tau acetylation and phosphorylation at disease residues in neurons derived from induced pluripotent stem cells obtained from APOEε4-carrying AD patients. These data indicate that HDAC3 plays an important regulatory role in the expression and regulation of proteins associated with AD pathophysiology, supporting the notion that HDAC3 may be a disease-modifying therapeutic target.

Accumulation of misfolded and aggregated forms of tau protein in distinct brain regions is characteristic for the progressive neurodegenerative disorder, namely Alzheimer´s disease (AD). In the last decade, the studies focused on a better understanding of processes underlying the spreading of tau pathology. Previous work displayed the potential of insoluble tau seeds from AD to induce propagation of tau pathology in a transgenic rodent model. Recruitment of the suggested transgenic rodent model of tauopathy may lead to the advanced perception of processes associated with the progressive spread of tau protein in AD. Our study aimed to identify differentiated molecular signatures and signalling pathways linked to the initiation and spreading of abnormal tau forms in the transgenic rat model of tauopathy. Our findings show that microglia in the vicinity of AD-Tau pathology in transgenic model triggered morphological changes to phagocytic phenotype in comparison to PBS injected rats. Subsequently, transcriptomic analysis revealed dysregulation of 15 genes in transgenic rats 3-month after AD-Tau injection. Consecutive bioinformatic analysis identified 31 enriched signalling pathways linked to the progression of tauopathy in AD. Activation of inflammatory, mitophagy, autophagy and endoplasmic reticulum stress regulatory mechanisms were observed. The shown data imply specific alteration of molecular signaling associated with AD-Tau-induced pathology in tauopathic background and warrants further exploration of tau spreading pathways. Transcriptomic signature of Alzheimer's disease tau seed-induced pathology.
Spreading of tau pathology to anatomical distinct regions in Alzheimer's disease (AD) is associated with progression of the disease. Studies in recent decade have strived to understand the processes involved in this characteristic spread. We recently showed that AD-derived insoluble tau seeds are able to initiate neurofibrillary pathology in transgenic rodent model of tauopathy. In the present study, we pursued to identify the molecular changes that govern the induction and propagation of tau pathology on the transcriptomic level. We first show that microglia in vicinity to AD-Tau-induced pathology has phagocytic morphology when compared to PBS-injected group. On transcriptomic level, we observed deregulation of 15 genes 3-month post AD-Tau seeds inoculation. Integrated bioinformatic analysis identified 31 significantly enriched pathways. Amongst these, the inflammatory signalling pathway mediated by cytokine and chemokine networks, along with, toll-like receptor and JAK-STAT signalling were the most dominant. Furthermore, the enriched signalling also involved the regulation of autophagy, mitophagy and endoplasmic reticulum stress pathways. To our best of knowledge, the study is the first to investigate the transcriptomic profile of AD-Tau seed-induced pathology in hippocampus of transgenic model of tauopathy.

Peripheral microRNA alteration and pathway signaling after mild traumatic brain injury.
Discovering novel diagnostic biomarkers and signatures for traumatic brain injury (TBI) represents a major challenge in the brain trauma research. Detailed analysis of post-concussive molecular pathways based on experimental data could provide a new insight into the pathophysiological sequelae and mapping of recovery mechanisms involved in TBI. MicroRNAs (miRNAs) detectable in peripheral body fluids after TBI are promising carriers of this missing knowledge. In order to define the signature of peripheral miRNAs signaling associated with mild TBI (mTBI), we performed a comprehensive meta-analysis of miRNA profiles in mTBI patients using multiple curated pathway databases. Using a bioinformatic pipeline with integrated data analysis we identified a set of genes that are connected to deregulated circulating miRNAs following the mTBI. Identified

genes belong to specific pathways of MAPK, TGF-β, WNT, TLR2/4, PI3K/AKT, insulin, and growth factor signaling. Since the enriched pathways markedly overlap among the various biological fluids, signaling associated with mTBI that is concomitantly reflected in serum, plasma and saliva is robust and unique. Furthermore, we identified a network of 33 validated interacting proteins and their regulatory miRNAs that link the post-mTBI signaling in peripheral fluids with neurodegeneration-associated interaction pathways. Presented data provide a comprehensive insight into molecular events following mTBI, and the top predicted genes represent a group of novel candidate targets to be validated in connection with mTBI.

Environmental Enrichment Rescues Functional Deficit and Alters Neuroinflammation in a Transgenic Model of Tauopathy.
Alzheimer's disease (AD) is the most frequent neurodegenerative disorder, affecting over 44 million people worldwide. There are no effective pharmaco-therapeutic options for prevention and treatment of AD. Non-pharmacological approaches may help patients suffering from AD to significantly ameliorate disease progression. In this study, we exposed a transgenic rat model (tg) of human tauopathy to enriched environment for 3 months. Behavioral testing at 6 months of age revealed improvement in functional deficits of tg rats reared under enriched conditions, while sedentary tg rats remained severely impaired. Interestingly, enriched environment did not reduce tau pathology. Analysis of neurotrophic factors revealed an increase of nerve growth factor (NGF) levels in the hippocampus of both enriched groups (tg and non-tg rats), reflecting a known effect of enriched environment on the hippocampal formation. On the contrary, NGF levels decreased markedly in the brainstem of enriched groups. The non-pharmacological treatment also reduced levels of tissue inhibitor of metalloproteinase 1 in the brainstem of transgenic rats. Expression analysis of inflammatory pathways revealed upregulation of microglial markers, such as MHC class II and Cd74, whereas levels of pro-inflammatory cytokines remained unaffected by enriched environment. Our results demonstrate that exposure to enriched environment can rescue functional impairment in tau transgenic rats without reducing tau pathology. We speculate that non-pharmacological treatment modulates the immune response to pathological tau protein inclusions, and thus reduces the damage caused by neuroinflammation.

Traumatic brain injury (TBI) is a global health issue with millions of cases reported annually. The history of TBI, including mild concussion, is associated with increased risk for development of various neurodegenerative disorders. The mechanisms and molecular events following TBI that lead to neurodegeneration remain partially unknown. The discovery of novel diagnostic and prognostic biomarkers for TBI represents a major challenge in current brain trauma research. MicroRNAs (miRNAs) are important regulators of molecular signaling pathways and biological processes, and therefore represent a valuable source of potential biomarkers for monitoring post-concussive molecular changes. In this study, we used an integrative computational approach with multiple curated pathway databases, to define the signature of mild TBI (mTBI)-associated peripheral miRNA signaling. The presented meta-analysis identified a set of target genes of deregulated circulating miRNAs after mTBI, which are involved in specific pathways of MAPK, TGF-β, WNT, TLR2/4, PI3K/AKT, insulin, and growth factor signaling. In addition, the bioinformatic analysis revealed a network of protein-protein interactions consisting of 33 key hub proteins and their regulatory miRNAs, representing a link between post-mTBI and neurodegenerative signaling. Our results provide a comprehensive insight into molecular events following mTBI, plus predicted genes could represent novel candidate markers or targets to be validated in connection with a mTBI. This project was supported by research grants VEGA 2/0118/19, VEGA 2/0153/22 and APVV-17-0668, APVV-19-0568, APVV-20-0615, ERA-NET NEURON Neu-Vasc.

Preserving spatial information of cells' transcriptome significantly improves our understanding of the relationships among events taking place in living organisms. However, as throughput, sensitivity and financial demands remain a common obstacle, we ventured to develop a high-resolution method, which would overcome many of these hurdles and make spatial transcriptome analyses more commonplace. To reach this goal, we adopted surface-modified slides capable of mRNA binding, which preserves spatial information present in a tissue down to several micrometers. Immobilized mRNA sequences with their locations remain even after the digestion of the tissue itself, which significantly boosts the method’s sensitivity and signal-to-noise ratio. Following mRNA sequence capture, selected genes can be targeted through a multitude of padlock probes, grown on a gene chip array, and maintained through in-house amplification. Contact between a padlock probe and its target gene enables circularization of the probe and creation of a concatemer containing thousands of copies of the original molecule through rolling circle amplification. Through an appropriate design, probes can be used to create a general overview of the tissue composition as well as to monitor further events taking place in the tissue. With high throughput being made possible by relatively low cost of the method, it is feasible to eventually create inferred 3D maps of tissues with single cell resolution as well as creation on connection graphs within the nervous system. Moreover, as this method does not require tissue dissociation, cell type bias observed in many neuronal samples is removed, leading to more accurate cell representation.

REVEALING NOVEL REGULATORS OF NEUROTRANSMISSION BY ACTIVITY-DRIVEN SYNAPTIC EXOCYTOMICS

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Carlos Pascual-Caro[1], Daniel Perez-Hernandez[2], Jaime De Juan-Sanz[1]
[1]Sorbonne Université, Institut du Cerveau - Paris Brain Institute - ICM, Inserm, CNRS, APHP, Hôpital de la Pitié Salpêtrière, Paris, France, Neurophysiology, Paris, France, [2]Luxembourg Institute of Health, Quantitative Biology Unit, Luxembourg, Luxembourg

Neuronal communication drives all cognitive activities, including movement, perception, learning and memory. At the molecular level, neurotransmitter release is orchestrated by the coordinated function of more than one thousand proteins and although there is extensive literature describing synaptic proteomes, even at the subcellular level, the field has only reported static proteomic snapshots that lack information about the essential trafficking events constantly occurring to sustain synaptic function. Developing a comprehensive picture of the trafficking proteome of firing synapses would provide a complete molecular view of synaptic biology and may unbiasedly identify previously-unannotated synaptic proteins whose trafficking on demand is essential to support neurotransmission. To tackle this issue, we combine HRP-based proximity-labeling of the synaptic cleft surface in primary cortical neurons with electrical stimulation or KCl depolarization, labeling newly-exposed proteins in the cleft during activity. Using this methodology, we can demonstrate the trafficking of endogenous presynaptic proteins but also postsynaptic proteins which control excitatory synaptic structure and function during firing. Here, we plan to identify unbiasedly molecules exposed by activity using state-of-the-art mass spectrometry to later dissect the role of new synaptic trafficking proteins in controlling neurotransmitter release by combining cutting-edge optophysiology and genetic manipulations. By isolating these surface synaptic regulators in living neurons during experimentally controlled firing, we aim to generate for the first time a holistic picture of the dynamic synaptic proteome, identifying novel proteins involved in neurotransmission and providing a solid framework for future studies into the molecular basis of synaptic pathologies such as schizophrenia, epilepsy or autism.

INSTRUMENT-FREE SINGLE-CELL RESOLUTION OF TRANSCRIPTOME CHANGES IN HUMAN STEM CELLS DURING ACCELERATED NEURONAL DEVELOPMENT TRIGGERED BY KNOCKING OUT THE AMYLOID PRECURSOR PROTEIN

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Jun Komatsu[1], Khadijeh Shabani[2], Azadeh Saffarian[1], Bassem Hassan[3], Stuart Edelstein[1]
[1]Scipio bioscience, R&d, Paris, France, [2]Institut du Cerveau – Paris Brain Institute – ICM, Brain Development, Paris, France, [3]Paris Brain Institute, Brain Development, Paris, France

During embryogenesis, human cortical neural stem cells initially generate neurons at a particularly slow rate while preserving their progenitor state for a relatively extended time. Here we show that the characteristic potential of human neural stem cells to remain in a progenitor state as they generate neurons for a prolonged period of time requires the Amyloid Precursor Protein (APP). To explores the phenotype of neural stem cells without APP, we generated *APP*-knockout human iPSCs and characterized their transcriptomes using the novel instrument-free scRNA-seq kit recently developed by Scipio bioscience. With this kit, single-cell RNA sample preparation was achieved using the proprietary reversible hydrogel technology that provides results comparable to current microfluidic instrument-based techniques. In the application reported here, chemically linked barcode bead—cell tandems were dispersed in the hydrogel in the liquid state. Upon gelation the tandems were immobilized, but small lysis agents that diffuse freely were subsequently added. Following cell lysis mRNA molecules from individual cells were captured on the adjacent barcodes. Successive steps of reverse transcription, PCR amplification, cDNA sequencing, and bioinformatic analysis permitted comparing native and APP-knockout cells. The cell clustering results demonstrated that the differences observed point to a mechanism whereby loss of APP accelerates neurogenesis through activation of the AP1 transcription factor and repression of WNT signaling. Based on these observations, we propose that the fine balance between self-renewal and differentiation human cortical neural stem cells is homeostatically regulated by APP, which may contribute to human-specific temporal patterns of neurogenesis.

Efficient integration of exogenous transgenes in neural stem cells is essential to investigate their development and expand their therapeutic potential. We recently introduced the iOn (integration-coupled On) gene expression switch, a configuration of DNA vector that conditions transgene expression to genomic integration with the piggyBac transposition system. By silencing expression from non-integrated episomes, this approach considerably simplifies additive transgenesis in eukaryotic cells. Among others, it enables efficient multiplexed drug-free stable transgenesis in cultured cells, and also permits genetic mosaic manipulations through simple somatic transgenesis in animal models. Here, we present several developments of the iOn system that further increase its usefulness for neurodevelopmental studies. We generated vectors expressing different colors of fluorescent markers for increased multiplexing and versatility in stable transfection assays and cell lineage studies. To temporally control transgene expression in vitro and in vivo, we designed drug-inducible iOn vectors controlled by transactivation. We also investigated iOn-based strategies to inhibit endogenous gene expression in identified cells. Finally, to further simplify transgenesis with iOn, we created all-in-one vectors that do not require co-transfection with a separate transposase-encoding vector. These additions to the iOn toolkit, validated in vitro and in vivo, expand its applicability to a large range of manipulations permitted by germline transgenesis.

PD is a neurodegenerative disorder characterized by loss of dopamine (DA) neurons of the Substantia Nigra (SN). There are studies suggesting that alpha-synuclein (aSyn) plays a central role in the pathogenesis of PD. However, there is no molecularly precise, single-cell *in vivo* transcriptomic studies with accurately defined aSyn overload. Here we describe a novel strategy based on AAVs engineering and transgenic animals. The MNM008 AAVs capsid, capable of retrograde transport in DA neurons, is injected in the striatum of TH-Cre rats and DAT-Cre mice. The nuclei from the SN area are enriched for DA neurons using FANS thanks to a Cre-inducible histone-linked-GFP (H2B-GFP), which is only expressed in the population of interest. Using a combinatorial-indexing based single nuclei sequencing approach called Sci-Fi-Seq we can pre-label all mRNA in each nucleus with an identifier for that specific sample. These samples are then pooled together and prepared for sequencing using 10X genomic. Immunohistochemistry results showed that the virus injected in the striatum was retrogradely transported and expressed in DA neurons of the SNpc. The FANS enrichment strategy showed to be robust with an average of 2500 GFP positive (DA) nuclei retrieved per animal. Transcriptomic analysis on the GFP positive sorted nuclei revealed DA markers specific to the SN population, and the viral vector expression was restricted to this population, confirming the high selectivity of our approach. The combinatorial indexing and molecular barcoding will allow us to accurately measure the aSyn expression level in each DA neuron arranging them into disease stages in what we call pseudo-time. From this study, we will further our knowledge on PD disease progression as well as possible new treatments.

Destabilizing Domains Enable Long-Term and Inert Regulation of GDNF Expression in the Brain.
Regulation of therapeutic transgene expression can increase the safety of gene therapy interventions, especially when targeting critical organs such as the brain. Although several gene expression systems have been described, none of the current systems has the required safety profile for clinical applications. Our group has previously adapted a system for novel gene regulation based on the destabilizing domain degron technology to successfully regulate glial cell-line derived neurotrophic factor in the brain (GDNF-F-DD). In the present study, we used GDNF-F-DD as a proof-of-principle molecule to fully characterize DD regulation in the brain. Our results indicate that DD could be regulated in a dose-dependent manner. In addition, GDNF-F-DD could also be induced repeatedly, without loss of activity or efficacy . Finally, DD regulation was able to be sustained for 24 weeks without loss of expression or any overt toxicity. The present study shows that DD has great potential to regulate gene expression in the brain.

GDNF-mediated rescue of the nigrostriatal system depends on the degree of degeneration.
Glial cell-line derived neurotrophic factor (GDNF) is a promising therapeutic molecule to treat Parkinson's disease. Despite an excellent profile in experimental settings, clinical trials testing GDNF have failed. One of the theories to explain these negative outcomes is that the clinical trials were done in late-stage patients that have advanced nigrostriatal degeneration and may therefore not respond to a neurotrophic factor therapy. Based on this idea, we tested if the stage of nigrostriatal degeneration is important for GDNF-based therapies. Lentiviral vectors expressing regulated GDNF were delivered to the striatum of rats to allow GDNF expression to be turned on either while the nigrostriatal system was degenerating or after the nigrostriatal system had been fully lesioned by 6-OHDA. In the group of animals where GDNF expression was on during degeneration, neurons were rescued and there was a reversal of motor deficits. Turning GDNF expression on after the nigrostriatal system

was lesioned did not rescue neurons or reverse motor deficits. In fact, these animals were indistinguishable from the control groups. Our results suggest that GDNF can reverse motor deficits and nigrostriatal pathology despite an ongoing nigrostriatal degeneration, if there is still a sufficient number of remaining neurons to respond to therapy.

Excitatory Transmission to the Lateral Habenula Is Critical for Encoding and Retrieval of Spatial Memory.
The lateral habenula (LHb) is viewed as a relay between the limbic system, the basal ganglia (BG), and monoaminergic neurons of the midbrain. If a prominent role has been evidenced in BG-mediated functions such as value-based decision-making, very little is known about the involvement of the LHb in limbic functions such as memory processing. In the present study, we used two pharmacological approaches-LHb reversible inactivation with intra-LHb infusion of muscimol, an agonist of the GABA-A receptor, or blockade of excitatory inputs with intra-LHb infusion of 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX), an antagonist of the glutamatergic AMPA receptor-to investigate the involvement of the LHb in encoding, consolidation, and retrieval of spatial memory in the water maze (WM) in rats. We found that intra-LHb infusion of muscimol or CNQX prevented encoding and retrieval, but not consolidation of spatial information. In addition, muscimol but not CNQX induced impairments during a cued version of the WM task, and marked anxiety in the elevated plus maze. These results confirm the involvement of the LHb in higher cognitive functions. They further suggest a dichotomy between the role of glutamatergic and other inputs to the LHb in hippocampus-dependent memory processing, as well as in emotional aspects of goal-directed behaviors.

CRISPR/CAS9 GENE-EDITED FLUORESCENT ORGANOIDS AS A NOVEL MODEL TO STUDY ALZHEIMER'S DISEASE PATHOLOGY.

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Lucia Carmen Gallego Villarejo, Lisa Bachmann, David Marks, Thorsten Müller
Ruhr-University Bochum, Biochemistry Ii, Bochum, Germany

Alzheimer's disease (AD) has been intensively studied over the last decades. However, the underlying mechanisms are rarely understood, and a cure is still not available, which is also the consequence of non-appropriate model systems. To fill this gap, we aimed to develop a new platform combining CRISPR/Cas9, hiPSC, and organoid technology. Therefore, a hiPSC line harboring the PAISA PSEN1 mutation (PSEN1 E280A) and the isogenic "healthy" control (WT) line were used. The WT hiPSC line was gene-edited by CRISPR/Cas9 to include a fluorescent protein N-terminal to the highly expressed LMNB1 protein, using it as a reporter marker.This allowed the development of a fused cerebral organoids, composed of AD-mutated (non-fluorescent) and healthy (fluorescent) hiPSc cells. For each cell of the organoid the genotype was precisely identifiable and traceable back to their origin providing a direct comparison between both conditions, and thus reducing comparability problems that arise from the high organoid-to-organoid variability. The established model was used to treat the organoids with synthetic Aβ oligomers and brain extract from aged Aβ precursor protein transgenic mice (APPPS1 tg) to study the seeding and spreading pattern of amyloid plaques in relation with PSEN1 E280A mutation in a human brain-like 3D tissue. Aditionally, we studied the affected cell types and the presence of hyperphosphorylated Tau. We demonstrate increased Aβ deposition and seeding in a time-dependent manner, that was based on the previous existence of Aβ aggregates. Our results demonstrate cerebral organoids to be a new model to investigate AD related pathways, especially very early aberrations.

Amyloid precursor protein elevates fusion of promyelocytic leukemia nuclear bodies in human hippocampal areas with high plaque load.
The amyloid precursor protein (APP) is a type I transmembrane protein with unknown physiological function but potential impact in neurodegeneration. The current study demonstrates that APP signals to the nucleus causing the generation of aggregates consisting of its adapter protein FE65, the histone acetyltransferase TIP60 and the tumour suppressor proteins p53 and PML. APP C-terminal (APP-CT50) complexes co-localize and co-precipitate with p53 and PML. The PML nuclear body generation is induced and fusion occurs over time depending on APP signalling and STED imaging revealed active gene expression within the complex. We further show that the nuclear aggregates of APP-CT50 fragments together with PML and FE65 are present in the aged human brain but not in cerebral organoids differentiated from iPS cells. Notably, human Alzheimer's disease brains reveal a highly significant reduction of these nuclear aggregates in areas with high plaque load compared to plaque-free areas of the same individual. Based on these results we conclude that APP-CT50 signalling to the nucleus takes place in the aged human brain and is involved in the pathophysiology of AD.

Gene-Edited Fluorescent and Mixed Cerebral Organoids.
Cerebral organoids are a promising model to study human brain function and disease, although the high inter-organoid variability is still challenging. To overcome this limitation, we introduce the method of labeled mixed organoids generated from two different human induced pluripotent stem cell (hiPSC) lines, which enables the identification of cells from different origin within a single organoid. The method combining gene editing and organoid differentiation offers a unique tool to study gene function in a complex human three-dimensional model. Using a CRISPR-Cas9 gene-editing approach, different fluorescent proteins were fused to β-actin or lamin B1 in hiPSCs, and mixtures of differently edited cells were seeded to induce cerebral organoid differentiation. Consequently, the development of the organoids was detectable by live confocal fluorescence microscopy of whole organoids and immunofluorescence staining in fixed samples. We demonstrate that a direct comparison

of the individual cells is possible by having the edited and the control (or the two differentially labeled) cells within the same organoid, thus overcoming the inter-organoid inhomogeneity limitations. Furthermore, the approach enables mosaic analysis of mutant clones in a wild-type three-dimensional cellular environment. It paves the way for the reliable analysis of human genetic disorders using organoids and the gain of fundamental understanding of the molecular mechanisms underlying pathological conditions.

Sera from Patients with NMOSD Reduce the Differentiation Capacity of Precursor Cells in the Central Nervous System.
AQP4 (aquaporin-4)-immunoglobulin G (IgG)-mediated neuromyelitis optica spectrum disorder (NMOSD) is an inflammatory demyelinating disease that affects the central nervous system, particularly the spinal cord and optic nerve; remyelination capacity in neuromyelitis optica is yet to be determined, as is the role of AQP4-IgG in cell differentiation.

Blood-brain barrier (BBB) exhibits a hurdle for drug delivery and development. One reason for poor successes to target drugs to the brain is the lack of good *in vitro* models that could recapitulate the BBB function. Our Aim was to develop an in vitro model of BBB by using human iPSC-derived cells in a microfluidic organ-on-a-chip platform. Methods: Our microfluidic BBB-on-chip platform design includes static conditions of the brain-side, as well as the dynamic conditions of the brain microvasculature within the same platform, mimicking in-vivo conditions. The BBB-on-chip is established using a co-culture of endothelial cells (ECs) and astrocytes, cultured on opposing sides of a semipermeable membrane. Results: First, we compared iPSC-ECs to human immortalized cell line, HCMEC/D3, and found that iPSC-ECs are forming a better barrier much faster in our BBB-on-chip. Secondly, we tested the effect of different pore sizes to iPSC-EC barrier formation and morphology. We concluded that 3 µm pore size supported the growth of ECs the best. Finally, a co-culture of iPSC-ECs with astrocytes showed a marked improvement in permeability compared to monoculture. Conclusion: Our microfluidic BBB model accurately reflects the in vivo conditions of the BBB by modeling both the static conditions of the brain-side of the BBB, as well as the dynamic conditions of the brain microvasculature within the same platform. As the highest-throughput platform currently in the field, our BBB model enables the development and screening of new therapeutics for neurological disorders still lacking effective treatments, such as Alzheimer's and Parkinson's disease.

Proteostasis Disturbances and Inflammation in Neurodegenerative Diseases.
Protein homeostasis (proteostasis) disturbances and inflammation are evident in normal aging and some age-related neurodegenerative diseases. While the proteostasis network maintains the integrity of intracellular and extracellular functional proteins, inflammation is a biological response to harmful stimuli. Cellular stress conditions can cause protein damage, thus exacerbating protein misfolding and leading to an eventual overload of the degradation system. The regulation of proteostasis network is particularly important in postmitotic neurons due to their limited regenerative capacity. Therefore, maintaining balanced protein synthesis, handling unfolding, refolding, and degrading misfolded proteins are essential to preserve all cellular functions in the central nervous sysytem. Failing proteostasis may trigger inflammatory responses in glial cells, and the consequent release of inflammatory mediators may lead to disturbances in proteostasis. Here, we review the mechanisms of proteostasis and inflammatory response, emphasizing their role in the pathological hallmarks of neurodegenerative diseases such as Alzheimer's disease, Parkinson's disease, and amyotrophic lateral sclerosis. Furthermore, we discuss the interplay between proteostatic stress and excessive immune response that activates inflammation and leads to dysfunctional proteostasis.

Dysfunction of Cellular Proteostasis in Parkinson's Disease.
Despite decades of research, current therapeutic interventions for Parkinson's disease (PD) are insufficient as they fail to modify disease progression by ameliorating the underlying pathology. Cellular proteostasis (protein homeostasis) is an essential factor in maintaining a persistent environment for neuronal activity. Proteostasis is ensured by mechanisms including regulation of protein translation, chaperone-assisted protein folding and protein degradation pathways. It is generally accepted that deficits in proteostasis are linked to various neurodegenerative diseases including PD. While the proteasome fails to degrade large protein aggregates, particularly alpha-synuclein (α-SYN) in PD, drug-induced activation of autophagy can efficiently remove aggregates and prevent degeneration of dopaminergic (DA) neurons. Therefore, maintenance of these mechanisms is essential to preserve all cellular functions relying on a correctly folded proteome. The

correlations between endoplasmic reticulum (ER) stress and the unfolded protein response (UPR) that aims to restore proteostasis within the secretory pathway are well-established. However, while mild insults increase the activity of chaperones, prolonged cell stress, or insufficient adaptive response causes cell death. Modulating the activity of molecular chaperones, such as protein disulfide isomerase which assists refolding and contributes to the removal of unfolded proteins, and their associated pathways may offer a new approach for disease-modifying treatment. Here, we summarize some of the key concepts and emerging ideas on the relation of protein aggregation and imbalanced proteostasis with an emphasis on PD as our area of main expertise. Furthermore, we discuss recent insights into the strategies for reducing the toxic effects of protein unfolding in PD by targeting the ER UPR pathway.

Blood-Brain Barrier and Neurodegenerative Diseases-Modeling with iPSC-Derived Brain Cells.
The blood-brain barrier (BBB) regulates the delivery of oxygen and important nutrients to the brain through active and passive transport and prevents neurotoxins from entering the brain. It also has a clearance function and removes carbon dioxide and toxic metabolites from the central nervous system (CNS). Several drugs are unable to cross the BBB and enter the CNS, adding complexity to drug screens targeting brain disorders. A well-functioning BBB is essential for maintaining healthy brain tissue, and a malfunction of the BBB, linked to its permeability, results in toxins and immune cells entering the CNS. This impairment is associated with a variety of neurological diseases, including Alzheimer's disease and Parkinson's disease. Here, we summarize current knowledge about the BBB in neurodegenerative diseases. Furthermore, we focus on recent progress of using human-induced pluripotent stem cell (iPSC)-derived models to study the BBB. We review the potential of novel stem cell-based platforms in modeling the BBB and address advances and key challenges of using stem cell technology in modeling the human BBB. Finally, we highlight future directions in this area.

Metabolic alterations in Parkinson's disease astrocytes.
In Parkinson`s disease (PD), the loss of dopaminergic (DA) neurons in the substantia nigra pars compacta is associated with Lewy bodies arising from the accumulation of alpha-synuclein protein which leads ultimately to movement impairment. While PD has been considered a disease of the DA neurons, a glial contribution, in particular that of astrocytes, in PD pathogenesis is starting to be uncovered. Here, we report findings from astrocytes derived from induced pluripotent stem cells of LRRK2 G2019S mutant patients, with one patient also carrying a GBA N370S mutation, as well as healthy individuals. The PD patient astrocytes manifest the hallmarks of the disease pathology including increased expression of alpha-synuclein. This has detrimental consequences, resulting in altered metabolism, disturbed Ca homeostasis and increased release of cytokines upon inflammatory stimulation. Furthermore, PD astroglial cells manifest increased levels of polyamines and polyamine precursors while lysophosphatidylethanolamine levels are decreased, both of these changes have been reported also in PD brain. Collectively, these data reveal an important role for astrocytes in PD pathology and highlight the potential of iPSC-derived cells in disease modeling and drug discovery.

Generation of a human induced pluripotent stem cell line (UEFi003-A) carrying heterozygous A673T variant in amyloid precursor protein associated with a reduced risk of Alzheimer's disease.
A673T mutation in the amyloid precursor protein (APP) is a rare variant associated with a reduced risk of late-onset Alzheimer's disease (AD) and age-related cognitive decline. The A673T mutation decreases beta-amyloid (Aβ) production and aggregation in neuronal cultures in vitro. Here we have identified a Finnish non-diseased male individual carrying a heterozygous A673T mutation, obtained a skin biopsy sample from him, and generated an iPSC line using commercially available integration-free Sendai virus-based kit. The established iPSC line retained the mutation, expressed pluripotency markers, had a normal karyotype, and differentiated into all three germ layers in vitro.

Krabbe disease (KD) is a fatal pediatric neurodegenerative lysosomal storage disorder (LSD) caused by deficient activity of the enzyme galactosylceramidase (GALC). This condition leads to severe demyelination and consequent neurodegeneration of both the central nervous system and peripheral nervous system. Despite the disease gravity, the current standard of care is mostly supportive only. The enzyme replacement therapy has gained broad interest thanks to the effective results achieved in other LSD. However, applications of such therapy to KD still do not exist. Here, an enzyme delivery system based on the encapsulation of cross-linked enzyme aggregates (CLEAs) into poly-(lactide-co-glycolide) (PLGA) nanoparticles (NPs) functionalized with brain targeting peptide (Ang-2) is investigated for the treatment of the natural murine model of KD, called Twitcher (TWI). The enzymatic activity (E.A) in the TWI mice with GALC mutation in homozygosity is significantly higher than in untreated mice from 4 to 72 hours after the injection. Overall, these data demonstrate that the formulation provides and maintains E.A. in the brain in the range of clinical interest up to 72 h from the treatment. An increase in E.A.is also observed in the sciatic nerve compared to untreated mice. Regarding liver and kidney, we found a high E.A. after 24 hours from the treatment without accumulation phenomena. Thus, given the established ability of our developed drug to pass the blood-brain barrier and release the active enzyme until 3 days, experiments of prolonged treatment have currently been ongoing.

Circulating microRNAs as biomarkers for early diagnosis of cutaneous melanoma.
: Cutaneous melanoma is the deadliest form of skin cancer, with a dramatic increase in the incidence rate worldwide over the past decade. Early detection has been shown to improve the outcome of melanoma patients. The identification of noninvasive biomarkers able to identify melanoma at an early stage remains an unmet clinical need. Circulating miRNAs (c-miRNAs), small non-coding RNAs, appear as potential ideal candidate biomarkers due to their stability in biological fluids and easy detectability. Moreover, c-miRNAs are reported to be heavily deregulated in cancer patients.: This review examines evidence of the specific c-miRNAs or panels of c-miRNAs reported to be useful in discriminating melanoma from benign cutaneous lesions.: Although the interesting reported by published studies, the non-homogeneity of detection and normalization methods prevents the individuation of single c-miRNA or panel of c-miRNAs that are specific for early detection of cutaneous melanoma. In the future, prospective wide and well-designed clinical trials will be needed to validate the diagnostic potential of some of the c-miRNA candidates in clinical practice.

Circulating cell-free microRNAs in cutaneous melanoma staging and recurrence or survival prognosis.
Cutaneous melanoma is a skin cancer with increasing incidence. Identification of novel clinical biomarkers able to detect the stage of disease and suggest prognosis could improve treatment and outcome for melanoma patients. Cell-free microRNAs (cf-miRNAs) are the circulating copies of short non-coding RNAs involved in gene expression regulation. They are released into the interstitial fluid, are detectable in blood and other body fluids and have interesting features of ideal biomarker candidates. They are stable outside the cell, tissue specific, vary along with cancer development and are sensitive to change in the disease course such as progression or therapeutic response. Moreover, they are accessible by non-invasive methods or venipuncture. Some articles have reported different cf-miRNAs with the potential of diagnostic tools for melanoma staging, recurrence and survival prediction. Although some concordance of results is already emerging, differences in analytical

methods, normalization strategies and tumour staging still will require further research and standardization prior to clinical usage of cf-miRNA analysis. This article reviews this literature with the aim of contributing to a shared focusing on these new promising tools for melanoma treatment and care.

Chronic lithium administration in a mouse model for Krabbe disease.
Krabbe disease (KD; or globoid cell leukodystrophy) is an autosomal recessive lysosomal storage disorder caused by deficiency of the galactosylceramidase (GALC) enzyme. No cure is currently available for KD. Clinical applied treatments are supportive only. Recently, we demonstrated that two differently acting autophagy inducers (lithium and rapamycin) can improve some KD hallmarks in-vitro, laying the foundation for their in-vivo pre-clinical testing. Here, we test lithium carbonate in-vivo, in the spontaneous mouse model for KD, the Twitcher (TWI) mouse. The drug is administered ad libitum via drinking water (600 mg/L) starting from post natal day 20. We longitudinally monitor the mouse motor performance through the grip strength, the hanging wire and the rotarod tests, and a set of biochemical parameters related to the KD pathogenesis [i.e., GALC enzymatic activity, psychosine (PSY) accumulation and astrogliosis]. Additionally, we investigate the expression of some crucial markers related to the two pathways that could be altered by lithium: the autophagy and the β-catenin-dependent pathways. Results demonstrate that lithium has not a significant rescue effect on the TWI phenotype, although it can slightly and transiently improves muscle strength. We also show that lithium, with this administration protocol, is unable to stimulate autophagy in the TWI mice central nervous system, whereas results suggest that it can restore the β-catenin activation status in the TWI sciatic nerve. Overall, these data provide intriguing inputs for further evaluations of lithium treatment in TWI mice.

Tailoring of silica-based nanoporous pod by spermidine multi-activity.
Ubiquitous in nature, polyamines (PAs) are a class of low-molecular aliphatic amines critically involved in cell growth, survival and differentiation. The polycation behavior is validated as a successful strategy in delivery systems to enhance oligonucleotide loading and cellular uptake. In this study, the chemical features and the functional roles of the PA spermidine are synergistically exploited in the synthesis and bioactive functionalization of SiO-based structures. Inspired by biosilicification, the role of spermidine is assessed both as catalyst and template in a biomimetic one-pot synthesis of dense silica-based particles (SPs) and as a competitive agent in an interfacial reassembly strategy, to empty out SPs and generate spermidine-decorated hollow silica nanoporous pods (spd-SNPs). Spermidine bioactivity is then employed for targeting tumor cell over-expressed polyamine transport system (PTS) and for effective delivery of functional miRNA into melanoma cells. Spermidine decoration promotes spd-SNP cell internalization mediated by PTS and along with hollow structure enhances oligonucleotide loading. Accordingly, the functional delivery of the tumor suppressor miR-34a 3p resulted in intracellular accumulation of histone-complexed DNA fragments associated with apoptosis. Overall, the results highlight the potential of spd-SNP as a multi-agent anticancer therapy.

The Extra Virgin Olive Oil Polyphenol Oleocanthal Exerts Antifibrotic Effects in the Liver.
Liver fibrosis, which is the outcome of wound-healing response to chronic liver damage, represents an unmet clinical need. This study evaluated the anti-fibrotic and anti-inflammatory effects of the polyphenol oleocanthal (OC) extracted from extra virgin olive oil (EVOO) by an approach. The hepatic cell lines LX2 and HepG2 were used as models. The mRNA expression of pro-fibrogenic markers, namely alpha-smooth muscle actin (α-SMA), collagen type I alpha 1 chain (COL1A1), a panel of metalloproteinases (MMP1, MMP2, MMP3, MMP7, MMP9) and vascular endothelial growth factor A (VEGFA) as well as the pro-oxidant genes NADPH oxidases (NOXs) 1 and 4 were evaluated in TGF-β activated LX2 cells by qRT-PCR. α-SMA and COL1A1 protein expression was assessed by immunofluorescence coupled to confocal microscopy. VEGFA release from LX2 was measured by ELISA. We also evaluated the amount of reactive oxygen species (ROS) produced by HO activated-HepG2 cells. , OC was administered daily by oral gavage to Balb/C mice with CCl-induced liver fibrosis. In this model, we measured the mRNA hepatic expression of the three pro-inflammatory interleukins (IL) IL6, IL17, IL23, chemokines such as C-C Motif Chemokine Ligand 2 (CCL2) and C-X-C Motif Chemokine Ligand 12 (CXCL12), and selected miRNAs (miR-181-5p, miR-221-3p, miR-29b-3p and miR-101b-3p) by qRT-PCR. We demonstrated that OC significantly downregulated the gene/protein expression of α-SMA, COL1A1, MMP2, MMP3, MMP7 and VEGF as well as the oxidative enzymes NOX1 and 4 in TGFβ1-activated LX2 cells, and reduced the production of ROS by HepG2. OC, beside causing a significant reduction of fibrosis at histological assessment, counteracted the CCl-induced upregulation of pro-fibrotic and inflammatory genes.

Moreover, OC upregulated the anti-fibrotic miRNAs (miR-29b-3p and miR-101b-3p) reduced in fibrotic mice, while downregulated the pro-fibrotic miRNAs (miR-221-3p and miR-181-5p), which were dramatically upregulated in fibrotic mice. In conclusion, OC exerts a promising antifibrotic effect a combined reduction of oxidative stress and inflammation involving putative miRNAs, which in turn reduces hepatic stellate cells activation and liver fibrosis.

Harnessing therapeutic viruses as a delivery vehicle for RNA-based therapy.
Messenger RNA (mRNA) and microRNA (miRNA)-based therapeutics have become attractive alternatives to DNA-based therapeutics due to recent advances in manufacture, scalability and cost. Also, RNA-based therapeutics are considered safe since there are no risk of inducing genomic changes as well as the potential adverse effects would be only temporary due to the transient nature of RNA-based therapeutics. However, efficient in vivo delivery of RNA-based therapeutics remains a challenge. We have developed a delivery platform for RNA-based therapeutics by exploiting the physicochemical properties of enveloped viruses. By physically attaching cationic liposome/RNA complexes onto the viral envelope of vaccinia virus, we were able to deliver mRNA, self-replicating RNA as well as miRNA inside target cells. Also, we showed that this platform, called viRNA platform, can efficiently deliver functional miRNA mimics into B16.OVA tumour in vivo.

Cholinesterase-like organocatalysis by imidazole and imidazole-bearing molecules.
Organocatalysis, which is mostly explored for its new potential industrial applications, also represents a chemical event involved in endogenous processes. In the present study, we provide the first evidence that imidazole and imidazole derivatives have cholinesterase-like properties since they can accelerate the hydrolysis of acetylthiocholine and propionylthiocholine in a concentration-dependent manner. The natural imidazole-containing molecules as L-histidine and histamine show a catalytic activity, comparable to that of imidazole itself, whereas synthetic molecules, as cimetidine and clonidine, were less active. In the experimental conditions used, the reaction progress curves were sigmoidal and the rational of such unexpected behavior as well as the mechanism of catalysis is discussed. Although indirectly, findings of the present study suggests that imidazolic compounds may interfere with the homeostasis of the cholinergic system in vivo.

Hydroxytyrosol Modulates Adipocyte Gene and miRNA Expression Under Inflammatory Condition.
Chronic inflammation of the adipose tissue (AT) is a major contributor to obesity-associated cardiometabolic complications. The olive oil polyphenol hydroxytyrosol (HT) contributes to Mediterranean diet cardiometabolic benefits through mechanisms still partially unknown. We investigated HT (1 and 10 μmol/L) effects on gene expression (mRNA and microRNA) related to inflammation induced by 10 ng/mL tumor necrosis factor (TNF)-α in human Simpson-Golabi-Behmel Syndrome (SGBS) adipocytes. At real-time PCR, HT significantly inhibited TNF-α-induced mRNA levels, of monocyte chemoattractant protein-1, C-X-C Motif Ligand-10, interleukin (IL)-1β, IL-6, vascular endothelial growth factor, plasminogen activator inhibitor-1, cyclooxygenase-2, macrophage colony-stimulating factor, matrix metalloproteinase-2, Cu/Zn superoxide dismutase-1, and glutathione peroxidase, as well as surface expression of intercellular adhesion molecule-1, and reverted the TNF-α-mediated inhibition of endothelial nitric oxide synthase, peroxisome proliferator-activated receptor coactivator-1α, and glucose transporter-4. We found similar effects in adipocytes stimulated by macrophage-conditioned media. Accordingly, HT significantly counteracted miR-155-5p, miR-34a-5p, and let-7c-5p expression in both cells and exosomes, and prevented NF-κB activation and production of reactive oxygen species. HT can therefore modulate adipocyte gene expression profile through mechanisms involving a reduction of oxidative stress and NF-κB inhibition. By such mechanisms, HT may blunt macrophage recruitment and improve AT inflammation, preventing the deregulation of pathways involved in obesity-related diseases.

DEVELOPMENT OF FOLATE RECEPTOR ALPHA-FUNCTIONALIZED GENE-THERAPY VECTORS FOR TARGETED BRAIN DELIVERY

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Cristina Bellotti[1,2], Andreas Stäuble[1,2], Robert Steinfeld[1,2]
[1]University of Zurich, Faculty Of Medicine, Zurich, Switzerland, [2]Children's Hospital Zurich, Neurology, Zurich, Switzerland

One of the major obstacle to drug delivery in the central nervous system is the presence of biological barriers like the blood-brain barrier (BBB) or the blood-cerebrospinal fluid barrier (BCSFB). For this reason, there is a research focus on finding strategies to elude these barriers in order to treat CNS disorders. Extracellular vesicles have the ability to carry cargo substances and have thus become a research focus for their potential as therapeutic vehicle. Folate receptor alpha (FRα) is the main transporter of folates to the CNS and can be found on the surface of EVs in the CSF. We have designed FRα-functionalized EV-like vectors for selective gene targeting to the CNS. Using functionalized magnetic beads and flow cytometry, we demonstrated the presence of FRα on the majority of CD9- and CD63-positive EVs in HEK 293 cells that overexpress FRα. This confirmed the coexpression of FRα with EVs marker. Since it was previously reported that overexpression of some EVs markers could have an influence on lentiviral transduction efficiency, we first tested FRα-functionalized lentiviruses *in vitro*. However, FRα did not increase transduction efficiency. Finally, we started to investigate hybridosomes, i.e. lipid nanoparticles conjugated with plasma membranes. Using membrane from FRα-expressing cells, we currently test membrane-enveloped lipid nanoparticles for their *in vitro* and *in vivo* gene-delivery efficiency.

High-grade extracellular vesicles preparation by combined size-exclusion and affinity chromatography.
Extracellular vesicles (EVs) have recently gained growing interest for their diagnostic and therapeutic potential. Despite this, few protocols have been reported for the isolation of EVs with preserved biological function. Most EV purification methods include a precipitation step that results in aggregation of vesicles and most available techniques do not efficiently separate the various types of EVs such as exosomes and ectosomes, which are involved in distinct biological processes. For this reason, we developed a new two-step fast performance liquid chromatography (FPLC) protocol for purification of large numbers of EVs. The method comprises size exclusion chromatography followed by immobilized metal affinity chromatography, which is enabled by expression of poly-histidine tagged folate receptor α in the parental cells. Characterisation and comparison of the EVs obtained by this method to EVs purified by differential centrifugation, currently the most common method to isolate EVs, demonstrated higher purity and more selective enrichment of exosomes in EV preparations using our FPLC method, as assessed by comparison of marker proteins and density distribution. Our studies reveal new possibilities for the isolation of defined subpopulations of EVs with preserved biological function that can easily be upscaled for production of larger amounts of EVs.

MICROGLIAL UPTAKE OF FUNCTIONALIZED NANOTUBES DERIVED FROM BACTERIOPHAGE TAIL SHEATH PROTEIN

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Dovydas Gabrielaitis[1], Lina Saveikytė[1], Greta Labutytė[2], Vida Časaitė[2], Urte Neniskyte[3]
[1]Vilnius University, Department Of Neurobiology And Biophysics, Vilnius, Lithuania, [2]Vilnius University, Department Of Molecular Microbiology And Biotechnology, Vilnius, Lithuania, [3]Vilnius University, Vu-embl Partnership Institute, Life Sciences Center, Vilnius, Lithuania

Aims: Self-assembled protein nanostructures that have been proven to be a suitable media for the deliveryof bioactive materials into the central nervous system. We aimed to show that the internalization mechanism of different protein nanotubes can differ depending on their structure. Methods: We generated two types of chimeric proteins: bacteriophage vB_KleM-RaK2 tail sheath protein 041 fused with GFP (*041-GFP*) and bacteriophage vB_EcoM_FV3 tail sheath protein 053 fused with SNAP-tag (*053-SNAPtag*). These chimeric nanotubes differed in size: *041-GFP* had an average length of 300 nm and a diameter of 44 nm, while *053-SNAPtag* nanotubes had an average length of 100 nm and a diameter of 27 nm. We then tested the mechanism and the efficiency of the internalization of these nanotubes by primary mouse microglia and BV2 cells, using fluorescence microscopy. Results: The treatment of microglia with an inflammatory activator LPS and an actin polymerisation inhibitor cytochalasin D revealed that *041-GFP* nanotubes were taken up via active machinery, while *053-SNAPtag* nanotubes were internalized passively. In addition, we assessed the differences of nanotube uptake efficiency in primary microglia isolated from young adult and aged mice and found no age-related differences. Conclusions: Our findings showed that the internalization mechanism of protein nanotubes into microglia depended on their structures.

Intrinsic anti-Stokes emission in living HeLa cells.
Intrinsic fluorescence of biological material, also called auto-fluorescence, is a well-known phenomenon and has in recent years been used for imaging, diagnostics and cell viability studies. Here we show that in addition to commonly observed auto-fluorescence, intrinsic anti-Stokes emission can also be observed under 560 nm or 633 nm excitation. The anti-Stokes emission is shown to be spatially located on/in the mitochondria. The findings presented here show that sensitive imaging experiments e.g. single molecule experiments or two-photon excitation imaging can be compromised if intracellular anti-Stokes emission is not accounted for. On the other hand, we suggest that this anti-Stokes emission could be exploited as an additional modality for mitochondria visualization and cell viability investigation even in systems that are already labeled with commonly used fluorophores that rely on normal Stokes-based detection.

Functionalized Protein Nanotubes Based on the Bacteriophage vB_KleM-RaK2 Tail Sheath Protein.
We report on the construction of functionalized nanotubes based on tail sheath protein 041 from vB_KleM-RaK2 bacteriophage. The truncated 041 protein (041Δ200) was fused with fluorescent proteins GFP and mCherry or amidohydrolase YqfB. The generated chimeric proteins were successfully synthesized in BL21 (DE3) cells and self-assembled into tubular structures. We detected the fluorescence of the structures, which was confirmed by stimulated emission depletion microscopy. When 041Δ200GFP and 041Δ200mCherry were coexpressed in BL21 (DE3) cells, the formed nanotubes generated Förster resonance energy transfer, indicating that both fluorescent proteins assemble into a single nanotube. Chimeric 041Δ200YqfB nanotubes possessed an enzymatic activity, which was confirmed by hydrolysis of -acetyl-2'-deoxycytidine. The enzymatic properties of 041Δ200YqfB were similar to those of a free wild-type YqfB. Hence, we conclude that 041-based chimeric nanotubes have the potential for the development of delivery vehicles and targeted imaging and are applicable as scaffolds for biocatalysts.

One Thousand and One Software for Proteomics: Tales of the Toolmakers of Science.

FENS Forum 2022
9-13 July 2022 | Paris, France

Proteomics is a highly dynamic field driven by frequent introduction of new technological approaches, leading to high demand for new software tools and the concurrent development of many methods for data analysis, processing, and storage. The rapidly changing landscape of proteomics software makes finding a tool fit for a particular purpose a significant challenge. The comparison of software and the selection of tools capable to perform a certain operation on a given type of data rely on their detailed annotation using well-defined descriptors. However, finding accurate information including tool input/output capabilities can be challenging and often heavily depends on manual curation efforts. This is further hampered by a rather low half-life of most of the tools, thus demanding the maintenance of a resource with updated information about the tools. We present here our approach to curate a collection of 189 software tools with detailed information about their functional capabilities. We furthermore describe our efforts to reach out to the proteomics community for their engagement, which further increased the catalog to >750 tools being about 70% of the estimated number of 1097 tools existing for proteomics data analysis. Descriptions of all annotated tools are available at https://proteomics.bio.tools.

The past three decades have witnessed tremendous research in visual restorative therapies which continue to fuel interest amongst the scientific community globally. Age related macular degeneration (AMD) and retinitis pigmentosa (RP) are among the top untreatable, chronic neurodegenerative retina diseases responsible for debilitating millions of lives. Different therapeutic methods have been investigated, among which electronic retinal prostheses hold the longest period of development. Subretinal approaches show encouraging results for a partial vision enhancement acquired by targeting the residual inner retinal neurons. Recently, nanoparticles made of photovoltaic polymer Poly(3-hexylthiophene-2,5-diyl) (P3HT) have shown to mediate light-evoked firing of retinal neurons and persistently rescue visual functions when subretinally injected in Royal College of Surgeons (RCS) rats, a model of RP. In the current work, we compared the firing modulation of excised dystrophic RCS retinas upon chronic versus acute exposure to the nanomaterials. We investigated the involvement of particle concentration, eye pressure and duration of contact in the phototransduction mechanism driven by nanoparticles. For this purpose, we analyzed the electrophysiological properties of acutely subretinally injected dystrophic retinal explants using nanoparticles at different concentrations. We then compared the acute exposure recordings to the light-evoked firing of retinas explanted from animals that had been subretinally injected with nanoparticles 30 days before. The findings show an enhanced photostimulation owing to prolonged contact of nanoparticles with retinal tissue. These results lead to a deeper understanding of the P3HT nanoparticles interaction with the retinal tissue and open the path towards the development of enhanced prototypes of the “liquid prosthetics”.

Glioblastoma is one of the rarest and most complicated malignancies seeking an efficient clinical solution. Obscuring mechanisms of drug resistance are making it more difficult to treat these malignant tumors effectively. To tackle this issue along with the side effects imposed by drugs on other organs, researchers are turning to phytochemicals. Thymoquinone and curcumin have been widely studied as adjuvants with drugs, for their anti-cancer and sensitizing activities in such malignancies. In this study, we aimed to explore the combinatory effects of these multitargeting phytochemicals. Our preliminary investigations include cytotoxic evaluations using MTT and apoptotic evaluations using fluorescence microscopy. The cytotoxic assay followed by an evaluation of mitochondrial membrane potential shows their anti-cancer activities in U-87 MG (malignant glioma) cells. Further morphological changes seen using the nuclear stain DAPI show the apoptotic activities of the combination, which will be further delved into, in our future studies. Keywords: Anti-cancer, Curcumin, Glioblastoma, Thymoquinone, Phytochemical

Gadolinium-based bimodal probes to enhance T1-Weighted magnetic resonance/optical imaging.
Gd-based contrast agents have been extensively used for signal enhancement of T-weighted magnetic resonance imaging (MRI) due to the large magnetic moment and long electron spin relaxation time of the paramagnetic Gd ion. The key requisites for the development of Gd-based contrast agents are their relaxivities and stabilities which can be achieved by chemical modifications. These modifications include coordinating Gd with a chelator such as diethylenetriamine pentaacetic acid (DTPA) or 1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA), encapsulating Gd in nanoparticles, conjugation to biomacromolecules such as polymer micelles and liposomes, or non-covalent binding to plasma proteins. In order to have a coherent diagnostic and therapeutic approach and to understand diseases better, the combination of MRI and optical imaging (OI) techniques into one technique entity has been developed to overcome the conventional boundaries of either imaging modality used alone through bringing the excellent spatial resolution of MRI and high sensitivity of OI into full play. Novel MRI and OI bimodal probes have been extensively studied in this regard. This review is an attempt to shed some light on the bimodal imaging probes by summarizing all recent noteworthy publications involving Gd containing MR-optical imaging probes. The several key elements such as novel synthetic strategy, high sensitivity, biocompatibility, and targeting of the probes are highlighted in the review. STATEMENT OF SIGNIFICANCE: The present article aims at giving an overview of the existing bimodal MRI and OI imaging probes. The review structured as a series of examples of paramagnetic Gd ions, either as ions in the crystalline structure of inorganic materials or chelates for contrast enhancement in MRI, while they are used as optical imaging probes in different modes. The comprehensive review focusing on the synthetic strategies, characterizations and properties of these bimodal imaging probes will be helpful in a way to prepare related work.

Stroke is one of the major causes of death and long-term disability in the world, with a huge economic and social impact. Stroke survivors remain with major disabilities since there are no therapeutic options to protect neurons and promote regeneration. Therefore, there is an urgent need to develop new therapies to mitigate the extension of stroke damage. Nanotechnology has gained relevance in this field since nanobiomaterials are promising delivery platforms of potential therapeutics to the brain, increasing their blood stability and brain bioavailability. Currently, zebrafish is classified as an alternative animal model to the classic mammalian ones. Its widespread acceptance for drug screening has increased due to the high genome similarity to human's, high-fertility, low-cost and easy maintenance. Here we describe the establishment and optimization of an adapted stroke model in the adult zebrafish. A focal ischemic brain model, close to what happens in clinics, is being attained by photo-thrombolysis in adult zebrafish. Neuronal apoptosis and neurodegeneration after ischemia is under analysis. Neurological outcome analysis is also being evaluated by monitoring behaviour. Pilot experiments performed to determine the infarcted area using micro-CT, showed the clear visualization of the brain damaged area using several contrast agents. The neurodegeneration in the affected area has been determined by immunofluorescence assays, with apoptotic, glial and neuronal markers, showing apoptosis close to the occlusion site. Overall, this model is expected to open new avenues towards the assessment of the most promising and recent nanobiocarriers to deliver neuroprotective agents after an ischemic stroke.

Breaking Barriers: Bioinspired Strategies for Targeted Neuronal Delivery to the Central Nervous System.
Central nervous system (CNS) disorders encompass a vast spectrum of pathological conditions and represent a growing concern worldwide. Despite the high social and clinical interest in trying to solve these pathologies, there are many challenges to bridge in order to achieve an effective therapy. One of the main obstacles to advancements in this field that has hampered many of the therapeutic strategies proposed to date is the presence of the CNS barriers that restrict the access to the brain. However, adequate brain biodistribution and neuronal cells specific accumulation in the targeted site also represent major hurdles to the attainment of a successful CNS treatment. Over the last few years, nanotechnology has taken a step forward towards the development of therapeutics in neurologic diseases and different approaches have been developed to surpass these obstacles. The versatility of the designed nanocarriers in terms of physical and chemical properties, and the possibility to functionalize them with specific moieties, have resulted in improved neurotargeted delivery profiles. With the concomitant progress in biology research, many of these strategies have been inspired by nature and have taken advantage of physiological processes to achieve brain delivery. Here, the different nanosystems and targeting moieties used to achieve a neuronal delivery reported in the open literature are comprehensively reviewed and critically discussed, with emphasis on the most recent bioinspired advances in the field. Finally, we express our view on the paramount challenges in targeted neuronal delivery that need to be overcome for these promising therapeutics to move from the bench to the bedside.

PAMAM dendrimers: blood-brain barrier transport and neuronal uptake after focal brain ischemia.
Drug delivery to the central nervous system is restricted by the blood-brain barrier (BBB). However, with the onset of stroke, the BBB becomes leaky, providing a window of opportunity to passively target the brain. Here, cationic poly(amido amine) (PAMAM) dendrimers of different generations were functionalized with poly(ethylene glycol) (PEG) to reduce cytotoxicity and prolong blood circulation half-life, aiming for a safe in vivo drug delivery system in a stroke scenario. Rhodamine B

isothiocyanate (RITC) was covalently tethered to the dendrimer backbone and used as a small surrogate drug as well as for tracking purposes. The biocompatibility of PAMAM was markedly increased by PEGylation as a function of dendrimer generation and degree of functionalization. The PEGylated RITC-modified dendrimers did not affect the integrity of an in vitro BBB model. Additionally, the functionalized dendrimers remained safe when in contact with the bEnd.3 cells and rat primary astrocytes composing the in vitro BBB model after hypoxia induced by oxygen-glucose deprivation. Modification with PEG also decreased the interaction and uptake by endothelial cells of PAMAM, indicating that the transport across a leaky BBB due to focal brain ischemia would be facilitated. Next, the functionalized dendrimers were tested in contact with red blood cells showing no haemolysis for the PEGylated PAMAM, in contrast to the unmodified dendrimer. Interestingly, the PEG-modified dendrimers reduced blood clotting, which may be an added beneficial function in the context of stroke. The optimized PAMAM formulation was intravenously administered in mice after inducing permanent focal brain ischemia. Twenty-four hours after administration, dendrimers could be detected in the brain, including in neurons of the ischemic cortex. Our results suggest that the proposed formulation has the potential for becoming a successful delivery vector for therapeutic application to the injured brain after stroke reaching the ischemic neurons.

Neurological diseases represent the highest global burden of disease, with stroke being the biggest contributor. For most neurological diseases there are no available treatments available that can improve neuronal survival. Recently, gene therapy has been proposed as a powerful therapeutic tool to promote neuronal repair and regeneration. Moreover, major advancements in targeted gene therapy have opened avenues for the treatment of these diseases. However, the success of this therapeutic option relies on the development of effective and clinically suitable delivery vectors that are able to compact and protect nucleic acids (NAs). Dendrimers are promising carriers due to their globular, nanosize and very branched architecture, with several functional groups in the periphery, which allow their functionalization with different ligands simulating the multivalency of biological systems. Here, we explored a neurotargeted NA delivery nanosystem based on our PEG-GATGE dendrimers functionalized with the non-toxic HC fragment of the tetanus toxin. Dendriplexes (complexes of dendrimers and NA) were prepared at different N/P ratios by adding Cy5-siRNA to different volumes of dendrimer solution. The trafficking of this nanosystem was evaluated in two-chamber microfluidic devices with compartmentalized cultures of primary mouse cortical neurons (Fig 1). The device allowed to mimic the bio-interaction between nanosystem and neurons and to monitor of the intracellular trafficking of dendriplexes. Furthermore, targeting proprieties were also evaluated. The encouraging retrograde intracellular route of dendriplexes, make them a great promise to be the long-awaited therapeutic strategy for many diseases, not only as NAs delivery vector but also for other

cargoes.

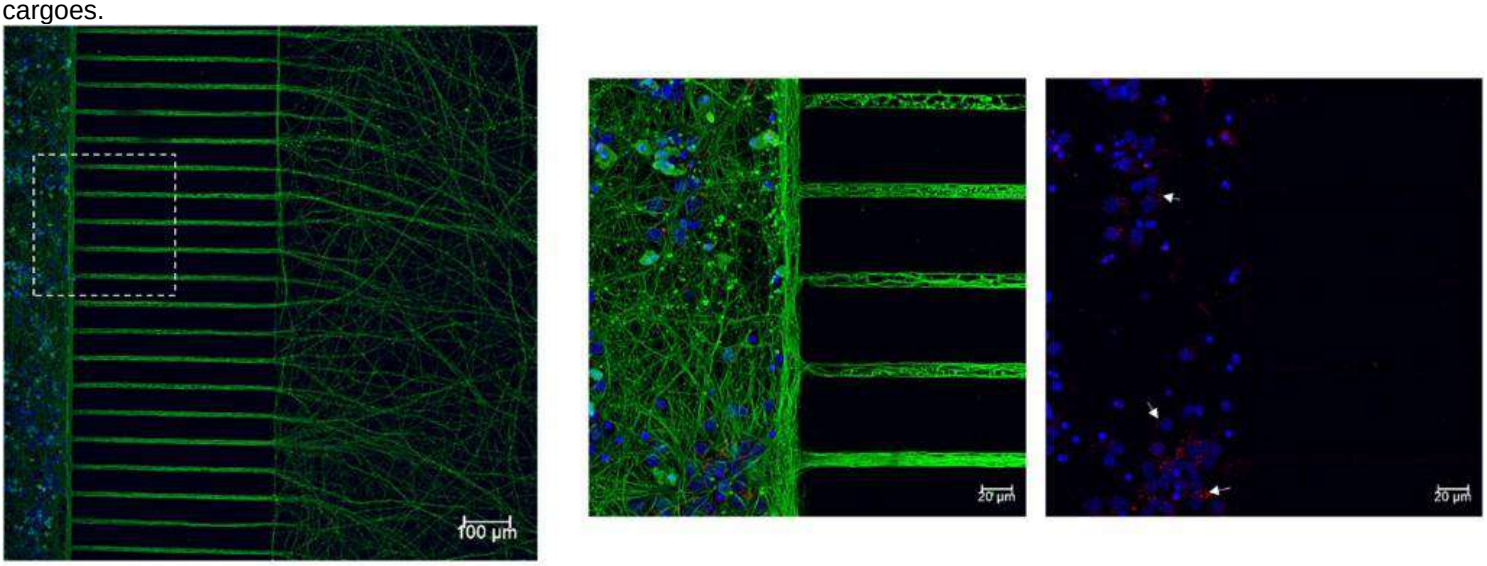

Figure 1. Dendriplexes' trafficking assessment set-up in primary cortical neurons. Cortical neurons were seeded in a two-chamber microfluidic device. At DIV5, N/P 5 dendriplexes were added on the terminal side (right) and movement assessed by confocal microscopy (for 20 hours). After a 48-h incubation, cells were fixed and analysed. After this period, dendriplexes were mainly located in the cell bodies of neurons. Staining: Nuclei with Hoechst 33342 (in blue), βIII-tubulin (in green), and Cy5-siRNAmi dendriplexes (in red).

Versatile fully biodegradable dendritic nanotherapeutics.
The repeated administration of non-degradable dendrimers can lead to toxicity due to their bioaccumulation. Furthermore, in drug delivery applications, carrier stability can result in low biological performance due to insufficient intracellular cargo release. A novel family of versatile, biosafe, water-soluble, and fully biodegradable PEG-dendritic nanosystems is proposed, which overcomes the limitations of the most used dendrimers. Their novelty relies on the full and adjustable degradability thanks to the presence of tunable ester bonds in every dendritic arm. These dendritic nanosystems present peripheral azides that allow their easy multivalent functionalization, by "click" chemistry, with a vast range of ligands to act as versatile carriers. Here, their amine-functionalization to serve as nucleic acid vectors for gene therapy is explored. These nanosystems complex and protect efficiently siRNA in very small dendriplexes (<60 nm), being successfully cell-internalized, including in hard-to-transfect neuronal cells even when in full tissue explants (dorsal root ganglia). Importantly, full biodegradability was crucial for an efficient nucleic acid intracellular release and the attainment of excellent transfection efficiencies. The reported fully biodegradable dendritic nanosystems can act as multi-function nanotherapeutics for gene therapy, and also for broader applications in nanomedicine. Therefore, they represent top-notch and clinically translatable health facilitating nanotechnologies for further developments in theranostics.

Data-Driven Modeling of the Cellular Pharmacokinetics of Degradable Chitosan-Based Nanoparticles.
Nanoparticle drug delivery vehicles introduce multiple pharmacokinetic processes, with the delivery, accumulation, and stability of the therapeutic molecule influenced by nanoscale processes. Therefore, considering the complexity of the multiple interactions, the use of data-driven models has critical importance in understanding the interplay between controlling processes. We demonstrate data simulation techniques to reproduce the time-dependent dose of trimethyl chitosan nanoparticles in an ND7/23 neuronal cell line, used as an in vitro model of native peripheral sensory neurons. Derived analytical expressions of the mean dose per cell accurately capture the pharmacokinetics by including a declining delivery rate and an intracellular particle degradation process. Comparison with experiment indicates a supply time constant, $\tau = 2$ h. and a degradation rate constant, $b = 0.71$ h. Modeling the dose heterogeneity uses simulated data distributions, with time dependence incorporated by transforming data-bin values. The simulations mimic the dynamic nature of cell-to-cell dose

variation and explain the observed trend of increasing numbers of high-dose cells at early time points, followed by a shift in distribution peak to lower dose between 4 to 8 h and a static dose profile beyond 8 h.

Fine tuning neuronal targeting of nanoparticles by adjusting the ligand grafting density and combining PEG spacers of different length.
Poly(ethylene glycol) (PEG) has been extensively used to coat the surface of nanocarriers to improve their physicochemical properties and allow the grafting of targeting moieties. Still, to date there is no common agreement on the ideal PEG coverage-density or length to be used for optimum vector performance. In this study, we aimed to investigate the impact of both PEG density and length on the vectoring capacity of neuron-targeted gene-carrying trimethyl chitosan nanoparticles. The non-toxic fragment from the tetanus toxin (HC) was coupled to a 5 kDa heterobifunctional PEG (HC-PEG) reactive for the thiol groups inserted into the polymer backbone and grafted at different densities onto the nanoparticles. Internalization and transfection studies on neuronal versus non-neuronal cell lines allowed to determine the PEG density of 2 mol% of PEG chains per mol of primary amine groups as the one with superior biological performance. To enhance HC exposure and maximize cell-nanoparticle specific interaction, NPs containing different ratios of HC-PEG and 2 kDa methoxy-PEG at the same grafting density were produced. By intercalating HC-PEG with methoxy-PEG we attained the best performance in terms of internalization (higher payload delivery into cells) and transfection efficiency, using twice lower amount of HC. This outcome highlights the need for fine-tuning of PEG-modified nanoparticles towards the achievement of optimal targeting.

Biodegradable PEG-dendritic block copolymers: synthesis and biofunctionality assessment as vectors of siRNA.
One important drawback of most of the currently used dendrimers for biomedical applications is their high stability under physiological conditions that can result in cytotoxicity or complications induced by the accumulation of non-degradable synthetic materials in the organism. Particularly in the gene therapy field, vector stability can further hinder the intracellular release of the nucleic acid from the dendriplex, consequently leading to low transfection efficiencies. Therefore, biodegradable cationic dendritic structures have been eagerly awaited. However, the development of these dendritic nanocarriers is challenging because of the undesired and/or premature degradation observed during their synthesis and/or application. Here, we report new hybrid-biodegradable, biocompatible, non-toxic, and water-soluble azide-terminated PEG-GATGE dendritic block copolymers, based on a gallic acid (GA) core and triethylene glycol (TG) butanoate arms, incorporating ester bonds (E) at the dendritic arms/shell. Their successful functionalization by "click" chemistry with unprotected alkynated amines allowed complexation and delivery of siRNA. The hydrophobic character of the GATGE building unit confers to these hydrolyzable dendritic bionanomaterials a great ability to complex, protect and mediate the cellular internalization of siRNA. Moreover, the localization of the degradation points at the dendritic periphery, close to the complexed siRNA, was found to be important for nucleic acid release from the nanoparticles, rendering a significant improvement of the transfection efficiency compared to their hydrolytically stable PEG-GATG copolymer counterparts. The present study puts forward these biodegradable PEG-dendritic block copolymers not only as suitable vectors for nucleic

acids, but also as new avenues for further developments exploring their use in theranostics.

DRUG LIPID NANO-CARRIERS ENTER THE INJURED BRAIN AT MICROVASCULAR OCCLUSIONS

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Igor Khalin[1], Severin Filser[1], Antonia Wehn[1], Martina Schifferer[2], Andrey Klymchenko[3], Nikolaus Plesnila[1]
[1]Klinikum Der Universitat Muenchen, Institute For Stroke And Dementia Research, Muenchen, Germany, [2]German Center for Neurodegenerative Diseases, Munich,, Nanosclae Hub, Muenchen, Germany, [3]University of Strasbourg, Laboratory De Biophotonique Et Pharmacologie, University Of Strasbourg, Illkirch, France

Background: Targeting drugs to the CNS is difficult because of the blood-brain-barrier (BBB). Nano carriers (NC) may represent an option for drug delivery to the brain provided the understand the underlying mechanisms are clear in detail. **Aim.** To directly visualize whether and how individual NCs cross the blood-brain barrier (BBB) under various pathological conditions *in vivo*. **Methods.** Super-bright fluorescent lipid nanodroplets (SBFLnDs; diameter: 30 and 80 nm) were loaded with a counterion-coupled rhodamine dye or with two dyes, F888 and cyanine-3.5, undergoing Förster Resonance Energy Transfer (FRET). SBFLnDs were injected systemically into mice following brain trauma or ischemic stroke and visualized by *in vivo* by 2-photon, confocal microscopy or correlative light-electron microscopy (CLEM). **Results.** Shortly after brain injury microvascular occlusions (VO) formed within the cerebral microcirculation. SBFLnDs accumulated within VOs in still viable brain tissue, crossed the BBB, and entered the brain parenchyma reaching healthy neurons. 30 nm NCs passed the opened BBB more readily than 80 nm NCs. CLEM revealed that NCs crossed the BBB at microvascular clots via endothelial transcytosis. Using FRET NCs we were able to demonstrate that NCs did not decompose in blood but in the brain parenchyma and inside clots implicating specific targeting in brain diseases accompanied with microthrombosis. **Conclusion**. The current study demonstrates that NC accumulate and enter the injured brain at sites of VOs. Thus, VOs function as a size-selective gate to the brain. Taking advantage of this process may pave the way for novel drug-delivery approach for brain disorders.

Electrical cochlear (eCI) implants provide hearing restoration to individuals with profound sensorineural hearing loss by direct electrical stimulation of spiral ganglion neurons (SGNs). To overcome wide-spread electrical neural excitation in eCIs, optogenetic stimulation of SGNs provides an alternative to address limitations current eCI users experience. For the translation of this promising technology, it is critical to select channelrhodopsins (ChR) with fast kinetics, large photocurrents, and low desensitization; in order to maintain the temporal characteristics of physiological sound encoding in the cochlea. Here we evaluate the optogenetic utility of ChR mutants recently engineered for optogenetic stimulation of SGNs (ChR2-, Chronos- and ChRmine- mutants), in mice. Adeno-associated-virus (AAV) carrying transgene ChR-variants under the human synapsin promotor were injected into the round window of neonatal mice (postnatal day 6). Six to thirteen weeks after injections, a laser-coupled fiber (573nm) was inserted into the round window to measure optically evoked auditory brainstem responses (oABRs). Subsequently, the cochleae were extracted for immunohistological analysis by confocal and lightsheet microscopy to evaluate the number of transduced cells as well as membrane expression profiles. Preliminary data sets of seven animals, each injected with a promising ChR2-mutant, show high oABR amplitudes in the range of 8 to 15µV during optical stimulations of 1ms at a 10Hz stimulation rate. Hence, our findings suggest a potential of the novel ChR mutants for optogenetic applications such as in auditory research and future optogenetic cochlear implants.

Intronic CRISPR Repair in a Preclinical Model of Noonan Syndrome-Associated Cardiomyopathy.
Noonan syndrome (NS) is a multisystemic developmental disorder characterized by common, clinically variable symptoms, such as typical facial dysmorphisms, short stature, developmental delay, intellectual disability as well as cardiac hypertrophy. The underlying mechanism is a gain-of-function of the RAS-mitogen-activated protein kinase signaling pathway. However, our understanding of the pathophysiological alterations and mechanisms, especially of the associated cardiomyopathy, remains limited and effective therapeutic options are lacking.

Neuronal ceroid lipofuscinoses (NCL) are a group of neurodegenerative disorders characterized by mutations in fourteen genes (CLN1 to CLN14) with still unknown regarding the roles and functions of some of those genes. During the last decade, the development of disease modelling and high-throughput or high-content screening approaches focused on the identification of new NCL treatments resulted in a substantial accumulation of knowledge. Extracting relevant information regarding drug-gene co-occurrence in literature, using automated techniques might be a novel and cost-effective approach, to the identification and development of new treatments. We used a set of non-redundant 2,880 FDA and EMA-approved compounds, and a text mining tool with the PubMed database. This study is part of NeuroLead project. Among the 2,880 compounds, 2005 are FDA-approved drugs, and 875 EMA-approved. 1867 compounds were found on PubChem and selected for further analysis, through the PubMed requesting of abstracts and titles including the name of the drugs and one of the 14 CLN genes. Abstracts were further selected based on the presence of sentences with both include at least one these genes and one of the 1867 selected compounds. 6 of the 14 genes were not associated with any of the selected compounds. Moreover, a range between 2 and 40 molecules was associated with the 8 remaining genes. This study is a proof-of-concept of text mining approach to investigate a large corpus of gene-drug associations in genetic disorders. Further in silico and experimental investigations are necessary to assess more precisely the therapeutic potential of these drugs.

AIMS: Notable death/disability is due to different types of neurodegenerative disorders. A viable strategy is needed for large scale MRI analysis and for investigating how different brain regions show diverging sensitivity/resistance to neurodegenerative changes during aging. Hence, we will adopt MRI/immunohistochemistry/genomic analysis of that region to probe causative factors/targets and potential drugs. **METHODS: MRI Analysis:** We selected well-segregated cerebellum from cerebral hemispheres. This study consolidates 177 normal subjects (20-90 years) under Philips 3T-scanning. FDT-FSL, TBSS, Track-Vis Analysis used. **Genomics Analysis:** We analyzed collateral available human brain proteomics profile of Mass-spectrometry to identify neuroprotective genes in cerebellum. We identified 26 significantly regulated genes using signal transduction and pathway enrichment analysis. Afterward, DGIdb and cytological analysis facilitated the identification of candidate drugs for neuroprotection. **RESULTS: MRI Analysis:** The Grey Matter volume of cerebellum remains steady across lifetime (p=0.22), cerebellar White Matter volume increases notably (p=0.003), and cerebellar White Matter's Fractional Anisotropy remains constant (p=0.06). These cerebellar behaviors starkly contrast to cerebral hemispheres during aging. **Genomics Analysis:** The predicted upregulated target gene (and corresponding drugs) that can enhance neuronal growth and plasticity are: (i) Glycoprotein of Immunoglobulin superfamily gene (drugs: Flavanone-glycoside derivative - suppresses amyloid-β, $p<0.01$), and (ii) Transitional endoplasmic-reticulum ATPase gene (drugs: noradrenaline-serotonin transporter-modulators, $p<0.01$). Moreover, some genes are downregulated to prevent excessive protein synthesis (corresponding drug: guanidine derivative that inhibits production of Reactive oxygen-species, $p<0.01$). Collateral empirical clinical trials furnishes validation of the proposed pharmacological agents. **CONCLUSIONS:** Radio-genomics is a simple, low-cost technology for repurposing neuroprotective drugs with clinical validation.

AAV BIODISTRIBUTION IN THE MOUSE BRAIN AND PERIPHERY: EFFECTS OF CAPSID AND ROUTE OF ADMINISTRATION

POSTER SESSION 07 - SECTION: FUNCTIONAL NEUROGENOMICS & THERAPEUTICS

Astrid Mentani, Celine Fournier, Marco Bruestle, Nicole Hellbach, Eva Harde
F. Hoffmann-La Roche Ltd, Pharma Research And Early Development / Neuroscience And Rare Diseases, Basel, Switzerland

Adeno-associated viruses (AAVs) are leading the platform for in vivo delivery of gene therapy in the central nervous system (CNS). However, efficient crossing of the blood brain barrier (BBB) is required for systemically administered AAVs to reach the CNS. In the last few years, several studies have shown the ability of AAV9 and AAV-PHP.eB serotypes to pass the BBB and to transduce CNS neurons with different efficiency. Here, we assessed gene expression of AAV9 and AAV-PHP.eB capsids using the reporter gene eGFP in CNS and liver in wild-type mice. For this purpose, we injected AAV9 stereotactically in the brain ventricles, while AAV-PHP.eB was administered systemically in the tail vein. We quantified eGFP expressing neurons in the cortex, midbrain and hippocampus. The histological assessment was complemented by viral genome (v.g.) copy number determination studies and mRNA quantification. Systemically delivered AAV-PHP.eB produces more homogenous CNS expression in cortex, hippocampus and cerebellar nuclei than intracerebroventricular injected AAV9, where eGFP is expressed only in the proximity of the injection site. In AAV-PHP.eB-injected mice, v.g. determination studies show dose-dependent increase of viral DNA and mRNA levels. This is reflected by a dose-dependent increase of eGFP signal intensity per cell. Interestingly, the number of transduced neurons is similar across AAV doses. Moreover, AAV9 shows strong liver expression although administered locally into the brain. All together, these data indicate the pivotal role of the choice of AAV capsid and route of administration in the design of CNS-targeting gene therapy approaches.

Human prion diseases are fatal neurodegenerative disorders that include sporadic, infectious and genetic forms. Inherited *Creutzfeldt-Jakob* disease due to the E200K mutation of the prion protein-coding gene is the most common form of genetic prion diseases. The phenotype resembles that of sporadic Creutzfeldt-Jakob disease at both the clinical and pathological levels. To date, there is no available treatment for delaying the occurrence or slowing the progression of human prion diseases. Existing *in vivo* models do not allow high-throughput approaches that may facilitate the discovery of compounds targeting pathological assemblies of human prion protein (PrP) or their effects on neuronal survival. Here, we generated a genetic model in *C. elegans* by expressing human isoform with the E200K mutation in the mechanosensitive neuronal system. Expression of E200K PrP induced specific behavioural pattern and neurodegeneration of GFP-expressing mechanosensitive neurons, in addition to the formation of intraneuronal inclusions associated with the accumulation of a protease-resistant form of the PrP. We demonstrated that this experimental system is a powerful tool to study the efficacy of anti-prion compounds on both prion-induced neurodegeneration and prion protein misfolding, moreover in a human PrP context. Within a library of 320 compounds approved for human use and crossing the blood-brain-barrier, we identified five molecules that were active against the aggregation of E200K PrP and the neurodegeneration it induced in transgenic animals. This model breaks a technological limitation in prion therapeutic research and provides a key tool to study the deleterious effect of misfolded PrP in a well-described neuronal system.

NEUROIMMUNE ACTIVATION OF THE OLFACTORY BULB IS REGULATED BY TIME OF DAY

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Gregory Pearson, Brennan Falcy, Jiexin Wang, Said Akli, Ilia Karatsoreos
University of Massachusetts Amherst, Department Of Psychological And Brain Sciences, Amherst, United States of America

Aims: Given its proximity to the nasal cavity, the olfactory bulb (OB) must generate robust neuroimmune responses to defend against neurotropic pathogens. The circadian (daily) clock primes cells and tissues to anticipate physiologically relevant environmental changes. Given that the circadian system regulates inflammation and immune responses, we hypothesized that daily changes in OB neuroinflammatory state would differentially "prime" responses to an intranasal inflammatory challenge. Aim 1 probed the OB's neuroinflammatory transcriptional profile throughout the day. Aim 2 was to determine how time of day of an intranasal inflammatory challenge influences the transcriptional and cellular responses within the OB. **Methods:** For Aim 1, OBs were isolated from male mice at 8 times of day (*n* = 3 mice/time). Transcriptional profiles of OBs were assessed using a NanoString Murine nCounter Neuroinflammation Panel. For Aim 2, we intranasally challenged mice at different times of day with Poly(I:C). We then measured transcriptional and cellular responses within the OB using the nCounter Neuroinflammation Panel and imaging flow cytometry, respectively. **Results:** We report that mRNA transcripts within the gene sets of microglia function, inflammatory signaling, and innate immune response were among the most differentially regulated by time of day. Further, we observed upregulated expression of mRNA transcripts involved in virus detection, type I interferon response, and chemotaxis at the beginning of the active phase. **Conclusions:** The circadian clock primes the OB's response to intranasal inflammatory stimuli differently depending on time of day of exposure, potentially providing an important gating mechanism underlying differential susceptibility to neurotropic pathogens.

Circadian desynchronization alters metabolic and immune responses following lipopolysaccharide inoculation in male mice. Metabolism and inflammation are linked at many levels. Sickness behaviors are elicited by the immune system's response to antigenic stimuli, and include changes in feeding and metabolism. The immune system is also regulated by the circadian (daily) clock, which generates endogenous rhythms, and synchronizes these rhythms to the light-dark cycle. Modern society has resulted in chronic misalignment or desynchronization of the circadian clock and the external environment. We have demonstrated that circadian desynchronization (CD) in mice alters metabolic function, and also affects both peripheral and central immune responses following a low-dose lipopolysaccharide (LPS) challenge. However, it is unclear how this altered immune response impacts sickness behaviors and metabolism following challenge. To test this, we housed male mice in circadian desynchronized (10-hours light:10-hours dark) or control (12-hours light:12-hours dark) conditions for 5-6 weeks. We then challenged mice with LPS (i.p., 0.4 mg/kg) or PBS and measured changes in body mass, feeding, drinking and locomotion using a comprehensive phenotyping system. Plasma, liver, and brain were collected 36 h post-inoculation (hpi) and inflammatory messengers were measured via multiplex cytokine/chemokine array and qPCR. We find that recovery of locomotion and body mass is prolonged in CD mice following LPS challenge. Additionally, at 36 hpi the expression of several proinflammatory cytokines differ depending on pre-inoculation lighting conditions. Our findings add to the growing literature which documents how desynchronization of circadian rhythms can lead to disrupted immune responses and changes in metabolic function.

EXPERIMENTAL ARTHRITIS INHIBITS ADULT HIPPOCAMPAL NEUROGENESIS IN MICE

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Boldizsár Czéh[1], Kitti Rusznák[1], Ádám Horváth[2], Kinga Pohli-Tóth[1], Anett Futácsi[1], Ágnes Kemény[2], Gabriella Kiss[3], Zsuzsanna Helyes[2]

BACKGROUND: Neuroinflammation inhibits adult neurogenesis, but the effect of peripheral inflammation on this form of neuroplasticity is ambiguous. **AIMS:** Our aim was to investigate the influence of acute and chronic experimental arthritis on adult hippocampal neurogenesis and to elucidate putative regulatory mechanisms. **METHODS**: Arthritis was triggered by injection of complete Freund's adjuvant (CFA) to the hind paws of male mice. Animals were killed either 7 days (acute inflammation), or 21 days (chronic inflammation) after CFA injection. Behavioral tests, in vivo bioluminescence imaging, complete blood cell counts and measurements of cytokine concentrations of TNF-α, IL-1α, IL-4, IL-6, IL-10, KC and MIP-2 were carried out to characterize the inflammatory responses. In the dentate gyrus, the total number of newborn neurons were quantified with BrdU- and doublecortin-immunohistochemistry. Microglial activation was determined by quantifying Iba1- and CD68-positive cells. **RESULTS**: Both acute and chronic arthritis resulted in mechanical and thermal hyperalgesia, phagocytic infiltration and increased levels of TNF-α, IL-4, IL-6, KC and MIP-2 in the inflamed hind paws. Circulating neutrophil granulocytes and IL-6 levels were increased in the blood, but only in the acute phase. In the dentate gyrus, chronic arthritis reduced the number of doublecortin-positive cells and we found increased density of CD68-positive macrophages both in the acute and chronic phases. Cytokine levels however were not altered in the hippocampus. **CONCLUSIONS**: Our data suggests that acute peripheral inflammation initiates a cascade of molecular and cellular changes that eventually leads to reduced adult hippocampal neurogenesis, which was detectable only in the chronic inflammatory phase.

TEMPORAL DYNAMICS OF LYMPHOCYTE DISTRIBUTION IN THE BRAIN DURING POSTNATAL DEVELOPMENT

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Danillo Dantas, Luciana Conde, Rosália Mendez-Otero, André Vale, Pedro Pimentel-Coelho
Universidade Federal Do Rio De Janeiro, Instituto De Biofísica Carlos Chagas Filho, Rio de Janeiro, Brazil

The concept of brain immunoprivilege has been revised with the findings of the presence of lymphocytes in the brain. Furthermore, the characterization of the meningeal lymphopoietic niche has raised interest in the importance of these cells for brain functioning and immunosurveillance. However, little is known about how and when lymphocytes begin to populate the brain. The aim of this study was to characterize the presence of B and T lymphocyte cells during murine brain development and to identify their location in relation to blood vessels. C57BL/6 mice aged P0 (day of birth), P3, and P14 were used, as well as 3-month-old young adult mice of both sexes. Antibodies to CD3 and CD45R were used to identify T and B cells, respectively. Laminin was used as a marker of blood vessels. Different regions of the mouse brain were evaluated by immunofluorescence and confocal microscopy. Flow cytometry was used to characterize the lymphocyte populations in a BD LSR Fortessa flow cytometer. All experiments were approved by the Animal Ethics Committee (protocol CEUA/CCS-UFRJ 080/17). B cells were present since P0 until adulthood when their numbers decreased significantly in all analyzed regions. In contrast, there were fewer T cells during early postnatal development in comparison to the adult brain. We found T and B cells associated with the vessels, but also some T cells in the brain parenchyma. Flow cytometry results are in progress. Lymphocyte distribution is dynamic during brain development and essentially associated with blood vessels in different brain regions.

Intracerebral Injection of Heme Induces Lipid Peroxidation, Neuroinflammation, and Sensorimotor Deficits.
Heme is a red blood cell component released in the brain parenchyma following intracerebral hemorrhage. However, the study of the pathophysiological mechanisms triggered by heme in the brain is hampered by the lack of well-established in vivo models of intracerebral heme injection. This study aims to optimize and characterize a protocol of intrastriatal heme injection in mice, with a focus on the induction of lipid peroxidation, neuroinflammation and, ultimately, sensorimotor deficits. We also evaluated the involvement of NLRP3 (NOD-, LRR-, and pyrin domain-containing protein 3), an inflammasome sensor, in the behavior deficits induced by heme in this model.

EFFECTS OF VTA ACTIVATION ON THE RECOVERY PROCESS FOLLOWING MYOCARDIAL INFARCTION

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Hedva Haykin, Maria Krot, Asya Rolls, Lior Gepstein, Eden Avishai
Technion Israel Institute of Technology, Rappaport Faculty Of Medicine, Haifa, Israel

Background: Epidemiological data indicate a correlation between negative emotional state as depression or stress, to increased incidence of acute cardiovascular events as myocardial infarction (MI) with worst mortality rates and consequent comorbidities. Consistently, positive emotional state practices as meditation or stress reduction correlated with cardiovascular health and reduced mortality and hospitalization following MI. However, it is unknown how the emotional state influences the recovery process following MI. While some patients regain much of their cardiac function and maintain good overall health, others will go on to develop complications, such as heart failure. To approach emotional state in the animal model we choose to focus on a specific network, the reward system, which mediates positive-valanced emotions, motivation, and expectation. Here we test whether and how activation of the ventral tegmental area (VTA), a main component of the reward system, affects recovery following MI. **Results:** VTA activation in mice enhanced recovery following MI and prevented the additional 20% decrease in cardiac function normally observed. VTA activation reduced the area occupied by non-contractile scar tissue and amplified cardiac vascularization. Proteomic analysis revealed that reward system activation induced a systemic response including complement activation and metabolic processes, which were previously correlated with a favorable recovery from MI. **Conclusion:** VTA activation improves cardiac function following MI characterized by diverse adaptive recovery processes and potentially an orchestrated systemic response. These pre-clinical data introduce a novel therapeutic approach to enhance cardiac recovery and potentially prevent comorbid conditions from occurring.

The neuroimmune response during stress: A physiological perspective.
Stress is an essential adaptive response that enables the organism to cope with challenges and restore homeostasis. Different stressors require distinctive corrective responses in which immune cells play a critical role. Hence, effects of stress on immunity may vary accordingly. Indeed, epidemiologically, stress can induce either inflammation or immune suppression in an organism. However, in the absence of a conceptual framework, these effects appear chaotic, leading to confusion. Here, we examine how stressor diversity is imbedded in the neuroimmune axis. Stressors differ in the brain patterns they induce, diversifying the neuronal and endocrine mediators dispatched to the periphery and generating a wide range of potential immune effects. Uncovering this complexity and diversity of the immune response to different stressors will allow us to understand the involvement of stress in pathological conditions, identify ways to modulate it, and even harness the therapeutic potential embedded in an adaptive response to stress.

Insular cortex neurons encode and retrieve specific immune responses.
Increasing evidence indicates that the brain regulates peripheral immunity, yet whether and how the brain represents the state of the immune system remains unclear. Here, we show that the brain's insular cortex (InsCtx) stores immune-related information. Using activity-dependent cell labeling in mice (Fos), we captured neuronal ensembles in the InsCtx that were active under two different inflammatory conditions (dextran sulfate sodium [DSS]-induced colitis and zymosan-induced peritonitis). Chemogenetic reactivation of these neuronal ensembles was sufficient to broadly retrieve the inflammatory state under which these neurons were captured. Thus, we show that the brain can store and retrieve specific immune responses, extending the classical concept of immunological memory to neuronal representations of inflammatory information.

Aims: *Corpora amylacea* of human brain, recently renamed wasteosomes, are granular structures that appear during aging and also accumulate in specific areas of the brain in neurodegenerative conditions. Acting as waste containers, wasteosomes are formed by polyglucosan aggregates that entrap waste substances of different origins, are expelled from the brain to the cerebrospinal fluid (CSF), and are thereafter phagocytosed by macrophages. In the present study, we analyze the mechanisms involved in this last process. **Methods:** We purified wasteosomes from human CSF and incubated them with THP-1 macrophages. Immunofluorescence staining techniques were later performed to evaluate the mechanisms involved in their phagocytosis. We also immunostained human hippocampal sections to study the interactions between wasteosomes and macrophages at central nervous system interfaces. **Results:** The phagocytosis by THP-1 macrophages can be triggered through the CD206 and the CD35 receptors, but not the FAIM3 receptor, whereas all these receptors may be involved, *in vivo*, in the phagocytosis of wasteosomes at the central nervous system interfaces or beyond. Moreover, we observed that the wasteosomes obtained from the CSF are opsonized by MBL and the complement protein C3b, and can also contain mannose or other targets of CD206. **Conclusions:** Our findings indicate that, *in vivo*, different mechanisms can be involved in the phagocytosis of wasteosomes, some of them triggering non-inflammatory responses and avoiding tissue damage. Altogether supports the role of the immune system in the elimination of wasteosomes.

DISRUPTION OF HIPPOCAMPUS-BASED SPATIAL CODING IN LONG–SEPSIS SURVIVORS IS MEDIATED BY HMGB1

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Pedro Gómez, Tomás Huerta, Joshua Strohl, Patricio Huerta
Northwell Health, Feinstein Institutes For Medical Research, Manhasset, United States of America

Sepsis is a potentially lethal condition triggered by dysregulated immune responses to infection, which leads to the failure of several organs, including the brain. Survivors often suffer lasting cognitive impairment, which might be partly mediated by the cytokine high mobility group box 1 (HMGB1) (PMC3459473). Therefore, we sought to determine whether specific ablation of the *HMGB1* gene within neurons of long–sepsis surviving (LSS) mice might be able to protect hippocampus–based spatial cognition as well as place cell (PC) dynamics. We modeled sepsis using the cecal ligation and puncture method in male C57BL/6 (WT) and Syn-Cre/HMGB1$^{fl/fl}$ (KO) mice. A sham laparotomy was used for controls (CON). After a 6-week recovery, tetrodes were implanted into the dorsal CA1 field. Our results demonstrate that WT–LSS PCs have expanded place fields, with lower spatial information, when compared to WT–CON PCs. Moreover, spatial encoding is disrupted in WT–LSS mice as demonstrated by larger errors in Bayesian path reconstruction algorithms. Remarkably, KO–LSS mice show PC properties (place field area, spatial information) completely similar to CON (WT, KO) mice. Moreover, spatial encoding is normal in KO–LSS mice, as they have path reconstruction errors comparable to CON (WT, KO) groups. Finally, the clockmaze task (PMC6568215) confirms that KO–LSS mice use spatial strategy similarly to CON (WT, KO) groups. We conclude that genetic ablation of neuronal HMGB1 protects the hippocampus from sepsis-induced failure, strongly suggesting that HMGB1 is involved in mediating the fate of the spatial cognitive network following sepsis.

METABOLIC AND OSCILLATORY DISRUPTIONS OF THE BRAIN FEAR NETWORK IN LONG–SEPSIS SURVIVORS

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Joshua Strohl, Pedro Gómez, Patricio Huerta
Northwell Health, Feinstein Institutes For Medical Research, Manhasset, United States of America

Sepsis is triggered by dysregulated immune responses to infection leading to failure of several organs, such as the brain. Patients that survive a septic shock frequently suffer lasting cognitive deficits and emotional imbalance. Long–sepsis murine models display impaired contextual fear memory (PMC5193462). Our goal is to elucidate whether long–sepsis surviving (LSS) animals exhibit abnormalities within the brain's fear network, comprising the hippocampus (HPC), basolateral amygdala (BLA) and prefrontal cortex (PFC). We modeled sepsis in male C57BL/6 mice, using the cecal ligation and puncture procedure, and sham laparotomy for controls. After 6-week recovery, mice were subjected to trace–fear–conditioning and microPET, using [^{18}F]-fluorodeoxyglucose (FDG), followed by multielectrode–array implants directed to HPC, BLA and PFC. Our results demonstrate that, when comparing familiarization to context–fear–memory sessions, control mice show significantly higher FDG uptakes in BLA and PFC but decreased FDG signal in HPC. Strikingly, LSS mice have no FDG changes in BLA, PFC and HPC across fear sessions. Neural recordings reveal altered oscillations in LSS mice, such as persistently elevated powers in the theta and gamma bands during contextual–fear–memory sessions. Autocorrelation–power–matrix and wavelet–power analyses allow us to examine alterations in theta–gamma coupling and phase–amplitude modulation index in LSS mice. We conclude that the fear network is severally altered in LSS mice. Oscillatory patterns, critical for coordination across brain regions, are disrupted following sepsis reducing the ability of the brain to recall and maintain a healthy fear state.

Framework for automated sorting of neural spikes from Neuralynx-acquired tetrode recordings in freely-moving mice.
Extracellular recording represents a crucial electrophysiological technique in neuroscience for studying the activity of single neurons and neuronal populations. The electrodes capture voltage traces that, with the help of analytical tools, reveal action potentials ('spikes') as well as local field potentials. The process of spike sorting is used for the extraction of action potentials generated by individual neurons. Until recently, spike sorting was performed with manual techniques, which are laborious and unreliable due to inherent operator bias. As neuroscientists add multiple electrodes to their probes, the high-density devices can record hundreds to thousands of neurons simultaneously, making the manual spike sorting process increasingly difficult. The advent of automated spike sorting software has offered a compelling solution to this issue and, in this study, we present a simple-to-execute framework for running an automated spike sorter.

Endogenous retroviruses are associated with hippocampus-based memory impairment.
Retrotransposons compose a staggering 40% of the mammalian genome. Among them, endogenous retroviruses (ERV) represent sequences that closely resemble the proviruses created from exogenous retroviral infection. ERVs make up 8 to 10% of human and mouse genomes and range from evolutionarily ancient sequences to recent acquisitions. Studies in have provided a causal link between genomic retroviral elements and cognitive decline; however, in mammals, the role of ERVs in learning and memory remains unclear. Here we studied 2 independent murine models for ERV activation: muMT strain (lacking B cells and antibody production) and intracerebroventricular injection of streptozotocin (ICVI-STZ). We conducted

behavioral assessments (contextual fear memory and spatial learning), as well as gene and protein analysis (RNA sequencing, PCR, immunohistochemistry, and western blot assays). Mice lacking mitochondrial antiviral-signaling protein (MAVS) and mice lacking stimulator of IFN genes protein (STING), 2 downstream sensors of ERV activation, provided confirmation of ERV impact. We found that muMT mice and ICVI-STZ mice induced hippocampal ERV activation, as shown by increased gene and protein expression of the Gag sequence of the transposable element intracisternal A-particle. ERV activation was accompanied by significant hippocampus-related memory impairment in both models. Notably, the deficiency of the MAVS pathway was protective against ICVI-STZ-induced cognitive pathology. Overall, our results demonstrate that ERV activation is associated with cognitive impairment in mice. Moreover, they provide a molecular target for strategies aimed at attenuating retroviral element sensing, via MAVS, to treat dementia and neuropsychiatric disorders.

Large-Scale Validation of the Paddling Pool Task in the Clockmaze for Studying Hippocampus-Based Spatial Cognition in Mice.
Rationally designed behavioral tests are important tools to assess the function of specific brain regions. The hippocampus is a crucial neural substrate for spatial cognition, and many studies have linked hippocampal dysfunction with defects on spatial learning and memory in neurological conditions ranging from Alzheimer's disease to autoimmune syndromes, such as neuropsychiatric lupus. While our understanding of hippocampal function, from the molecular to the system levels, has increased dramatically over the last decades, this effort has not yet translated into efficacious therapies for cognitive impairment. We think that the availability of highly validated behavioral paradigms to measure cognition in mouse models is likely to enhance the potential success of preclinical therapeutic modalities. Here, we present an extensive study of the paddling pool task (PPT), first reported by Deacon and Rawlins, in which mice learn to escape from shallow water through a peripheral exit in a circular arena dubbed the clockmaze. We show that the PPT provides highly reliable results when assaying spatial cognition in C57/BL6 mice (120 males, 40 females) and BALB/c mice (40 males, 90 females). Additionally, we develop a robust algorithm for the assessment of escape strategies with clearly quantifiable readouts, enabling fine-granular phenotyping. Notably, the use of spatial strategy increases linearly across trials in the PPT. In a separate cohort of mice, we apply muscimol injections to silence the dorsal CA1 region of the hippocampus and show that the use of the spatial strategy in the PPT relies on the integrity of the dorsal hippocampus. Additionally, we compare directly the PPT and the Morris water maze (MWM) task in C57/BL6 mice (20 males, 20 females) and BALB/c mice (20 males, 20 females) and we find that the PPT induces significantly lower anxiety, exhaustion and hypothermia than the MWM. We conclude that the PPT provides a robust assessment of spatial cognition in mice, which can be applied in conjunction with other tests, to facilitate hypothesis testing and drug development to combat cognitive impairment.

CALHM1 deficiency impairs cerebral neuron activity and memory flexibility in mice.
CALHM1 is a cell surface calcium channel expressed in cerebral neurons. CALHM1 function in the brain remains unknown, but recent results showed that neuronal CALHM1 controls intracellular calcium signaling and cell excitability, two mechanisms required for synaptic function. Here, we describe the generation of Calhm1 knockout (Calhm1(-/-)) mice and investigate CALHM1 role in neuronal and cognitive functions. Structural analysis revealed that Calhm1(-/-) brains had normal regional and cellular architecture, and showed no evidence of neuronal or synaptic loss, indicating that CALHM1 deficiency does not affect brain development or brain integrity in adulthood. However, Calhm1(-/-) mice showed a severe impairment in memory flexibility, assessed in the Morris water maze, and a significant disruption of long-term potentiation without alteration of long-term depression, measured in ex vivo hippocampal slices. Importantly, in primary neurons and hippocampal slices, CALHM1 activation facilitated the phosphorylation of NMDA and AMPA receptors by protein kinase A. Furthermore, neuronal CALHM1 activation potentiated the effect of glutamate on the expression of c-Fos and C/EBPβ, two immediate-early gene markers of neuronal activity. Thus, CALHM1 controls synaptic activity in cerebral neurons and is required for the flexible processing of memory in mice. These results shed light on CALHM1 physiology in the mammalian brain.

INHALED CANNABIS DELIVERY DURING PREGNANCY: EFFECTS ON FETAL BRAIN, ENDOCANNABINOID, AND IMMUNE SYSTEM DEVELOPMENT IN RATS

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Samantha Baglot[1], Catherine Hume[2], Robert Aukema[3], Gavin Petrie[3], Ryan Mclaughlin[4], Matthew Hill[2]
[1]University of Calgary, Hotchkiss Brain Institute, Alberta Children's Hospital Research Institute, Calgary, Canada, [2]University of Calgary, Hotchkiss Brain Institute, Cumming School Of Medicine, Department Of Cell Biology & Anatomy, Calgary, Canada, [3]University of Calgary, Hotchkiss Brain Institute, Calgary, Canada, [4]Washington State University, Department Of Integrative Physiology And Neuroscience, Pullman, United States of America

Cannabis use during pregnancy is increasingly common, as high as 10-20%. Evidence from clinical studies suggests that prenatal cannabis exposure (PCE) may lead to growth retardation and alterations in neurobehavioral trajectories. However, little is known about the mechanism through which Δ⁹-tetrahydrocannabinol (THC; main psychoactive component of cannabis) alters neurodevelopment. THC exerts its effects through acting on the endocannabinoid (eCB) system, which is involved in many processes of neurodevelopment. Further, the eCB system is highly interconnected to the immune system, which also has imperative functions during neurodevelopment. Thus, THC may exert its effects through direct modulation of the eCB system and/or indirect modulation of the immune system. Utilizing a validated vapor chamber system our animal model aims to perform translational work with pregnant rats exposed to cannabis via inhalation (10% THC; 15-min session) throughout pregnancy. In this experiment, dams and their fetuses were euthanized on gestational day 15, 17, or 19 to examine neurodevelopmental outcomes across various timepoints. Maternal and fetal samples were collected for examination of: 1) eCB levels via mass spectrometry, 2) cytokine (immune-signalling molecules) levels via multiplex assay; and 3) eCB and immune-related gene expression via qPCR. We have found no impact of PCE on fetal brain eCB levels or cannabinoid receptor gene expression. Analysis of eCB and immune-related gene expression and cytokine levels are ongoing. In conjunction with ongoing research, our results may help determine the mechanism through which PCE alters neurodevelopment and help determine the safety of cannabis consumption during pregnancy.

Pharmacokinetics and central accumulation of delta-9-tetrahydrocannabinol (THC) and its bioactive metabolites are influenced by route of administration and sex in rats.
Up to a third of North Americans report using cannabis in the prior month, most commonly through inhalation. Animal models that reflect human consumption are critical to study the impact of cannabis on brain and behaviour. Most animal studies to date utilize injection of delta-9-tetrahydrocannabinol (THC; primary psychoactive component of cannabis). THC injections produce markedly different physiological and behavioural effects than inhalation, likely due to distinctive pharmacokinetics. The current study directly examined if administration route (injection versus inhalation) alters metabolism and central accumulation of THC and metabolites over time. Adult male and female Sprague-Dawley rats received either an intraperitoneal injection or a 15-min session of inhaled exposure to THC. Blood and brains were collected at 15, 30, 60, 90 and 240-min post-exposure for analysis of THC and metabolites. Despite achieving comparable peak blood THC concentrations in both groups, our results indicate higher initial brain THC concentration following inhalation, whereas injection resulted in dramatically higher 11-OH-THC concentration, a potent THC metabolite, in blood and brain that increased over time. Our results provide evidence of different pharmacokinetic profiles following inhalation versus injection. Accordingly, administration route should be considered during data interpretation, and translational animal work should strongly consider using inhalation models.

Maternal-fetal transmission of delta-9-tetrahydrocannabinol (THC) and its metabolites following inhalation and injection exposure during pregnancy in rats.

Cannabis use during pregnancy has increased over the past few decades, with recent data indicating that, in youth and young adults especially, up to 22% of people report using cannabis during pregnancy. Animal models provide the ability to study prenatal cannabis exposure (PCE) with control over timing and dosage; however, these studies utilize both injection and inhalation approaches. While it is known that Δ9-tetrahydrocannabinol (THC; primary psychoactive component of cannabis) can cross the placenta, examination of the transmission and concentration of THC and its metabolites from maternal blood into the placenta and fetal brain remains relatively unknown, and the influence of route of administration has never been examined. Pregnant female rats were exposed to either vaporized THC-dominant cannabis extract for pulmonary consumption or subcutaneous injection of THC repeatedly during the gestational period. Maternal blood, placenta, and fetal brains were collected following the final administration of THC for analysis of THC and its metabolites, as well as endocannabinoid concentrations, through mass spectrometry. Both routes of administration resulted in the transmission of THC and its metabolites in placenta and fetal brain. Repeated exposure to inhaled THC vapor resulted in fetal brain THC concentrations that were about 30% of those seen in maternal blood, whereas repeated injections resulted in roughly equivalent concentrations of THC in maternal blood and fetal brain. Neither inhalation nor injection of THC during pregnancy altered fetal brain endocannabinoid concentrations. Our data provide the first characterization of maternal-fetal transmission of THC and its metabolites following both vaporized delivery and injection routes of administration. These data are important to establish the maternal-fetal transmission in preclinical injection and inhalation models of PCE and may provide insight into predicting fetal exposure in human studies.

Positive allosteric modulation of type 1 cannabinoid receptors reduces spike-and-wave discharges in Genetic Absence Epilepsy Rats from Strasbourg.
Childhood Absence Epilepsy (CAE) accounts for approximately 10% of all pediatric epilepsies. Current treatments for CAE are ineffective in approximately 1/3 of patients and can be associated with severe side effects such as hepatotoxicity. Certain cannabinoids, such as cannabidiol (CBD), have shown promise in the treatment of pediatric epilepsies. However, CBD remains limited or prohibited in many jurisdictions, and has not been shown to have efficacy in CAE. Modulation of the type 1 cannabinoid receptor (CB1R) may provide more desirable pharmacological treatments. Genetic Absence Epilepsy Rats from Strasbourg (GAERS) model many aspects of CAE, including cortical spike and wave discharges (SWDs). We have recently demonstrated that Δ-tetrahydrocannabinol (THC) increases SWDs in GAERS whereas CBD decreases these events. Here, we characterized aspects of the endocannabinoid system in brain areas relevant to seizures in GAERS and tested whether positive allosteric modulators (PAMs) of CB1R reduced SWDs. Both female and male GAERS had reduced (>50%) expression of CB1R and elevated levels of the endocannabinoid 2-AG in cortex compared to non-epileptic controls (NEC). We then administered the CB1R PAMs GAT211 and GAT229 to GAERS implanted with cortical electrodes. Systemic administration of GAT211 to male GAERS reduced SWDs by 40%. Systemic GAT229 administration reduced SWDs in female and male GAERS. Intracerebral infusion of GAT229 into the cortex of male GAERS reduced SWDs by >60% in a CB1R-dependent manner that was blocked by SR141716A. Together, these experiments identify altered endocannabinoid tone in GAERS and suggest that CB1R PAMs should be explored for treatment of absence seizures.

Cannabis vapor self-administration elicits sex- and dose-specific alterations in stress reactivity in rats.
Cannabis users frequently report stress relief as their primary reason for use. Recent studies indicate that human cannabis users exhibit blunted stress reactivity; however, it is unknown whether this is a cause or a consequence of chronic cannabis use.

Colonization with the commensal fungus Candida albicans perturbs the gut-brain axis through dysregulation of endocannabinoid signaling.
Anxiety disorders are the most prevalent mental health disorder worldwide, with a lifetime prevalence of 5-7 % of the human population. Although the etiology of anxiety disorders is incompletely understood, one aspect of host health that affects anxiety disorders is the gut-brain axis. Adolescence is a key developmental window in which stress and anxiety disorders are a major health concern. We used adolescent female mice in a gastrointestinal (GI) colonization model to demonstrate that the commensal fungus Candida albicans affects host health via the gut-brain axis. In mice, bacterial members of the gut microbiota can influence the host gut-brain axis, affecting anxiety-like behavior and the hypothalamus-pituitary-adrenal (HPA) axis which produces the stress hormone corticosterone (CORT). Here we showed that mice colonized with C. albicans demonstrated increased anxiety-like behavior and increased basal production of CORT as well as dysregulation of CORT

production following acute stress. The HPA axis and anxiety-like behavior are negatively regulated by the endocannabinoid N-arachidonoylethanolamide (AEA). We demonstrated that C. albicans-colonized mice exhibited changes in the endocannabinoidome. Further, increasing AEA levels using the well-characterized fatty acid amide hydrolase (FAAH) inhibitor URB597 was sufficient to reverse both neuroendocrine phenotypes in C. albicans-colonized mice. Thus, a commensal fungus that is a common colonizer of humans had widespread effects on the physiology of its host. To our knowledge, this is the first report of microbial manipulation of the endocannabinoid (eCB) system that resulted in neuroendocrine changes contributing to anxiety-like behavior.

Vaporized Cannabis Extracts Have Reinforcing Properties and Support Conditioned Drug-Seeking Behavior in Rats.
Recent trends in cannabis legalization have increased the necessity to better understand the effects of cannabis use. Animal models involving traditional cannabinoid self-administration approaches have been notoriously difficult to establish and differences in the drug used and its route of administration have limited the translational value of preclinical studies. To address this challenge in the field, we have developed a novel method of cannabis self-administration using response-contingent delivery of vaporized Δ-tetrahydrocannabinol-rich (CAN) or cannabidiol-rich (CAN) whole-plant cannabis extracts. Male Sprague-Dawley rats were trained to nose-poke for discrete puffs of CAN, CAN, or vehicle (VEH) in daily 1 h sessions. Cannabis vapor reinforcement resulted in strong discrimination between active and inactive operanda. CAN maintained higher response rates under fixed ratio schedules and higher break points under progressive ratio schedules compared with CAN or VEH, and the number of vapor deliveries positively correlated with plasma THC concentrations. Moreover, metabolic phenotyping studies revealed alterations in locomotor activity, energy expenditure, and daily food intake that are consistent with effects in human cannabis users. Furthermore, both cannabis regimens produced ecologically relevant brain concentrations of THC and CBD and CAN administration decreased hippocampal CB1 receptor binding. Removal of CAN reinforcement (but not CAN) resulted in a robust extinction burst and an increase in cue-induced cannabis-seeking behavior relative to VEH. These data indicate that volitional exposure to THC-rich cannabis vapor has bona fide reinforcing properties and collectively support the utility of the vapor self-administration model for the preclinical assessment of volitional cannabis intake and cannabis-seeking behaviors. The evolving legal landscape concerning recreational cannabis use has increased urgency to better understand its effects on the brain and behavior. Animal models are advantageous in this respect; however, current approaches typically used forced injections of synthetic cannabinoids or isolated cannabis constituents that may not capture the complex effects of volitional cannabis consumption. We have developed a novel model of cannabis self-administration using response-contingent delivery of vaporized cannabis extracts containing high concentrations of Δ tetrahydrocannabinol (THC) or cannabidiol. Our data indicate that THC-rich cannabis vapor has reinforcing properties that support stable rates of responding and conditioned drug-seeking behavior. This approach will be valuable for interrogating effects of cannabis and delineating neural mechanisms that give rise to aberrant cannabis-seeking behavior.

Effects of prenatal alcohol exposure on social competence: Asymmetry in play partner preference among heterogeneous triads of male and female rats.
Social behavior deficits associated with prenatal alcohol exposure (PAE) are frequently described in terms of impaired social competence, which can be defined as the effectiveness in social interaction and the ability to employ social skills successfully within different interpersonal contexts. Play behavior-which peaks during adolescence-is critical for developing social competence, as well as for motor, cognitive, and emotional development. Studies of play behavior typically utilize protocols where animals interact in dyads. However, less is understood about how the social environment may shape PAE-related social behavior deficits, particularly in more complex social contexts. Here, we assess play partner preference utilizing a novel approach in which adolescent male and female animals interact within same-sex triads comprised of animals from mixed prenatal treatments to determine how play partner identity and social group composition interact to shape behavior. When triads included one PAE animal and two control animals (i.e., control animals had the option to play either with a fellow control or a PAE playmate), we observed play target asymmetry whereby controls preferentially played with fellow controls. Notably, these results were consistent for triads of both males and females, with subtle differences in frequency of initiations versus reciprocations. We found no play target asymmetry, however, when triads included two PAE animals and one control animal or different configurations of control and pair-fed animals. Taken together, play target asymmetry resulting from ineffective social interactions, including a failure to engage with, respond to, and/or solicit play from control play partners appropriately, suggests that PAE negatively impacts the development of social competence.

Effects of early-life adversity on immune function are mediated by prenatal environment: Role of prenatal alcohol exposure. The contribution of the early postnatal environment to the pervasive effects of prenatal alcohol exposure (PAE) is poorly understood. Moreover, PAE often carries increased risk of exposure to adversity/stress during early life. Dysregulation of immune function may play a role in how pre- and/or postnatal adversity/stress alters brain development. Here, we combine two animal models to examine whether PAE differentially increases vulnerability to immune dysregulation in response to early-life adversity. PAE and control litters were exposed to either limited bedding (postnatal day [PN] 8-12) to model early-life adversity or normal bedding, and maternal behavior and pup vocalizations were recorded. Peripheral (serum) and central (amygdala) immune (cytokines and C-reactive protein - CRP) responses of PAE animals to early-life adversity were evaluated at PN12. Insufficient bedding increased negative maternal behavior in both groups. Early-life adversity increased vocalization in all animals; however, PAE pups vocalized less than controls. Early-life adversity reduced serum TNF-α, KC/GRO, and IL-10 levels in control but not PAE animals. PAE increased serum CRP, and levels were even higher in pups exposed to adversity. Finally, PAE reduced KC/GRO and increased IL-10 levels in the amygdala. Our results indicate that PAE alters immune system development and both behavioral and immune responses to early-life adversity, which could have subsequent consequences for brain development and later life health.

GUT MICROBIOME DEPLETION LEADS TO ALTERED NEURAL DYNAMICS AND METABOLISM IN THE DORSAL CA1 FIELD OF THE HIPPOCAMPUS

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Joshua Glynn, Joshua Strohl, Patricio Huerta, Joseph Carrión
Northwell Health, Feinstein Institutes For Medical Research, Manhasset, United States of America

Growing evidence implicates the gut microbiome in brain health and disease. Since worldwide consumption of oral antibiotics continues to rise, it is imperative to understand how antibiotics affect cognition through the gut–brain axis. Male C57BL/6J mice (2–4 months) were given drinking water containing broad–spectrum antibiotics (ABX cohort; ampicillin, neomycin, gentamicin, metronidazole, and vancomycin). A separate ABXBut cohort received both antibiotics and butyrate, a key microbiome-derived metabolite. Four weeks later, mice underwent microPET studies using [^{18}F]-fluorodeoxyglucose (FDG) to assess brain metabolism. Hippocampus–related spatial cognition was evaluated with the object place memory (OPM) and clockmaze tasks (PMC6568215), at 2–3 weeks of treatment. Finally, mice were implanted with tetrode arrays to record CA1 place cells (PCs) in the dorsal hippocampus. Our results demonstrate that, compared to controls, ABX mice have reduced FDG uptake in entorhinal cortex, amygdala, and CA1. Moreover, ABX mice show significant spatial impairments in the OPM and clockmaze tasks. Analysis of PC dynamics during OPM reveals that ABX–PCs have larger field size, lower spatial information, as well as altered remapping and path reconstruction properties. Remarkably, ABXBut mice display completely normal spatial cognition and place cell dynamics. We conclude that depletion of the gut microbiome with antibiotics leads to disruptions within the hippocampal formation, which are reflected in weaker metabolism, disrupted spatial cognition and aberrant place cell properties. Coadministration of butyrate preserves spatial cognition and hippocampal dynamics in microbiome–depleted mice, pointing to potential therapeutic approaches.

Framework for automated sorting of neural spikes from Neuralynx-acquired tetrode recordings in freely-moving mice. Extracellular recording represents a crucial electrophysiological technique in neuroscience for studying the activity of single neurons and neuronal populations. The electrodes capture voltage traces that, with the help of analytical tools, reveal action potentials ('spikes') as well as local field potentials. The process of spike sorting is used for the extraction of action potentials generated by individual neurons. Until recently, spike sorting was performed with manual techniques, which are laborious and unreliable due to inherent operator bias. As neuroscientists add multiple electrodes to their probes, the high-density devices can record hundreds to thousands of neurons simultaneously, making the manual spike sorting process increasingly difficult. The advent of automated spike sorting software has offered a compelling solution to this issue and, in this study, we present a simple-to-execute framework for running an automated spike sorter.

FUNCTIONAL ROLE OF THE CGAS-STING PATHWAY IN THE HOMEOSTASIS OF NEURONS

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Sergio Passarella[1], Shananthan Kethiswaran[1], Karina Brandes[1], Saskia Kresse[1], Andrea Kröger[2], Peter Landgraf[1], Daniela Dieterich[1]
[1]Otto von Guericke Universität, Institute For Pharmacology And Toxicology, Magdeburg, Germany, [2]University Magdeburg, Institute Of Microbiology, Magdeburg, Germany

The cGAS-STING pathway has a pivotal role in innate immune responses and represents the first-line natural barrier of the host for the elimination of pathogenic infections. In recent years, there has been an increasing interest in the cGAS-STING pathway not only regarding viral defense but also in terms of cellular senescence and autophagy. Moreover, recently it could be shown that cGAS and STING are present in the central nervous system as well, especially in microglia. To date there is ample evidence for a functional role of the cGAS-STING pathway in microglia but comparable less about its role in other CNS cells such as neurons and astrocytes. Based on these observations we analyzed the differences between neurons from wild type (WT) and STING$^{-/-}$ mice. Our data *in vitro* yield clear differences in neurons of STING$^{-/-}$ mice in comparison to WT animals, including altered dendritic arborization and reduced number of synapses. Another interesting finding is the clear impairment of the autophagic flux of neurons both *in vitro* as well as *in vivo,* with a reduction of p62 and reduced amounts of LC3II proteins. In conclusion, our data demonstrate that the cGAS-STING pathway has an important role not only in microglia but also in the remaining cells of the CNS. Especially in neurons, the absence of the cGAS-STING pathway may cause dysfunctions in physiological processes.

SILENCING OF AMYGDALA CIRCUITS DURING SEPSIS PREVENTS THE DEVELOPMENT OF ANXIETY-RELATED BEHAVIOURS

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Lena Bourhy[1], Aurélien Mazeraud[2], Gabriel Lepousez[1], Tarek Sharshar[2], Pierre-Marie Lledo[1]
[1]Perception and Memory Unit, Institut Pasteur, Neuroscience, Paris, France, [2]GHU Paris Psychiatrie Neurosciences, Service Hospitalo-universitaire De Neuro-anesthésie Réanimation, Paris, France

Sepsis is a life-threatening condition induced by a deregulated host response to severe infection. Post-sepsis syndrome includes long-term psychiatric disorders, such as persistent anxiety and post-traumatic stress disorder, whose neurobiological mechanisms remain unknown. Using a reference mouse model of sepsis, we showed that mice that recovered from sepsis further developed anxiety-related behaviours associated with an exaggerated fear memory. In the brain, sepsis induced an acute pathological activation of a specific neuronal population of the central nucleus of the amygdala, which projects to the ventral bed nucleus of the stria terminalis. Using viral-genetic circuit tracing and in vivo calcium imaging, we observed that sepsis induced persistent changes in the connectivity matrix and in the responsiveness of the ventral bed nucleus of the stria terminalis-projecting central nucleus of the amygdala neurons. The transient and targeted silencing of this subpopulation only during the acute phase of sepsis with a viral pharmacogenetic approach, or with the antiepileptic and neuroprotective drug levetiracetam, prevented the subsequent development of anxiety-related behaviours. Specific inhibition of brain anxiety and fear circuits during the sepsis acute phase constitutes a preventive approach to preclude the post-infection psychiatric outcomes.

Aims
Exposure to psychostimulants has been associated with increased glial activity, which seems to be implicated in the neuronal changes that underlie addiction. Anti-inflammatory cytokines seem to counterbalance damage driven by excessive glial activation. Here, we tested the hypothesis that increased levels of interleukin(IL)-10 could be protective in substance abuse disorders.
Methods
We took advantage of a transgenic mouse model with controlled overexpression of IL-10 to investigate mechanisms of protection elicited by IL-10 in the context of acute exposure to methamphetamine(Meth). Since IL-10 may modulate gammadelta(γδ) T cells, which were described to be involved in regulating behaviours that are important for drug use, we also use a transgenic mouse model with controlled overexpression of IL-10 but KO for γδ T cells and test them in the elevated plus maze(EPM), where we have previously show that binge Meth promotes loss of risk assessment.
Results
Our results successfully show that IL-10 overexpression prevents Meth-induced behaviour in the EPM following a binge administration. IL-10 also seems to be protective in Meth-induced microglia reactivity, preventing microglia proliferation, altered morphology and increased phagocytic activity, hallmarks of microglia reactivity. Importantly, this protective effect seems to be dependent on γδ T cells.
Conclusions
These results confirm the relevance of modulating anti-inflammatory cytokines in the context of drug use, and allow us to predict that IL-10 may to be an innovative treatment strategy for substance abuse disorders. To better unravel IL-10 potential, we are now exploring in primary glial cultures the mechanisms involved in IL-10 action under Meth exposure.

Astrocyte-derived TNF and glutamate critically modulate microglia activation by methamphetamine.
Methamphetamine (Meth) is a powerful illicit psychostimulant, widely used for recreational purposes. Besides disrupting the monoaminergic system and promoting oxidative brain damage, Meth also causes neuroinflammation, contributing to synaptic dysfunction and behavioral deficits. Aberrant activation of microglia, the largest myeloid cell population in the brain, is a common feature in neurological disorders triggered by neuroinflammation. In this study, we investigated the mechanisms underlying the aberrant activation of microglia elicited by Meth in the adult mouse brain. We found that binge Meth exposure caused microgliosis and disrupted risk assessment behavior (a feature that usually occurs in individuals who abuse Meth), both of which required astrocyte-to-microglia crosstalk. Mechanistically, Meth triggered a detrimental increase of glutamate exocytosis from astrocytes (in a process dependent on TNF production and calcium mobilization), promoting microglial expansion and reactivity. Ablating TNF production, or suppressing astrocytic calcium mobilization, prevented Meth-elicited microglia reactivity and re-established risk assessment behavior as tested by elevated plus maze (EPM). Overall, our data indicate that glial crosstalk is critical to relay alterations caused by acute Meth exposure.

Aims. Anorexia nervosa is a complex and multifactorial psychiatric disorder where immunological and metabolic alterations contribute to the worsening of the disease. Excessive physical activity is often associated with this disorder. Using a mouse model of chronic food restriction, we sought to determine whether the metabolic status (fed or fasted) impacts the hypothalamic mRNA expression of neuropeptides involved in the regulation of food intake and of pro-inflammatory cytokines and chemokines. **Methods**. For two weeks, we subjected mice to either 1) chronic food restriction (FR), 2) FR combined with voluntary activity (free access to a running wheel, FRW), 3) *ad libitum* feeding (AL), or 4) AL with voluntary activity (ALW). Then, we assessed the hypothalamic gene expression of cytokines (IL-1ß, IL-6, TNF-α), chemokines (RANTES, MCP1) and neuropeptides (POMC, NPY, AgRP, MCH and orexin) in the different conditions. **Results**. In the fed condition, no significant changes were found regarding cytokines or chemokines. Regarding the food restricted groups, POMC mRNA expression was significantly decreased in FRW mice, while AgRP and NPY levels were increased both in FR and FRW mice. Interestingly, only in the FR group we observed significant increases in the gene expression of all proinflammatory cytokines and MCP-1. Similarly, increases in MCH and ORX levels only occurred in the FR group, while AgRP and NPY levels increased in similarly in both FR and FRW groups. **Conclusion**. Our data highlighted that physical activity may, but only in a condition of food restriction, protect the hypothalamus from neuroinflammation.

Aims: the reactogenicity of the anti-COVID-19 vaccination seems partially overlapped to Sickness Behavior (SB); both conditions appear to be related to the activation of cytokines which, acting on specific brain hubs involved in the interoceptive processes, give rise to behavioral changes. The aim of this research was to identify the presence of SB after vaccination and its possible triggering variables. Methods: A cross-sectional online survey was conducted on 647 participants who received anti-COVID-19 vaccination. Demographics, health status, mood, sleep, and interoceptive awareness were explored through psychometric questionnaires. To investigate the independent variables potentially correlated with high levels of SB after vaccination, we divided the sample in two groups: participants with low (L-SB; n=252) and high (H-SB, n=227) levels of SB. The statistical analysis was carried out using supervised machine learning (ML) techniques using k-fold cross validation. Results: the baseline variables exhibiting optimal efficiency in classifying the participant within the L-SB and H-SB groups have been identified with an accuracy of 72.65%. The analysis revealed that specific variables – interoceptive awareness, levels of depression and anxiety, and sleep quality –were the best predictors in discriminating H-SB from L-SB groups with an accuracy higher than 75% for all classifiers (Table 1). Conclusions: anti-COVID-19 vaccination could generate core symptoms of SB involving mood and sleep. Moreover, the data suggest that interoceptive awareness could be considered a

neuro-immunological bridge able to convey the psychophysiological response to the vaccine and to modulate the intensity of

The pathological changes leading to cognitive impairment in patients with systemic lupus erythematosus (SLE) are poorly understood. We study a subset of DNA–binding antibodies, termed DNRAbs, that also bind the NMDA receptor and contribute to neuropsychiatric SLE (NPSLE). We have developed a lupus model in which C57BL6H2d$^{+/+}$ mice express high DNRAb titer (PMC6170183, PMC7075964). To elucidate the neural substrate of NPSLE (how cognitive impairment emerges at the ensemble level), we performed tetrode recordings of local field potentials (LFP) and place cells (PC) in CA1 during the open field (OF) and object–place memory (OPM) tasks. DNRAb mice have impaired spatial memory (poor exploration of moved object in OPM). Notably, DNRAb mice exhibit abnormally high LFP power (theta–beta–gamma bands) during OF and OPM, which contrasts sharply with the decremental LFP power in controls. Autocorrelation power matrix and wavelet power analyses reveal that DNRAb mice have weaker theta–gamma coupling and reduced phase–amplitude modulation index. Analysis of PC dynamics during OPM reveals that DNRAb–PCs display larger place field size, lower spatial information, diminished remapping capabilities, and higher error in path reconstruction. Finally, tSNE analysis across behavioral, LFP and PC data demonstrates a robust disease phenotype in DNRAb mice. We conclude that NPSLE's cognitive impairment is associated with neural pathologies including abnormally high LFP patterns with reduced coupling dynamics, and disrupted PC dynamics with low quality place fields. Thus, systems–level analyses of neuroimmune pathophysiology might uncover novel biomarkers for previously elusive autoimmune diseases, such as NPSLE.

Integrative neuroscience approach to neuropsychiatric lupus.
We present a succinct review of our approach to study the interactions between the DNA-reactive antibodies that cross-react with the GluN2A and GluN2B subunits of the N-methyl-D-aspartate receptor, denoted DNRABs, and their brain targets in subjects with neuropsychiatric systemic lupus erythematosus (NPSLE). We have analyzed the DNRAB-based brain symptomatology in mouse models of NPSLE by using an integrative neuroscience approach, which includes behavioral assessment coupled with electrophysiological studies of neural networks and synaptic connections in target brain regions, such as the CA1 region of the hippocampus. Our results suggest a framework for understanding the interactions between immune factors and neural networks.

Targeted peripheral focused ultrasound stimulation attenuates obesity-induced metabolic and inflammatory dysfunctions.
Obesity, a growing health concern, is associated with an increased risk of morbidity and mortality. Chronic low-grade inflammation is implicated in obesity-driven metabolic complications. Peripheral focused ultrasound stimulation (pFUS) is an emerging non-invasive technology that modulates inflammation. Here, we reasoned that focused ultrasound stimulation of the liver may alleviate obesity-related inflammation and other comorbidities. After 8 weeks on a high-fat high-carbohydrate "Western" diet, C57BL/6J mice were subjected to either sham stimulation or focused ultrasound stimulation at the porta hepatis. Daily liver-focused ultrasound stimulation for 8 weeks significantly decreased body weight, circulating lipids and mitigated dysregulation of adipokines. In addition, liver-focused ultrasound stimulation significantly reduced hepatic cytokine levels and leukocyte infiltration. Our findings demonstrate the efficacy of hepatic focused ultrasound for alleviating obesity and obesity-associated complications in mice. These findings suggest a previously unrecognized potential of hepatic focused ultrasound as a possible novel noninvasive approach in the context of obesity.

Lupus autoantibodies act as positive allosteric modulators at GluN2A-containing NMDA receptors and impair spatial memory.
Patients with Systemic lupus erythematosus (SLE) experience various peripheral and central nervous system manifestations including spatial memory impairment. A subset of autoantibodies (DNRAbs) cross-react with the GluN2A and GluN2B subunits of the NMDA receptor (NMDAR). We find that these DNRAbs act as positive allosteric modulators on NMDARs with GluN2A-containing NMDARs, even those containing a single GluN2A subunit, exhibiting a much greater sensitivity to DNRAbs than those with exclusively GluN2B. Accordingly, GluN2A-specific antagonists provide greater protection from DNRAb-mediated neuronal cell death than GluN2B antagonists. Using transgenic mice to perturb expression of either GluN2A or GluN2B in vivo, we find that DNRAb-mediated disruption of spatial memory characterized by early neuronal cell death and subsequent microglia-dependent pathologies requires GluN2A-containing NMDARs. Our results indicate that GluN2A-specific antagonists or negative allosteric modulators are strong candidates to treat SLE patients with nervous system dysfunction.

Endogenous retroviruses are associated with hippocampus-based memory impairment.
Retrotransposons compose a staggering 40% of the mammalian genome. Among them, endogenous retroviruses (ERV) represent sequences that closely resemble the proviruses created from exogenous retroviral infection. ERVs make up 8 to 10% of human and mouse genomes and range from evolutionarily ancient sequences to recent acquisitions. Studies in have provided a causal link between genomic retroviral elements and cognitive decline; however, in mammals, the role of ERVs in learning and memory remains unclear. Here we studied 2 independent murine models for ERV activation: muMT strain (lacking B cells and antibody production) and intracerebroventricular injection of streptozotocin (ICVI-STZ). We conducted behavioral assessments (contextual fear memory and spatial learning), as well as gene and protein analysis (RNA sequencing, PCR, immunohistochemistry, and western blot assays). Mice lacking mitochondrial antiviral-signaling protein (MAVS) and mice lacking stimulator of IFN genes protein (STING), 2 downstream sensors of ERV activation, provided confirmation of ERV impact. We found that muMT mice and ICVI-STZ mice induced hippocampal ERV activation, as shown by increased gene and protein expression of the Gag sequence of the transposable element intracisternal A-particle. ERV activation was accompanied by significant hippocampus-related memory impairment in both models. Notably, the deficiency of the MAVS pathway was protective against ICVI-STZ-induced cognitive pathology. Overall, our results demonstrate that ERV activation is associated with cognitive impairment in mice. Moreover, they provide a molecular target for strategies aimed at attenuating retroviral element sensing, via MAVS, to treat dementia and neuropsychiatric disorders.

Large-Scale Validation of the Paddling Pool Task in the Clockmaze for Studying Hippocampus-Based Spatial Cognition in Mice.
Rationally designed behavioral tests are important tools to assess the function of specific brain regions. The hippocampus is a crucial neural substrate for spatial cognition, and many studies have linked hippocampal dysfunction with defects on spatial learning and memory in neurological conditions ranging from Alzheimer's disease to autoimmune syndromes, such as neuropsychiatric lupus. While our understanding of hippocampal function, from the molecular to the system levels, has increased dramatically over the last decades, this effort has not yet translated into efficacious therapies for cognitive impairment. We think that the availability of highly validated behavioral paradigms to measure cognition in mouse models is likely to enhance the potential success of preclinical therapeutic modalities. Here, we present an extensive study of the paddling pool task (PPT), first reported by Deacon and Rawlins, in which mice learn to escape from shallow water through a peripheral exit in a circular arena dubbed the clockmaze. We show that the PPT provides highly reliable results when assaying spatial cognition in C57/BL6 mice (120 males, 40 females) and BALB/c mice (40 males, 90 females). Additionally, we develop a robust algorithm for the assessment of escape strategies with clearly quantifiable readouts, enabling fine-granular phenotyping. Notably, the use of spatial strategy increases linearly across trials in the PPT. In a separate cohort of mice, we apply muscimol injections to silence the dorsal CA1 region of the hippocampus and show that the use of the spatial strategy in the PPT relies on the integrity of the dorsal hippocampus. Additionally, we compare directly the PPT and the Morris water maze (MWM) task in C57/BL6 mice (20 males, 20 females) and BALB/c mice (20 males, 20 females) and we find that the PPT induces significantly lower anxiety, exhaustion and hypothermia than the MWM. We conclude that the PPT provides a robust assessment of spatial cognition in mice, which can be applied in conjunction with other tests, to facilitate hypothesis testing and drug development to combat cognitive impairment.

Lupus antibodies induce behavioral changes mediated by microglia and blocked by ACE inhibitors.
Cognitive impairment occurs in 40-90% of patients with systemic lupus erythematosus (SLE), which is characterized by autoantibodies to nuclear antigens, especially DNA. We discovered that a subset of anti-DNA antibodies, termed DNRAbs, cross reacts with the N-methyl-d-aspartate receptor (NMDAR) and enhances NMDAR signaling. In patients, DNRAb presence associates with spatial memory impairment. In a mouse model, DNRAb-mediated brain pathology proceeds through an acute phase of excitotoxic neuron loss, followed by persistent alteration in neuronal integrity and spatial memory impairment. The latter pathology becomes evident only after DNRAbs are no longer detectable in the brain. Here we investigate the mechanism of long-term neuronal dysfunction mediated by transient exposure to antibody. We show that activated microglia and C1q are critical mediators of neuronal damage. We further show that centrally acting inhibitors of angiotensin-converting enzyme (ACE) can prevent microglial activation and preserve neuronal function and cognitive performance. Thus, ACE inhibition represents a strong candidate for clinical trials aimed at mitigating cognitive dysfunction.

Selective Impairment of Spatial Cognition Caused by Autoantibodies to the N-Methyl-D-Aspartate Receptor.
Patients with systemic lupus erythematosus (SLE) experience cognitive abnormalities in multiple domains including processing speed, executive function, and memory. Here we show that SLE patients carrying antibodies that bind DNA and the GluN2A and GluN2B subunits of the N-methyl-d-aspartate receptor (NMDAR), termed DNRAbs, displayed a selective impairment in spatial recall. Neural recordings in a mouse model of SLE, in which circulating DNRAbs penetrate the hippocampus, revealed that CA1 place cells exhibited a significant expansion in place field size. Structural analysis showed that hippocampal pyramidal cells had substantial reductions in their dendritic processes and spines. Strikingly, these abnormalities became evident at a time when DNRAbs were no longer detectable in the hippocampus. These results suggest that antibody-mediated neurocognitive impairments may be highly specific, and that spatial cognition may be particularly vulnerable to DNRAb-mediated structural and functional injury to hippocampal cells that evolves after the triggering insult is no longer present.

Dynamic NMDAR-mediated properties of place cells during the object place memory task.
N-methyl-D-aspartate receptors (NMDAR) in the hippocampus participate in encoding and recalling the location of objects in the environment, but the ensemble mechanisms by which NMDARs mediate these processes have not been completely elucidated. To address this issue, we examined the firing patterns of place cells in the dorsal CA1 area of the hippocampus of mice (n = 7) that performed an object place memory (OPM) task, consisting of familiarization (T1), sample (T2), and choice (T3) trials, after systemic injection of 3-[(±)2-carboxypiperazin-4yl]propyl-1-phosphate (CPP), a specific NMDAR antagonist. Place cell properties under CPP (CPP-PCs) were compared to those after control saline injection (SAL-PCs) in the same mice. We analyzed place cells across the OPM task to determine whether they signaled the introduction or movement of objects by NMDAR-mediated changes of their spatial coding. On T2, when two objects were first introduced to a familiar chamber, CPP-PCs and SAL-PCs showed stable, vanishing or moving place fields in addition to changes in spatial information (SI). These metrics were comparable between groups. Remarkably, previously inactive CPP-PCs (with place fields emerging de novo on T2) had significantly weaker SI increases than SAL-PCs. On T3, when one object was moved, CPP-PCs showed reduced center-of-mass (COM) shift of their place fields. Indeed, a subset of SAL-PCs with large COM shifts (>7 cm) was largely absent in the CPP condition. Notably, for SAL-PCs that exhibited COM shifts, those initially close to the moving object followed the trajectory of the object, whereas those far from the object did the opposite. Our results strongly suggest that the SI changes and COM shifts of place fields that occur during the OPM task reflect key dynamic properties that are mediated by NMDARs and might be responsible for binding object identity with location.

[1]Trinity College Dublin, Physiology, PN, Ireland, [2]Trinity College Dublin, Schools Of Medicine And Psychology, Dublin, Ireland

Physical inactivity is one of the top five leading causes of death worldwide and is associated with life-limiting diseases, including dementia and other brain disorders. Exercise is suggested to protect brain health, potentially via the action of muscle-derived factors, such as lactate, on brain tissue. Lactate concentrations are known to increase post-exercise, and peripheral lactate has been shown to cross the blood-brain barrier via monocarboxylate transporters (MCT), where it can act as a fuel or signalling molecule. Exercise-derived lactate has been associated with multiple roles within the central nervous system, potentially modulating cognitive function. The focus of this study was to investigate central and peripheral lactate dynamics after low to moderate-intensity aerobic exercise in young adult male mice and the effects of pharmacological administration of an MCT1/2 inhibitor in combination with exercise on lactate concentrations as well as lactate-mediated signalling and gene expression in the hippocampus. Gene expression analysis indicates that metabolic genes and microglia polarization markers are not affected under homeostatic conditions. Moreover, no changes in lactate concentrations were observed in the hippocampus of young adult male C57BL/6J mice at the time scale used in our study, suggesting that lactate dynamics may be dependent on exercise duration and intensity. Interestingly, mice treated with the MCT1/2 inhibitor exhibited a slight decrease in the relative lactate concentrations, indicating that the efficacy of the inhibitor may be lactate-dependent. Finally, it remains to be investigated if muscle-derived lactate contributes to heightened cognitive resilience and protection conferred by exercise in response to immune challenges.

INVESTIGATING THE IMPACT OF SHORT-TERM, MODERATE INTENSITY EXERCISE ON MICROGLIA IMMUNOMETABOLIC REPROGRAMMING FOLLOWING SYSTEMIC LPS CHALLENGE

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Zsuzsanna Barad[1], Joana Augusto[1], Aine Kelly[2]
[1]Trinity College Dublin, Physiology, Dublin, Ireland, [2]Trinity College Dublin, School Of Medicine, Dublin, Ireland

Microglia are tissue resident macrophages of the central nervous system (CNS) with varied functions in both steady-state and disease-related conditions which are critical for neuronal activity and cognitive function. Accumulating evidence indicates that, similar to peripheral macrophages, microglia functional states are underpinned by cellular metabolism. Neuroinflammation and microglia activation have been characterized by a shift in metabolic pathways towards aerobic glycolysis, which critically regulates microglia immune functions such as cytokine release and phagocytosis. Nonetheless, homeostatic microglia states are also influenced by changes in CNS microenvironment, which may modulate microglia responses to danger signals, such as pathogens. Regular aerobic exercise is long considered to have a considerable impact on brain health, with recent evidence indicating its potential to modulate microglia states and functions, mediated by muscle-derived factors that can cross the blood-brain barrier. Here, we investigate the impact of 7 days of moderate intensity treadmill exercise on microglia metabolic phenotype and function in 3-4-month-old C57/BL6J mice, by assessing the bioenergetic phenotype of primary microglia in exercising and sedentary mice. Furthermore, microglia metabolic adaptations and immune functions are elucidated in exercising vs sedentary mice upon a peripheral immune challenge via subseptic dose of lipopolysaccharide (LPS). Our evidence indicates that prior exercise can prevent the bioenergetic and inflammatory changes induced by LPS, suggesting that physical activity can impact on glial and neuronal function in a neuroprotective manner. This provides a potential mechanism underlying the long-term effects of regular physical activity in developing resilience of brain tissue to injury and inflammatory insult.

Effects of salt loading on the organisation of microtubules in rat magnocellular vasopressin neurones.
Magnocellular vasopressin (VP) neurones are activated by increases in blood osmolality, leading to the secretion of VP into the circulation to promote water retention in the kidney, thus constituting a key mechanism for the regulation of body fluid homeostasis. However, chronic high salt intake can lead to excessive activation of VP neurones and increased circulating levels of VP, contributing to an elevation in blood pressure. Multiple extrinsic factors, such as synaptic inputs and glial cells, modulate the activity of VP neurones. Moreover, magnocellular neurones are intrinsically osmosensitive, and are activated by hypertonicity in the absence of neighbouring cells or synaptic contacts. Hypertonicity triggers cell shrinking, leading to the activation of VP neurones. This cell-autonomous activation is mediated by a scaffold of dense somatic microtubules, uniquely present in VP magnocellular neurones. Treating isolated magnocellular neurones with drugs modulating microtubule stability modifies the sensitivity of neuronal activation in response to acute hypertonic stimuli. However, whether the microtubule network is altered in conditions associated with enhanced neuronal activation and increased VP release, such as chronic high salt intake, remains unknown. We examined the organisation of microtubules in VP neurones of the supraoptic and paraventricular hypothalamic nuclei (SON and PVN, respectively) of rats subjected to salt-loading (drinking 2% NaCl for 7 days). Using super-resolution imaging, we found that the density of microtubules in magnocellular VP neurones from the SON and PVN was significantly increased, whereas the density and organisation of microtubules remain unchanged in other hypothalamic neurones, as well as in neurones from other brain areas (e.g., hippocampus, cortex). We propose that the increase in microtubule density in magnocellular VP neurones in salt-loading promotes their enhanced activation, possibly contributing to elevated blood pressure in this condition.

Impaired prolactin transport into the brain and functional responses to prolactin in aged male mice.
Ageing is related to changes in a number of endocrine systems that impact on the central actions of hormones. The anterior pituitary hormone prolactin is present in the circulation in both males and females, with widespread expression of the prolactin

receptor throughout the forebrain. We aimed to investigate prolactin transport into the brain, as well as circulating levels of prolactin and functional responses to prolactin, in aged male mice (23 months). Transport of I-labelled prolactin (I-prolactin) from the peripheral circulation into the brain was suppressed in aged compared to young adult (4 months) male mice, with no significant transport into the brain occurring in aged males. We subsequently investigated changes in the negative-feedback regulation of prolactin secretion and prolactin-induced suppression of luteinising hormone (LH) pulsatile secretion in aged male mice. Feedback regulation of prolactin secretion appeared to be unaffected in aged males, with no change in levels of circulating prolactin, and normal prolactin-induced phosphorylated signal transducer and activator of transcription 5(pSTAT5) immunoreactivity in tuberoinfundibular dopaminergic (TIDA) neurones in the arcuate nucleus. There were, however, significant impairments in the ability of prolactin to suppress LH pulsatile secretion in aged males. In young adult males, acute prolactin administration significantly decreased LH pulses from 1.5 ± 0.19 pulses of LH in 4 hours to 0.5 ± 0.27 pulses. In contrast, prolactin did not suppress LH pulse frequency in aged males, with prolactin leading to an increase in mean LH concentration. These data demonstrate the emergence of impairments in prolactin transport into the brain and deficits in specific functional responses to prolactin with ageing.

Unique Organization of Actin Cytoskeleton in Magnocellular Vasopressin Neurons in Normal Conditions and in Response to Salt-Loading.
Magnocellular neurosecretory cells (MNCs) are intrinsically osmosensitive and can be activated by increases in blood osmolality, triggering the release of antidiuretic hormone vasopressin (VP) to promote water retention. Hence, the activity of magnocellular VP neurons is one of the key elements contributing to the regulation of body fluid homeostasis in healthy organisms. Chronic exposure to high dietary salt leads to excessive activation of VP neurons, thereby elevating levels of circulating VP, which can cause increases in blood pressure contributing to salt-dependent hypertension. However, the molecular basis underlying high-salt diet-induced hyperactivation of magnocellular VP neurons remains not fully understood. Previous studies suggest that magnocellular neurosecretory neurons contain a subcortical layer of actin filaments and pharmacological stabilization of this actin network potentiates osmotically-induced activation of magnocellular neurons. Using super-resolution imaging , we investigated the organization of the actin cytoskeleton in rat MNCs under normal physiological conditions and after a chronic increase in blood osmolality following 7 d of salt-loading (SL). We found that, in addition to the subcortical layer of actin filaments, magnocellular VP neurons are endowed with a unique network of cytoplasmic actin filaments throughout their somata. Moreover, we revealed that the density of both subcortical and cytoplasmic actin networks in magnocellular VP neurons is dramatically increased following SL. These results suggest that increased osmo-responsiveness of VP neurons following chronic exposure to high dietary salt may be mediated by the modulation of unique actin networks in magnocellular VP neurons, possibly contributing to elevated blood pressure in this condition.

NMDA Receptor Expression in the Thalamus of the Stargazer Model of Absence Epilepsy.
In the stargazer mouse model of absence epilepsy, altered corticothalamic excitation of reticular thalamic nucleus (RTN) neurons has been suggested to contribute to abnormal synchronicity in the corticothalamic-thalamocortical circuit, leading to spike-wave discharges, the hallmark of absence seizures. AMPA receptor expression and function are decreased in stargazer RTN, due to a mutation of AMPAR auxiliary subunit stargazin. It is unresolved and debated, however, if decreased excitation of RTN is compatible with epileptogenesis. We tested the hypothesis that relative NMDAR expression may be increased in RTN and/or thalamic synapses in stargazers using Western blot on dissected thalamic nuclei and biochemically isolated synapses, as well as immunogold cytochemistry in RTN. Expression of main NMDAR subunits was variable in stargazer RTN and relay thalamus; however, mean expression values were not statistically significantly different compared to controls. Furthermore, no systematic changes in synaptic NMDAR levels could be detected in stargazer thalamus. In contrast, AMPAR subunits were markedly decreased in both nucleus-specific and synaptic preparations. Thus, defective AMPAR trafficking in stargazer thalamus does not appear to lead to a ubiquitous compensatory increase in total and synaptic NMDAR expression, suggesting that elevated NMDAR function is not mediated by changes in protein expression in stargazer mice.

Acute Suppression of LH Secretion by Prolactin in Female Mice Is Mediated by Kisspeptin Neurons in the Arcuate Nucleus.
Hyperprolactinemia causes infertility, but the specific mechanism is unknown. It is clear that elevated prolactin levels suppress pulsatile release of GnRH from the hypothalamus, with a consequent reduction in pulsatile LH secretion from the pituitary. Only a few GnRH neurons express prolactin receptors (Prlrs), however, and thus prolactin must act indirectly in the underlying neural circuitry. Here, we have tested the hypothesis that prolactin-induced inhibition of LH secretion is mediated

by kisspeptin neurons, which provide major excitatory inputs to GnRH neurons. To evaluate pulsatile LH secretion, we collected serial blood samples from diestrous mice and measured LH levels by ultrasensitive ELISA. Acute prolactin administration decreased LH pulses in wild-type mice. Kisspeptin neurons in the arcuate nucleus and in the rostral periventricular area of the third ventricle (RP3V) acutely responded to prolactin, but prolactin-induced signaling in kisspeptin neurons was up to fourfold higher in the arcuate nucleus when compared with the RP3V. Consistent with this, conditional knockout of Prlr specifically in arcuate nucleus kisspeptin neurons prevented prolactin-induced suppression of LH secretion. Our data establish that during hyperprolactinemia, suppression of pulsatile LH secretion is mediated by Prlr on arcuate kisspeptin neurons.

Sex differences in rapid nonclassical action of 17β-oestradiol on intracellular signalling and oestrogen receptor α expression in basal forebrain cholinergic neurones in mouse.
Rapid nonclassical effects of 17β-oestradiol (E) on intracellular signalling have been identified in the basal forebrain, although the extent to which these actions may be different in males and females is unknown. Previous work has shown that E rapidly phosphorylates cAMP responsive element binding protein (CREB) via ERα in female cholinergic neurones. Using this indicator, the present study examined whether nonclassical actions of E occur in a sexually dimorphic manner within basal forebrain cholinergic neurones in mice. In addition, we investigated the expression and intracellular distribution of oestrogen receptor (ER)α in cholinergic neurones in female and male mice. Animals were gonadectomised and treated 2 weeks later with E . The number of CREB-expressing cholinergic neurones was not altered in any of the brain regions after E treatment in both males and females. However, E treatment rapidly (< 15 minutes) increased ($P < 0.05$) the number of cholinergic neurones expressing phosphorylated CREB (pCREB) in the substantia innominata and medial septum but not in the striatum in female mice. By contrast, E did not change pCREB expression in cholinergic neurones in male mice at any time point (15 minutes, 1 hour, 4 hours), irrespective of the neuroanatomical location. We also observed that, in females, more cholinergic neurones expressed nuclear ERα in all regions, whereas males showed more cholinergic neurones with cytoplasmic or both nuclear and cytoplasmic expression of ERα. Taken together, these results demonstrate a marked sex difference in the E -induced nonclassical effect and intracellular distribution of ERα in basal forebrain cholinergic neurones in vivo.

The Role of Interleukin-10 in Mediating the Effect of Immune Challenge on Mouse Gonadotropin-Releasing Hormone Neurons .
Immune challenge alters neural functioning via cytokine production. Inflammation has profound impact on the central regulation of fertility, but the mechanisms involved are not clearly defined. The anti-inflammatory cytokine interleukin (IL)-10 is responsible for balancing the immune response in the brain. To examine whether IL-10 has an effect on the function of the gonadotropin-releasing hormone (GnRH) neurons, we first examined the effect of immune responses with distinct cytokine profiles, such as the T cell-dependent (TD) and T cell-independent (TI) B-cell response. We investigated the effect of the TD and TI immune responses on ERK1/2 phosphorylation in GnRH neurons by administering fluorescein isothiocyanate/keyhole limpet hemocyanin (KLH-FITC) or dextran-FITC to female mice. Although dextran-FITC had no effect, KLH-FITC induced ERK1/2 phosphorylation in GnRH neurons after 6 d. KLH-FITC treatment increased the levels of IL-10 in the hypothalamus (HYP), but this treatment did not cause lymphocyte infiltration or an increase in the levels of proinflammatory cytokines. In IL-10 knock-out (KO) mice, KLH-FITC-induced ERK1/2 phosphorylation in the GnRH neurons was absent. We also showed that in IL-10 KO mice, the estrous cycle was disrupted. Perforated patch-clamp recordings from GnRH-GFP neurons, IL-10 immunohistochemistry, and in vitro experiments on acute brain slices revealed that IL-10 can directly alter GnRH neuron firing and induce ERK1/2 phosphorylation. These observations demonstrate that IL-10 plays a role in influencing signaling of GnRH neurons in the TD immune response. These results also provide the first evidence that IL-10 can directly alter the function of GnRH neurons and may help the maintenance of the integrity of the estrous cycle.

Estrogen augments the T cell-dependent but not the T-independent immune response.
Estrogen plays a critical regulatory role in the development and maintenance of immunity. Its role in the regulation of antibody synthesis in vivo is still not completely clear. Here, we have compared the effect of estrogen on T cell-dependent (TD) and T cell-independent type 2 (TI-2) antibody responses. The results provide the first evidence that estrogen enhances the TD but not the TI-2 response. Ovariectomy significantly decreased, while estrogen re-administration increased the number of hapten-specific IgM- and IgG-producing cells in response to TD antigen. In vitro experiments also show that estrogen may have a

direct impact on B and T cells by inducing rapid signaling events, such as Erk and AKT phosphorylation, cell-specific Ca(2+) signal, and NFkappaB activation. These non-transcriptional effects are mediated by classical estrogen receptors and partly by an as yet unidentified plasma membrane estrogen receptor. Such receptor- mediated rapid signals may modulate the in vivo T cell-dependent immune response.

Changes in the GRIP 1&2 scaffolding proteins in the cerebellum of the ataxic stargazer mouse.
Glutamate receptor-interacting proteins (GRIP1&2) and protein-interacting with C kinase-1 (PICK1) are synaptic scaffold proteins associated with the stabilization and recycling of synaptic GluA2-, 3- and 4c-containing α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptors (AMPARs). PICK1-mediated phosphorylation of GluA serine880 uncouples GRIP1&2 leading to AMPAR endocytosis, important in mediating forms of synaptic plasticity underlying learning and memory. Ataxic and epileptic stargazer mice possess a mutation in the CACNG2 gene encoding the transmembrane AMPAR-regulatory protein (TARP)-γ2 (stargazin). TARPs are AMPAR-auxiliary subunits required for efficient AMPAR trafficking to synapses. Stargazin is abundantly expressed in the cerebellum and its loss results in severe deficits in AMPAR trafficking to cerebellar synapses, particularly at granule cell (GC) synapses, leading to the ataxic phenotype of stargazers. However, how the stargazin mutation impacts on the expression of other AMPAR-interacting scaffold proteins is unknown. This study shows a significant increase in GRIP1&2, but not PICK1, levels in whole tissue and synapse-enriched extracts from stargazer cerebella. Post-embedding immunogold-cytochemistry electron microscopy showed GRIP1&2 levels were unchanged at mossy fiber-GC synapses in stargazers, which are silent due to virtual total absence of synaptic and extrasynaptic GluA2/3-AMPARs. These results indicate that loss of synaptic AMPARs at this excitatory synapse does not affect GRIP1&2 expression within the postsynaptic region of mossy fiber-GC synapses. Interestingly, increased GRIP and reduced GluA2-AMPARexpression also occur in cerebella of autistic patients. Further research establishing the role of elevated cerebellar GRIP1&2 in stargazers may help identify common cellular mechanisms in the comorbid disorders ataxia, epilepsy and autism leading to more effective treatment strategies.

Selective loss of AMPA receptors at corticothalamic synapses in the epileptic stargazer mouse.
Absence seizures are common in the stargazer mutant mouse. The mutation underlying the epileptic phenotype in stargazers is a defect in the gene encoding the normal expression of the protein stargazin. Stargazin is involved in the membrane trafficking and synaptic targeting of α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptors (AMPARs) at excitatory glutamatergic synapses. Thus, the genetic defect in the stargazer results in a loss of AMPARs and consequently, excitation at glutamatergic synapses. Absence seizures are known to arise in thalamocortical networks. In the present study we show for the first time, using Western blot analysis and quantitative immunogold cytochemistry, that in the epileptic stargazer mouse, there is a global loss of AMPAR protein in nucleus reticularis (RTN) and a selective loss of AMPARs at corticothalamic synapses in inhibitory neurons of the RTN thalamus. In contrast, there is no significant loss of AMPARs at corticothalamic synapses in excitatory relay neurons in the thalamic ventral posterior (VP) region. The findings of this study thus provide cellular and molecular evidence for a selective regional loss of synaptic AMPAR within the RTN that could account for the loss of function at these inhibitory neuron synapses, which has previously been reported from electrophysiological studies. The specific loss of AMPARs at RTN but not relay synapses in the thalamus of the stargazer, could contribute to the absence epilepsy phenotype by altering thalamocortical network oscillations. This is supported by recent evidence that loss of glutamate receptor subunit 4 (GluA4) (the predominant AMPAR-subtype in the thalamus), also leads to a specific reduction in strength in the cortico-RTN pathway and enhanced thalamocortical oscillations, in the Gria4(-/-) model of absence epilepsy. Thus further study of thalamic changes in these models could be important for future development of drugs targeted to absence epilepsy.

Aims: *Corpora amylacea* of human brain, recently renamed as wasteosomes, are granular structures that appear during aging and also accumulate in specific areas of the brain in neurodegenerative conditions. Acting as waste containers of the brain, wasteosomes are formed by polyglucosan aggregates that entrap waste substances of different cell types, are expelled from the brain to the cerebrospinal fluid (CSF) and are phagocytosed by macrophages. In the present study, we analyse the phagocytosis of wasteosomes and the mechanisms involved in this process. **Methods:** We purified wasteosomes from human CSF and stained them with Concanavalin A-rhodamine, NHS-AF555 protein labelling probe or PAS staining. Then, they were incubated with THP-1 macrophages stained with the Vybrant® CFDA-SE Cell Tracer Kit. Time-lapse recording techniques were performed to evaluate the phagocytosis. **Results:** THP-1 macrophages phagocytose and process wasteosomes. Once phagocytosed, Concanavalin A-rhodamine-labelled and NHS-AF555-labelled wasteosomes were digested or fragmented and (at least) the fluorescent protein fraction was exposed on the surface of macrophages as well as transferred from one macrophage to another. We observed a lower reactivity of macrophages towards PAS-stained wasteosomes. In any case, these time-lapse studies revealed that under all the experimental conditions THP-1 macrophages phagocytose or interact with wasteosomes. **Conclusions:** Our findings support the role of the immune system in wasteosomes elimination and thus, in the removal of brain waste substances

act as containers that remove waste products from the brain.
(CA) in the human brain are granular bodies formed by polyglucosan aggregates that amass waste products of different

origins. They are generated by astrocytes, mainly during aging and neurodegenerative conditions, and are located predominantly in periventricular and subpial regions. This study shows that CA are released from these regions to the cerebrospinal fluid and are present in the cervical lymph nodes, into which cerebrospinal fluid drains through the meningeal lymphatic system. We also show that CA can be phagocytosed by macrophages. We conclude that CA can act as containers that remove waste products from the brain and may be involved in a mechanism that cleans the brain. Moreover, we postulate that CA may contribute in some autoimmune brain diseases, exporting brain substances that interact with the immune system, and hypothesize that CA may contain brain markers that may aid in the diagnosis of certain brain diseases.

Corpora Amylacea in the Human Brain Exhibit Neoepitopes of a Carbohydrate Nature.
Corpora amylacea (CA) in the human brain are polyglucosan bodies that accumulate residual substances originated from aging and both neurodegenerative and infectious processes. These structures, which act as waste containers, are released from the brain to the cerebrospinal fluid, reach the cervical lymph nodes the meningeal lymphatic system and may be phagocytosed by macrophages. Recent studies indicate that CA present certain neoepitopes (NEs) that can be recognized by natural antibodies of the IgM class, and although evidence of different kinds suggests that these NEs may be formed by carbohydrate structures, their precise nature is unknown. Here, we adapted standard techniques to examine this question. We observed that the preadsorption of IgMs with specific carbohydrates has inhibitory effects on the interaction between IgMs and CA, and found that the digestion of CA proteins had no effect on this interaction. These findings point to the carbohydrate nature of the NEs located in CA. Moreover, the present study indicates that, , the binding between certain natural IgMs and certain epitopes may be disrupted by certain monosaccharides. We wonder, therefore, whether these inhibitions may also occur . Further studies should now be carried out to assess the possible effect of glycemia on the reactivity of natural IgMs and, by extension, on natural immunity.

From corpora amylacea to wasteosomes: History and perspectives.
Corpora amylacea (CA) have been described in several human organs and have been associated with ageing and several pathological conditions. Although they were first discovered two centuries ago, their function and significance have not yet been identified. Here, we provide a chronological summary of the findings on CA in various organs and identify their similarities. After collecting and integrating these findings, we propose to consider CA as waste containers created by specific cells, which sequester waste products and foreign products, and assemble them within a glycan structure. The containers are then secreted into the external medium or interstitial spaces, in this latter case subsequently being phagocytosed by macrophages. This proposal explains, among others, why CA are so varied in content, why only some of them contain fibrillary amyloid proteins, why all of them contain glycan structures, why some of them contain neo-epitopes and are phagocytosed, and why they can be intracellular or extracellular structures. Lastly, in order to avoid the ambiguity of the term amyloid (which can indicate starch-like structures but also insoluble fibrillary proteins), we propose renaming CA as "wasteosomes", emphasising the waste products they entrap rather than their misleading amyloid properties.

Introduction: PACAP (pituitary adenylate cyclase-activating polypeptide) is a neuropeptide expressed in many organs that has been shown to have general cytoprotective, anti-inflammatory, and antiapoptotic effects. We have limited data about the examinations of the Gut-associated lymphoid tissue (GALT) in PACAP wild-type (WT) and PACAP deficient (PACAP KO) mice. The aim of the present experiment was to reveal qualitative and quantitave changes between the two mice groups found in the Peyer's patches. Methods: Samples were taken from aging (12-15 monthes old) WT (n=10) and PACAP KO (n=10) mice. We investigated the percentage of numerous immune cell populations in the GALT of WT and PACAP KO mice. We performed immunophenotyping of GALT immune cells and investigated the expression of TIM-3 and PD-1 immune checkpoint molecules with the detection of galectin-9 and PD-L1. We monitored the activation (CD69) and citotoxicity (perforin) as well. Results: We demonstrated a significant decrease in the frequency of GALT CD3+ T cells obtained from PACAP KO mice compared with wild-type mice. Monitoring the T cell subpopulations in CD3+ T cells we found significant increase in CD4+ T cells and significant decrease in CD8+ T-cells. Investigating immune-checkpoint receptors, TIM-3 showed a significantly decreased expression in all T cell subpopulations, while PD-1 expression significantly decreased only in CD8+ T cells in PACAP KO mice compared to wild-type mice. Conclusion: We hypothesize that these local changes might have a role of the impaired antiinflammatory responses in PACAP KO mice, however, determining the exact function requires further investigations.

Accelerated pre-senile systemic amyloidosis in PACAP knockout mice - a protective role of PACAP in age-related degenerative processes.
Dysregulation of neuropeptides may play an important role in aging-induced impairments. Among them, pituitary adenylate cyclase-activating polypeptide (PACAP) is a potent cytoprotective peptide that provides an endogenous control against a variety of tissue-damaging stimuli. We hypothesized that the progressive decline of PACAP throughout life and the well-known general cytoprotective effects of PACAP lead to age-related pathophysiological changes in PACAP deficiency, supported by the increased vulnerability to various stressors of animals partially or totally lacking PACAP. Using young and aging CD1 PACAP knockout (KO) and wild type (WT) mice, we demonstrated pre-senile amyloidosis in young PACAP KO animals and showed that senile amyloidosis appeared accelerated, more generalized, more severe, and affected more individuals. Histopathology showed age-related systemic amyloidosis with mainly kidney, spleen, liver, skin, thyroid, intestinal, tracheal, and esophageal involvement. Mass spectrometry-based proteomic analysis, reconfirmed with immunohistochemistry, revealed that apolipoprotein-AIV was the main amyloid protein in the deposits together with several accompanying proteins. Although the local amyloidogenic protein expression was disturbed in KO animals, no difference was found in laboratory lipid parameters, suggesting a complex pathway leading to increased age-related degeneration with amyloid deposits in the absence of PACAP. In spite of no marked inflammatory histological changes or blood test parameters, we detected a disturbed cytokine profile that possibly creates a pro-inflammatory milieu favoring amyloid deposition. In summary, here we describe accelerated systemic senile amyloidosis in PACAP gene-deficient mice, which might indicate an early aging phenomenon in this mouse strain. Thus, PACAP KO mice could serve as a model of accelerated aging with human relevance. © 2018 The Authors. A ROLE FOR MYELOID MIR-155 IN REGULATING NEONATAL HYPOXIA INDUCED SEIZURES

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Hypoxic ischaemic injury (HIE) in the neonatal brain has significant consequences on neurodevelopment and increases the occurrence of neurological deficits in infants. Currently, therapeutic options for the treatment of HIE are very limited. In this study we have assessed the role of the inflammatory microRNA, miR-155, expressed in myeloid cells specifically, on regulating inflammation and seizure severity in a preclinical model of neonatal hypoxia-induced seizures (Hx-seizures). Wildtype (WT) miR-155 (miR-155+/+ LysMCre) mice were compared to a mouse line in which miR-155 was deleted in myeloid cells (miR-155fl/fl LysMCre). We demonstrate that following Hx-seizures expression of miR-155 target genes including brain-derived neurotrophic factor (BDNF), arginase-2 (Arg-2), SHIP-1 and SOCS-1 in miR-155fl/fl LysMCre was significantly increased compared to WT controls . Furthermore, BDNF protein levels were significantly higher in miR-155fl/fl LysMCre mice with Hx-seizures. Conversely, there was decreased transcription of pro-inflammatory cytokines IL-1b and IL-6 and lower protein levels of IL-1b in miR-155fl/fl LysMCre mice with Hx-seizures as compared to WTs. Finally, myeloid miR-155 deletion significantly reduced behavioural seizure severity score and reduced electrographically (EEG) measured seizure frequency ($p = 0.0516$) and seizure burden by 292.9 seconds ($p < 0.01$) as compared to mice with wildtype miR-155, suggesting miR-155 regulation of seizure occurrence in this model. Behavioural tests for cognitive and motor functions at 5 weeks post Hx-seizures demonstrated differences between genotypes. Excitingly this work highlights that inhibition of miR-155, specifically in myeloid cells, may hold therapeutic benefit for both seizures and comorbidities associated with hypoxic brain injury.

Multi-factorial nerve guidance conduit engineering improves outcomes in inflammation, angiogenesis and large defect nerve repair.
Nerve guidance conduits (NGCs) are sub-optimal for long-distance injuries with inflammation and poor vascularization related to poor axonal repair. This study used a multi-factorial approach to create an optimized biomaterial NGC to address each of these issues. Through stepwise optimization, a collagen-chondroitin-6-sulfate (Coll-CS) biomaterial was functionalized with extracellular matrix (ECM) components; fibronectin, laminin 1 and laminin 2 (FibL1L2) in specific ratios. A snap-cooled freeze-drying process was then developed with optimal pore architecture and alignment to guide axonal bridging. Culture of adult rat dorsal root ganglia on NGCs demonstrated significant improvements in inflammation, neurogenesis and angiogenesis in the specific Fib:L1:L2 ratio of 1:4:1. In clinically relevant, large 15 mm rat sciatic nerve defects, FibL1L2-NGCs demonstrated significant improvements in axonal density and angiogenesis compared to unmodified NGCs with functional equivalence to autografts. Therefore, a multiparameter ECM-driven strategy can significantly improve axonal repair across large defects, without exogenous cells or growth factors.

Mitochondrial arginase-2 is essential for IL-10 metabolic reprogramming of inflammatory macrophages.

Mitochondria are important regulators of macrophage polarisation. Here, we show that arginase-2 (Arg2) is a microRNA-155 (miR-155) and interleukin-10 (IL-10) regulated protein localized at the mitochondria in inflammatory macrophages, and is critical for IL-10-induced modulation of mitochondrial dynamics and oxidative respiration. Mechanistically, the catalytic activity and presence of Arg2 at the mitochondria is crucial for oxidative phosphorylation. We further show that Arg2 mediates this process by increasing the activity of complex II (succinate dehydrogenase). Moreover, Arg2 is essential for IL-10-mediated downregulation of the inflammatory mediators succinate, hypoxia inducible factor 1α (HIF-1α) and IL-1β in vitro. Accordingly, HIF-1α and IL-1β are highly expressed in an LPS-induced in vivo model of acute inflammation using Arg2 mice. These findings shed light on a new arm of IL-10-mediated metabolic regulation, working to resolve the inflammatory status of the cell.

Biomaterial and Therapeutic Approaches for the Manipulation of Macrophage Phenotype in Peripheral and Central Nerve Repair.
Injury to the peripheral or central nervous systems often results in extensive loss of motor and sensory function that can greatly diminish quality of life. In both cases, macrophage infiltration into the injury site plays an integral role in the host tissue inflammatory response. In particular, the temporally related transition of macrophage phenotype between the M1/M2 inflammatory/repair states is critical for successful tissue repair. In recent years, biomaterial implants have emerged as a novel approach to bridge lesion sites and provide a growth-inductive environment for regenerating axons. This has more recently seen these two areas of research increasingly intersecting in the creation of 'immune-modulatory' biomaterials. These synthetic or naturally derived materials are fabricated to drive macrophages towards a pro-repair phenotype. This review considers the macrophage-mediated inflammatory events that occur following nervous tissue injury and outlines the latest developments in biomaterial-based strategies to influence macrophage phenotype and enhance repair.

Impact of Exercise on Immunometabolism in Multiple Sclerosis.
Multiple Sclerosis (MS) is a chronic, autoimmune condition characterized by demyelinating lesions and axonal degradation. Even though the cause of MS is heterogeneous, it is known that peripheral immune invasion in the central nervous system (CNS) drives pathology at least in the most common form of MS, relapse-remitting MS (RRMS). The more progressive forms' mechanisms of action remain more elusive yet an innate immune dysfunction combined with neurodegeneration are likely drivers. Recently, increasing studies have focused on the influence of metabolism in regulating immune cell function. In this regard, exercise has long been known to regulate metabolism, and has emerged as a promising therapy for management of autoimmune disorders. Hence, in this review, we inspect the role of key immunometabolic pathways specifically dysregulated in MS and highlight potential therapeutic benefits of exercise in modulating those pathways to harness an anti-inflammatory state. Finally, we touch upon current challenges and future directions for the field of exercise and immunometabolism in MS.

Novel mineralocorticoid receptor mechanisms regulate cardiac tissue inflammation in male mice.
MR activation in macrophages is critical for the development of cardiac inflammation and fibrosis. We previously showed that MR activation modifies macrophage pro-inflammatory signalling, changing the cardiac tissue response to injury via both direct gene transcription and JNK/AP-1 second messenger pathways. In contrast, MR-mediated renal electrolyte homeostasis is critically determined by DNA-binding-dependent processes. Hence, ascertaining the relative contribution of MR actions via DNA binding or alternative pathways on macrophage behaviour and cardiac inflammation may provide therapeutic opportunities which separate the cardioprotective effects of MR antagonists from their undesirable renal potassium-conserving effects. We developed new macrophage cell lines either lacking MR or harbouring a mutant MR incapable of DNA binding. Western blot analysis demonstrated that MR DNA binding is required for lipopolysaccharide (LPS), but not phorbol 12-myristate-13-acetate (PMA), induction of the MAPK/pJNK pathway in macrophages. Quantitative RTPCR for pro-inflammatory and pro-fibrotic targets revealed subsets of LPS- and PMA-induced genes that were either enhanced or repressed by the MR via actions that do not always require direct MR-DNA binding. Analysis of the MR target gene and profibrotic factor MMP12 identified promoter elements that are regulated by combined MR/MAPK/JNK signalling. Evaluation of cardiac tissue responses to an 8-day DOC/salt challenge in mice selectively lacking MR DNA-binding in macrophages demonstrated levels of inflammatory markers equivalent to WT, indicating non-DNA binding-dependent MR signalling in macrophages is sufficient for DOC/salt-induced tissue inflammation. Our data demonstrate that the MR regulates a macrophage pro-inflammatory phenotype and cardiac tissue inflammation, partially via pathways that do not require DNA binding.

Parsing the IL-37-Mediated Suppression of Inflammasome Function.
Interleukin (IL)-37 is a member of the IL-1 family of cytokines. Although its broad anti-inflammatory properties are well described, the effects of IL-37 on inflammasome function remain poorly understood. Performing gene expression analyses, ASC oligomerization/speck assays and caspase-1 assays in bone marrow-derived macrophages (BMDM), and employing an in vivo endotoxemia model, we studied how IL-37 affects the expression and maturation of IL-1β and IL-18, inflammasome activation, and pyroptosis in detail. IL-37 inhibited IL-1β production by NLRP3 and AIM2 inflammasomes, and IL-18 production by the NLRP3 inflammasome. This inhibition was partially attributable to effects on gene expression: whereas IL-37 did not affect lipopolysaccharide (LPS)-induced mRNA expression of or inflammasome components, IL-37-transgenic BMDM displayed an up to 83% inhibition of baseline and LPS-stimulated compared to their wild-type counterparts. Importantly, we observed that IL-37 suppresses nigericin- and silica-induced ASC oligomerization/speck formation (a step in inflammasome activation and subsequent caspase-1 activation), and pyroptosis (-50%). In mice subjected to endotoxemia, IL-37 inhibited plasma IL-1β (-78% compared to wild-type animals) and IL-18 (-61%). Thus, our study adds suppression of inflammasome activity to the portfolio of anti-inflammatory pathways employed by IL-37, highlighting this cytokine as a potential tool for treating inflammasome-driven diseases.

The Single Nucleotide Polymorphism Mal-D96N Mice Provide New Insights into Functionality of Mal in TLR Immune Responses.
MyD88 adaptor-like (Mal) protein is the most polymorphic of the four key adaptor proteins involved in TLR signaling. TLRs play a critical role in the recognition and immune response to pathogens through activation of the prototypic inflammatory transcription factor NF-κB. The study of single nucleotide polymorphisms in TLRs, adaptors, and signaling mediators has provided key insights into the function of the corresponding genes but also into the susceptibility to infectious diseases in humans. In this study, we have analyzed the immune response of mice carrying the human Mal-D96N genetic variation that has previously been proposed to confer protection against septic shock. We have found that Mal-D96N macrophages display reduced cytokine expression in response to TLR4 and TLR2 ligand challenge. Mal-D96N macrophages also display reduced MAPK activation, NF-κB transactivation, and delayed NF-κB nuclear translocation, presumably via delayed kinetics of Mal interaction with MyD88 following LPS stimulation. Importantly, Mal-D96N genetic variation confers a physiological protective phenotype to in vivo models of LPS-, -, and influenza A virus-induced hyperinflammatory disease in a gene dosage-dependent manner. Together, these results highlight the critical role Mal plays in regulating optimal TLR-induced inflammatory signaling pathways and suggest the potential therapeutic advantages of targeting the Mal D96 signaling nexus.

PB1-F2 Peptide Derived from Avian Influenza A Virus H7N9 Induces Inflammation via Activation of the NLRP3 Inflammasome.
The emergence of avian H7N9 influenza A virus in humans with associated high mortality has highlighted the threat of a potential pandemic. Fatal H7N9 infections are characterized by hyperinflammation and increased cellular infiltrates in the lung. Currently there are limited therapies to address the pathologies associated with H7N9 infection and the virulence factors that contribute to these pathologies. We have found that PB1-F2 derived from H7N9 activates the NLRP3 inflammasome and induces lung inflammation and cellular recruitment that is NLRP3-dependent. We have also shown that H7N9 and A/Puerto Rico/H1N1 (PR8)PB1-F2 peptide treatment induces significant mitochondrial reactive oxygen production, which contributes to NLRP3 activation. Importantly, treatment of cells or mice with the specific NLRP3 inhibitor MCC950 significantly reduces IL-1β maturation, lung cellular recruitment, and cytokine production. Together, these results suggest that PB1-F2 from H7N9 avian influenza A virus may be a major contributory factor to disease pathophysiology and excessive inflammation characteristic of clinical infections and that targeting the NLRP3 inflammasome may be an effective means to reduce the inflammatory burden associated with H7N9 infections.

Toll-like receptors: the swiss army knife of immunity and vaccine development.
Innate immune cells have a critical role in defense against infection and disease. Central to this is the broad specificity with which they can detect pathogen-associated patterns and danger-associated patterns via the pattern recognition receptors (PRRs) they express. Several families of PRRs have been identified including: Toll-like receptors (TLRs), C-type lectin-like

receptors, retinoic acid-inducible gene-like receptors and nucleotide-binding oligomerization domain-like receptors. TLRs are one of the most largely studied families of PRRs. The binding of ligands to TLRs on antigen presenting cells (APCs), mainly dendritic cells, leads to APC maturation, induction of inflammatory cytokines and the priming of naive T cells to drive acquired immunity. Therefore, activation of TLRs promotes both innate inflammatory responses and the induction of adaptive immunity. Consequently, in the last two decades mounting evidence has inextricably linked TLR activation with the pathogenesis of immune diseases and cancer. It has become advantageous to harness these aspects of TLR signaling therapeutically to accelerate and enhance the induction of vaccine-specific responses and also target TLRs with the use of biologics and small molecule inhibitors for the treatment of disease. In these respects, TLRs may be considered a 'Swiss Army' knife of the immune system, ready to respond in a multitude of infectious and disease states. Here we describe the latest advances in TLR-targeted therapeutics and the use of TLR ligands as vaccine adjuvants.

MILD LIVER DAMAGE INDUCES SPATIAL LEARNING AND MEMORY IMPAIRMENT IN RATS. UNDERLYING MECHANISMS AND PREVENTION BY RIFAXIMIN

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Gergana Mincheva[1], Paola Leone[2], Tiziano Balzano[3], Michele Malaguarnera[4], Vicente Felipo[1], Marta Llansola[1]

Universidad de Valencia, Department Of Psychobiology, Valencia, Spain

Background: Patients with non-alcoholic fatty liver disease (NAFLD) may show mild cognitive impairment. Neuroinflammation in hippocampus contributes to cognitive impairment in rats with hyperammonemia and minimal hepatic encephalopathy (MHE). Treatment with rifaximin reverses cognitive impairment in a large proportion of cirrhotic patients with MHE. The underlying mechanisms remain unclear. **Aims:** The aims of this work were to assess if rats with mild liver damage show neuroinflammation in hippocampus associated to alterations in neurotransmission and cognitive function and if treatment with rifaximin reverses the cognitive impairment and the underlying mechanisms. **Methods:** Mild liver damage was induced by intraperitoneal injection of carbon-tetrachloride for four weeks and some rats were treated daily orally with rifaximin. Spatial and non-spatial learning and memory were evaluated. We analyzed immune cells infiltration, microglia and astrocytes activation, proinflammatory cytokine levels and glutamatergic neurotransmission in hippocampus. **Results:** Rats with mild liver damage show impaired spatial learning and memory, whereas non-spatial and working memory are not altered. Mild liver damage increased CCL2 in hippocampus, associated with infiltration of monocytes, activation of microglia and increased TNFα in hippocampal neurons, associated with reduced membrane expression of NR1 and NR2A subunits of NMDA receptor. These effects are reversed by rifaximin, that improves spatial learning and memory. Mild liver damage also triggers CD4+ lymphocytes infiltration, astrocytes activation, increased IL-1b and enhanced membrane expression of GluA2 subunit of AMPA receptors in hippocampus. These changes are not reversed by rifaximin. **Conclusions:** Treatment with rifaximin may improve cognitive function in patients with NAFLD showing mild cognitive impairment.

Rifaximin Prevents T-Lymphocytes and Macrophages Infiltration in Cerebellum and Restores Motor Incoordination in Rats with Mild Liver Damage.
In patients with liver cirrhosis, minimal hepatic encephalopathy (MHE) is triggered by a shift in peripheral inflammation, promoting lymphocyte infiltration into the brain. Rifaximin improves neurological function in MHE by normalizing peripheral inflammation. Patients who died with steatohepatitis showed T-lymphocyte infiltration and neuroinflammation in the cerebellum, suggesting that MHE may already occur in these patients. The aims of this work were to assess, in a rat model of mild liver damage similar to steatohepatitis, whether: (1) the rats show impaired motor coordination in the early phases of liver damage; (2) this is associated with changes in the immune system and infiltration of immune cells into the brain; and (3) rifaximin improves motor incoordination, associated with improved peripheral inflammation, reduced infiltration of immune cells and neuroinflammation in the cerebellum, and restoration of the alterations in neurotransmission. Liver damage was induced by carbon tetrachloride (CCl) injection over four weeks. Peripheral inflammation, immune cell infiltration, neuroinflammation, and neurotransmission in the cerebellum and motor coordination were assessed. Mild liver damage induces neuroinflammation and altered neurotransmission in the cerebellum and motor incoordination. These alterations are associated with increased TNFa, CCL20, and CX3CL1 in plasma and cerebellum, IL-17 and IL-15 in plasma, and CCL2 in cerebellum. This promotes T-lymphocyte and macrophage infiltration in the cerebellum. Early treatment with rifaximin prevents the shift in peripheral inflammation, immune cell infiltration, neuroinflammation, and motor incoordination. This report provides new clues regarding the mechanisms of the beneficial effects of rifaximin, suggesting that early rifaximin treatment could prevent neurological impairment in patients with steatohepatitis.

MECHANISTIC INSIGHTS INTO CEREBRAL MALARIA ASSOCIATED HIPPOCAMPAL DAMAGE AND MEMORY-IMPAIRMENT IN PLASMODIUM BERGHEI ANKA-INFECTED BALB/C MICE

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Meetali Girdhar, Anju Katyal
University of Delhi, Dr. B.r. Ambedkar Center For Biomedical Research, Delhi, India

Cerebral malaria (CM) is a neurological complication of *Plasmodium falciparum* making it the fourth major cause of morbidity in children <5 years of age. **Neurocognitive deficits** remain the **hidden burden** of malaria accounting for memory impairment in **25% of the survivors**. Despite these striking numbers, we **lack a complete understanding of events** leading to memory impairment during CM and therapeutic targets for its reversal. Thus, here we aim to delineate the mechanism and extent of hippocampal damage responsible for working-memory impairment in *Plasmodium berghei* ANKA (PbA) infected Balb/c mice with progressing parasitaemia. Present work involved assessment for working-memory deficits via **novel object recognition (NOR) and passive avoidance task (PAT**), evaluation of hippocampal damage by **HE and CV staining, immunofluorescence** studies to establish the involvement of brain resident cells (astrocytes, microglia, and neurons) in inducing the damage, and **qRT-PCR** analysis of BDNF and VEGF at different parasitemia levels viz 1%, 5%, 10%, 15% and 20%. Histopathological analysis clearly indicates severe hippocampal damage, neuronal loss, and piknosis with progressing parasitaemia, substantiated by NOR and PAT depicting severe memory deficits with most severe damage at 15 and 20%. Further, through IF studies we observed increased activation of microglia and astrocytes; 4-fold decrease in BDNF and 3-fold increase in VEGF gene expression; leading to enhanced neuroinflammation disrupting the neuronal signaling and memory. **Thus, our results provide novel insights into the involvement of BDNF, VEGF, and brain resident cells mediated mechanism of memory impairment**. However, further work is required to validate the exact molecular mechanism.

COVID-19 is a respiratory disease affecting multiple organ systems including the central nervous system (CNS), with a characteristic loss of smell and taste that could distinguish COVID-19 from other respiratory diseases. Although frequently reported and extensively studied, the neurological symptoms remain enigmatic; there is no consensus on the consequences, variability or the extent of the CNS infection. Human induced pluripotent stem cell (hiPSC) derived neural progenitor cells (NPCs) and the cortical excitatory neurons were used as a model to address the questions of sensitivity and permissiveness to the SARS-CoV-2 brain infection, to study the extent and possible consequences and to explore the mechanisms of viral entry. The cells were infected with SARS-CoV-2 variants Alpha, Delta and the ancestral Wuhan and D614G variants in two different conditions; with the endogenous levels of the main docking receptor the virus utilizes - ACE2 and in a condition where the receptor is stably overexpressed. The infection properties and the differences between the conditions were assessed by microscopy, measuring the viral kinetics, infectivity assays and by S-pseudotyped single-cycle lentiviral infections, in addition. While the ACE2 overexpressing neurons display typical hallmarks of the viral infection, the infection of the neurons expressing endogenous levels of ACE2 remains sporadic and without prospects to set off a productive infection across the experimental conditions and SARS-CoV-2 variants applied.

HEMIZYGOUS KO OF MID1 RECAPITULATES THE BEHAVIOURAL PHENOTYPE INDUCED BY PRENATAL IMMUNE ACTIVATION

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Monica Iachizzi, Joseph Scarborough, Juliet Richetto, Urs Meyer
University of Zurich, Institute Of Veterinary Pharmacology And Toxicology, University of Zurich - Vetsuisse, Switzerland

Environmental insults during prenatal or postnatal developmental periods are critical in shaping adult physiology and CNS function, the effects of which may play a role in the pathogenesis of neuropsychiatric illnesses. Maternal immune activation causes long-term and genome-wide changes in the offspring's methylome, and *Mid1* stood out as the gene showing the most extensive changes. The aim of this study was to investigate whether a transgenic mouse model of Mid-1 (*Mid1*-KO) could recapitulate the behavioral changes induced by prenatal immune activation, supporting the idea that the *Mid1* gene might be a molecular mechanism mediating the negative effects of prenatal maternal immune activation. Behavioural testing in adult Mid-1 KO males included paradigms assessing spatial recognition memory, social interaction, and prepulse inhibition of the acoustic startle reflex. Perfusion was performed prior to brain collection for total RNA analysis and IHC staining on the *Corpus Callosum* respectively. Behavioural tests and molecular analyses recapitulated our previous findings in male offspring of immunologically challenged mothers. IHC analyses show a different composition in the white matter of Mid-1 KO mice compared to Wt. Furthermore, qRT-PCR analyses of mRNA from different brain regions of mice treated with prenatal viral-like immune activation Poly I:C, confirm our results, showing a decrease in *Mid1* gene expression. Depletion of the *Mid1* gene in male animals recapitulates the behavioural profile induced by prenatal immune activation, suggesting that the epigenetic dampening of *Mid1* expression in PolyI:C mice could be a molecular mechanism mediating the adverse effects of exposure to prenatal infection

Loss of olfaction is a consequence of SARS-CoV-2 infection, suggesting viral invasion of the brain via the olfactory system. However, the underlying mechanisms remain unclear. This project utilizes a novel 3D *in vitro* model of the olfactory mucosa from non-demented individuals and Alzheimer's disease (AD) patients to provide key insights into SARS-CoV-2 infection at this key entry site of airborne viruses. We developed a 3D model consisting of primary human olfactory mucosal cells collected from nasal biopsies and cultured at air-liquid interface. Cells grown for 21 days were infected with SARS-CoV-2 and cell phenotype and function were assessed. Infection was determined by viral RNA content and SARS-CoV-2 receptor expression by immunocytochemistry. Differential responses of healthy and AD-patient derived cells to SARS-CoV-2 were determined by RNA-sequencing. Primary olfactory mucosal cells express several known SARS-CoV-2 receptors and are highly vulnerable to infection. AD-patient derived cells display alterations in the cellular responses to the virus. RNA analyses revealed distinct profiles of susceptibility to infection and COVID19-associated biomarkers including cathepsins. Our data demonstrate that AD olfactory mucosal cells display a differential response to infection than healthy cells. These data provide important insight into the mechanisms of SARS-CoV-2 infection at a key entry point of airborne viruses. It also provides new targets for limiting or intervening with adverse effects of viral infection at the olfactory mucosa of AD patients.

A SYSTEMS BIOLOGY METHODOLOGY TO DRUG DISCOVERY FOR NEUROTROPIC VIRUS INFECTION WITH CLINICAL CORROBORATION

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Anindita Bhattacharjee[1], Pratik Purohit[2], Prasun Roy[2]

Aims: SARS-Cov2-virus can cause neuroinvasion leading to central respiratory-failure. Polyketide class of drugs is effective against neurotropic viral diseases, as HIV, Japanese-Encephalitis, and Simian Immunodeficiency-virus. Furthermore, beta-lactams (cefems) can be also given for combination therapy. Anti-viral pharmacological agents can provide two-modes of action: virucidal vis-a-vis virostatic. We aim to determine how combined polyketide and beta-lactam drugs can mitigate neurotropic-viral infection. **Method:** To gauge anatomical substrate of neurotropic invasion, the possible viral migration pathways between cranial nerves and brain-stem/limbic region were assessed by fiber-tractography. Furthermore, pharmacological docking analyses were performed to estimate drug-binding affinity of polyketide molecules and beta-lactam molecules towards (i) Human host-receptor [Angiotensin-Converting-Enzyme-2], (ii) Main protease of SARS-CoV-2 virus, as an exemplar. We develop a bi-exponential mathematical-model of antiviral combination pharmacotherapy, to formulate a quantitative framework of combination drugs on virus and human host-cell. **Results:** Our MRI-DTI tractography analysis shows connection between pulmonary/respiratory neural system and different brain nuclei, showing anatomical substrate of signs/symptoms of viral-infected patients. Viral neuroinvasion route was inferred from the interlinkages as estimated by neuroimaging connectometry parameters. Moreover, pharmacological docking-studies revealed higher binding affinity of polyketide drugs and beta-lactam drugs towards both: (i) Virus-receptor, (ii) Human host-cell receptors where virus-receptor binds itself. Contrastingly, single pharmacological agent as cephem showed significantly less affinity towards host-receptor. The bi-exponential mathematical equation is validated using findings of clinical trial using combination therapy on neurotropic virus as JE-virus ($n=112$, $p<0.05$). **Conclusion:** Systems Biology analysis optimizes the combination pharmacotherapy efficiency in viral neuroinfection, as validated by neuroimaging investigation and clinical trial.

Supplementation of taurine improves ionic homeostasis and mitochondrial function in the rats exhibiting post-traumatic stress disorder-like symptoms.
Current pharmacotherapy for post-traumatic stress disorder (PTSD) is limited to few antidepressants. Mitochondrial dysfunction is observed in PTSD, along with altered potassium homeostasis. Nutritional supplementation of taurine can improve ionic homeostasis and thereby treat PTSD-like symptoms in rats.

AGE-DEPENDENT MENINGEAL MACROPHAGES PROTECT AGAINST VIRAL NEUROINFECTION

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Julie Rebejac, Roussel-Queval, Rejane Rua
Universite de Marseille, Centre D'immunologie De Marseille Luminy, Marseille, France

Due to the vital importance of the Central Nervous System (CNS), its potential infection and inflammation have to be tightly controlled. The surface of the CNS is connected to the periphery by a rich and complex tissue, the meninges. They contain a vast network of macrophages subdivided in at least two subpopulations endowed with elusive functions: a neonatal, MHC-II negative macrophage population, and an age-dependent population expressing MHC-II. Using *in situ*-histocytometry, flow cytometry, and single-cell RNA sequencing approaches, we show that those populations have opposite dynamic behaviors in response to *in vivo* peripheral challenges such as LPS, SARS-CoV2 and lymphocytic choriomeningitis virus (LCMV), with an apparent contraction of the MHC-II+ population. Focusing on LCMV infection in experimental mouse models and using innovative pharmacological and genetic depletion strategies, we show that MM represent an early line of protection against this neuroinvasive pathogen. In their absence, specific areas in the meninges become highly infected, leading to fatal brain disease. While their intrinsic sensing of viral replication through the Mitochondrial antiviral-signaling protein (MAVS) is dispensable, sensing of IFNs through the STAT1 pathway plays an important role in controlling viral spread. Unexpectedly, the age-dependent MHC-II+ macrophage population has a major role in controlling neuroinfection, and this is independent of the MHC-II molecule itself. This work helps understand the spatial organization of the brain defense system and the cellular and molecular mechanisms involved in CNS protection.

UNRAVELING THE MOLECULAR MECHANISMS UNDERLYING PARASITE-HOST INTERACTION IN TAENIA SOLIUM NEUROCYSTICERCOSIS

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Maria Carolina Pedro Athié[1], Fernando Cendes[2], Iscia Lopes-Cendes[1], Andre Vieira[3]
[1]Universidade Estadual de Campinas, Department Of Translational Medicine, Campinas, Brazil, [2]Universidade Estadual de Campinas, Department Of Neurology, Campinas, Brazil, [3]Universidade Estadual de Campinas, Department Of Structural And Functional Biology, Campinas, Brazil

Neurocysticercosis is the most frequent parasitic disease in the human CNS. It is most prevalent in low and middle-income countries where poor sanitation is common. The analysis of the transcriptome of the host's brain, adjacent to the cyst, and how the cyst changes throughout infection would help unravel the parasite-host immune systems interactions and facilitate understanding of the resulting disease. However, despite the previous initiatives to sequence the *Taenia solium* genome, it is still not entirely resolved. Thus, in the present work, we seek to improve the annotation of the Taenia solium genome using public transcriptome data (SRX1899230). We followed Ji *et al.*,2018 pipeline for alignment (HISAT2), assembly (Stringtie; QUAPRA), and creation of a new *gtf* file (Cuffcompare) generating ~3,200 potentially new transcripts. Furthermore, the new transcripts with FPKM > 1 were submitted to CPAT using a *C. elegans* training dataset, classifying ~900 above the coding-score cutoff. The UniProtKb/SwissProt curated proteome database found ~600 new mRNAs highly similar to cestoda species or *C. elegans*. Transcripts below the CPAT coding score cutoff that also do not present similarity with any known protein will be considered as potential non-coding genes. In conclusion, our adapted pipeline for discovering new genetic elements based on transcriptomic data demonstrated excellent potential for improving the current *T. solium* reference genome annotation, with the possibility of including at least 600 new protein-coding genes. The next steps are to quantify the potential non-coding transcripts, annotate a new *gtf* file and start the neuro-experimental part of the project.

Modulating Expression of Endogenous Interleukin 1 Beta in the Acute Phase of the Pilocarpine Model of Epilepsy May Change Animal Survival.
The pilocarpine-induced (PILO) model has helped elucidate the electrophysiological and molecular aspects related to mesial temporal lobe epilepsy. It has been suggested that the extensive cell death and edema observed in the brains of these animals could be induced by increased inflammatory responses, such as the rapid release of the inflammatory cytokine interleukin 1 beta (Il1b). In this study, we investigate the role of endogenous Il1b in the acute phase of the PILO model. Our aim is twofold. First, we want to determine whether it is feasible to silence Il1b in the central nervous system using a non-invasive procedure. Second, we aim to investigate the effect of silencing endogenous Il1b and its antagonist, Il1rn.We used RNA interference applied non-invasively to knockdown Il1b and its endogenous antagonist Il1rn. We found that knocking down Il1b prior to pilocarpine injection increased the mortality rate of treated animals. Furthermore, we observed that, when exposing the animals to more Il1b by silencing its endogenous antagonist Il1rn, there was a better response to status epilepticus with decreased animal mortality in the acute phase of the PILO model. Thus, we show the feasibility of using a novel, less invasive approach to study genes involved in the inflammatory response in the central nervous system. Furthermore, our results provide suggestive evidence that modulating endogenous Il1b improves animal survival in the acute phase of the PILO model and may have effects that extend into the chronic phase.

Junctional instability in neuroepithelium and network hyperexcitability in a focal cortical dysplasia human model.
Focal cortical dysplasia (FCD) is a highly epileptogenic cortical malformation with few treatment options. Here we generated human cortical organoids from patients with FCD type II. Using this human model, we mimicked some FCD hallmarks, such

as impaired cell proliferation, the presence of dysmorphic neurons and balloon cells, and neuronal network hyperexcitability. Furthermore, we observed alterations in the adherens junctions zonula occludens-1 and partitioning defective 3, reduced polarization of the actin cytoskeleton, and fewer synaptic puncta. FCD cortical organoids showed downregulation of the small GTPase RHO A, a finding that was confirmed in brain tissue resected from these patients. Functionally, both spontaneous and optogenetically-evoked electrical activity revealed hyperexcitability and enhanced network connectivity in FCD organoids. Taken together, our findings suggest a ventricular zone instability in tissue cohesion of neuroepithelial cells, leading to a maturational arrest of progenitors or newborn neurons, which may predispose to cellular and functional immaturity and compromise the formation of neural networks in FCD.

New avenues in molecular genetics for the diagnosis and application of therapeutics to the epilepsies.
Genetic epidemiology studies have shown that most epilepsies involve some genetic cause. In addition, twin studies have helped strengthen the hypothesis that in most patients with epilepsy, a complex inheritance is involved. More recently, with the development of high-density single-nucleotide polymorphism (SNP) microarrays and next-generation sequencing (NGS) technologies, the discovery of genes related to the epilepsies has accelerated tremendously. Especially, the use of whole exome sequencing (WES) has had a considerable impact on the identification of rare genetic variants with large effect sizes, including inherited or de novo mutations in severe forms of childhood epilepsies. The identification of pathogenic variants in patients with these childhood epilepsies provides many benefits for patients and families, such as the confirmation of the genetic nature of the diseases. This process will allow for better genetic counseling, more accurate therapy decisions, and a significant positive emotional impact. However, to study the genetic component of the more common forms of epilepsy, the use of high-density SNP arrays in genome-wide association studies (GWAS) seems to be the strategy of choice. As such, researchers can identify loci containing genetic variants associated with the common forms of epilepsy. The knowledge generated over the past two decades about the effects of the mutations that cause the monogenic epilepsy is tremendous; however, the scientific community is just starting to apply this information in order to generate better target treatments.

Diabetes-induced Neuropathic Mechanical Hyperalgesia Depends on P2X4 Receptor Activation in Dorsal Root Ganglia.
Peripheral diabetic neuropathy (PDN) manifests in 50-60% of type I and II diabetic patients and is the major cause of limb amputation. Adequate therapy for PDN is a current challenge. There are evidences that the activation of the P2X4 receptor (P2X4R) expressed on microglial cells of the central nervous system takes part in the development of neuropathic pain. However, there is an open question: Is P2X4R activation on dorsal root ganglia (DRG) involved in the development of neuropathic pain? To answer this question, this study verified the involvement of P2X4R expressed in DRG cells on diabetes-induced neuropathic mechanical hyperalgesia in rats. We found that intrathecal or ganglionar (L5-DRG) administration of a novel P2X4R antagonist (PSB-15417) or intrathecal administration of oligodeoxynucleotides (ODN)-antisense against the P2X4R reversed diabetes-induced neuropathic mechanical hyperalgesia. The DRG of the diabetic neuropathic rats showed an increase in P2X4R expression, and the DRG immunofluorescence suggested that P2X4R is expressed mainly in satellite glial cells (SGC). Finally, our study showed a functional expression of P2X4R in SGCs of the rat's DRG, because the P2X4R agonist BzATP elicits an increase in intracellular calcium concentration in SGCs, which was reduced by PSB-15417. These findings indicate that P2X4R activation in DRG is essential to diabetes-induced neuropathic mechanical hyperalgesia. Therefore, this purinergic receptor in DRG could be an interesting therapeutic target for quaternary P2X4R antagonists that do not cross the hematoencephalic barrier, for the control of neuropathic pain, preserving central nervous system functions.

Transcriptome analysis of dorsal root ganglia's diabetic neuropathy reveals mechanisms involved in pain and regeneration.
Peripheral diabetic neuropathy (DN) manifests in nearly 60% of diabetic patients, being pain its most debilitating symptom. Although electrophysiological and morphological aspects are well described, little is known about its development and progression, undermining effective therapies. Hyperglycemia and insulin signaling impairment are considered the triggering events of oxidative stress observed in the dying nerves, however there are still many gaps in the knowledge of intracellular plastic changes it generates.

NMDA Receptor Activation Underlies the Loss of Spinal Dorsal Horn Neurons and the Transition to Persistent Pain after Peripheral Nerve Injury.

Peripheral nerve lesions provoke apoptosis in the dorsal horn of the spinal cord. The cause of cell death, the involvement of neurons, and the relevance for the processing of somatosensory information are controversial. Here, we demonstrate in a mouse model of sciatic nerve injury that glutamate-induced neurodegeneration and loss of γ-aminobutyric acid (GABA)ergic interneurons in the superficial dorsal horn promote the transition from acute to chronic neuropathic pain. Conditional deletion of Grin1, the essential subunit of N-methyl-d-aspartate-type glutamate receptors (NMDARs), protects dorsal horn neurons from excitotoxicity and preserves GABAergic inhibition. Mice deficient in functional NMDARs exhibit normal nociceptive responses and acute pain after nerve injury, but this initial increase in pain sensitivity is reversible. Eliminating NMDARs fully prevents persistent pain-like behavior. Reduced pain in mice lacking proapoptotic Bax confirmed the significance of neurodegeneration. We conclude that NMDAR-mediated neuron death contributes to the development of chronic neuropathic pain.

Nucleus accumbens dopaminergic neurotransmission switches its modulatory action in chronification of inflammatory hyperalgesia.
Dopaminergic neurotransmission in the nucleus accumbens, a central component of the mesolimbic system, has been associated with acute pain modulation. As there is a transition from acute to chronic pain ('chronification'), modulatory structures may be involved in chronic pain development. Thus, this study aimed to elucidate the role of nucleus accumbens dopaminergic neurotransmission in chronification of pain. We used a rat model in which daily subcutaneous injection of prostaglandin E2 in the hindpaw for 14 days induces a long-lasting state of nociceptor sensitization that lasts for at least 30 days following the end of the treatment. Our findings demonstrated that the increase of dopamine in the nucleus accumbens by local administration of GBR12909 (0.5 nmol/0.25 μL), a dopamine reuptake inhibitor, blocked prostaglandin E2 -induced acute hyperalgesia. This blockade was prevented by a dopamine D2 receptor antagonist (raclopride, 10 nmol/0.25 μL) but not changed by a D1 receptor antagonist (SCH23390, 0.5, 3 or 10 nmol/0.25 μL), both co-administered with GBR12909 in the nucleus accumbens. In contrast, the induction of persistent hyperalgesia was facilitated by continuous infusion of GBR12909 in the nucleus accumbens (0.021 nmol/0.5 μL/h) over 7 days of prostaglandin E2 treatment. The development of persistent hyperalgesia was impaired by SCH23390 (0.125 nmol/0.5 μL/h) and raclopride (0.416 nmol/0.5 μL/h), both administered continuously in the nucleus accumbens over 7 days. Taken together, our data suggest that the chronification of pain involves the plasticity of dopaminergic neurotransmission in the nucleus accumbens, which switches its modulatory role from antinociceptive to pronociceptive.

Effect of pain chronification and chronic pain on an endogenous pain modulation circuit in rats.
We tested the hypothesis that chronic pain development (pain chronification) and ongoing chronic pain (chronic pain) reduce the activity and induce plastic changes in an endogenous analgesia circuit, the ascending nociceptive control. An important mechanism mediating this form of endogenous analgesia, referred to as capsaicin-induced analgesia, is its dependence on nucleus accumbens μ-opioid receptor mechanisms. Therefore, we also investigated whether pain chronification and chronic pain alter the requirement for nucleus accumbens μ-opioid receptor mechanisms in capsaicin-induced analgesia. We used an animal model of pain chronification in which daily subcutaneous prostaglandin E2 (PGE2) injections into the rat's hind paw for 14 days, referred to as the induction period of persistent hyperalgesia, induce a long-lasting state of nociceptor sensitization referred to as the maintenance period of persistent hyperalgesia, that lasts for at least 30 days following the cessation of the PGE2 treatment. The nociceptor hypersensitivity was measured by the shortening of the time interval for the animal to respond to a mechanical stimulation of the hind paw. We found a significant reduction in the duration of capsaicin-induced analgesia during the induction and maintenance period of persistent mechanical hyperalgesia. Intra-accumbens injection of the μ-opioid receptor selective antagonist Cys(2),Tyr(3),Orn(5),Pen(7)amide (CTOP) 10 min before the subcutaneous injection of capsaicin into the rat's fore paw blocked capsaicin-induced analgesia. Taken together, these findings indicate that pain chronification and chronic pain reduce the duration of capsaicin-induced analgesia, without affecting its dependence on nucleus accumbens μ-opioid receptor mechanisms. The attenuation of endogenous analgesia during pain chronification and chronic pain suggests that endogenous pain circuits play an important role in the development and maintenance of chronic pain.

The analgesic effect of dipyrone in peripheral tissue involves two different mechanisms: neuronal K(ATP) channel opening and CB(1) receptor activation.
Dipyrone (metamizole) is an analgesic pro-drug used to control moderate pain. It is metabolized in two major bioactive metabolites: 4-methylaminoantipyrine (4-MAA) and 4-aminoantipyrine (4-AA). The aim of this study was to investigate the

participation of peripheral CB1 and CB2 cannabinoid receptors activation in the anti-hyperalgesic effect of dipyrone, 4-MAA or 4-AA. PGE2 (100ng/50µL/paw) was locally administered in the hindpaw of male Wistar rats, and the mechanical nociceptive threshold was quantified by electronic von Frey test, before and 3h after its injection. Dipyrone, 4-MAA or 4-AA was administered 30min before the von Frey test. The selective CB1 receptor antagonist AM251, CB2 receptor antagonist AM630, cGMP inhibitor ODQ or KATP channel blocker glibenclamide were administered 30min before dipyrone, 4-MAA or 4-AA. The antisense-ODN against CB1 receptor expression was intrathecally administered once a day during four consecutive days. PGE2-induced mechanical hyperalgesia was inhibited by dipyrone, 4-MAA, and 4-AA in a dose-response manner. AM251 or ODN anti-sense against neuronal CB1 receptor, but not AM630, reversed the anti-hyperalgesic effect mediated by 4-AA, but not by dipyrone or 4-MAA. On the other hand, the anti-hyperalgesic effect of dipyrone or 4-MAA was reversed by glibenclamide or ODQ. These results suggest that the activation of neuronal CB1, but not CB2 receptor, in peripheral tissue is involved in the anti-hyperalgesic effect of 4-aminoantipyrine. In addition, 4-methylaminoantipyrine mediates the anti-hyperalgesic effect by cGMP activation and KATP opening.

Peripheral inflammatory hyperalgesia depends on the COX increase in the dorsal root ganglion.
It is well established that dorsal root ganglion (DRG) cells synthesize prostaglandin. However, the role that prostaglandin plays in the inflammatory hyperalgesia of peripheral tissue has not been established. Recently, we have successfully established a technique to inject drugs (3 µL) directly into the L5-DRG of rats, allowing in vivo identification of the role that DRG cell-derived COX-1 and COX-2 play in the development of inflammatory hyperalgesia of peripheral tissue. IL-1β (0.5 pg) or carrageenan (100 ng) was administered in the L5-peripheral field of rat hindpaw and mechanical hyperalgesia was evaluated after 3 h. Administration of a nonselective COX inhibitor (indomethacin), selective COX-1 (valeryl salicylate), or selective COX-2 (SC-236) inhibitors into the L5-DRG prevented the hyperalgesia induced by IL-1β. Similarly, oligodeoxynucleotide-antisense against COX-1 or COX-2, but not oligodeoxynucleotide-mismatch, decreased their respective expressions in the L5-DRG and prevented the hyperalgesia induced by IL-1β in the hindpaw. Immunofluorescence analysis demonstrated that the amount of COX-1 and COX-2, constitutively expressed in TRPV-1(+) cells of the DRG, significantly increased after carrageenan or IL-1β administration. In addition, indomethacin administered into the L5-DRG prevented the increase of PKCε expression in DRG membrane cells induced by carrageenan. Finally, the administration of EP1/EP2 (7.5 ng) or EP4 (10 µg) receptor antagonists into L5-DRG prevented the hyperalgesia induced by IL-1β in the hindpaw. In conclusion, the results of this study suggest that the inflammatory hyperalgesia in peripheral tissue depends on activation of COX-1 and COX-2 in C-fibers, which contribute to the induction and maintenance of sensitization of primary sensory neurons.

AUTONOMIC DISBALANCE DURING SYSTEMIC INFLAMMATION IS ASSOCIATED WITH OXIDATIVE STRESS CHANGES IN SEPSIS SURVIVOR RATS

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Luiz Branco[1], Mateus Amorin[2], Evelin Carnio[3]
[1]Unversity of Sao Paulo, Dental School Of Ribeirao Preto, Ribeirao Preto, Brazil, [2]University of Sao Paulo, Dental School Of Ribeirao Preto, Ribeirao Preto, Brazil, [3]University of Sao Paulo, Nursing School Of Ribeirao Preto, Ribeirão Preto, Brazil

Sepsis is characterized by a drop in blood pressure driving to morbidity and mortality. Modern supportive care has increased survival; however, after sepsis, several complications are observed. Nevertheless, the interplay between sepsis survivors and a new immune challenge in cardiovascular regulation has not been previously defined. We hypothesized that cecal ligation and puncture (CLP) cause persistent cardiovascular dysfunctions and changes in autonomic-induced cardiovascular responses to lipopolysaccharide (LPS). Male rats had mean arterial pressure (MAP) and heart rate (HR) recorded before and after LPS administration to control or CLP survivor rats. CLP survivor rats had similar baseline MAP and HR. LPS caused a drop in MAP accompanied by tachycardia in control, while CLP survivor rats had a enhanced MAP and a blunted tachycardia. LPS-induced hemodynamic changes were related to an autonomic disbalance to the heart and resistance vessels that were expressed as an increased low- and high-frequency power of pulse interval in CLP survivors after saline and enhancement in the low-frequency power of systolic arterial pressure in control rats after LPS. LPS-induced plasma interferon γ, but not interleukin-10 surges, was blunted in CLP survivor rats. To further access if LPS-induced autonomic disbalance in CLP survivor rats was associated with oxidative stress dysregulation, superoxide dismutase (SOD) activity and thiobarbituric acid reactive substances (TBARS) plasma levels changes were measured. LPS-induced oxidative stress was higher in CLP survivor rats. The data indicate that changes in hemodynamic regulation of CLP survivors rats take place in response to LPS that are associated with oxidative stress.

NOVEL STRATEGY FOR AMPLIFICATION OF ABETA-SPECIFIC REGULATORY T CELLS IN A MOUSE MODEL OF ALZHEIMER'S DISEASE

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Jessica Lambe, Caitlin Ni Chasaide, Kwok Im, Marie-Victoire Guillot-Sestier, Marina Lynch
Trinity College Dublin, Physiology, Dublin, Ireland

Alzheimer's disease (AD) is characterised by cerebral amyloid-beta (Abeta) accumulation, microgliosis, neuroinflammation and brain infiltration of T lymphocytes. While effector T cells (Teff) exacerbate neuroinflammation and inhibit normal microglial phagocytic function, T regulatory cells (Treg) can dampen Teff activation and brain infiltration. However, AD patients have compromised Treg suppressive function on Teff. We hypothesised that rebalancing Treg/Teff may influence microglial phenotype toward resolution of pathology. Our aim was to establish a novel strategy for amplification of Abeta-specific Treg in the APP/PS1 mouse model of AD to assess if this could promote Abeta clearance by microglia. Eight-week-old APP/PS1 mice were immunised with Interleukin-2 (IL-2)+ Retinoic Acid (RA)+Abeta, Abeta alone, IL-2+RA or CT and aged until 9 months old. To validate Treg production, splenocytes were cultured and Interleukin-10 (IL-10), Interleukin-17 (IL-17) and Interferon-gamma (IFN-g) production in response to recall stimulation with Abeta was analysed by ELISA. Abundance and phenotype of CD4+ T cells in lymph nodes and the brain was evaluated by flow cytometry. In mice immunised with Abeta+IL-2+RA or Abeta alone, splenocytes produced IL-10 and IFN-γ upon recall stimulation with Abeta. A population of CD4+CD25+FoxP3+ Treg was increased in the lymph nodes with some expressing the checkpoint inhibitor CTLA4. CD4+ T cells infiltrated the brain in low numbers. Our new immunisation strategy allowed for generation of a memory Treg population, primed by Abeta and reactivated upon exposure to the antigen. The Treg generated produced IL-10 and IFN-g which is consistent with inducible Type 1 regulatory T cells.

PREDICTING SARS-COV-2 SPREADING AND GREY MATTER LOSS IN THE HUMAN BRAIN

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Philip Sommer, Danylo Batulin, Jochen Triesch
Frankfurt Institute For Advanced Studies, Triesch Lab, Frankfurt am Main, Germany

It is well established that SARS-CoV-2 can invade neurons and other cell types of the central nervous system. This has raised concern that SARS-CoV-2 could replicate inside the human brain and induce grey matter loss and ultimately cognitive decline and dementia. A wide range of viruses, including coronaviruses, have been shown to evade the blood-brain barrier and invade the central nervous system via axonal transport. However, the dynamics of SARS-CoV-2 spreading through the central nervous system and resulting tissue damage have not been adequately characterized. Here we use computational modeling and mathematical analysis to predict viral spreading and grey matter loss in the human brain. We predict the qualitative time course of SARS-CoV-2 accumulation and grey matter loss based on recent human connectome measurements. Depending on parameters, our model shows two qualitatively distinct spreading patterns. In the case of fast virus exchange between connected brain areas, a single brain-wide wave of virus proliferation and subsequent grey matter loss is observed. In the case of slow virus exchange between brain areas, we observe a characteristic two-phase pattern with a “first wave” exclusively affecting brain regions serving as entry points for the virus and a delayed “second wave” at the whole brain scale. These findings are in line with recent reports of diffuse brain atrophy and impaired performance on cognitive tasks in patients several months after COVID-19 infection. Further research is urgently needed to quantify SARS-CoV-2 spreading and brain alterations in human
patients.

ROLE OF THE LIFESTYLE AND ENVIRONMENTAL FACTORS IN THE COMPLEXITY OF THE MIGRAINE AURA

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Srdjan Mavija[1], Igor Petrušić[2]
[1]University Clinical Center of the Republic of Srpska, Neurology Clinic, Banja Luka, Bosnia and Herzegovina, [2]University of Belgrade, Faculty of Physical Chemistry, Laboratory For Advanced Analysis Of Neuroimages, Belgrade, Serbia

Aims: Environmental factors play an essential role in triggering migraine with aura (MwA). Also, lifestyle can tremendously influence the MwA frequency. Our goals were to evaluate how lifestyle and environmental factors influence the complexity of migraine aura and to explore changes in MwA frequency during the COVID-19 pandemic crisis. Methods: Data about aura features, environmental triggers, and lifestyle variables were obtained via an electronic questionnaire which MwA patients regularly filled after every MwA attack. Migraine Aura Complexity Score (MACS) was calculated for each attack to correlate MwA complexity with lifestyle and environmental factors. Results: Fifty-two MwA patients were included and 159 attacks were evaluated during the 2020-2021 period. MACS was positively correlated with increased physical effort and exposure to strong odors several hours before the MwA attack. The surface of the disturbed visual field by aura symptoms positively correlated with increased exposure to bright light. Report of visual higher cortical disturbances (HCDs) positively correlated with dehydration, while the higher incidence of somatosensory HCDs was connected to the increased physical effort before the MwA attack. Stress, food intake, fasting, alcohol, sleep disturbances, and weather changes did not correlate with MACS. COVID-19 pandemic crisis led to a decrease in MwA frequency (during 2019: 7.33±5.72 vs during COVID-19: 3.06±2.27 attacks per year, $p<0.001$). Conclusions: Increased physical effort, dehydration, exposure to strong odors, or bright light are linked to more complex symptoms of migraine aura. Lifestyle and changes in exposure to environmental factors during the COVID-19 crisis are connected to a decreased MwA frequency.

THE INFLUENCE OF CARDIOVASCULAR HEALTH IN MIDDLE-AGED ADULT POPULATIONS ON COGNITIVE HEALTH IN LATER LIFE: A SYSTEMATIC REVIEW AND META-ANALYSIS

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Oisín Joyce[1,2], Aine Kelly[1,2], Cliodhna Mchugh[1,2], Fiona Wilson[3], David Mockler[4]

Background: Hypertension is a known risk factor for cognitive deterioration and vascular dementia. Despite a large body of research, significant heterogeneity between studies has limited our ability in making causal inference about the association of hypertension with cognition at midlife. **Aim:** Perform a comprehensive analysis of the published evidence to ascertain the extent to which hypertension status during midlife impacts cognitive function. **Methods:** Online electronic databases EMBASE, MEDLINE, PubMed, Web of Science, and CINAHL were searched from their inception to January 2022. Studies which determined the relationship between hypertension status and cognition were eligible. **Results:** 113 studies were included (100,056 participants, weighted mean age: 55.7 ± 3.9 yrs), of which 46 were deemed high-quality. Hypertension status was assessed in 54 studies. Hypertension was most defined using the ESC definition (n= 29). A total of 41,675 participants were classified as hypertensive, 1,553 classified as pre-hypertensive and 3,459 were taking anti-hypertensive medication. A larger proportion of studies found no identifiable relationship between hypertension status with memory, attention, executive function, and global cognition. Due to the high levels of heterogeneity no causal association between hypertension and cognition could be determined. **Conclusion:** Current evidence suggests large caveats in understanding pathological mechanisms contributing to cognitive decline among hypertensives. Our results suggest mixed findings. Methodological differences diminished study quality and limited the formation of objective conclusions. Future researcher warrants the use of a more standardised battery of cognitive tests consistency of reporting to determine brain health and cognitive status alongside objective markers of ageing and CV health.

Background: Cardiovascular risk factors including hypertension and inflammation, are detrimental to general health, and particularly brain health, with potential cognitive impairment resulting. The cardiovascular and cognitive health implications associated with professional rugby is a cause of concern, given athletes' large size and the collision nature of the sport. Our aim was to assess the prevalence of cardiovascular risk factors in professional male rugby athletes. **Methods:** A cross-sectional study of 46 professional male rugby union athletes from a convenience sample from one European Rugby Championship Cup team (August 2020-February 2021) was conducted. The prevalence of traditional cardiovascular disease risk factors (family history, obesity, hypertension, dyslipidemia, glucose intolerance and smoking) and inflammatory biomarkers were examined. **Results:** 74% of athletes had at least one risk factor, with 50% having one- to -two risk factors. A subset of athletes (24%), predominately forwards, had high-risk (three- to -four risk factors). The most common risk factors were elevated CRP (65%), hypertension (30%), older age (20%), dyslipidemia, categorised by low HDL (17%), and elevated %BF (11%). Rugby athletes had significantly higher values of inflammation (CRP, ICAM-1 and VCAM-1) compared to healthy controls with one third demonstrating equivalent values to active rheumatoid arthritis patients. **Conclusion: S**ome rugby athletes are free from cardiovascular risk factors, but a large proportion are not, with almost 25% presenting with a high cardiovascular risk. The prevalence of hypertension and low-grade inflammation, coinciding with the collision-based nature of rugby, potentially exposes athletes to negative long-term cardiovascular and cognitive health implications that warrant further investigation.

STREPTOCOCCUS AGALACTIAE BRAIN INVASION VIA THE OLFACTORY AND TRIGEMINAL NERVES

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Streptococcus agalactiae causes neonatal meningitis and can also infect the adult central nervous system. S. agalactiae can cross the blood-brain barrier but may also reach the central nervous system via other paths. Several species of bacteria can directly invade the central nervous system via the olfactory and trigeminal nerves, which extend between the nasal cavity and brain and injury to the nasal epithelium can increase the risk/severity of infection. We investigated whether S. agalactiae serotype III, which is epidemiologically the most relevant in neonatal and adult Group B streptococcal meningitis, can infect the brain via the olfactory and/or trigeminal nerves after intranasal inoculation in mice. Because epithelial injury is associated with increased infection of the olfactory nerve, we also determined the effects of prior experimental injury to the nasal epithelium on infection via this path. Additionally, glial response to bacterial invasion in both cranial nerves and the brain is vital, hence, we also determined how the glial cells of the olfactory/trigeminal nerves and glia limitans layer responded to the bacteria. We observed, S. agalactiae rapidly infected the olfactory nerve and brain, including the trigeminal nerve which was aggravated by epithelial injury. Our in vitro assay showed that the bacterial capsule significantly altered cytokine and chemokine responses and affected intracellular survival in trigeminal glia. Thus, this study shows that S. agalactiae can infect the central nervous system via the nose-to-brain path with increased load after epithelial injury, and that the bacteria can survive in glia.

Antimicrobial responses of peripheral and central nervous system glia against Staphylococcus aureus.
Staphylococcus aureus infections of the central nervous system are serious and can be fatal. S. aureus is commonly present in the nasal cavity, and after injury to the nasal epithelium it can rapidly invade the brain via the olfactory nerve. The trigeminal nerve constitutes another potential route of brain infection. The glia of these nerves, olfactory ensheathing cells (OECs) and trigeminal nerve Schwann cells (TgSCs), as well as astrocytes populating the glia limitans layer, can phagocytose bacteria. Whilst some glial responses to S. aureus have been studied, the specific responses of different glial types are unknown. Here, we compared how primary mouse OECs, TgSCs, astrocytes and microglia responded to S. aureus. All glial types internalized the bacteria within phagolysosomes, and S. aureus-conjugated BioParticles could be tracked with subtle but significant differences in time-course of phagocytosis between glial types. Live bacteria could be isolated from all glia after 24 h in culture, and microglia, OECs and TgSCs exhibited better protection against intracellular S. aureus survival than astrocytes. All glial types responded to the bacteria by cytokine secretion. Overall, OECs secreted the lowest level of cytokines, suggesting that these cells, despite showing strong capacity for phagocytosis, have immunomodulatory functions that can be relevant for neural repair.

Can Invade the Central Nervous System the Olfactory and Trigeminal Nerves and Infect Peripheral Nerve Glial Cells.
can infect the brain and has been linked to late-onset dementia. , which infects mice, is often used to model human chlamydial infections. While it has been suggested to be also important for modelling brain infection, nervous system infection by has not been reported in the literature. has been shown to infect the olfactory bulb in mice after intranasal inoculation, and has therefore been suggested to invade the brain the olfactory nerve; however, nerve infection has not been shown to date. Another path by which certain bacteria can reach the brain is the trigeminal nerve, but it remains unknown whether species can infect this nerve. Other bacteria that can invade the brain the olfactory and/or trigeminal nerve can do so rapidly,

however, whether spp. can reach the brain earlier than one-week post inoculation remains unknown. In the current study, we showed that can within 48 h invade the brain the olfactory nerve, in addition to infecting the trigeminal nerve. We also cultured the glial cells of the olfactory and trigeminal nerves and showed that readily infected the cells, constituting a possible cellular mechanism explaining how the bacteria can invade the nerves without being eliminated by glial immune functions. Further, we demonstrated that olfactory and trigeminal glia differed in their responses to , with olfactory glia showing less infection and stronger immune response than trigeminal glia.

Burkholderia pseudomallei invades the olfactory nerve and bulb after epithelial injury in mice and causes the formation of multinucleated giant glial cells in vitro.
The infectious disease melioidosis is caused by the bacterium Burkholderia pseudomallei. Melioidosis is characterised by high mortality and morbidity and can involve the central nervous system (CNS). We have previously discovered that B. pseudomallei can infect the CNS via the olfactory and trigeminal nerves in mice. We have shown that the nerve path is dependent on mouse strain, with outbred mice showing resistance to olfactory nerve infection. Damage to the nasal epithelium by environmental factors is common, and we hypothesised that injury to the olfactory epithelium may increase the vulnerability of the olfactory nerve to microbial insult. We therefore investigated this, using outbred mice that were intranasally inoculated with B. pseudomallei, with or without methimazole-induced injury to the olfactory neuroepithelium. Methimazole-mediated injury resulted in increased B. pseudomallei invasion of the olfactory epithelium, and only in pre-injured animals were bacteria found in the olfactory nerve and bulb. In vitro assays demonstrated that B. pseudomallei readily infected glial cells isolated from the olfactory and trigeminal nerves (olfactory ensheathing cells and trigeminal Schwann cells, respectively). Bacteria were degraded by some cells but persisted in other cells, which led to the formation of multinucleated giant cells (MNGCs), with olfactory ensheathing cells less likely to form MNGCs than Schwann cells. Double Cap mutant bacteria, lacking the protein BimA, did not form MNGCs. These data suggest that injuries to the olfactory epithelium expose the primary olfactory nervous system to bacterial invasion, which can then result in CNS infection with potential pathogenic consequences for the glial cells.

Neisseria meningitidis Induces Pathology-Associated Cellular and Molecular Changes in Trigeminal Schwann Cells.
, a common cause of sepsis and bacterial meningitis, infects the meninges and central nervous system (CNS), primarily via paracellular traversal across the blood-brain barrier (BBB) or blood-cerebrospinal fluid barrier. is often present asymptomatically in the nasopharynx, and the nerves extending between the nasal cavity and the brain constitute an alternative route by which the meningococci may reach the CNS. To date, the cellular mechanisms involved in nerve infection are not fully understood. Peripheral nerve glial cells are phagocytic and are capable of eliminating microorganisms, but some pathogens may be able to overcome this protection mechanism and instead infect the glia, causing cell death or pathology. Here, we show that readily infects trigeminal Schwann cells (the glial cells of the trigeminal nerve) in both two-dimensional and three-dimensional cell cultures. Infection of trigeminal Schwann cells may be one mechanism by which is able to invade the CNS. Infection of the cells led to multinucleation and the appearance of atypical nuclei, with the presence of horseshoe nuclei and the budding of nuclei increasing over time. Using sequential window acquisition of all theoretical mass spectra (SWATH-MS) proteomics followed by bioinformatics pathway analysis, we showed that induced protein alterations in the glia that were associated with altered intercellular signaling, cell-cell interactions, and cellular movement. The analysis also suggested that the alterations in protein levels were consistent with changes occurring in cancer. Thus, infection of the trigeminal nerve by may have ongoing adverse effects on the biology of Schwann cells, which may lead to pathology.

Why are olfactory ensheathing cell tumors so rare?
The glial cells of the primary olfactory nervous system, olfactory ensheathing cells (OECs), are unusual in that they rarely form tumors. Only 11 cases, all of which were benign, have been reported to date. In fact, the existence of OEC tumors has been debated as the tumors closely resemble schwannomas (Schwann cell tumors), and there is no definite method for distinguishing the two tumor types. OEC transplantation is a promising therapeutic approach for nervous system injuries, and the fact that OECs are not prone to tumorigenesis is therefore vital. However, why OECs are so resistant to neoplastic transformation remains unknown. The primary olfactory nervous system is a highly dynamic region which continuously undergoes regeneration and neurogenesis throughout life. OECs have key roles in this process, providing structural and neurotrophic support as well as phagocytosing the axonal debris resulting from turnover of neurons. The olfactory mucosa and underlying tissue is also frequently exposed to infectious agents, and OECs have key innate immune roles preventing

microbes from invading the central nervous system. It is possible that the unique biological functions of OECs, as well as the dynamic nature of the primary olfactory nervous system, relate to the low incidence of OEC tumors. Here, we summarize the known case reports of OEC tumors, discuss the difficulties of correctly diagnosing them, and examine the possible reasons for their rare incidence. Understanding why OECs rarely form tumors may open avenues for new strategies to combat tumorigenesis in other regions of the nervous system.

Nanosized tamoxifen-porphyrin-glucose [TPG] conjugate: novel selective anti-breast-cancer agent, synthesis and in vitro evaluations.
Tumor and especially breast cancer is among the most common causes of death worldwide. Finding novel nanosized therapeutic compounds have important role to decrease the chance of death and increase the survival. Cancer cells are highly attractive to glucose [with a nanosize bimolecular structure 1nm] as an energy source more than normal cell and nanosized therapeutics due to possessing different pharmacokinetic and pharmacodynamic have advantageous over classical dosage forms in cancer therapy. The aim of the study was to synthesize Glucosamin-Porphyrin-Tamoxifen [TPG] nanosized complex as a novel selective biocompatible anti breast cancer agent. After the synthesis procedure, this complex was purified and then tested In Vitro on breast cancer cells [MCF-7] in the absence or presence of the red light and found totally successful. The results showed a good anti breast cancer activity mediated by the activation of TNF-α and necrosis/apoptosis pathways for the nanosized complex with no alteration effects on blood PT/APTT and glucose or hexokinase levels/ activity. TPG nanoconjugate seems to be very good opponents to current anti breast cancer drugs and needs to be further investigated in near future.

THE ROLE OF ANTI-FGFR3 ANTIBODIES IN SENSITIVE NEURONOPATHIES NEURONAL CELL DEATH

POSTER SESSION 07 - SECTION: NEUROIMMUNOLOGY AND NEUROINFLAMMATION

Yara Nasser, Jean-Philippe Camdessanché, Julien Falk, Jean-Christophe Antoine, Nadia Boutahar
INSTITUT NEUROMYOGÈNE, Université Claude Bernard Lyon 1, Lyon, France

Dysimmune sensitive neuropathies (SSN) are characterized by neuron cell death in dorsal root ganglia. We have identified FGFR3 antibodies which recognized the intracellular domain (TRK) of FGFR3 as a biomarker of a subset of SSN patients. We submitted mice cortical neurons cultures to different concentrations of a rabbit polyclonal antibody recognizing the FGFR3 intracellular domain. FGFR3 antibody induced neuron cell death in a dose dependent manner. In order to decipher the molecular mechanism involved in neuronal death induced by FGFR3 antibodies, we submitted neuron cultures to FGFR3 antibodies with and without the presence of the p38 MAPK inhibitor or the ERK1/2 MAPK inhibitor. FGFR3 antibodies treatment increased FGFR3 receptor, NMDA receptor subunits and AMPA receptor subunits expression and this increase was prevented by ERK1/2 or P38 MAPK inhibitor. These results suggest that cytotoxicity induced by FGFR3 antibodies increases NMDA and AMPA receptor expression through FGFR3 tyrosine kinase site blocking and RAS/MAP kinase pathway activation. FGFR3 antibodies recognize the intracellular domain of FGFR3; this suggests the antibodies internalization which can enhance autophagy. The analysis of several autophagy markers showed that optineurin and p62 expression increased in neuron cultures submitted to FGFR3 antibodies and this increase was prevented by ERK1/2 or P38 MAPK inhibitor suggesting that autophagy activation may also play a role in neuron degeneration. A similar expression profile of FGFR3, NMDA subunits and autophagy markers was observed in SSN serum-treated mice cortical neurons and sensory neurons cell cultures when compared to healthy donors' serum-treated cultures.

NR5A2 AS A POTENTIAL DRUG TARGET IN GLIOBLASTOMAS

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Dimitrios Gkikas[1], Dimitris Stellas[2], Alexia Polissidis[3], Valeria Kaltezioti[1], Maroula Kokotou[4], George Kokotos[4], Panagiotis Politis[1]
[1]Biomedical Research Foundation of the Academy of Athens, Basic Research, Athens, Greece, [2]National Hellenic Research Foundation, Institute Of Chemical Biology, Athens, Greece, [3]Biomedical Research Foundation of the Academy of Athens, 3centre For Clinical, Experimental Surgery & Translational Research, Athens, Greece, [4]National and Kapodistrian University of Athens, Chemistry, Athens, Greece

Glioblastomas are nervous system tumors that originate from astrocytes and neural stem or progenitor cells. They are characterized by rapid progression and poor survival rates. Despite recent advances in the provided therapy, the average survival time remains extremely low, between 12 to 15 months. These clinical observations underscore the need for novel therapeutic insights and pharmacological targets. To this end, here we identify the orphan nuclear receptor NR5A2/LRH1 as a negative regulator of cancer cell proliferation and promising pharmacological target for nervous system-related tumors. In particular, by meta-analysing clinical data from TCGA and Oncomine databases, we find that high expression levels of NR5A2 are associated with favourable prognosis in patients with glioblastoma tumors. In addition, we experimentally show that two well-established pharmacological agonists of NR5A2, DLPC and DUPC, are able to inhibit proliferation of neural stem cells and glioblastoma cells through NR5A2 activation. Most importantly, treatment with DLPC inhibits glioblastoma tumor growth *in vivo*, in heterotopic and orthotopic xenograft mouse models. These data render NR5A2 as a potential pharmacological target for the treatment of nervous tissue related tumors.

Nuclear receptor NR5A2 negatively regulates cell proliferation and tumor growth in nervous system malignancies.
Nervous system malignancies are characterized by rapid progression and poor survival rates. These clinical observations underscore the need for novel therapeutic insights and pharmacological targets. To this end, here, we identify the orphan nuclear receptor NR5A2/LRH1 as a negative regulator of cancer cell proliferation and promising pharmacological target for nervous system-related tumors. In particular, clinical data from publicly available databases suggest that high expression levels of NR5A2 are associated with favorable prognosis in patients with glioblastoma and neuroblastoma tumors. Consistently, we experimentally show that NR5A2 is sufficient to strongly suppress proliferation of both human and mouse glioblastoma and neuroblastoma cells without inducing apoptosis. Moreover, short hairpin RNA-mediated knockdown of the basal expression levels of NR5A2 in glioblastoma cells promotes their cell cycle progression. The antiproliferative effect of NR5A2 is mediated by the transcriptional induction of negative regulators of the cell cycle, (encoding for p21), (encoding for p27) and Interestingly, two well-established agonists of NR5A2, dilauroyl phosphatidylcholine (DLPC) and diundecanoyl phosphatidylcholine, are able to mimic the antiproliferative action of NR5A2 in human glioblastoma cells via the induction of the same critical genes. Most importantly, treatment with DLPC inhibits glioblastoma tumor growth in vivo in heterotopic and orthotopic xenograft mouse models. These data indicate a tumor suppressor role of NR5A2 in the nervous system and render this nuclear receptor a potential pharmacological target for the treatment of nervous tissue-related tumors.

Synthesis of benzoxazole-based vorinostat analogs and their antiproliferative activity.
Hydroxamic acid derivatives constitute an interesting novel class of antitumor agents. Three of them, including vorinostat, are approved drugs for the treatment of malignancies, while several others are currently under clinical trials. In this work, we present new vorinostat analogs containing the benzoxazole ring as the cap group and various linkers. The benzoxazole-based analogs were synthesized starting either from 2-aminobenzoxazole, through conventional coupling, or from benzoxazole, through a metal-free oxidative amination. All the synthesized compounds were evaluated for their antiproliferative activity on three diverse human cancer cell lines (A549, Caco-2 and SF268), in comparison to vorinostat.

Compound 12 (GK601), carrying a benzoxazole ring replacement for the phenyl ring of vorinostat, was the most potent inhibitor of the growth of three cell lines (IC 1.2-2.1 μM), similar in potency to vorinostat. Compound 12 also inhibited human HDAC1, HDAC2 and HDAC6 like vorinostat. This new analog also showed antiproliferative activity against two colon cancer cell lines genetically resembling pseudomyxoma peritonei (PMP), namely HCT116 GNAS R201C/+ and LS174T (IC 0.6 and 1.4 μM, respectively) with potency comparable to vorinostat (IC 1.1 and 2.1 μM, respectively).

Saturated Oxo Fatty Acids (SOFAs): A Previously Unrecognized Class of Endogenous Bioactive Lipids Exhibiting a Cell Growth Inhibitory Activity.
The discovery of novel bioactive lipids that promote human health is of great importance. Combining "suspect" and targeted lipidomic liquid chromatography-high-resolution mass spectrometry (LC-HRMS) approaches, a previously unrecognized class of oxidized fatty acids, the saturated oxo fatty acids (SOFAs), which carry the oxo functionality at various positions of the long chain, was identified in human plasma. A library of SOFAs was constructed, applying a simple green photochemical hydroacylation reaction as the key synthetic step. The synthesized SOFAs were studied for their ability to inhibit in vitro the cell growth of three human cancer cell lines. Four oxostearic acids (OSAs) were identified to inhibit the cell growth of human lung carcinoma A549 cells. 6OSA and 7OSA exhibited the highest cell growth inhibitory potency, suppressing the expression of both STAT3 and c-myc, which are critical regulators of cell growth and proliferation. Thus, naturally occurring SOFAs may play a role in the protection of human health.

Nuclear Receptor NR5A2 Promotes Neuronal Identity in the Adult Hippocampus.
Neurogenesis in the dentate gyrus (DG) of the adult hippocampus is actively involved in brain homeostasis. Thus, identification of novel regulators in adult neurogenesis could significantly contribute to new therapies. We have recently unraveled the regulatory role of NR5A2 (also known as LRH1), a druggable orphan nuclear receptor, in embryonic neurogenesis. However, its involvement in adult neurogenesis is still an open question. Here we show that NR5A2 is differentially expressed in the DG of the adult hippocampus with neurons exhibiting higher levels of expression than adult neural stem/progenitor cells (aNSCs), suggesting a correlation with neuronal differentiation. Notably, NR5A2 overexpression in ex vivo cultured aNSCs induces expression of Prox1, a critical regulator of adult hippocampal neurogenesis. In agreement, NR5A2 is sufficient to reduce proliferation, increase neuronal differentiation, and promote axon outgrowth. Moreover, depletion of NR5A2 in DG cells in vivo caused a decrease in the number of NeuN as well as Calbindin-positive neurons, indicating its necessity for the maintenance of neuronal identity. Our data propose a regulatory role of NR5A2 in neuronal differentiation and fate specification of adult hippocampal NSCs.

Saturated Hydroxy Fatty Acids Exhibit a Cell Growth Inhibitory Activity and Suppress the Cytokine-Induced β-Cell Apoptosis.
The field of bioactive lipids is ever expanding with discoveries of novel lipid molecules that promote human health. Adopting a lipidomic-assisted approach, two new families of previously unrecognized saturated hydroxy fatty acids (SHFAs), namely, hydroxystearic and hydroxypalmitic acids, consisting of isomers with the hydroxyl group at different positions, were identified in milk. Among the various regio-isomers synthesized, those carrying the hydroxyl at the 7- and 9-positions presented growth inhibitory activities against various human cancer cell lines, including A549, Caco-2, and SF268 cells. In addition, 7- and 9-hydroxystearic acids were able to suppress β-cell apoptosis induced by proinflammatory cytokines, increasing the possibility that they can be beneficial in countering autoimmune diseases, such as type 1 diabetes. 7-()-Hydroxystearic acid exhibited the highest potency both in cell growth inhibition and in suppressing β-cell death. We propose that such naturally occurring SHFAs may play a role in the promotion and protection of human health.

GemC1 governs multiciliogenesis through direct interaction with and transcriptional regulation of p73.
A distinct combination of transcription factors elicits the acquisition of a specific fate and the initiation of a differentiation program. Multiciliated cells (MCCs) are a specialized type of epithelial cells that possess dozens of motile cilia on their apical surface. Defects in cilia function have been associated with ciliopathies that affect many organs, including brain and airway epithelium. Here we show that the geminin coiled-coil domain-containing protein 1 GemC1 (also known as Lynkeas) regulates the transcriptional activation of , a transcription factor central to multiciliogenesis. Moreover, we show that GemC1 acts in a trimeric complex with transcription factor E2F5 and tumor protein p73 (officially known as TP73), and that this

complex is important for the activation of the promoter. We also provide evidence that GemC1 is necessary for p73 expression in different multiciliated epithelia. We further show that GemC1 regulates multiciliogenesis through the control of chromatin organization, and the epigenetic marks/tags of and Our results highlight novel signaling cues involved in the commitment program of MCCs across species and tissues.This article has an associated First Person interview with the first author of the paper.

Nuclear receptors in neural stem/progenitor cell homeostasis.
In the central nervous system, embryonic and adult neural stem/progenitor cells (NSCs) generate the enormous variety and huge numbers of neuronal and glial cells that provide structural and functional support in the brain and spinal cord. Over the last decades, nuclear receptors and their natural ligands have emerged as critical regulators of NSC homeostasis during embryonic development and adult life. Furthermore, substantial progress has been achieved towards elucidating the molecular mechanisms of nuclear receptors action in proliferative and differentiation capacities of NSCs. Aberrant expression or function of nuclear receptors in NSCs also contributes to the pathogenesis of various nervous system diseases. Here, we review recent advances in our understanding of the regulatory roles of steroid, non-steroid, and orphan nuclear receptors in NSC fate decisions. These studies establish nuclear receptors as key therapeutic targets in brain diseases.

IONTRONIC PUMP AS A NEW TOOL FOR LOCAL BRAIN TUMOR TREATMENT ON AN EX OVO MODEL

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Verena Handl[1], Linda Waldherr[1], Nassim Ghaffari Trabizi-Wiszy[2], Martin Asslaber[3], Rainer Schindl[1], Silke Patz[4]

Aims: The treatment of brain tumors known as glioblastoma multiforme (GBM) remains a challenging task. Although brain tumors are resected by surgery, combined with subsequent chemotherapy and radiotherapy the median survival only comprises 15 months. To this date, treatment is hampered due to limitation of drug application. The blood brain barrier (BBB) acts as a semipermeable gate, that prevents many potent chemotherapeutic drugs from reaching their site of action. To overcome this restriction, it is inevitable to establish a new kind of brain cancer treatment. Serendipitously, Iontronic pumps (IPs) are able to serve as drug delivery tools by using an ion exchange membrane and therefore suit for triggered drug release. Methods: The Chick Embryo Chorioallantoic Membrane Assay (CAM) was used to cultivate U87 GBM tumors. Iontronic Pumps were filled with Gemcitabine (GEM), a chemotherapeutic drug that is stable at its protonated state. Due to an electric power supply, the grown CAM-tumors were treated with the IPs. Subsequently, tumors were either embedded in paraffin for histological read-out or digested for cell-cycle analysis via FACS. Results: U87 tumor cells generate highly vascularized, solid tumors on CAM suitable for IP treatment. We examined tumor volume of treated vs. non-treated tumors and exhibited a pivotal distinction with respect to size measurement. Furthermore, we evaluated the effect of GEM within the treated tumors by FACS analysis as well as apoptosis evaluation. Conclusion: IPs are a promising tool for drug delivery and have the potential to emerge as a new application for local brain tumor treatment.

Blockage of Store-Operated Ca Influx by Synta66 is Mediated by Direct Inhibition of the Ca Selective Orai1 Pore.
The Ca sensor STIM1 and the Ca channel Orai1 that form the store-operated Ca (SOC) channel complex are key targets for drug development. Selective SOC inhibitors are currently undergoing clinical evaluation for the treatment of auto-immune and inflammatory responses and are also deemed promising anti-neoplastic agents since SOC channels are linked with enhanced cancer cell progression. Here, we describe an investigation of the site of binding of the selective inhibitor Synta66 to the SOC channel Orai1 using docking and molecular dynamics simulations, and live cell recordings. Synta66 binding was localized to the extracellular site close to the transmembrane (TM)1 and TM3 helices and the extracellular loop segments, which, importantly, are adjacent to the Orai1-selectivity filter. Synta66-sensitivity of the Orai1 pore was, in fact, diminished by both Orai1 mutations affecting Ca selectivity and permeation of Na in the absence of Ca. Synta66 also efficiently blocked SOC in three glioblastoma cell lines but failed to interfere with cell viability, division and migration. These experiments provide new structural and functional insights into selective drug inhibition of the Orai1 Ca channel by a high-affinity pore blocker.

Targeted Chemotherapy of Glioblastoma Spheroids with an Iontronic Pump.
Successful treatment of glioblastoma multiforme (GBM), the most lethal tumor of the brain, is presently hampered by (i) the limits of safe surgical resection and (ii) "shielding" of residual tumor cells from promising chemotherapeutic drugs such as Gemcitabine (Gem) by the blood brain barrier (BBB). Here, the vastly greater GBM cell-killing potency of Gem compared to the gold standard temozolomide is confirmed, moreover, it shows neuronal cells to be at least 10-fold less sensitive to Gem than GBM cells. The study also demonstrates the potential of an electronically-driven organic ion pump ("GemIP") to achieve controlled, targeted Gem delivery to GBM cells. Thus, GemIP-mediated Gem delivery is confirmed to be temporally and electrically controllable with pmol min precision and electric addressing is linked to the efficient killing of GBM cell

monolayers. Most strikingly, GemIP-mediated GEM delivery leads to the overt disintegration of targeted GBM tumor spheroids. Electrically-driven chemotherapy, here exemplified, has the potential to radically improve the efficacy of GBM adjuvant chemotherapy by enabling exquisitely-targeted and controllable delivery of drugs irrespective of whether these can cross the BBB.

Glioblastoma multiforme (GBM) is the most common primary malignant brain tumor in adults. The poor prognosis of the patients and the increasing incidence over the years urge the identification of novel targets for the development of new functional treatments. Intriguingly, the role of reactive astrocytes in GBM, potentially one of the most abundant cells within the brain tumor microenvironment, remains unclear. In the present study, we evaluate the effects of the Janus kinase/signal transducer and activator of transcription 3 (JAK/STAT3) pathway inhibition, a master regulator of reactive astrogliosis, using adeno-associated virus (AAV) encoding suppressor of cytokine signaling 3 (SOCS3), an inhibitor of the JAK/STAT3 pathway in a GBM experimental model *in vivo*. SOCS3 overexpression decreased glial fibrillary acidic protein (GFAP) and vimentin expression, as well as the % of GBM cells expressing S100β suggesting that reactive astrocytes play a key role in GBM progression and malignancy. Moreover, the number of GBM-associated microglia/macrophages (GAAMs) was reduced with SOCS3 treatment, which reinforces the existence of a crosstalk between reactive astrocytes and GAMMs. In the *in vitro* setting, we study whether the presence of primary astrocytes affects GBM cells in coculture. Preliminary experiments showed an increased number of glioma cells in the presence of primary astrocytes, which suggests that reactive astrocytes create a suitable microenvironment for GBM cells proliferation and survival. Overall, our data demonstrate that reactive astrocytes play an important role in GBM progression and malignancy. Therefore, targeting reactive astrogliosis with SOCS3 genetic pre-treatment could be a potential approach for GBM.

NEURONAL NA+/CA2+ EXCHANGER 2 (NCX2) AS A TUMOR SUPPRESSOR PROTEIN IN GLIOBLASTOMA PROGRESSION AND MALIGNITY

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Lucrezia Calabrese[1], Angelo Serani[2], Natascia Guida[3], Silvia Natale[1], Anna Pannaccione[1], Luigi Formisano[1], Lucio Annunziato[3], Pasquale Molinaro[1]
[1]University of Naples Federico II, Dipartimento Di Neuroscienze Scienze Riproduttive Ed Odontostomatologiche, Naples, Italy, [2]IIT, Italian Institute of Techonology, Genetics And Epigenetics Of Behavior, Genoa, Italy, [3]IRCCS Synlab SDN S.p.a., Sdn Research Institute Diagnostic And Nuclear, Naples, Italy

Glioblastoma multiforme (GBM) is the most frequent and malignant brain tumor with an aggressive phenotype and resistance to chemotherapy. Notably, GBM selectively downregulates several genes mainly exerting a tumor suppression activity. Interestingly, among the genes downregulated in GBM there is the Sodium/Calcium Exchanger 2 (NCX2), a plasma membrane antiporter expressed in cells of CNS. These data suggest that Slc8a2, encoding NCX2, might represent a new tumor suppressor gene. To this aim, we explored the genetic and epigenetic mechanisms underlying the transcriptional downregulation of NCX2 in GBM, the contribute of NCX2 in tumor proliferation and malignity, and new possible pharmacological approaches to increase its expression/activity. In particular, we identified and cloned Slc8a2 promoter (HP) from human glioblastoma cells (U87). Afterward, we identified NF-kB as the main downstream transcription factor of EGF-R pathway involved in NCX2 downregulation. In addition, we found that the most used drug in the treatment of GBM, temozolomide (TMZ), increased NCX2 expression in U87 cells, suggesting that this antiporter might mediate some antineoplastic effects of TMZ. Notably, GBM cells were hampered in vitality and invasiveness by either NCX2 transfection, pharmacological inhibition of NF-kB or enhancement of NCX2 activity. Altogether, these data showed that: (i) NCX2 is downregulated by an NFkB-dependent EGF-R pathway in glioblastoma, and (ii) the increase in NCX2 activity/expression slows-down glioblastoma cell growth and invasiveness.

Aim: Exposed to ionizing radiation, brain endothelial cells can be damaged/activated with consequences on BBB permeability, resulting the necessity of a complex post-irradiation characterization. The objective of this study is to understand how proton beams affects the brain microvascular endothelial cells functionality. Methods: Mouse brain microvascular cell line bEnd.3 was used in these experiments. One beam line of a TR19 cyclotron was adapted for in vitro radiobiology experiments. Cell cultures were exposed to proton irradiation (<10 MeV, doses range of 0-10 Gy, dose rate of 1 Gy/min). The cytotoxic (clonogenic and MTT assays), genotoxic (micronuclei and g- H2AX assays) and functional (purinergic signaling pathway and wound healing assay) effects were analyzed. Results: An inhibition (~90%) of the cellular proliferation and a strong increase of micronuclei number at doses over 5 Gy were observed. DNA repair capacity was significantly diminished by the increased values of the dose (~100%) and the linear energy transfer - LET (~20%). At intermediate doses and high LET values the cell relative migration rate was diminished (~25%). In the case of the ATP-dependent purinergic signaling pathway a more complex analysis of the specific parameters is necessary. Conclusions: Radiation dose and LET are important parameters in hadrontherapy procedures. These preliminary data suggest that proton beams in the range of Bragg peak diminishes the recovery capacity of brain microvascular endothelial cells in a manner depending on dose and LET. The results emphasize the necessity to gather more information about how the cell respond in this irradiation regimen.

Aims: The glycobiology of cancer cells is closely associated with their malignant properties, including invasiveness and metastatic potential. The composition of the glycocalyx, a layer of multifunctional glycans covering the surfaces of cells, and the expression of the terminal sialic acids were shown to be altered on neoplastic cells. We aimed to explore the glycobiology of glioma, the most malignant brain tumour, and to map the sialylation in a model consisting of patient-derived GBM cell lines on human neocortical organotypic slices. *Methods:* We used human organotypic brain slice culture as a framework to investigate the glycobiology of the brain, allowing metabolic labelling of sialic acid moieties and quantifying the changes of the glycocalyx. Spatial transcriptomics and RNA-sequencing approach was used to indicate sialic acid turnover related genes in both tumour-infiltrated patient samples and patient-derived GBM cell lines. Functional role of sialic acid turnover was investigated by inter- and trans- cellular Ca2+ signalling. *Results:* The visualization and quantitative analysis of newly synthesized sialic acids revealed a high rate of de novo sialic sialylation in glioblastoma cells. Sialyltrasferases and sialidases were highly expressed indicating that sialylation is involved in tumour metabolism. Altered GBM sialylation affected the pattern of tumour growth and lead to the alterations of glioblastoma network activity. *Conclusions:* Our results provided new insights into under-investigated role of sialic acid in the functional activity of GBM and highlighted its importance for glioblastoma cell migration and network formation. In the future, these interactions have the potential to be targeted therapeutically.

FUNCTIONAL CONSEQUENCES OF IDH1 AND CIC MUTATIONS ON OLIGODENDROGLIOMA CELLS OF ORIGIN

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Nina Pottier
Institut du Cerveau, Equipe Huillard Sanson, Paris, France

Oligodendrogliomas are primitive tumors of the central nervous system characterized by mutations in *isocitrate dehydrogenase 1 (IDH1*) gene, codeletion of 1p and 19q chromosomic arms and mutations in *Capicua (CIC*) gene. Oligodendrocyte precursors cells (OPCs) are potential cells of origin for oligodendrogliomas and OPC-like tumor cells are responsible for tumor amplification at early stages of gliomagenesis. Individually, IDH1 and CIC mutations can induce neoplastic characteristics but are not sufficient for tumoral development. Our goal is to characterize the combined effect of IDH1 and CIC mutations on OPC development and tumoral initiation. To this aim, we generated an inducible mouse model allowing endogenous expression of $IDH1^{R132H}$ and inactivation of CIC in postnatal OPCs. In this model we analyzed by immunofluorescence the consequences of IDH1 and CIC mutations on the proliferation and differentiation of OPCs and other brain cells. Our preliminary observations suggest that $IDH1^{R132H}$ increases the proliferation of OPCs and other cell types, suggesting paracrine effects of this mutation in the brain. Surprisingly, these effects are not observed when CIC is concomitantly inactivated. Our project describes for the first time the phenotypic impact of the combined expression of IDH1 and CIC mutations on oligodendroglial lineage cells and other brain cells, leading to a better understanding of oligodendroglioma development.

GLUCOCORTICOID DRUG WITHDRAWAL EXACERBATES GLIOBLASTOMA MULTIFORME MALIGNANCY

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Mauro Pessia
UNITED ARAB EMIRATES UNIVERSITY, Department Of Physiology, Al AIN, United Arab Emirates

Glioblastoma Multiforme (GBM) is the most aggressive brain tumour. Globally, over 100,000 patients die each year as a result of this type of brain cancer. The current therapeutic interventions are highly unsatisfactory and the average life expectancy remains approximately 14–18 months. One of the main clinical complications concerning GBM is the development of tumour-related cerebral oedema. *Dexamethasone* (DEX) represents the drug of choice among the synthetic glucocorticoids used to reduce oedema by decreasing tumour capillary permeability and enhancing extracellular water clearance. Nevertheless, the effects reported for DEX treatment on GBM cell proliferation remain controversial and the underlying mechanisms of action are unclear. Thus, we investigated the effects of DEX on the proliferative features of several GBM cell lines, including cells cultured from patients' GBM biopsies and tumour xenograft in athymic nude mice, clarifying the cell pathways involved in DEX actions. DEX treatment inhibited cell proliferation in a dose- and time-dependent manner through the promotion of the G0/G1 phase of cell cycle. WB analysis indicated that DEX treatment inhibited Cyclin D1 and enhanced p53 and p21 expression. DEX enhanced ROS production and, i*n vivo*, reduced tumour growth, effectively. By contrast, control mice displayed tumour overgrowth to such an extent that an early sacrifice was necessary. Despite these temporary beneficial effects, upon discontinuation or reduction of DEX dosage an unexpected withdrawal phenomenon developed characterized by enhanced cell proliferation and migration through activation of the p53-cyclin D3 pathway resulting in tumour overgrowth, *in vivo*.

BCAS1 AS A NOVEL MARKER OF A PROLIFERATIVE CELL POPULATION IN OLIGODENDROGLIOMAS

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Raquel Morales Gallel[1], María José Ulloa Navas[2], Ricardo Prat Acín[3], Gaspar Reynés Muntaner[4], Vivian Capilla González[5], Jaime Ferrer Lozano[6], Jose Manuel García Verdugo[1]

Aims: The cell of origin of glial-derived tumors, such as oligodendrogliomas (OGs), is still elusive. Different state-of-the-art studies point towards immature oligodendrocytes as a possible source of gliomagenesis. Therefore, studying markers that identify oligodendrocyte precursors has become of great interest. Breast carcinoma amplified sequence 1 (BCAS1) has emerged as a novel marker that defines an immature oligodendrocyte population in human brain. However, the tumorigenic potential of this cell population has never been explored in gliomas. Methods: In this study, we analysed the expression of BCAS1 in tumor tissue surgically removed from patients with OGs (n=17), glioblastomas (GBs, n=58) and astrocytomas (ASs, n=8). To study the distribution and proliferative status of the different cell subpopulations within these glial-derived tumors, we co-stained BCAS1, with EGFR, Vimentin and Ki-67. Additionally, we analysed the ultrastructure of BCAS1$^+$ cells by immunoelectron microscopy and we performed stereological quantification of the cell density and proliferation of BCAS1$^+$ cells. Results: Our results show that BCAS1$^+$ cells constitute a heterogeneously distributed population in glial-derived tumors. We found two different morphologies for this cell population: stellate and spherical cells. Stellate cells can form tightly packaged nodules or staying individualised, whereas spherical cells are isolated. These nodules present a high proliferative rate and they have been detected only in OGs, becoming a distinctive feature of more aggressive clinical behaviour. Conclusions: Our findings suggest that BCAS1 defines a specific cell subpopulation within glial-derived tumors, that could correspond to a transient amplifying cell state, thus contributing to tumor malignancy, specifically in OGs.

Ultrastructural Characterization of Human Oligodendrocytes and Their Progenitor Cells by Pre-embedding Immunogold. Oligodendrocytes are the myelinating cells of the central nervous system. They provide trophic, metabolic, and structural support to neurons. In several pathologies such as multiple sclerosis (MS), these cells are severely affected and fail to remyelinate, thereby leading to neuronal death. The gold standard for studying remyelination is the g-ratio, which is measured by means of transmission electron microscopy (TEM). Therefore, studying the fine structure of the oligodendrocyte population in the human brain at different stages through TEM is a key feature in this field of study. Here we study the ultrastructure of oligodendrocytes, its progenitors, and myelin in 10 samples of human white matter using nine different markers of the oligodendrocyte lineage (NG2, PDGFRα, A2B5, Sox10, Olig2, BCAS1, APC-(CC1), MAG, and MBP). Our findings show that human oligodendrocytes constitute a very heterogeneous population within the human white matter and that its stages of differentiation present characteristic features that can be used to identify them by TEM. This study sheds light on how these cells interact with other cells within the human brain and clarify their fine characteristics from other glial cell types.

CHANGES IN ADENOSINE A2A RECEPTOR AVAILABILITY IN GLIOBLASTOMA

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Kavya Prasad[1], Erik De Vries[1], Rudi Dierckx[1], Lara Barazzuol[2], Aren Waarde[1]
[1]University Medical Center Groningen, Department Of Nuclear Medicine And Molecular Imaging, Groningen, Netherlands, [2]University Medical Center Groningen, Department Of Biomedical Sciences Of Cells And Systems, Groningen, Netherlands

Introduction: Glioblastoma (GBM) is an aggressive and infiltrating type of intracranial tumor with poor response to conventional therapy. In the GBM microenvironment, adenosine elicits its functions through 4 adenosine G-protein-coupled receptors. We investigated whether PET with the novel $A_{2A}R$ ligand [^{11}C]preladenant is able to detect changes in adenosine A_{2A} receptor density in the tumor microenvironment as a result of tumor progression. **Methods:** Glioblastoma rat model was induced by unilateral (right frontoparietal cortex) implantation of C6 glioma cells in male and female Wistar rats (n=9). Rats underwent a 60-min dynamic PET scan with [^{11}C]preladenant to measure A_{2A} receptor density on days 6,9 and 12 post surgery. Animals were sacrificed on day 12 and anti-Iba1 immunohistochemical staining was performed to quantify microglia in cortical regions. **Results:** At day 12, tumor volume in males was 3 times higher than in females. [^{11}C]preladenant uptake in the tumor area was also higher in male rats ($p<0.05$), at all time-points. The highest uptake was in each animal always observed in the right caudate-putamen. However, the difference in [^{11}C]preladenant uptake between tumor and contralateral cortex was significantly higher in in females than in males, at all time-points. At day 12, males had a significantly higher Iba1^{+} microglial cell density in the tumor region than females, even though their tumors showed more necrosis. **Conclusions:** Although male rats had higher [^{11}C]preladenant uptake, female rats showed a greater difference in uptake between tumor and healthy brain. Increased microglial density suggests a more severe neuroinflammation in males.

Allosteric Interactions between Adenosine A and Dopamine D Receptors in Heteromeric Complexes: Biochemical and Pharmacological Characteristics, and Opportunities for PET Imaging.
Adenosine and dopamine interact antagonistically in living mammals. These interactions are mediated via adenosine A and dopamine D receptors (R). Stimulation of AR inhibits and blockade of AR enhances DR-mediated locomotor activation and goal-directed behavior in rodents. In striatal membrane preparations, adenosine decreases both the affinity and the signal transduction of DR via its interaction with AR. Reciprocal AR/DR interactions occur mainly in striatopallidal GABAergic medium spiny neurons (MSNs) of the indirect pathway that are involved in motor control, and in striatal astrocytes. In the nucleus accumbens, they also take place in MSNs involved in reward-related behavior. AR and DR co-aggregate, co-internalize, and co-desensitize. They are at very close distance in biomembranes and form heteromers. Antagonistic interactions between adenosine and dopamine are (at least partially) caused by allosteric receptor-receptor interactions within AR/DR heteromeric complexes. Such interactions may be exploited in novel strategies for the treatment of Parkinson's disease, schizophrenia, substance abuse, and perhaps also attention deficit-hyperactivity disorder. Little is known about shifting AR/DR heteromer/homodimer equilibria in the brain. Positron emission tomography with suitable ligands may provide in vivo information about receptor crosstalk in the living organism. Some experimental approaches, and strategies for the design of novel imaging agents (e.g., heterobivalent ligands) are proposed in this review.

Comenius University Bratislava, Jessenius Faculty of Medicine in Martin, Department Of Medical Biochemistry, Martin, Slovak Republic

Essential amino acids (EAAs) play several roles in cellular metabolism. They are indispensable monomers for protein synthesis, serve signaling roles, or they could be further catabolized. With the aim to estimate to which extent could EAAs enter the metabolism of human glioblastoma cells, we determined the ratio to which EAAs were consumed from the medium. The analysis of media composition with either 1H-NMR or LC-MS method was used to estimate the specific rates of disappearance for all EAAs. The branched-chain amino acids (BCAA), leucine, isoleucine and valine, were removed from media at similar rates, which excited the rates of all other EAAs. Glioblastoma cells were tested for the expression of the enzymes essential for catabolism of BCAA. By applying the immuno-probing methods we tested the expression of the enzymes that are involved in both, prime and final, parts of BCAA catabolism. Indeed, human glioblastomas express enzymes for catabolism of BCAA. This way cancer cells can obtain acetyl-CoA, propionyl-CoA, succinyl-CoA and other compounds, which could be used either as building blocks for the synthesis of new cell components or as fuel molecules for energy metabolism.

Glioblastoma is the most lethal tumor in the brain, affecting children and adults. This tumor may be regulated by the effects of ketogenic therapy, known for its high concentration of fatty acids. This diet is designed to reduce glucose levels and increase the ketone bodies produced in the metabolism of fatty acids, which could interrupt several processes of tumor metabolism, such as the viability and growth of these cells. Fatty acids also act as natural ligands of the peroxisome proliferator-activated receptors (PPARs) and could have a neuroprotective effect, regulating inflammatory, metabolic, and cell growth processes. However, it is still necessary to investigate the mechanisms of action that medium-chain fatty acids could have as signaling molecules and modulators of gene transcription through the activation of PPARs in the control of glioblastoma development. For this, an in vivo zebrafish model was used to evaluate the activity of these receptors against the effects of ketogenic therapy on inflammatory, metabolic, and cell growth response. It was found that there is no significant difference in the behavior of these animals. Brain and muscle gene expression analysis revealed an anti-inflammatory profile of this diet and favorable metabolic activity in the groups analyzed. The in vitro glioblastoma model was silenced for each PPAR isotype highlighting the relevance of PPARs in the fatty acid signaling in tumor growth and inflammatory response, pointing out this diet as a promising therapeutic alternative for glioblastoma treatment.

A CELLULAR ATLAS OF HUMAN CHOROID PLEXUS AND CHOROID PLEXUS TUMORS

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Anthony Hill, Annarita Patrizi
German Cancer Research Center DKFZ, Neuronal Signaling And Morphogenesis, Heidelberg, Germany

The choroid plexus (ChP) serves as a major site for CSF production, a critical interface between the immune system and brain, and a source of signals affecting neuronal development and function. Choroid plexus tumors (CPT) are relatively rare, often pediatric tumors that account for 10-20% of brain tumors during the first year of life. They range in severity from benign choroid plexus papillomas to the more malignant choroid plexus carcinomas. While a small number of genes have been linked to CPT occurrence (most notably TP53 and MYC), little is known about the signaling pathways and cellular interactions that lead to ChP tumor formation. As a first step to elucidating the cellular mechanisms giving rise to CPT, we have used single nucleus RNAseq to create cellular atlases of normal human ChP and CPT. The resulting atlases detail epithelial, mesenchymal and immune cell types, as well as their patterns of interaction and gene expression. Furthermore, they reveal tumor specific cell types and alterations in immune cell function. Finally, they identify tumor type specific alterations in intracellular signaling pathways, including some involving known oncogenes and tumor suppressors. Taken together, these data expand our knowledge of choroid plexus function and suggest mechanisms for CPT pathology.

EXTRACELLULAR PROTEINS – A SOURCE OF AMINO ACIDS FOR HUMAN GLIOBLASTOMA CELLS

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Jakub Šofranko[1], Eduard Gondáš[1], Alzbeta Kralova Trancikova[2,3], Radovan Murin[1]
[1]Comenius University Bratislava, Jessenius Faculty of Medicine in Martin, Department Of Medical Biochemistry, Martin, Slovak Republic, [2]Comenius University in Bratislava, Jessenius Faculty of Medicine in Martin, Biomedical Centre Martin, Martin, Slovak Republic, [3]Slovak Academy of Sciences, Institute Of Neuroimmunology, Bratislava, Slovak Republic

The transformed metabolism of glioblastoma cells is characterized by the increased demand for substrates, which are supposed to supply the cells with the energy and the building blocks required for the biosynthetic processes. In this respect, the synthesis of proteins is one of the metabolic processes that is strongly dependent on the availability of essential amino acids. We hypothesize that the limited availability of essential amino acids in the microenvironment of glioblastoma cells could be compensated by importing extracellular proteins, which are supposed to be utilized as a source of amino acids. To evaluate the capability of human glioblastoma cells to exploit the extracellular proteins as a complementary source of amino acids, we used two types of human glioblastoma cell lines, A172 and T98G. The culture media analysis suggests that glioblastoma cells can remove the extracellular proteins and enrich them with tryptophane. Indeed, cells readily removed also fluorescently labeled albumin, which was intracellularly localized into lysosomes. Furthermore, we revealed that albumin hydrolysis occurred after its endocytosis. In general, our results show that human glioblastoma cells are able to import and subsequently metabolize the extracellular proteins, and that proteins may serve as a valuable source of amino acids for human glioblastoma cells. This work was supported by the Slovak Research and Development Agency under Contract No. APVV-18-0088, APVV-20-0331 and VEGA 1/0255/20.

Expression of 3-Methylcrotonyl-CoA Carboxylase in Brain Tumors and Capability to Catabolize Leucine by Human Neural Cancer Cells.
Leucine is an essential, ketogenic amino acid with proteinogenic, metabolic, and signaling roles. It is readily imported from the bloodstream into the brain parenchyma. Therefore, it could serve as a putative substrate that is complementing glucose for sustaining the metabolic needs of brain tumor cells. Here, we investigated the ability of cultured human cancer cells to metabolize leucine. Indeed, cancer cells dispose of leucine from their environment and enrich their media with the metabolite 2-oxoisocaproate. The enrichment of the culture media with a high level of leucine stimulated the production of 3-hydroxybutyrate. When C-leucine was offered, it led to an increased appearance of the heavier citrate isotope with a molar mass greater by two units in the culture media. The expression of 3-methylcrotonyl-CoA carboxylase (MCC), an enzyme characteristic for the irreversible part of the leucine catabolic pathway, was detected in cultured cancer cells and human tumor samples by immunoprobing methods. Our results demonstrate that these cancer cells can catabolize leucine and furnish its carbon atoms into the tricarboxylic acid (TCA) cycle. Furthermore, the release of 3-hydroxybutyrate and citrate by cancer cells suggests their capability to exchange these metabolites with their milieu and the capability to participate in their metabolism. This indicates that leucine could be an additional substrate for cancer cell metabolism in the brain parenchyma. In this way, leucine could potentially contribute to the synthesis of metabolites such as lipids, which require the withdrawal of citrate from the TCA cycle.

Glioblastomas (GBM) are the most frequent and aggressive form of gliomas. Standard treatments consist of surgery, radiotherapy, and chemotherapy, which conduct a median survival of less than 15 months. Our project aims to explore the role of protein LINGO-1 in the physiopathology of GBM, a transmembrane protein mainly expressed in nervous systems that belong to the family LRIG. We first selected a series of compounds by virtual screening with LINGO-1 protein structure, then used BRET to identify the potential hits. We confirmed the interaction of the lead compound LPI3432 with LINGO-1, then tested the anti-tumor activity in different glioblastoma cell lines. LPI3432 is capable of inhibiting the proliferation of GBM cells, even in the stem-like cells isolated from biopsy tissues of GBM patients. We studied the signaling pathways implicated in the effect of LPI3432. We revealed dysregulation of the phosphorylation level of several proteins well-known in the EGFR pathway for their roles in cell proliferation, survival, and migration, such as kinase Erk1/2. LPI3432 also decreases glioblastoma cell migration and angiogenesis. Finally, we worked in a xenograft subcutaneous mice model of GBM to verify the anti-tumor activity *in vivo* and found LPI3432 significantly slowed down the tumor growth. qRT-PCR results showed several factors in angiogenesis and vasculature for cancer progression are decreased in mice group treated with LPI3432. Altogether, we have identified the first small chemical molecule which binds to LINGO-1 and demonstrated its antitumor activity *in vivo* as well as the potential mechanism of action for the treatment of GBM.

WNK1 kinase and its partners Akt, SGK1 and NBC-family Na/HCO3 cotransporters are potential therapeutic targets for glioblastoma stem-like cells linked to Bisacodyl signaling.
Glioblastoma is a highly heterogeneous brain tumor. The presence of cancer cells with stem-like and tumor initiation/propagation properties contributes to poor prognosis. Glioblastoma cancer stem-like cells (GSC) reside in hypoxic and acidic niches favoring cell quiescence and drug resistance. A high throughput screening recently identified the laxative Bisacodyl as a cytotoxic compound targeting quiescent GSC placed in acidic microenvironments. Bisacodyl activity requires its hydrolysis into DDPM, its pharmacologically active derivative. Bisacodyl was further shown to induce tumor shrinking and increase survival in glioblastoma models. Here we explored the cellular mechanism underlying Bisacodyl cytotoxic effects using quiescent GSC in an acidic microenvironment and GSC-derived 3D macro-spheres. These spheres mimic many aspects of glioblastoma tumors , including hypoxic/acidic areas containing quiescent cells. Phosphokinase protein arrays combined with pharmacological and genetic modulation of signaling pathways point to the WNK1 serine/threonine protein kinase as a mediator of Bisacodyl cytotoxic effect in both cell models. WNK1 partners including the Akt and SGK1 protein kinases and NBC-family Na/HCO3 cotransporters were shown to participate in the compound's effect on GSC. Overall, our findings uncover novel potential therapeutic targets for combatting glioblastoma which is presently an incurable disease.

Use of stress thallium imaging to stratify cardiac risk in patients undergoing vascular surgery.
Reduction of the cardiac morbidity associated with major vascular procedures requires identification of high risk patients prior to operation. This retrospective study reviews the records of 126 consecutive patients who underwent 141 major vascular procedures to determine the accuracy of preoperative clinical, laboratory (ECG), and cardiac function testing (stress thallium-201 scintigraphy, left ventricular ejection fraction scan) in predicting perioperative cardiac complications. An abnormality on oral dipyridamole or treadmill thallium imaging was demonstrated prior to 71 (61%) of 116 procedures and included 20 fixed

and 51 reperfusion (reversible) defects. No patient died within 30 days of operation, but 11 minor (ventricular arrhythmia) and 15 major (myocardial infarction, ischemic congestive heart failure) cardiac complications occurred. A reperfusion defect on stress thallium imaging accurately (94% sensitivity, 56% specificity, 98% negative predictive value) identified high-risk patients while accepted clinical rating systems (Goldman, Cooperman, Eagle) and preoperative level of left ventricular ejection fraction were less predictive of adverse cardiac events. Patients without myocardium at risk by coronary angiography, but a reperfusion defect on stress thallium imaging were found to be at high risk for a cardiac complication. The study data support the use of stress thallium imaging to stratify cardiac risk prior to major arterial surgery.

LINGO family receptors are differentially expressed in the mouse brain and form native multimeric complexes.
Leucine-rich repeat and immunoglobin-domain containing (LRRIG) proteins that are commonly involved in protein-protein interactions play important roles in nervous system development and maintenance. LINGO-1, one of this family members, is characterized as a negative regulator of neuronal survival, axonal regeneration, and oligodendrocyte precursor cell (OPC) differentiation into mature myelinating oligodendrocytes. Three LINGO-1 homologs named LINGO-2, LINGO-3, and LINGO-4 have been described. However, their relative expression and functions remain unexplored. Here, we show by in situ hybridization and quantitative polymerase chain reaction that the transcripts of LINGO homologs are differentially expressed in the central nervous system. The immunostaining of brain slices confirmed this observation and showed the co-expression of LINGO-1 with its homologs. Using BRET (bioluminescence resonance energy transfer) analysis, we demonstrate that LINGO proteins can physically interact with each of the other ones with comparable affinities and thus form the oligomeric states. Furthermore, co-immunoprecipitation experiments indicate that LINGO proteins form heterocomplexes in both heterologous systems and cortical neurons. Since LINGO-1 is a promising target for the treatment of demyelinating diseases, its ability to form heteromeric complexes reveals a new level of complexity in its functioning and opens the way for new strategies to achieve diverse and nuanced LINGO-1 regulation.

Chemical Library Screening and Structure-Function Relationship Studies Identify Bisacodyl as a Potent and Selective Cytotoxic Agent Towards Quiescent Human Glioblastoma Tumor Stem-Like Cells.
Cancer stem-like cells reside in hypoxic and slightly acidic tumor niches. Such microenvironments favor more aggressive undifferentiated phenotypes and a slow growing "quiescent state" which preserves them from chemotherapeutic agents that essentially target proliferating cells. Our objective was to identify compounds active on glioblastoma stem-like cells, including under conditions that mimick those found in vivo within this most severe and incurable form of brain malignancy. We screened the Prestwick Library to identify cytotoxic compounds towards glioblastoma stem-like cells, either in a proliferating state or in more slow-growing "quiescent" phenotype resulting from non-renewal of the culture medium in vitro. Compound effects were assessed by ATP-level determination using a cell-based assay. Twenty active molecules belonging to different pharmacological classes have thus been identified. Among those, the stimulant laxative drug bisacodyl was the sole to inhibit in a potent and specific manner the survival of quiescent glioblastoma stem-like cells. Subsequent structure-function relationship studies led to identification of 4,4'-dihydroxydiphenyl-2-pyridyl-methane (DDPM), the deacetylated form of bisacodyl, as the pharmacophore. To our knowledge, bisacodyl is currently the only known compound targeting glioblastoma cancer stem-like cells in their quiescent, more resistant state. Due to its known non-toxicity in humans, bisacodyl appears as a new potential anti-tumor agent that may, in association with classical chemotherapeutic compounds, participate in tumor eradication.

PRECLINICAL MOUSE STUDY ON MATERNAL SEPARATION IMPACTING CHILDHOOD CHEMOTHERAPY-INDUCED COGNITIVE IMPAIRMENT

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Livine Craeghs, Zsuzsanna Callaerts-Vegh, Rudi D'Hooge
KU Leuven, Biological Psychology, Leuven, Belgium

Exposure to chemotherapeutics can have long-lasting sequelae on behavioral and cognitive functioning in childhood-cancer survivors. Moreover, parental care might influence a child's resilience to adverse events. This includes the neurotoxic exposure to chemotherapeutics (chemo-brain), such as methotrexate (MTX), used in the treatment of the most prevalent childhood cancers. Therefore, the present preclinical mouse study investigates (1) the severity of MTX-induced socio-cognitive defects during weaning and adult life, and (2) how early life stress (maternal separation) affects the impact of MTX exposure. We implement a maternal separation or sham protocol in male and female C57BL/6 mice from postnatal day (P) 10 through 20. After weaning, pups are injected with MTX (100 mg/kg, i.p.) or vehicle on P21, P28 and P35, which mimics MTX exposure in children treated for acute lymphoblastic leukemia. We assess behavioral interaction in pups towards their dams (in comparison to unfamiliar adults) in a modified 3-chamber paradigm. Adult performance in MTX-exposed mice is assessed using an extensive test battery that includes a variety of exploratory, emotional, cognitive and social behaviors. We expect that maternal separation influences the animals' susceptibility to the socio-cognitive effects of MTX exposure. We shall discuss the broad relevance of these findings to our understanding of the late sequelae of chemotherapy, and the possible factors that could influence the increasingly prevalent condition of chemo-brain. This research is funded by the Fonds Wetenschappelijk Onderzoek (FWO) Vlaanderen and the Olivia Hendrickx Research Fund.

Background and aims: Glioblastoma is the most malignant human brain tumor characterized by heterogeneous cell populations, including undifferentiated cells defined Glioblastoma Stem cells (GSCs), responsible for the beginning of neoplastic process and recurrence formation. Previous studies demonstrated how the activation of M2 muscarinic receptor by orthosteric agonist Arecaidine Propargyl Ester (APE) and dualsteric agonist N-8-Iper caused a significant decrease of cell proliferation and survival both in GSCs and in glioblastoma cell lines. Interestingly N8-Iper is capable to activate M2 receptor with higher affinity and at a lower concentration than APE. The aim of this work was to investigate the mechanisms downstream of M2 receptor activation by both agonists responsible of the cytotoxic and pro-apoptotic effects both in U251 cell line and in GSCs. Methods: mitochondrial functionality was evaluated by MITO ID assay, TMRE staining and oxygen consumption measurement by oxygraph. Lipid homeostasis was analyzed by Oil Red O staining, TLC and WB analysis. Autophagy was analyzed by WB analysis and LC3-GFP construct transfection. Results: our results demonstrate the ability of the M2 agonists to induce oxidative stress, alteration of the mitochondrial morphology and activity with consequent alteration of cellular respiration, lipid homeostasis and lipid droplets formation. M2 agonists also induce autophagy, as demonstrated in U251 cells. Conclusions: these results suggest that the selective activation of M2 receptor in particular by N-8-Iper may be a promising therapeutic strategy for the glioblastoma treatment, reducing the possible side effects that may be caused by the high doses of the orthosteric agonist.

The Combined Treatment with Chemotherapeutic Agents and the Dualsteric Muscarinic Agonist Iper-8-Naphthalimide Affects Drug Resistance in Glioblastoma Stem Cells.
Glioblastoma multiforme (GBM) is characterized by heterogeneous cell populations. Among these, the Glioblastoma Stem Cells (GSCs) fraction shares some similarities with Neural Stem Cells. GSCs exhibit enhanced resistance to conventional chemotherapy drugs. Our previous studies demonstrated that the activation of M2 muscarinic acetylcholine receptors (mAChRs) negatively modulates GSCs proliferation and survival. The aim of the present study was to analyze the ability of the M2 dualsteric agonist Iper-8-naphthalimide (N-8-Iper) to counteract GSCs drug resistance.

M2 Muscarinic Receptor Activation Impairs Mitotic Progression and Bipolar Mitotic Spindle Formation in Human Glioblastoma Cell Lines.
Glioblastoma multiforme (GBM) is characterized by several genetic abnormalities, leading to cell cycle deregulation and abnormal mitosis caused by a defective checkpoint. We previously demonstrated that arecaidine propargyl ester (APE), an orthosteric agonist of M2 muscarinic acetylcholine receptors (mAChRs), arrests the cell cycle of glioblastoma (GB) cells, reducing their survival. The aim of this work was to better characterize the molecular mechanisms responsible for this cell cycle arrest.

M2 Receptor Activation Counteracts the Glioblastoma Cancer Stem Cell Response to Hypoxia Condition.
Glioblastoma multiforme (GBM) is the most malignant brain tumor. Hypoxic condition is a predominant feature of the GBM contributing to tumor growth and resistance to conventional therapies. Hence, the identification of drugs able to impair GBM malignancy and aggressiveness is considered of great clinical relevance. Previously, we demonstrated that the activation of M2 muscarinic receptors, through the agonist arecaidine propargyl ester (Ape), arrests cell proliferation in GBM cancer stem cells (GSCs). In the present work, we have characterized the response of GSCs to hypoxic condition showing an upregulation of hypoxia-inducible factors and factors involved in the regulation of GSCs survival and proliferation. Ape treatment in hypoxic conditions is however able to inhibit cell cycle progression, causing a significant increase of aberrant mitosis with consequent decreased cell survival. Additionally, qRT-PCR analysis suggest that Ape downregulates the expression of stemness markers and miR-210 levels, one of the main regulators of the responses to hypoxic condition in different tumor types. Our data demonstrate that Ape impairs the GSCs proliferation and survival also in hypoxic condition, negatively modulating the adaptive response of GSCs to hypoxia.

Cross Interaction between M2 Muscarinic Receptor and Notch1/EGFR Pathway in Human Glioblastoma Cancer Stem Cells: Effects on Cell Cycle Progression and Survival.
Glioblastomas (GBM) are the most aggressive form of primary brain tumors in humans. A key feature of malignant gliomas is their cellular heterogeneity. In particular, the presence of an undifferentiated cell population of defined Glioblastoma Stem cells (GSCs) was reported. Increased expression of anti-apoptotic and chemo-resistance genes in GCSs subpopulation favors their high resistance to a broad spectrum of drugs. Our previous studies showed the ability of M2 muscarinic receptors to negatively modulate the cell growth in GBM cell lines and in the GSCs. The aim of this study was to better characterize the inhibitory effects of M2 receptors on cell proliferation and survival in GSCs and investigate the molecular mechanisms underlying the M2-mediated cell proliferation arrest and decreased survival. Moreover, we also evaluated the ability of M2 receptors to interfere with Notch1 and EGFR pathways, whose activation promotes GSCs proliferation. Our data demonstrate that M2 receptors activation impairs cell cycle progression and survival in the primary GSC lines analyzed (GB7 and GB8). Moreover, we also demonstrated the ability of M2 receptor to inhibit Notch1 and EGFR expression, highlighting a molecular interaction between M2 receptor and the Notch-1/EGFR pathways also in GSCs.

NEURON-GLIOMA INTERACTIONS IN WHITE MATTER INVASION IN A PRECLINICAL MODEL OF GLIOBLASTOMA

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Quentin Lemercier[1], Laurence Desrues[1], David Godefroy[2], Lucie Martin[1], Pierrick Gandolfo[1], Hélène Castel[1], Oana Chever[1]

Aims: Glioblastoma, a brain tumor of glial origin, is the most common and aggressive primary tumor of the central nervous system in adults, with a median survival rate of 15 months after standard treatment. The poor prognosis is primary related to the invasiveness of glial tumor cells. Glioma cells can detach from the mass and infiltrate the brain, causing a high propensity of secondary tumors or recurrence after surgery. White matter tracts are a major pathway for glioma infiltration, but close physical and functional interactions between axons and glioma cells are far from comprehensive. **Methods/results:** Immunohistochemistry on brain slices and transparized brains of adult *Nude* and C57Bl/6J mice bearing glioblastoma (following stereotaxic injection of glioblastoma human U87 and murine GL261 cell lines) were performed to study invasiveness profile. Organotypic slices from 3-5 weeks-old mice were also used to investigate modulation of glioma cells invasion following chronic pharmacological treatment (tetrodotoxin, extracellular potassium in excess), through macroconfocal acquisitions for days and thunder/confocal imaging after immunostainings. *In situ*, U87 cells display collective behavior in the white matter and contact both axons and vessels. Myelinated and unmyelinated axons are both concerned. Reactive astrogliosis has been also observed. *Ex vivo*, chronic treatment of tetrodotoxin favor glioma invasion, both in the cortex and in the white matter. *Ex vivo*, U87 cells display high tropism for vessels. **Conclusion:** These results suggest that axonal activity modulate gliomal invasion. **Fundings** by Canceropole Nord-Ouest, Normandy Region and European Regional Development Fund.

The management of glioblastoma (GBM) has not been substantially improved since the implementation of the Stupp protocol, temozolomide plus surgery, and radiotherapy many years ago. In this work, using *in vivo* and *in vitro* models of GBM, we show that the lipophilic antioxidant Coenzyme Q_{10} (CoQ_{10}), a component of the mitochondrial electron transport chain, has a potential therapeutic effect in the pathology, acting as a pleiotropic molecule. Intraperitoneal administration of CoQ_{10} decreased by one-half the volume of U251-cells induced tumors in xenografts and orthotopic models. This effect was related with a delay in tumor hypoxia and a reduction in neovascularization and inflammation. Moreover, the volume of the brain infiltrated with tumor cells was diminished in CoQ_{10}-treated mice. *In vitro* experiments revealed that these beneficial effects of CoQ_{10} involve the remodeling of the proteome and the secretome regarding pro-inflammatory cytokines and angiogenic molecules. GBM cells migration and invasion were drastically reduced by mechanisms involving modulation of the actin cytoskeleton polarization and downregulation of MMPs. Overall, CoQ_{10} exerted pleiotropic effects *in vitro* and *in vivo*, simultaneously affecting several hallmarks of GBM, suggesting that the compound has therapeutic potential in treating this fatal disease.

SERUM DEPRIVATION ENHANCES THE CANNABIDIOL ANTINEUROBLASTOMA ACTION BY THE UPREGULATION OF CANNABINOID 2 AND GRP55 RECEPTORS.

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Cannabidiol (CBD) is one of the most promising phytocannabinoids derived from *Cannabis Sativa*. Among all their effects on different metabolic processes it is worthy to highlight their anti-neuroblastoma activity. However, this effect is potentiated upon serum deprivation. The aim of the present study is to shed some light on the mechanism of CBD as an anti-neuroblastoma compound in a serum restricted environment. To conduct this study, we have exposed a neuroblastoma cells line (SH-SY5Y) to serum restriction, in presence or absence of CBD. We have compared the result respect with a neuroblastoma cell in presence of serum. We have evaluated cell viability by MTT assay, and the gene expression by RT-qPCR of receptors implicated in the CBD signalling. We have also evaluated the protein expression of different markers of reactive oxygen spices (ROS) production and of endoplasmic reticulum (ER) stress by Western blot analysis. Results have shown that serum restriction significantly upregulates the gene expression of the isoform of cannabinoid receptor 2 (CB2) and of GRP55 in the firsts stages of serum restriction. Nevertheless, only neuroblastoma cells exposed to CBD in serum deprivation maintain the upregulation of these receptors, which induce a significant decrease of cell viability by increasing the protein expression of excised caspase 3, antioxidant enzymes and of proteins markers of ER stress. We can conclude that serum deprivation sensitizes the CBD signalling, upregulating CB2 and GPR55 receptors, which generates neuroblastoma cell death by ROS production and ER stress.

CO-TARGETING TUMOR MICROENVIRONMENT-INSTIGATED ADAPTATION TO HYPOXIA RENDERS GLIOBLASTOMA MORE SUSCEPTIBLE TO ONCOLYTIC VIRUS IMMUNOTHERAPY.

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Agnieszka Bronisz, Jakub Godlewski, Elżbieta Salinska
Polish Academy of Science, Mossakowski Medical Research Institute, Warsaw, Poland

Brain tumors (glioblastomas) are characterized by robust survival of a subpopulation of cancer stem-like cells (CSCs) in a hypoxic tumor microenvironment, and poor infiltration of immune cells. Thus, a recent promising oncolytic herpes virus (oHSV)-based immunotherapy meets inefficacy barriers due to a prevalence of stress-resistant CSCs. We hypothesized that gene signature separating CSC in the context of hypoxic tumor microenvironment would reveal relevant targets of oHSV efficacy, providing clinically-relevant cues on how CSCs thrive in the hypoxic niche being resistant to oHSV immunotherapy. As a proof of concept for co-targeting hypoxic signaling effectors, we singled out an RNA molecule (*HIF1A-AS2*) that is a vital sensor for the response and adaptation of CSCs to hypoxia. We compared (by gene microarray) transcriptomes in the intracranial xenograft tissue in vivo and ex vivo single-cell culture using a heterogeneous patient-derived CSC model. We targeted *HIF1A-AS2* expression in GSCs and tested for survival benefits of tumor-bearing animals upon oHSV immunotherapy. Transcriptome data revealed that the presence of the brain microenvironment shapes two distinguishing characteristics of CSCs: increased cell-to-cell communication with immune response cells and metabolic shift toward hypoxic adaptation, both with signatures predictive of glioblastoma patent survival. *HIF1A-AS2* silencing augmented sensitivity to oHSV immunotherapy and improved overall survival of tumor-bearing animals. The intertwined influence of the tumor microenvironment diminishes therapeutic efficiency by enabling cell adaptation to hypoxia. Thus, co-targeting hypoxia response by attenuating *HIF1A-AS2* rearranges gene expression, boosting glioblastoma's sensitivity to therapy.

The success of brain tumor removal depends on the detection of tumor borders. Therefore, it is crucial to identify cell markers and detection methods that would allow univocally distinguish between tumor, peritumoral area and healthy tissue. Here, Raman microspectroscopy (RMS), Ca^{2+} imaging, and patch-clamp recordings were used to compare cells in the access tissue, peritumoral regions and the dense tumor in the samples obtained from patients with II-IV grades of gliomas during surgery. All studies were carried out in accordance with the human tissue regulations. RMS allowed to distinguish tumor cells, peritumoral regions and the normal cortex. This method revealed that the relative amount of proteins is higher in IV grade gliomas than in the healthy cortex. The redox state of mitochondrial cytochromes was different in the peritumoral regions compared to the normal cortex in both types of gliomas (II and IV grades). The input resistance of tumor cells was higher than in cortical astrocytes in high grade gliomas. The Ca^{2+} events were more localized while the amplitude of Ca^{2+} transients was higher in tumor cells than in cortical astrocytes. Thus, we observed multiple metabolic and physiological differences in tumoral cells, peritumoral cells and healthy astrocytes which can be used for diagnostics purposes and identifying the tissue borders. This study was supported by RFBR (grant number 20-04-01011).

Calcium signaling mechanisms in brain tumors such as glioblastoma multiforme (GBM) have been extensively explored in order to better understand the etiology of the disease. Numerous *in vitro* studies have shown that calcium signaling facilitates GBM proliferation, motility and invasion. However, there are no *in vivo* demonstrations linking GBM cell motility and calcium signaling. To address this issue, we *ex novo* generated an orthotopic murine model, engineering a GL261 cell line; we co-expressed a red fluorescent protein staining the actin cytoskeleton, and a green fluorescent protein encoding GCaMP6s calcium sensor. By means of two photon imaging, we demonstrate that most of the tumor volume, i.e. the core, is occupied by tightly packed spherical cells characterized by reduced cellular motility and low intracellular calcium ($(Ca^{2+})_i$) activity. This core is surrounded by sparse cells displaying a very polarized morphology that migrate at a higher rate. These cells in the peripheral region are characterized by very active $(Ca^{2+})_i$signaling. Additionally, we observed a novel phenomenon where groups of cells display synchronized $(Ca^{2+})_i$waves propagating within the ensemble based on their common activation. Cells in these clusters/ensembles appear to have a direction-biased cellular motility. Thus, here we demonstrate that the GL261 model is considerably more infiltrative than previously shown, and we infer that the proliferative component is composed of tumor cells from peripheral locations and active ensembles.

Neuroinflammation: A Signature or a Cause of Epilepsy?
Epilepsy can be both a primary pathology and a secondary effect of many neurological conditions. Many papers show that neuroinflammation is a product of epilepsy, and that in pathological conditions characterized by neuroinflammation, there is a higher probability to develop epilepsy. However, the bidirectional mechanism of the reciprocal interaction between epilepsy and neuroinflammation remains to be fully understood. Here, we attempt to explore and discuss the relationship between epilepsy and inflammation in some paradigmatic neurological and systemic disorders associated with epilepsy. In particular, we have chosen one representative form of epilepsy for each one of its actual known etiologies. A better understanding of the mechanistic link between neuroinflammation and epilepsy would be important to improve subject-based therapies, both for prophylaxis and for the treatment of epilepsy.

Modelling genetic mosaicism of neurodevelopmental disorders in vivo by a Cre-amplifying fluorescent reporter.
Genetic mosaicism, a condition in which an organ includes cells with different genotypes, is frequently present in monogenic diseases of the central nervous system caused by the random inactivation of the X-chromosome, in the case of X-linked pathologies, or by somatic mutations affecting a subset of neurons. The comprehension of the mechanisms of these diseases and of the cell-autonomous effects of specific mutations requires the generation of sparse mosaic models, in which the genotype of each neuron is univocally identified by the expression of a fluorescent protein in vivo. Here, we show a dual-color reporter system that, when expressed in a floxed mouse line for a target gene, leads to the creation of mosaics with tunable degree. We demonstrate the generation of a knockout mosaic of the autism/epilepsy related gene PTEN in which the genotype of each neuron is reliably identified, and the neuronal phenotype is accurately characterized by two-photon microscopy.

detection of murine glioblastoma through Raman and reflectance fiber-probe spectroscopies.

FENS Forum 2022
9-13 July 2022 | Paris, France

Glioblastoma (GBM) is the most common and aggressive malignant brain tumor in adults. With a worldwide incidence rate of 2 to 3 per 100,000 people, it accounts for more than 60% of all brain cancers; currently, its 5-year survival rate is . GBM treatment relies mainly on surgical resection. In this framework, multimodal optical spectroscopy could provide a fast and label-free tool for improving tumor detection and guiding the removal of diseased tissues. Discriminating healthy brain from GBM tissues in an animal model through the combination of Raman and reflectance spectroscopies. EGFP-GL261 cells were injected into the brains of eight laboratory mice for inducing murine GBM in these animals. A multimodal optical fiber probe combining fluorescence, Raman, and reflectance spectroscopy was used to localize healthy and tumor brain areas and to collect their spectral information. Tumor areas were localized through the detection of EGFP fluorescence emission. Then, Raman and reflectance spectra were collected from healthy and tumor tissues, and later analyzed through principal component analysis and linear discriminant analysis in order to develop a classification algorithm. Raman and reflectance spectra resulted in 92% and 93% classification accuracy, respectively. Combining together these techniques allowed improving the discrimination between healthy and tumor tissues up to 97%. These preliminary results demonstrate the potential of multimodal fiber-probe spectroscopy for label-free detection and delineation of brain tumors, and thus represent an additional, encouraging step toward clinical translation and deployment of fiber-probe spectroscopy.

ACQUIRED INHERITABLE FACTORS FOR BRAIN FITNESS IN THE PROGRESSION OF GLIOBLASTOMA

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Teresa De Los Reyes, Sergio Casas-Tintó
Instituto Cajal (CSIC), Molecular, Cellular And Developmental Neurobiology, Madrid, Spain

Glioblastoma (GB) is the most common and aggressive malignant primary brain tumor of the central nervous system in humans, originated from neoplastic glial cells. Patients suffer from progressive memory loss, defects in speech and language, epileptic seizures and vomiting, symptoms of neurodegenerative processes, compatible with synapse loss as an early event that occurs in neurodegeneration. However, patients with similar epidemiological features and oncogenic mutations causing GB have a heterogeneous range of life expectancy, but causal determinants are unknown. Our hypothesis stands that different factors contribute to the heterogeneity in the survival of patients, including the physiological status of the healthy tissue in the brain.
Our preliminary data suggest that environmental conditions parental lineages are exposed can be inheritable to the next generation. We found that luminic stress promotes inheritable risk factors and modulate specific gene expression in the brain that leads on the resistance to GB induced neurodegeneration and premature lethality. In particular, we study the contribution of dODF family, a sperm cytoskeleton family and a potential target to drive new therapies against the tumor. Our results in the Drosophila tumor model show that ODF3L2 is upregulated in GB samples and the knockdown of dODF3L2 prevents tumor growth but also restores the glioma neurodegeneration-associated. This work aims to combat the GB by identifying the mechanisms that regulate TMs to reduce GB aggressiveness, extend the patient's life span and combine these protective strategies with oncological treatments

Neural functions of small heat shock proteins.
Stress response is a cellular widespread mechanism encoded by a common protein program composed by multiple cellular factors that converge in a defense reaction to protect the cell against damage. Among many mechanisms described, heat shock proteins were proposed as universally conserved protective factors in the stress core proteome, coping with different stress stimuli through its canonical role in protein homeostasis. However, emerging evidences reveal non-canonical roles of heat shock proteins relevant for physiological and pathological conditions. Here, we review the implications of inducible heat shock proteins in the central nervous system physiology. In particular, we discuss the relevance of heat shock proteins in the maintenance of synapses, as a balanced protective mechanism in central nervous system development, pathological conditions and aging.
Neural Regen Res, 2022; 17
32437379: Santana E, de Los Reyes T, Casas-Tintó S
Small heat shock proteins determine synapse number and neuronal activity during development.
Environmental changes cause stress, Reactive Oxygen Species and unfolded protein accumulation which hamper synaptic activity and trigger cell death. Heat shock proteins (HSPs) assist protein refolding to maintain proteostasis and cellular integrity. Mechanisms regulating the activity of HSPs include transcription factors and posttranslational modifications that ensure a rapid response. HSPs preserve synaptic function in the nervous system upon environmental insults or pathological factors and contribute to the coupling between environmental cues and neuron control of development. We have performed a biased screening in Drosophila melanogaster searching for synaptogenic modulators among HSPs during development. We explore the role of two small-HSPs (sHSPs), sHSP23 and sHSP26 in synaptogenesis and neuronal activity. Both sHSPs immunoprecipitate together and the equilibrium between both chaperones is required for neuronal development and activity. The molecular mechanism controlling HSP23 and HSP26 accumulation in neurons relies on a novel gene (CG1561), which we name Pinkman (pkm). We propose that sHSPs and Pkm are targets to modulate the impact of stress in neurons and to prevent synapse loss.

JNK Pathway in CNS Pathologies.

The c-Jun N-terminal kinase (JNK) signalling pathway is a conserved response to a wide range of internal and external cellular stress signals. Beside the stress response, the JNK pathway is involved in a series of vital regulatory mechanisms during development and adulthood that are critical to maintain tissue homeostasis. These mechanisms include the regulation of apoptosis, growth, proliferation, differentiation, migration and invasion. The JNK pathway has a diverse functionality and cell-tissue specificity, and has emerged as a key player in regeneration, tumorigenesis and other pathologies. The JNK pathway is highly active in the central nervous system (CNS), and plays a central role when cells need to cope with pathophysiological insults during development and adulthood. Here, we review the implications of the JNK pathway in pathologies of the CNS. More specifically, we discuss some newly identified examples and mechanisms of JNK-driven tumor progression in glioblastoma, regeneration/repair after an injury, neurodegeneration and neuronal cell death. All these new discoveries support the central role of JNK in CNS pathologies and reinforce the idea of JNK as potential target to reduce their detrimental effects.

MANIPULATING NEURAL STEM CELLS TO CREATE A TRANSGENIC INDEPENDENT MODEL FOR GLIOBLASTOMA

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Marie-Catherine Tiveron[1], Caroline Blanc[2], Harold Cremer[2]
[1]AIX Marseille University-CNRS, Ibdm Umr 7288, Marseille Cedex , France, [2]AIX Marseille University-CNRS, Ibdm Umr 7288, Marseille Cedex, France

Neural stem cells (NSCs) residing in the subventricular zone (SVZ) of the forebrain, are cells of origin of glioblastoma (GBM), the most frequent and aggressive of the primary brain cancers (Lee et al. Nature 2022). Indeed, somatic mutations in tumor suppressor genes in postnatal neural stem cells of the subventricular zone (SVZ) act as drivers of glioblastoma development. In order to better understand the etiology of the disease, and the molecular processes that are involved in the onset and progression of GBM, it is important to develop transgenic mouse models that enable mechanistic studies. However, currently GBM induction implicates complex genetic backgrounds and the use of conditional mutations based on the CRE-Lox system, limiting genetic studies of new candidate genes or regulators potentially involved in gliomagenesis. In order to circumvent this limitation, we developed an in vivo glioblastoma model that is is based on postnatal brain electroporation of neural stem cells in combination (Boutin et al., PlosOne 2008) with the PiggyBac transposase system and the use of CRISPR technology. The system is easily applicable and does not implicate the use of transgenic mouse lines or the CRE-LoxP system, freeing such approaches for functional studies. We show that this model enables the induction and analysis of GBM development in a temporally and spatially highly regulated fashion and may be implemented in any mutated genetic background.

The diversity of cancer cells populating glioblastoma participates to the complex biological system represented by these brain tumors defying treatments. Nonetheless cancer cells can adopt similar functional states despite the diversity in genomic anomalies encountered between and within patient tumors. Metabolism being downstream of all signaling pathways regulating cell behaviors, it constitutes a source of vulnerabilities that should help overcoming the inter- and intra-tumor genetic heterogeneity. We therefore looked for metabolic weaknesses in link with motility, a key functional state for glioblastoma aggressiveness. A signature-driven data reduction approach highlighted motile cells present in thirty tumors from four independent single-cell transcriptomic datasets. Analyses integrating trajectory modeling disclosed, as characteristic of motile cells, enhanced oxidative stress coupled with mobilization of the cysteine metabolism enzyme 3-Mercaptopyruvate sulfurtransferase (MPST). The soundness of this prediction was verified using migration and invasion assays with patient-derived cells and tissue organoids. Pharmacological and genetic manipulations showed that enhanced ROS production and MPST activity are required for the cells' motility. Biochemical assays indicated that MPST acts by protecting protein cysteine residues from dismal hyperoxidation. In vivo, MPST knockdown translated in reduced tumor burden, and a robust increase in mice survival. These results show that enhanced oxidative stress coupled with MPST mobilization plays a key role in glioblastoma cell motility. Overall, they demonstrate that single-cell transcriptomes can be leveraged to map cancer cell behaviors within the patients' tumors as well as their associated metabolic pathways.

Aims: Glioblastoma multiforme is the most aggressive and frequently occurring brain tumor. Pulsed electric fields (PEFs) are an emerging tool for treating cancer, though less studied in tumors of the brain. Whereas PEFs are known to induce irreversible permeabilization and death of cancer cells, we have explored their immunomodulatory role and their long-term impact on intracortical tumor development. **Methods:** Glioblastoma spheroids were seeded 200µm deep in the cortex of adult "AMU-Neuroinflam" multifluorescent mice prior to electrode placement and glass window implantation. Intravital two-photon microscopy was used to monitor the growth of a GL261-DsRed glioblastoma tumor exposed to pulse trains of 100 µs PEFs through epidurally implanted flexible gold electrodes. Animals were split into 3 groups, receiving either no treatment, or receiving daily pulse trains at 1Hz or 100Hz from day 26 onward. Densities of tumor cells, neurons, microglia and peripheral inflammatory cells were quantified in the same millimetric volume of interest 26 and 29 days after implantation. **Results:** The stimulation protocol, verified by impedance and current measurements, allowed the in situ three-dimensional mapping of the effect of electrical stimulation. Repeated stimulation and measurements were possible on a daily basis both from the electrical and from the physiological point of view. Stimulations immediately triggered the accumulation of peripheral innate immune cells in a subset of vessels located in between the electrode fingers. **Conclusions:** Our results support the immunomodulatory effects of PEFs in a gliobastoma mouse model, whose frequency dependence and antitumor actions are currently being characterized.

IDENTIFYING NOVEL MEDIATORS OF TUMOR-NERVE INTERACTIONS IN CANCER PAIN

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Yong Xie[1], Christiane Höper[1], Michael Hirth[1], Thilo Hackert[2], Rohini Kuner[1]
[1]Heidelberg University, Pharmacology Institute, Heidelberg, Germany, [2]Heidelberg University Hospital, General, Visceral And Transplantation Surgery, Heidelberg, Germany

Cancer-associated pain represents an essential determinant of the poor quality of life and an important predictor of the prognosis in patients with pancreatic adenoductal carcinoma (PDAC). Neuroplastic alterations and neural invasion are the pathological features of PDAC, which occur in almost all tumors and are highly correlated with cancer-associated pain. Molecular mediators such as chemokines are essential on the bi-directional interactions between nerves and cancer cells, which induce tumor-associated pain. In a screen, we identified Cardiotropin-1(CT-1), an IL-6 family member, to be secreted by cancer cells. We sought to study its effects on sensory nerves and tumor-nerve interactions in PDAC. We found expression of CT-1 in both PDAC patients and PDAC-bearing mice and was significantly increased in cancer states compared to healthy human subjects and naïve mice. Moreover, after blocking CT-1 signaling, the sensory hypersensitivity associated with PDAC-associated pain was significantly attenuated in tumor-bearing mice compared to the naïve mice. In conclusion, our study indicates that CT-1 contributes to PDAC-induced pain by activating signaling in sensory neurons. The authors acknowledge grant support from the German Cancer Aid to R.K.

INTRAVITAL IN-SITU CHARACTERIZATION OF THE EMISSION SPECTRA OF GENETICALLY ENCODED FLUORESCENT PROTEINS IN THE PATHOLOGICAL BRAIN TUMOR ENVIRONMENT

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Andrea Slezia[1,2], Attila Kaszas[1,2], Franck Debarbieux[1,2,3]
[1]ImaPath, Institut Des Neurosciences De La Timone, Cnrs Umr7289, Marseille, France, [2]Aix-Marseille Université, Centre Européen De Recherche En Imagerie Médicale, Marseille, France, [3]Institut Universitaire de France, Institut Universitaire De France, Paris, France

Aims: Imaging of multiple fluorescent labels in transgenic mice has become common practice to characterize cellular interactions in the brain. Nevertheless, spectral overlap between fluorophores requires efficient and reliable unmixing methods for the quantitative analysis of imaging data. In the context of intravital imaging of brain tumor development, we have here characterized the impact of imaging depth and of the pathological microenvironment on the success of multi-labeled cells identification. **Methods:** We used **i**ntravital two-photon images of the parietal cortices of Thy1-CFP, CD11c-EYFP, LyzM-EGFP triple transgenic mice implanted with GL261-DsRed murine glioblastoma cells. Five-color tiled images were acquired every 20 microns over 400 microns in Z to cover a millimetric volume of interest imaged repeatedly under the same conditions. Mono-labeled cellular processes were visually selected at different depths; from these, individual five-channels spectra were determined for each fluorophore and collected into a depth-dependent database. Sets of spectra were then used to feed the ZEN unmixing algorithms (black edition software) and to provide fluorophore specific images stacks. **Results:** Collected emission spectra showed different levels of variability. DsRed spectra were highly reproducible while CFP spectra were stable within 15% accuracy. EGFP and EYFP spectra were instead highly variable as expected from the sensitivity of their fluorescence to pH and chemical environment if expressed in immune cell subsets around a tumor. **Conclusion:** The patterned distribution of fluorescent cells thus has to be taken into account to implement locally adaptative unmixing strategies for accurate quantification of fluorophore expression in a pathological context.

Poor delivery and systemic toxicity of many chemotherapeutic agents limit their therapeutic success in brain cancer treatment. Local chemotherapy approaches offer a new path to efficiently interfere with brain tumor growth and are able to reduce tumor size. We present miniature bioelectronic devices for drug delivery able to administer chemotherapeutics via electric control with high spatiotemporal precision. The drug delivery is based on the electromigration of molecules in an ion selective matrix towards a target of choice. These devices, called chemotherapeutic ion pumps (chemoIPs), can be used for triggered release of chemotherapeutics that are usually shielded by the blood brain barrier. With chemoIPs it is possible to constantly administer drugs with highest precision towards cell culture spheroids, *ex ovo*-grown tumors and *in vivo* brain tumors. The treatment efficiency was analyzed via flow cytometry quantifying apoptosis and cell cycle arrest, as well as immunohistochemistry. ChemoIP treatment is able to trigger the disintegration of targeted tumor spheroids, and is able to inhibit the tumor growth of *ex ovo*-glioblastomas significantly. Furthermore, the proteomes of neurons and glioblastoma cells showed that only glioblastoma cells are harmed by the chemotherapeutic treatment, but not neurons. In parallel, we follow the pharmacokinetics of the chemoIP-mediated drug administration via mass spectrometry and compare it to computer simulations in different tumor models. The here exemplified electrically-driven drug delivery via chemoIPs is a drug administration method that can serve as basis for further implant development, which has the potential to increase the efficacy of chemotherapy due to highly-targeted and locally-controlled drug delivery.

HUNTINGTIN DEPLETION SENSITIZES GLIOMA CELLS TO TEMOZOLOMIDE.

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Rayane Kassem
Univ. Grenoble Alpes,Inserm, U1216, Grenoble Institute Neurosciences, Grenoble, France

Gliomas (GBM) are the most common and malignant form of primary brain tumors with a deadly outcome. Glioma cells are largely resistant to available treatments including to the alkylating agent temozolomide (TMZ), the standard of care for GBM. Given the poor outcome of the patients, there is a crucial need in finding a way to overcome TMZ resistance of GBM and to restore the efficiency of the drug. The huntingtin (HTT) protein is well known to be mutated in Huntington disease. HTT exerts many functions that are not restricted to neurons but also occur in cancer cells. HTT mediates the early response to DNA damage and regulates breast cancer metastasis. While the role of HTT in the biology of cell cancer is emerging in the literature, its contribution to chemoresistance is still unknown. We downregulated the protein levels of huntingtin (HTT) in the glioma cell lines U87, U251 and T98G. The compound and strategy used are patent pending. We found that HTT depletion sensitizes the cells to TMZ by exacerbating DNA damage, (as assessed by measuring levels of the DNA double stranded breaks marker phospho-γH2Ax, and poly (ADP-ribose) polymerase 1 (PARP1) cleavage. We are now examining whether our compound and strategy can overcome TMZ resistance in an orthotopic mouse model for GBM. Our findings suggest a novel role of HTT in the biology of brain tumors and underscore the importance of studying HTT in basic and translational cancer research.

SYMPATHETIC AXONAL SPROUTING INDUCES CHANGES IN MACROPHAGE POPULATIONS AND PROTECTS AGAINST PANCREATIC CANCER

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Sophie Chauvet[1], Jérémy Guillot[1], Chloé Dominici[1], Angélique Puget[1], Mélanie Hocine[1], Martha Rangel-Sosa[1], Anders Etzerodt[2], Toby Lawrence[2], Pierre Pudlo[3], Florence Hubert[3], Serge Van De Pavert[2], Richard Tomasini[4], Fanny Mann[1]
[1]Aix Marseille Univ, Cnrs, Ibdm, Marseille, France, [2]Aix Marseille Univ, Cnrs, Inserm, Ciml, Marseille, France, [3]Aix Marseille Univ, Cnrs, Centrale Marseille, I2m, Marseille, France, [4]Aix Marseille Univ, Cnrs, Inserm, Institut Paoli-calmettes, Crcm, Marseille, France

Aims: Neuronal nerve processes in the tumor microenvironment were highlighted recently. However, the origin of intra-tumoral nerves remains poorly known, in part because of technical difficulties in tracing nerve fibers via conventional histological preparations. We focused on Pancreatic ductal adenocarcinoma (PDAC) which is a cancer with poor prognosis that develops from the exocrine part of the pancreas. We study how the structure and distribution of sympathetic nerves change during PDAC development, and examined how sympathetic inputs affect disease progression and deciphered the mechanisms involved. **Methods:** We used three-dimensional imaging of cleared tissues to perform a comprehensive analysis of sympathetic innervation in a murine model of pancreatic ductal adenocarcinoma (KIC mice). To test the role of the neuroplastic changes in tumor progression, we performed chemical and chirurgical sympathectomy in KIC mice and orthotopic mouse models of PDAC. We used doxorubicin-loaded liposomes coated with CD163 antibody (DxR lipo) to test the contribution of $CD163^+$ macrophages. **Results:** Our results support two independents, but coexisting, mechanisms for tumor innervation: passive engulfment of pre-existing nerves within tumors and active, localized sprouting of nerve terminals into non-neoplastic lesions and tumor periphery. Ablation of the innervating sympathetic nerves increased tumor growth and spread. This effect was explained by the observation that sympathectomy increased intratumoral $CD163^+$ macrophage numbers, which contributed to the worse outcome. **Conclusions:** Altogether, our findings revealed new insights into the mechanisms by which the sympathetic nervous system exerts cancer-protective properties in a mouse model of PDAC.

ROLE OF SCHWANN CELL PLASTICITY IN THE INNERVATION OF PANCREATIC TUMORS

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Martha Rangel-Sosa, Fanny Mann, Sophie Chauvet
Aix Marseille Univ,, Cnrs, Ibdm, Marseille, France

Aims: Nerves are important components of the tumor microenvironment. As pancreatic ductal adenocarcinoma (PDAC) progresses from pre-cancerous to obvious cancerous stages, sympathetic fiber density increases and single axons branch. The mechanisms by which sympathetic axons remodel during PDAC progression are unknown. Schwann cells (SCs) are associated with nerve fibers and exhibit high plasticity in response to the microenvironment, becoming a source of growth and axon guidance signals when activated. Here we investigated how SCs could contribute to neuronal structural plasticity induced by tumor development. **Methods:** We investigated changes in density and distribution of SCs in the pancreas of transgenic mouse model of PDAC (KIC mice) and in a model of metaplastic lesions (precursor lesions of PDAC) induced by chronic inflammation. Dividing cells were labeled with EdU. Pancreatic SC were isolated by FACS and gene expression was analyzed by qPCR. **Results:** Nonmyelinating SCs were found along the entire sympathetic fibers in healthy tissue and in metaplastic/neoplastic lesions of the pancreas. We found a significant increase in the number of SCs in metaplastic lesions, concomitant with an increase in proliferating EdU^+ SCs. We further observed increased expression of glial-derived neurotrophic factor (GDNF) in SCs after chronic inflammation. Sympathetic axons innervating metaplastic lesions expressed the GDNF receptor GFRa1, and celiac ganglia neurons (which provide sympathetic inputs to the pancreas) showed increased axonal growth in response to GDNF in vitro. **Conclusions:** Pancreatic SCs proliferate during PDAC progression, reflecting their possible activation and contribution as source of neurotrophic signals to induce sympathetic fiber remodeling.

Uncommon runs of homozygosity disclose homozygous missense mutations in two ciliopathy-related genes (SPAG17 and WDR35) in a patient with multiple brain and skeletal anomalies.
We describe a patient severely affected with multiple congenital anomalies, including brain malformations and skeletal dysplasia suggestive of cranioectodermal dysplasia (CED) ciliopathy, who unusually carries several homozygosity tracts involving homozygous missense mutations in SPAG17 (exon 8; c.1069G > C; p.Asp357His) and WDR35 (exon 13; c.1415G > A; p.Arg472Gln) as revealed by homozygosity mapping and next generation sequencing. SPAG17 is essential for the function and structure of motile cilia, while WDR35 belongs to the same intraflagellar transport (IFT) gene family whose protein products are part of functional IFT A and B complexes. Formerly, SPAG17 was related - through polymorphic variants - to an influence on individuals' height; more recently, Spag17-/- mice models were reported to present skeletal and bone defects, reduced mucociliary clearance, respiratory distress, and cerebral ventricular enlargement. Homozygous or compound heterozygous mutations in WDR35 have mainly been related to CED2 or short-rib thoracic dysplasia 7, with only three cases showing some brain anomalies. Given that our patient presents these clinical features and the close functional relationship between SPAG17 and WDR35, it is feasible that the combined effects from both mutations contribute to his phenotype. To our knowledge, this patient is the first to harbor a likely pathogenic homozygous mutation in both genes at the same time. Thus, the resulting complex phenotype of this patient illustrates the heterogeneity associated with ciliopathies and further expands the clinical and mutational spectrum of these diseases. Finally, we highlight the combined use of high-throughput tools to diagnose and support the proper handling of this and other patients.

29213157: Rangel-Sosa MM, Aguilar-Córdova E, Rojas-Martínez A
Immunotherapy and gene therapy as novel treatments for cancer.
The immune system interacts closely with tumors during the disease development and progression to metastasis. The complex communication between the immune system and the tumor cells can prevent or promote tumor growth. New therapeutic approaches harnessing protective immunological mechanisms have recently shown very promising results. This is performed by blocking inhibitory signals or by activating immunological effector cells directly. Immune checkpoint blockade

with monoclonal antibodies directed against the inhibitory immune receptors CTLA-4 and PD-1 has emerged as a successful treatment approach for patients with advanced melanoma. Ipilimumab is an anti-CTLA-4 antibody which demonstrated good results when administered to patients with melanoma. Gene therapy has also shown promising results in clinical trials. Particularly, virus (HSV)-mediated delivery of the HSV thymidine kinase (TK) gene to tumor cells in combination with ganciclovir (GCV) may provide an effective suicide gene therapy for destruction of glioblastomas, prostate tumors and other neoplasias by recruiting tumor-infiltrating lymphocytes into the tumor. The development of new treatment strategies or combination of available innovative therapies to improve cell cytotoxic T lymphocytes trafficking into the tumor mass and the production of inhibitory molecules blocking tumor tissue immune-tolerance are crucial to improve the efficacy of cancer therapy.

29437235: Rangel-Sosa MM, Figuera-Villanueva LE, González-Ramos IA, Pérez-Páramo YX, Martínez-Jacobo LA, Arnaud-López L, Nastasi-Catanese JA, Rivas-Estilla AM, Galán-Huerta KA, Rojas-Martínez A, Ortiz-López R, Córdova-Fletes C
Exome sequencing reveals three homozygous missense variants in SNRPA in two sisters with syndromic intellectual disability.
Splicing-related gene mutations might affect the expression of a single gene or multiple genes and cause clinically heterogeneous diseases. With the advent of next-generation sequencing, several splicing gene mutations have been exposed, yet most major spliceosome genes have no reports of germline mutations and therefore, their effects are largely unknown. We describe the previously unreported concurrence of intellectual disability, short stature, poor speech, and minor craniofacial and hand anomalies in 2 female siblings with 3 homozygous missense variants in SNRPA (a component of the U1 small nuclear ribonucleoprotein complex) characterized by homozygosity mapping and whole exome sequencing. Combined, c.97A>G, c.98T>C, and c.100T>A, in exon 2 of SNRPA lead to p.Ile33Ala and p.Phe34Ile exchanges, which were predicted in silico to be deleterious. Although both patients exhibited some clinical features seen in other spliceosomal disorders, their complete clinical phenotype appears to be rather uncommon, a finding that may further support the notion that mutations in components of the major spliceosome do not strictly lead to the same syndromes/phenotypes.
Clin Genet, 2018; 93
32597225: Córdova-Fletes C, Rangel-Sosa MM, Martínez-Jacobo LA, Becerra-Solano LE, Arellano-Valdés CA, Tlacuilo-Parra JA, Galán-Huerta KA, Rivas-Estilla AM, Hernandez-Orozco AA, García-Ortiz JE
Whole-exome sequencing in three children with sporadic Blau syndrome, one of them co-presenting with recurrent polyserositis.
Blau syndrome (BS) is a rare, chronic autoinflammatory disease with onset before age 4 and mainly characterised by granulomatous arthritis, recurrent uveitis, and skin rash. Sporadic (also known as early-onset sarcoidosis) or familial BS is caused by gain-of-function mutations in the gene, which encodes for a multi-task protein that plays a crucial role in the innate immune defense. We report on three Mexican patients clinically diagnosed with BS who exhibited a likely pathogenic variant in as revealed by whole-exome sequencing (WES) and Sanger sequencing: two variants (c.1000 C > T/p.Arg334Trp and c.1538 T > C/p.Met513Thr) lie in the ATP/Mg2+ binding site, whereas the other (c.3019dupC/p.Leu1007ProfsTer2) introduces a premature stop codon disrupting the last LRR domain (LRR9) formation; all three variants are consistent with gain-of-function changes. Interestingly, all these patients presented concomitant likely pathogenic variants in other inflammatory disease-related genes, i.e. , , and/or . Although the clinical presentation in these patients included the BS diagnostic triad, overall it was rather heterogeneous. It is plausible that this clinical variability depends partly on the patients' genetic background as suggested by our WES results. After this molecular diagnosis and given the absence of mutations (demonstrated in two trios) and related symptoms in the respective parents (confirmed in all trios), patients 1 and 2 were considered to have sporadic BS, while patient 3, a sporadic BS-recurrent polyserositis compound phenotype. Altogether, our observations and findings underscore the overlapping among inflammatory diseases and the importance of determining the underlying genetic cause by high-throughput methods. Likewise, this study further reinforces a pathogenic link between the here found variants and BS and envisages potential additive effects from other loci in these, and probably other patients.

Genomic Characterization of a Rare, de Novo Unbalanced ins(3;1)(p25.3;q21.3q23.3) in a Female Child with Multiple Congenital Anomalies.
"Simple" 1-way interchromosomal insertions involving an interstitial 1q segment are rare, and therefore, their characterization at the base pair level remains understudied. Here, we describe the genomic characterization of a previously unreported de novo interchromosomal insertion (3;1) entailing an about 12-Mb pure gain of 1q21.3q23.3 that causes typical (microcephaly, developmental delay, and facial dysmorphism) and atypical (interauricular communication, small feet with bilateral deep plantar creases, syndactyly of II-IV toes, and mild pachyonychia of all toes) clinical manifestations associated with this region.

Based on our analyses, we hypothesize that the duplication of a subset of morbid genes (including LMNA, USF1, VANGL2, LOR, and POGZ) could account for most clinical findings in our patient. Furthermore, the apparent disruption of a promoter region (between CPNE9 and BRPF1) and a topologically associated domain also suggests likely pathogenic reconfiguration/position effects to contribute to the patient's phenotype. In addition to further expanding the clinical spectrum of proximal 1q duplications and evidencing the phenotypical heterogeneity among similar carriers, our genomic findings and observations suggest that randomness - rather than lethality issues - may account for the paucity of "simple" interchromosomal insertions involving the 1q21.3q23.3 region as genomic donor and distal 3p25.3 as receptor. Moreover, the microhomology sequence found at the insertion breakpoint is consistent with a simple nonhomologous end-joining mechanism, in contrast to a chromothripsis-like event, which has previously been seen in other nonrecurrent insertions. Taken together, the data gathered in this study allowed us to inform this family about the low recurrence risk but not to predict the reproductive prognosis for hypothetical carriers. We highlight that genomic-level assessment is a powerful tool that allows the visualization of the full landscape of sporadic chromosomal injuries and can be used to improve genetic counseling. DEVELOPMENT OF METHODS ABOUT SAFE APPLICATION OF DNA-VACCINE VIRAL STRAINS FOR PRODUCTION OF ANTI-MALIGNANT AND ANTI-VIRAL MOLECULAR VACCINES

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Iskra Sainova
Bulgarian Academy of Sciences (BAS), Bulgarian Academy Of Sciences (bas), Sofia, Bulgaria

The main *goal* was directed to development of molecular (DNA, RNA and/or protein) anti-malignant and anti-viral vaccines, but also against virus envelope protein (E) or against virus membrane (M) protein, as well as of specific siRNAs against the virus genes, coding virus proteins S and N and against cellular oncogenes. Recombinant DNA-constructs, based on the *adeno-associated virus* (*AAV*) (*Parvoviridae* family) DNA-genome were developed. Genomic assay was performed by standard Polymerase Chain Reaction (PCR), and expression of the respective inserted gene - by Reverse Transcriptase PCR (PR-PCR). Low infectious titers (high dilutions) of heterologous for mammalian cells and attenuated by passages vaccine avipoxvirus strains (*Poxviridae* family), were applied. The inoculated cellular monolayers were freezed in the presence of cryo-protector Dimethylsulfoxide (DMSO), thawed and re-incubated. After washing with Phosphate Buffered Saline (PBS), the monolayers were scraped-off and served as source of intra-cellular viral forms. Cultural fluids served as source of their extra-cellular forms. The higher titers of the intra-cellular forms could be explained with existance of viruses as integrated in the cellular genome, besides as free viral particles. These changes could be explained with changed properties of membrane molecules. The results confirm the proved in the literature possibility for expression of membrane receptor glycoproteins by non-myeloid and non-lymphoid cellular types in appropriate conditions, as presence of malignant cells/antigens, viruses or viral antigens, immunomodulators. A possibility for nucleotide (DNA- and/or RNA-) fragments transfer from virus to cellular genome, but also in the opposite direction because of the activated fusion processes was also suggested.

Investigation of the morphology of cell clones, derived from the mammalian EBTr cell line and their susceptibility to vaccine avian poxvirus strains FK and Dessau.
The ability for replication of vaccine avian pox viral strains FK and Dessau in cell clones, derived from the EBTr cell line, derived from embryonic bovine trachea, was studied. The derived seven cell clones showed different morphological characteristics and diverse sensitivity to both vaccine avian pox viral strains. Hence, the EBTr-derived cell clones could be used for cultivation, as well as for differentiation of vaccine avian pox viral strains. In addition, studies have been undertaken to elucidate the possible use of cultivated strains in these heterologous cell culture system's vaccine avian pox viral strains for biotechnology, as well as for solving problems, related to infection of people with avian viruses.

Whole blood viscosity and erythrocyte hematometric indices in chronic heroin addicts.
Whole blood viscosity (WBV) and hematometric indices of erythrocytes as red blood cell count (RBC), mean erythrocyte volume (MCV), hemoglobin (HGB), hematocrit (HCT), mean hemoglobin content of erythrocytes (MCH), HGB/HCT values (MCHC) and red blood cell distribution width (RDW) have been studied in a group of 15 chronic opioid addicts under methadone maintenance therapy with mean age 26.53 +/- 7.34 years. WBV elevation and changes in MCV, HGB, HCT, RDW were found in intravenous drug users compared to healthy individuals. As well, RBC was decreased leading to an increase in MCH and MCHC values. Correlation analysis suggested that the correlation among the RBC, HGB, HCT and WBV was the closest. Heroin macrocytosis (heroin macrocytic anemia) was established, related with the increased RDW in chronic heroin abusers. The results are in accordance with data revealing abnormal effects of alcohol and other drugs on whole blood rheology and hematometric/morphometric characteristics of erythrocytes.

Introduction and Aims: Gliomas, originating from neuroglia, are tumors differing in diagnosis, prognosis and treatment. Palladin (PALLD gene) is a structural protein widely expressed in mammals that has a role in cytoskeletal dynamics and motility in health and disease. Palladin has been linked to the progression of breast, pancreatic and renal cancers. In the CNS, palladin is expressed in the neural plate, neural progenitors, cortical neurons and astrocytes. It participates in embryonic development, neuronal maturation, cell-cycle, differentiation and apoptosis. In this study, we investigate the role of palladin in adult gliomas. **Results:** By analyzing 1130 samples, we determine that wild-type PALLD is overexpressed in gliomas compared to healthy tissue. PALLD expression pattern correlates with disease progression and decreased patient survival. Comparison of prognostic markers with palladin confirm PALLD expression as having the highest predictive value. We injected mouse GBM cells into C57Bl/6J mice brains. Imaging located palladin only in the area of cancer cells. We obtained multi-tissue arrays of 600 cores of CNS pathologies and probed them for palladin. We conclude that palladin is present in glioma tumors but not in healthy tissue. Finally, by analyzing scRNAseq data, we show that PALLD expression originates only from the malignant cell population. **Conclusions:** Our findings indicate that palladin expression correlates with glioma progression and suggest that its levels may impact prognosis. Overall, our results point to palladin's potential as a marker for glioma diagnosis, risk stratification and as a novel molecular target for the treatment of aggressive glioma tumors in the future.

Glioblastoma Multiforme is the most common and lethal primary brain tumor in human. After standard therapies the development of resistance is almost inevitable. An alternative could be represented by Cisplatin (cis-diaminedicloroplatinum-II, CDDP), which however shows important side effects, to overcome this limitation fourth-generation platinum compounds were synthesized. Pt(IV)Ac-POA, (OC-6-44)-acetate-diamine-chloride(2-(2-propinyl)octanoate)platinum(IV), is a prodrug having an Histone-3-DeAcetylase-Inhibitor as axial ligands. Promising sources for cancer therapy are also compounds of plant origin, that, interfering in the metabolism of reactive oxygen species (ROS), in synergy with new chemotherapy could give patients an improvement in quality of life. **Aims:** We evaluated the effect in the redox balance and in the activation of cell death pathways of a medicinal blend supplement (Agaricus blazei, Cordyceps sinensis, Grifola frondose, Lentinula edodes and Ganoderma lucidum) alone and in combination with platinum-based chemotherapies. **Methods:** Cytofluorimetric, ultrastructural and immunofluorescence analysis were adopted to evaluate the therapeutic effects of the studied compound. **Results:** The reduction of oxidative stress condition in the cytoplasm, favored by the use of micotherapy, emerged; contrary, oxidative-induced damage to the mitochondrial was found. Completion of the autophagic flux, typical of an adaptive response of tumor cells to chemotherapy, didn't occur after the use of micotherapy. Moreover, the activation of the intrinsic apoptotic pathway, mitophagy, and regulated form of necrosis (ferroptosis and parthanantos) were observable following combined therapy. **Conclusions:** The synergic activity of micotherapy and chemotherapy amplified the effects of the latter in the activation of programmed cell death reducing inflammatory conditions in the microenvironment and resistance mechanisms.

COGNITIVE EFFECTS IN NON-CNS CANCER SURVIVORS BEFORE AND 1-YEAR AFTER STANDARD ANTHRACYCLINE-BASED CHEMOTHERAPY TREATMENT

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Antonio Lentoor
Sefako Makgatho Health Sciences University, Clinical Psychology, Pretoria, South Africa

Background: While anthracycline-based treatments have increased cancer survival rates, they have also been proven to be neurotoxic, with negative consequences on cancer survivors' cognitive functioning. To date, little attention has been given to the cognitive effects associated with anthracycline regimens locally. Aim: This study examined the associated cognitive effects in a cohort of non-CNS cancer patients exposed to an anthracycline-based chemotherapy regimen. Setting: Patients were recruited from an outpatient oncology clinic at a semi-rural hospital in the North of Gauteng, South Africa. Methods: In this time-series study, we examined cognitive function in n = 20 (stages II and III) breast cancer survivors (mean age, 50 years) prior to starting a standard FAC regimen (fluorouracil 500 mg/m^2, adriamycin 50 mg/m^2, cyclophosphamide 500 mg/m^2- administered intravenously every 3 weeks for 6 cycles) and a follow-up self-reported cognitive assessment at least 12 months after treatment. Results: A significant decline in self-reported cognitive function from baseline (prior to chemotherapy) (M = 56.45, SD = 3.36) to T_2 (cycle 6) (M = 43.90, SD = 12.88), t (19) = 4.66, p = 0.0002 was found on standard FAC regimen. From completion of the regimen (T_2) (M = 43.90, SD = 12.88) to one-year post FAC chemotherapy treatment (T_3) (M = 60.6, SD = 16.66) significant improvement were reported in self-perceived cognitive function (p = 0.003). Conclusion: Preliminary findings point to the necessity for a major multi-center comparative study that includes objective neuropsychological testing and self-perceived cognitive function.

IN VITRO TARGETING-TREATMENT POTENTIAL OF CHLOROTOXIN PEPTIDE-FUNCTIONALIZED NANOPARTICLES IN NEUROBLASTOMA AND GLIOBLASTOMA CELLS

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Okobi Ekpo
Khalifa University, Anatomy And Cellular Biology, Abu Dhabi, United Arab Emirates

Introduction: The development of effective treatment for both glioblastoma (GB) and neuroblastoma (NB) remains a major challenge despite decades of multidisciplinary research efforts. Current chemotherapies appear to offer only short-term palliative relief to patients due to systemic toxicity, drug resistance, poor targeting efficiency, and inadequate blood-brain barrier (BBB) penetration. Nanoparticles (NPs) appear to offer novel alternatives. **Aims**: To investigate the uptake, targeting, and anticancer effects of chlorotoxin (CTX)-functionalized monometallic gold NPs (CTX-AuNPs) as well as bimetallic gold-platinum NPs (CTX-AuPtNPs) in the U87 and SH-SY5Y cancerous human cell lines as well as the non-cancerous human KMST-6 cell line used as control. **Methods**: The cells were treated for 48 hours at a concentration range of 75-300 µg/ml after which NPs uptake was evaluated and bioactivity investigated via standard assays for cell viability (WST-1), apoptosis (APOPercentage™ assay), oxidative stress (ROS-sensitive dye CM-H_2DCFDA), mitochondrial activity (TMRE dye), cell survival (clonogenic assay), cell migration (wound healing assay) and morphology (light microscopy). **Results**: showed that CTX facilitated targeted delivery of CTX-AuPtNPs, possibly via binding with MMP-2, a main molecular target of CTX expressed on the cancerous cells. Also, CTX-AuPtNPs were the most cytotoxic NPs while U87 cells were more sensitive to the effects of the NPs. The effects of CTX-AuPtNPs suggest possible synergistic effects of the two noble metal constituents. **Conclusions**: Functionalized monometallic and bimetallic NPs could be useful both for inducing cytotoxicity to cancer cells and as radiosensitizing agents for targeted radiofrequency (RF)-induced thermal ablation therapy.

P53 DIGITAL EXPRESSION ANALYSIS IN MENINGIOMAS BASED ON TISSUE MICROARRAYS

POSTER SESSION 07 - SECTION: NEURO-ONCOLOGY

Nikolaos Kavantzas[1], Dimitrios Roukas[2], Evangelos Tsiambas[3], Anastasios Kouzoupis[4], George Tsouvelas[5], Stylianos Mastronikolis[6], Andreas Lazaris[7]
[1]SCHOOL OF MEDICINE - NATIONAL AND KAPODISTRIAN UNIVERSITY OF ATHENS, 1st Department Of Pathology, ATHENS, Greece, [2]Psychiatry, Department Of Psychiatry, Athens, Greece, [3]417 VA (NIMTS) Hospital, Department Of Cytology, Athens, Greece, [4]School of Medicine, National and Kapodistrian University of Athens, 1st Department Of Psychiatry, Athens, Greece, [5]University of West Attica, Department Of Nursing, Athens, Greece, [6]James Cook University Hospital,, Department Of Neurosurgery, Middlesbrough, United Kingdom, [7]School of Medicine, National and Kapodistrian University of Athens, 1st Department Of Pathology, Athens, Greece

Aim: Meningiomas is the most common intracranial primary central nervous system (CNS) tumour in adults worldwide. Oncogenes' over activation combined with suppressor genes' silence affect negatively the biological behaviour of these neoplasms. Our purpose was to explore the role of p53 expression in meningiomas' clinic-pathological features based on a combination of sophisticated techniques. **Methods**: Fifty (n=50) meningiomas were included in the study comprising a broad spectrum of histopathological sub-types. An immunohistochemistry assay was applied on tissue microarray cores (diam 1.5 μm) followed by digital image analysis for measuring objectively the corresponding p53 staining intensity levels. **Results**: p53 protein over expression (high staining intensity values) was observed in 27/50 (54%) cases, whereas the rest (23/50-/46%) demonstrated moderate to low levels of the molecule. P53 over expression was statistically significant correlated to mitotic index of the examined cases (p-value =0.001). Interestingly, atypical/anaplastic group of histotypes demonstrated the strongest p53 expression rates compared to the others (p-value =0.001). **Conclusion**: p53 over expression is observed in a broad spectrum of meningiomas. High expression levels lead to an aggressive biological behavior of the malignancy (combined with increased mitotic rates), especially in atypical and anaplastic sub-types that are characterized also by a strong tendency to recurrence.

THE EFFECT OF A GRIN2D VARIANT IN DEVELOPMENTAL AND EPILEPTIC ENCEPHALOPATHY IN A CRISPR/CAS9 MOUSE MODEL AND IPS CELLS

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Danielle Galber[1], Mor Ovadia[2], Tatiana Rabinski[3], Sivan Sagiv[3], Gad Vatine[3], Moran Rubinstein[2], Karen Avraham[1]
[1]Department of Human Molecular Genetics and Biochemistry, Faculty of Medicine & Sagol School of Neuroscience, Tel Aviv University, Tel Aviv, Israel, [2]Department of Human Molecular Genetics and Biochemistry & Goldschleger Eye Research Institute, Faculty of Medicine & Sagol School of Neuroscience, Tel Aviv University, Tel Aviv, Israel, [3]Department of Physiology and Cell Biology, Faculty of Health Sciences and Regenerative Medicine and Stem Cell (RMSC) Research Center, Ben-gurion University Of The Negev, Beer Sheva, Israel

Aims: Developmental and Epileptic Encephalopathies (DEEs) are a group of devastating disorders that encompass global developmental delay and epileptic activity. Patients suffer from a wide range of cognitive and motoric impairments, intractable epilepsy, and additional comorbidities. Next generation sequencing resulted in a surge of gene discoveries related to DEEs, including a *de-novo* variant (c.1999G>A) in *GRIN2D* that has been associated with hypotonia, early onset epilepsy and intellectual disabilities. *GRIN2D* encodes GluN2D, a subunit of the NMDA receptor that plays a central role in synaptic transmission and long-term plasticity. Our aim is to understand the effect the implications of this missense mutation. Methods: We developed a mouse model representing this disorder using CRISPR/Cas9 technology and measured disease progression. Additionally, we harvested fibroblasts from a *GRIN2D* patient and his healthy parent and reprogrammed them into iPS cells. Results: The mouse model that we created exhibited motor deficits, seen as hind-limb clasping, and displayed severe, long-lasting epileptiform abnormalities. Furthermore, the mice suffered from premature death. Additionally, two iPS cell lines were created that expressed pluripotency markers and differentiated into the three germ layers with the patient derived line preserving the c.1999G>A variant. Conclusion: We created two independent models that each represent this extremely rare genetic disorder. These models grant us the ability to examine the effect of the c.1999G>A variant and to analyze the complex neuronal and network mechanism underlying the pathology it causes. This work enables us to broaden our knowledge regarding the role that *GRIN* genes play in DEEs.

A CASE OF PERAMPANEL OVERDOSE PRESENTING WITH RESPIRATORY FAILURE

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Dae Lim Koo, Yangmi Park, Hyunwoo Nam
Seoul National University Boramae Hospital, Department Of Neurology, Seoul, Korea, Republic of

Perampanel is a novel antiepileptic drug that has been used as an adjunctive treatment for focal-onset seizures. It has a long half-life of 105 h, and an oral preparation at a maximum dose of 12 mg/day is considered safe. Clinical trials have shown that perampanel is generally well-tolerated despite inducing dose-dependent adverse events of the central nervous system, such as dizziness, somnolence, irritability, headache, and psychiatric problems. However, no reports to date have documented respiratory suppression as a side effect of perampanel. Herein, we report a case of perampanel overdose with respiratory failure. A 51-year-old man with focal epilepsy visited the emergency department with altered mentality and irritability. He originally received perampanel (6 mg/day) and levetiracetam (1000 mg twice a day). However, we estimated that he had accidently consumed 66 mg of perampanel 1 h before visiting our hospital. At 2.5 h after arrival at our hospital, his respiratory function deteriorated with aggravation of hypercapnia (62.3 mmHg) and desaturation (saturation of percutaneous O2, 86%) despite O2 supply. Our patient required mechanical ventilator support. Considering the half-life of perampanel is approximately 105 h, respiratory suppression could be related to perampanel overdose. To the best of our knowledge, this is the first report of respiratory failure caused by acute perampanel overdose. Therefore, the possibility of respiratory compromise should be considered whenever a high dose of perampanel needs to be administered to patients.

BEYOND RETIGABINE: DESIGN, SYNTHESIS, AND PHARMACOLOGICAL CHARACTERIZATION OF A POTENT AND CHEMICALLY-STABLE NEURONAL KV7 CHANNELS ACTIVATOR WITH ANTICONVULSANT ACTIVITY

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Lidia Carotenuto[1], Francesco Miceli[1], Giulia Baroli[1], Nunzio Iraci[2,3], Vincenzo Barrese[1], Michele Manfra[4], Alessia Bertamino[2], Carmine Ostacolo[5], Pietro Campiglia[2], Maurizio Taglialatela[1]
[1]University of Naples Federico II, Neuroscience, Napoli, Italy, [2]University of Salerno, Pharmacy, Fisciano, Italy, [3]University of Messina, Chemical, Biological, Pharmaceutical And Environmental Sciences, Messina, Italy, [4]University of Basilicata, Sciences, Potenza, Italy, [5]University of Naples Federico II, Pharmacy, Naples, Italy

Activation of voltage-gated potassium channels formed by Kv7.2 and Kv7.3 subunits is a promising pharmacological strategy for the treatment of several neuropsychiatric diseases in which neuronal hyperexcitability is a relevant pathogenetic factor. Retigabine is the prototypical neuronal Kv7 activator; this drug is approved for the treatment of partial-onset seizures in adults but is no longer available because of its side effects, including skin discoloration caused by photo-induced dimers. In the present work, the structural determinants of the retigabine-binding site, of the dimerization reaction, and of the tendency to photodegradation were investigated, leading to the synthesis of a small library of retigabine analogues. This library was screened using a fluorescence-based assay (FluxOR) and patch-clamp electrophysiology in Kv7.2/Kv7.3-expressing cells. Among investigated photostable compounds unable to form dimers, when compared to retigabine, one (CP-69) was 3-times more potent in the FluxOR assay (EC_{50}=3.2 μM vs 11.2 μM, respectively; $p<0.05$) and at least 10-times more potent when Kv7.2/Kv7.3 maximal current level or activation voltage-dependence were investigated with patch-clamp. After intraperitoneal (i.p. 1 mg/kg) administration in rats, CP-69 showed higher brain/plasma ratio than retigabine (39.3 vs 2.4), with longer half-life (8h vs 3h). Finally, ip administration in mice of CP-69 reduced the severity and increased the latency to the maximal seizure induced in mice by pentylentetrazol (i.p.100 mg/kg), at lower doses when compared to retigabine (0.3 mg/kg vs 3 mg/kg). In conclusion, CP-69 shows an improved pharmacological profile with respect to retigabine, being, therefore, a promising candidate for further development as an antiepileptic drug.

A Novel Kv7.3 Variant in the Voltage-Sensing S Segment in a Family With Benign Neonatal Epilepsy: Functional Characterization and Rescue by β-Hydroxybutyrate.
Pathogenic variants in and , paralogous genes encoding Kv7.2 and Kv7.3 voltage-gated K channel subunits, are responsible for early-onset developmental/epileptic disorders characterized by heterogeneous clinical phenotypes ranging from benign familial neonatal epilepsy (BFNE) to early-onset developmental and epileptic encephalopathy (DEE). variants account for the majority of pedigrees with BFNE and variants are responsible for a much smaller subgroup, but the reasons for this imbalance remain unclear. Analysis of additional pedigrees is needed to further clarify the nature of this genetic heterogeneity and to improve prediction of pathogenicity for novel variants. We identified a BFNE family with two siblings and a parent affected. Exome sequencing on samples from both parents and siblings revealed a novel variant (c.719T>G; p.M240R), segregating in the three affected individuals. The M240 residue is conserved among human Kv7.2-5 and lies between the two arginines (R5 and R6) closest to the intracellular side of the voltage-sensing S transmembrane segment. Whole cell patch-clamp recordings in Chinese hamster ovary (CHO) cells revealed that homomeric Kv7.3 M240R channels were not functional, whereas heteromeric channels incorporating Kv7.3 M240R mutant subunits with Kv7.2 and Kv7.3 displayed a depolarizing shift of about 10 mV in activation gating. Molecular modeling results suggested that the M240R substitution preferentially stabilized the resting state and possibly destabilized the activated state of the Kv7.3 subunits, a result consistent with functional data. Exposure to β-hydroxybutyrate (BHB), a ketone body generated during the ketogenic diet (KD), reversed channel dysfunction induced by the M240R variant. In conclusion, we describe the first missense loss-of-function (LoF) pathogenic variant within the S segment of Kv7.3 identified in patients with BFNE. Studied under conditions mimicking heterozygosity, the M240R variant mainly affects the voltage sensitivity, in contrast to previously analyzed BFNE Kv7.3 variants that reduce current density. Our pharmacological results provide a rationale for the use of KD in patients carrying

LoF variants in Kv7.2 or Kv7.3 subunits.

ASSOCIATION BETWEEN ABCB1 POLYMORPHISMS AND RESPONSE TO ANTIEPILEPTIC DRUGS AMONG JORDANIAN EPILEPTIC PATIENTS.

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Rami Abduljabbar
University of Jordan, Clinical Pharmacy, Amman, Jordan

Background: Antiepileptic drug (AEDs) resistance is a major challenge to patients and physicians alike. Genetic polymorphisms of drug efflux transporters as ATP-binding cassette sub-family B, member1 (*ABCB1*) have been suggested to modulate antiepileptic treatment response. In this study, we aimed to explore the association of *ABCB1* polymorphisms and AEDs resistance among epileptic patients. **Methods:** A total of 86 Jordanian epileptic patients treated with AEDs were included in the study. DNA was extracted from blood samples and genotyping was conducted by polymerase chain reaction followed by sequencing. Nine single nucleotide polymorphisms (SNPs) on the *ABCB1* gene were investigated, including: rs2235048, rs2235047,rs1045642, rs2229107, rs2032583, rs2032582, rs2235033, rs2032588 and rs1128503. Haplotypes of the nine SNPs were analyzed, and linkage disequilibrium was evaluated. **Results:** Data revealed that none of the examined SNPs were associated with resistance to AEDs neither on the level of alleles nor on the level of genotypes. However, strong association was found between rs2235048 (OR =10.6; 95%CI =[1.89-59.8], *p*=0.01), rs1045642 (OR=14; 95%CI =[1.3-156.7], *p*=0.02), rs2032582 (OR= 9.1; 95%CI =[1.4-57.3], *p*=0.04) and rs1128503 (OR=18.7; 95%CI =[1.6-222.9], *p*=0.02), *ABCB1* polymorphisms and resistance to AEDs among females but not males. Haplotype analysis revealed statistically significant associations. The strongest significant associations were for haplotypes containing 2677G_1236T in two-SNPs-haplotypes (OR=4.2; 95%CI = [1.2 - 14.9], p=0.024); three-SNPs-haplotypes (OR=4.2; 95%CI= [1.2-14.9], p=0.02); four-SNPs-haplotypes (OR=4.1; 95%CI =[1.2-14.3], p=0.026). **Conclusion:** Data suggests that there is a gender-dependent association between *ABCB1* genetic polymorphisms and response to AEDs. Additionally, *ABCB1* haplotypes influence response to AEDs.

Assessment of Healthcare System Capabilities and Preparedness in Yemen to Confront the Novel Coronavirus 2019 (COVID-19) Outbreak: A Perspective of Healthcare Workers.
In the past decade, Yemen has witnessed several disasters that resulted in a crumbled healthcare system. With the declaration of COVID-19 a global pandemic, and later the appearance of first confirmed cases in Yemen, there is an urgent need to assess the preparedness of healthcare facilities (HCFs) and their capacities to tackle a looming COVID-19 outbreak. Herein, we present an assessment of the current state of preparedness and capabilities of HCFs in Yemen to prevent and manage the COVID-19 outbreak. An online survey for HCFs was developed, validated, and distributed. The questionnaire is divided into five main sections: (1) Demographic variables for participants. (2) HCFs capabilities for COVID-19 outbreak. (3) Support received to face the emergence and spread of COVID-19. (4). Current practices of infection prevention and control measures in the HCFs. The last section focused on the recommendations to ensure effective and timely response to this

outbreak in Yemen. Descriptive analysis was used to analyze data using statistical package for social sciences (SPSS), version 23. Responses were received from healthcare workers (HCWs) from 18 out of 22 governorates in Yemen. Out of the 296 HCWs who participated in the study, the vast majority (93.9%) believed that the healthcare system in Yemen does not have the resources and capabilities to face and manage a COVID-19 outbreak. Approximately 82.4% of participants rated the general preparedness level of their HCFs as very poor or poor. More specifically, the majority of HCWs rated their HCFs as very poor or poor in term of availability of the following: an adequate number of mechanical ventilators (88.8%), diagnostic devices (88.2%), ICU rooms and beds (81.4%), and isolation rooms (79.7%). The healthcare facilities in Yemen are unprepared and lack the most basic resources and capabilities to cope with or tackle a COVID-19 outbreak. With the current state of a fragile healthcare system, a widespread outbreak of COVID-19 in Yemen could result in devastating consequences. There is an urgent need to provide support to the healthcare workers and HCFs that are on the frontline against COVID-19.

INFLUENCE OF ESTROUS CYCLE IN SEIZURE SUSCEPTIBILITY USING A MOUSE MODEL OF TUBEROUS SCLEROSIS COMPLEX 2

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Mariana Pais[1,2,3], João Martins[2,3], Miguel Castelo-Branco[2,3,4], Joana Gonçalves[2,3]
[1]University of Coimbra, Faculty Of Sciences And Technology, Doctoral Program In Biomedical Engineering, Coimbra, Portugal, [2]Institute of Nuclear Sciences Applied to Health (ICNAS), Cibit, Coimbra, Portugal, [3]University of Coimbra, Coimbra Institute For Biomedical Imaging And Translational Research (cibit), Coimbra, Portugal, [4]University of Coimbra, Faculty Of Medicine, Coimbra, Portugal

Tuberous Sclerosis Complex 2 (TSC2) is a rare genetic disorder characterized by serious neurological complications such as severe epilepsy. For general epilepsy models, behavioural outcomes can differ across different variables, in particular biological sex. Specifically, seizures in females are influenced by gonadal hormone levels and, consequently, by the reproductive cycle. The purpose of the present work was to investigate the influence of estrous cycle in seizure susceptibility and anxiety-like behaviours in a female *Tsc2* mouse model. Heterozygous (*Tsc2*$^{+/-}$) and homozygous (*TSC2*$^{+/+}$) female mice aged 8-12 weeks were studied. Seizure severity was determined according to a modified Racine scale at control conditions (saline, i.p.) and following kainic acid (KA) administration (20 mg/kg, i.p.). Locomotor and anxiety-like behaviours were also evaluated at those conditions. Following pharmacological experiment, a vaginal swab was collected, and the phases of the estrous cycle were determined. We observed that, independently of their genetic background females at the ovulatory stage displayed an enhanced susceptibility with a significant difference between homozygous females that were at different stages of estrous cycle. In parallel, only females at post-ovulatory stage displayed a susceptibility that differed significantly between genotypes. No significant differences were found on behavioural profiles. These observations suggest that *Tsc2* mutation is not the only key factor interfering in epileptic progression. Moreover, our results reveal that hormonal fluctuations have an important role in seizure susceptibility and progression for females. So, future studies using this model should take to consideration estrous cycle to investigate new therapeutic strategies for epilepsy.

Single Low Dose of Cocaine-Structural Brain Injury Without Metabolic and Behavioral Changes.
Chronic cocaine use has been shown to lead to neurotoxicity in rodents and humans, being associated with high morbidity and mortality rates. However, recreational use, which may lead to addictive behavior, is often neglected. This occurs, in part, due to the belief that exposure to low doses of cocaine comes with no brain damage risk. Cocaine addicts have shown glucose metabolism changes related to dopamine brain activity and reduced volume of striatal gray matter. This work aims to evaluate the morphological brain changes underlying metabolic and locomotor behavioral outcome, in response to a single low dose of cocaine in a pre-clinical study. In this context, a Balb-c mouse model has been chosen, and animals were injected with a single dose of cocaine (0.5 mg/kg). Control animals were injected with saline. A behavioral test, positron emission tomography (PET) imaging, and anatomopathological studies were conducted with this low dose of cocaine, to study functional, metabolic, and morphological brain changes, respectively. Animals exposed to this cocaine dose showed similar open field activity and brain metabolic activity as compared with controls. However, histological analysis showed alterations in the prefrontal cortex and of mice exposed to cocaine. For the first time, it has been demonstrated that a single low dose of cocaine, which can cause no locomotor behavioral and brain metabolic changes, can induce structural damage. These brain changes must always be considered regardless of the dosage used. It is essential to alert the population even against the consumption of low doses of cocaine.

Mutations in KCNQ2, KCNQ3 and, more rarely, KCNQ5 genes encoding Kv7.2, Kv7.3, and Kv7.5 neuronal voltage-gated potassium channel subunits respectively are responsible for developmental and epileptic encephalopathies (DEEs), neurodevelopmental diseases characterized by refractory epilepsy, distinct EEG and neuroradiological features, and various degrees of developmental delay. In the present work, the clinical features of two DEE patients carrying de novo KCNQ5 variants affecting the same Kv7.5 pore residue (G347S/A) are described. The *in vitro* functional properties of channels incorporating these variants were also investigated. Site-directed mutagenesis was used to introduce specific mutations in KCNQ2, KCNQ3 and KCNQ5 plasmids. Electrophysiological and biochemical experiments were performed in CHO cells transiently transfected with these constructs. When compared to Kv7.5, Kv7.5 G347S/A channels displayed a marked increase in maximal current and a strong hyperpolarization in activation gating, both functional features consistent with a strong gain-of-function (GoF) in vitro phenotype. Similar functional changes were also observed upon introduction of the corresponding variants in Kv7.2 subunits. Non-stationary noise analysis revealed that GoF effects observed for both Kv7.2 and Kv7.5 variants were mainly attributable to an increase in single channel open probability, without changes in membrane abundance or single channel conductance. In addition, currents carried by mutant channels were insensitive to manipulation of the membrane levels of the critical Kv7 channel regulator PIP_2. These results reveal a novel pathophysiological mechanism for KCNQ5-related DEEs which might be exploited to implement personalized treatments.

Distinct epilepsy phenotypes and response to drugs in KCNA1 gain- and loss-of function variants.
A wide phenotypic spectrum of neurological diseases is associated with KCNA1 (Kv1.1) variants. To investigate the molecular basis of such a heterogeneous clinical presentation and identify the possible correlation with in vitro phenotypes, we compared the functional consequences of three heterozygous de novo variants (p.P403S, p.P405L, and p.P405S) in Kv1.1 pore region found in four patients with severe developmental and epileptic encephalopathy (DEE), with those of a de novo variant in the voltage sensor (p.A261T) identified in two patients with mild, carbamazepine-responsive, focal epilepsy. Patch-clamp electrophysiology was used to investigate the functional properties of mutant Kv1.1 subunits, both expressed as homomers and heteromers with wild-type Kv1.1 subunits. KCNA1 pore mutations markedly decreased (p. P405S) or fully suppressed (p. P403S, p. P405L) Kv1.1-mediated currents, exerting loss-of-function (LoF) effects. By contrast, channels carrying the p.A261T variant exhibited a hyperpolarizing shift of the activation process, consistent with a gain-of-function (GoF) effect. The present results unveil a novel correlation between in vitro phenotype (GoF vs LoF) and clinical course (mild vs severe) in KCNA1-related phenotypes. The excellent clinical response to carbamazepine observed in the patients carrying the A261T variant suggests an exquisite sensitivity of KCNA1 GoF to sodium channel inhibition that should be further explored.

Aim. Blood brain barrier (BBB) is the a critical structure for maintaining cerebral homeostasis and preventing the access of toxins, drugs or other substances to brain parenchyma. To goal of our study was to explore the mechanisms that determine BBB permeabilisation during status epilepticus (SE). **Methods**. Brain microvascular endothelial cells (bEnd.3) were exposed to pilocarpine (100 μM) for 2, 6 and 24 hours for mimicking SE. Tight junction proteins (ZO-1 and claudin-5), actin cytoskeleton filaments and nuclei were immunostained and gene expression was quantified by qRT-PCR. We developed/implemented Matlab scripts for confocal image analysis, including a Fiberscore algorithm for actin cytoskeleton orientation, a method for protein expression localisation in cellular compartments using Aggrecount and an adaptation of Voronoi diagram for cell detection. **Results**. Cell detection was improved with 26% compared to the standard Voronoi diagram method. Immunostaining and qRT-PCR demonstrated that ZO-1 was upregulated after 24 hr, while Claudin-5 was downregulated after 2 - 6 hr. After 6 hr, the perinuclear localisation of ZO-1 and Claudin-5 were increased and their membrane localisation decreased. Additionally, at the same timepoint, actin filaments were fragmented with a reduction in their mean length and were spatially reorganized with a reduced polarity. **Conclusions**. We demonstrated a direct correlation of tight junctions proteins expression and the rearangement of the actin cytoskeleton microtubules in the pilocarpine-induced in vitro model. Our data are relevant in understanding the BBB permeabilisation steps in epileptogenesis.

Static Magnetic Fields (SMF) reduce cortical excitability and improve epileptic signs in a pharmacological model of epilepsy (Rivadulla et al 2018). We test the efficacy of SMF in a mouse model of Dravet Syndrome, a severe epileptic encephalopathy characterized by frequent and long lasting seizures. Experiments were carried out on conditional *Scn1a-A1783V mice* which express the DS/SMEI-associated mutation A1783V in the Nav1.1 channel after Cre-mediated recombination by breeding with a transgenic mouse line that express Cre under actin-CMV promotor. EEG was recorded continuously from sevoflurane anesthetized mice through two copper wires chronically implanted. Seizures were triggered by increasing temperature (0.3º/min) from 37º (baseline) to above 42º and maintained by 5 minutes. Protocol was made in the presence of a 0,5T magnet or a sham replica, positioned 30 minutes before increasing temperature. In a subset of animals (n=4), an automatic epileptogenic event detection system based on Bergstrom et al 2012, detected 194% more incidences in the sham than in the magnet condition. When comparing a group of animals (n=4) in which placebo was applied in every session, versus a second group (n=3) that always received the magnet, the number of sessions with seizures dropped from 93% (26 out of 28 sessions) in the sham, to 37% (8 out of 22) in the magnet group. Furthermore, SMF reduced by 45% the duration of the remaining seizures. SMF are able to prevent or reduce the epileptic seizures in a model of DS and could be considered as a therapeutic approach. In the last decade, numerous studies focused on the molecular background of neurological disorders, such as epilepsy and multiple sclerosis. One important aim is to investigate the potential role of micro RNAs (miRNA) in the pathophysiology of these disorders and their potential application as peripheral biomarkers to assess disease progression and therapeutic response. *Aims*: The aim of our study was to investigate the expression levels of circulating miRNAs in peripheral blood and brain samples originating from humans and experimental mice. *Methods*: In the present study, we report on findings originating from patients with epilepsy (EP) and multiple sclerosis (MS). 52 serum samples from MS patients, 71 serum samples from EP patients and mouse brain samples were investigated. C57BL/6 male mice were used for induction of temporal lobe epilepsy (TLE). TLE mice were terminated 1, 2, 3 and 4 weeks after intra-hippocampal injection of kainic acid. Brain tissue was removed from animals, and samples containing the prefrontal cortex, hippocampus and cerebellum were collected. After that, total RNA/miRNA was isolated and described into cDNA. For downstream workflow droplet digital PCR reaction was prepared, using specific miRNA primers. *Results*: Our preliminary findings demonstrate an association between miRNA expression levels in human serum samples and clinical examination including MRI in MS patients. *Conclusion*: ddPCR is an extremely sensitive qPCR system, that allows absolute quantification of miRNAs in case of low yield samples, thereby it is a promising additional laboratory test method to improve making diagnosis or choosing the most efficiency therapy.

Stress-Induced Morphological, Cellular and Molecular Changes in the Brain-Lessons Learned from the Chronic Mild Stress Model of Depression.
Major depressive disorder (MDD) is a severe illness imposing an increasing social and economic burden worldwide. Numerous rodent models have been developed to investigate the pathophysiology of MDD. One of the best characterized and most widely used models is the chronic mild stress (CMS) model which was developed more than 30 years ago by Paul Willner. More than 2000 published studies used this model, mainly to assess novel compounds with potential antidepressant efficacy. Most of these studies examined the behavioral consequences of stress and concomitant drug intervention. Much fewer studies focused on the CMS-induced neurobiological changes. However, the stress-induced cellular and molecular changes are important as they may serve as potential translational biomarkers and increase our understanding of the pathophysiology of MDD. Here, we summarize current knowledge on the structural and molecular alterations in the brain that have been described using the CMS model. We discuss the latest neuroimaging and postmortem histopathological data as well as molecular changes including recent findings on microRNA levels. Different chronic stress paradigms occasionally deliver dissimilar findings, but the available experimental data provide convincing evidence that the CMS model has a high translational value. Future studies examining the neurobiological changes in the CMS model in combination with clinically effective antidepressant drug intervention will likely deliver further valuable information on the pathophysiology of MDD. First molecular detection of Apis mellifera filamentous virus in honey bees (Apis mellifera) in Hungary.
Western honey bees (Apis mellifera) are important pollinators in the ecosystem and also play a crucial economic role in the honey industry. During the last decades, a continuous decay was registered in honey bee populations worldwide, including Hungary. In our study, we used metagenomic approaches and conventional PCR screening on healthy and winter mortality

affected colonies from multiple sites in Hungary. The major goal was to discover presumed bee pathogens with viral metagenomic experiments and gain prevalence and distribution data by targeted PCR screening. We examined 664 honey bee samples that had been collected during winter mortality from three seemingly healthy colonies and from one colony infested heavily by the parasitic mite Varroa destructor in 2016 and 2017. The subsequent PCR screening of honey bee samples revealed the abundant presence of Apis mellifera filamentous virus (AmFV) for the first time in Central Europe. Based on phylogeny reconstruction, the newly-detected virus was found to be most closely related to a Chinese AmFV strain. More sequence data from multiple countries would be needed for studying the detailed phylogeographical patterns and worldwide spreading process of AmFV. Here we report the prevalent presence of this virus in Hungarian honey bee colonies.

Small Interfering RNAs Are Highly Effective Inhibitors of Crimean-Congo Hemorrhagic Fever Virus Replication In Vitro.
Crimean-Congo hemorrhagic fever virus (CCHFV) is one of the prioritized diseases of the World Health Organization, considering its potential to create a public health emergency and, more importantly, the absence of efficacious drugs and/or vaccines for treatment. The highly pathogenic characteristic of CCHFV restricts research to BSL-4 laboratories, which complicates effective research and developmental strategies. In consideration of antiviral therapies, RNA interference can be used to suppress viral replication by targeting viral genes. RNA interference uses small interfering RNAs (siRNAs) to silence genes. The aim of our study was to design and test siRNAs in vitro that inhibit CCHFV replication and can serve as a basis for further antiviral therapies. A549 cells were infected with CCHFV after transfection with the siRNAs. Following 72 h, nucleic acid from the supernatant was extracted for RT Droplet Digital PCR analysis. Among the investigated siRNAs we identified effective candidates against all three segments of the CCHF genome. Consequently, blocking any segment of CCHFV leads to changes in the virus copy number that indicates an antiviral effect of the siRNAs. In summary, we demonstrated the ability of specific siRNAs to inhibit CCHFV replication in vitro. This promising result can be integrated into future anti-CCHFV therapy developments.

Analysis of COVID-19-Related RT-qPCR Test Results in Hungary: Epidemiology, Diagnostics, and Clinical Outcome.
Effective testing is an essential tool for controlling COVID-19. We aimed to analyse the data from first-wave PCR test results in Hungary's Southern Transdanubian region to improve testing strategies. We performed a retrospective analysis of all suspected COVID-19 cases between 17 March and 8 May 2020, collecting epidemiological, demographic, clinical and outcome data (ICU admission and mortality) with RT-qPCR test results. Descriptive and comparative statistical analyses were conducted. Eighty-six infections were confirmed among 3,657 tested patients. There was no difference between the positive and negative cases in age and sex distribution; however, ICU admission (8.1 vs. 3.1%, = 0.006) and in-hospital mortality (4.7 vs. 1.6%, = 0.062) were more frequent among positive cases. Importantly, none of the initially asymptomatic patients (= 20) required ICU admission, and all survived. In almost all cases, if the first test was negative, second and third tests were performed with a 48-h delay for careful monitoring of disease development. However, the positive hit rate decreased dramatically with the second and third tests compared to the first (0.3 vs. 2.1%, OR = 0.155 [0.053-0.350]). Higher E-gene copy numbers were associated with a longer period of PCR positivity. In our immunologically naïve suspected COVID-19 population, coronavirus infection increased the need for intensive care and mortality by 3-4 times. In the event of the exponential phase of the pandemic involving a bottleneck in testing capacity, a second or third test should be reconsidered to diagnose more coronavirus infections.

CHARACTERISING EPILEPTOGENESIS IN A RECURRENT GENETIC MODEL OF DRAVET SYNDROME

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Nikolas Layer[1], Peter Mueller[1], Lukas Sonnenberg[2], Ulrike Hedrich[1], Henner Koch[3], Holger Lerche[1], Thomas Wuttke[1,4]
[1]Hertie Institute for Clincal Brain Research, Dept. Of Neurology And Epileptology, Tuebingen, Germany, [2]University of Tuebingen, Institute For Neurobiology, Tuebingen, Germany, [3]Aachen University, Universitätsklinikum Aachen, Aachen, Germany, [4]University of Tuebingen, Dept. Of Neurosurgery, Tuebingen, Germany

Dravet syndrome (DS) is characterized as a rare form of severe developmental and epileptic encephalopathy (DEE) often caused by de-novo mutations in the *SCN1A* gene, encoding the Na^+ subunit $Na_V1.1$. To understand pathophysiological changes and molecular mechanisms involved in epileptogenesis of DS, we aimed to analyse changes of sodium channel gating, neuronal excitability and neuronal subnetworks caused by the recurrent human DS missense variant *SCN1A*^{A1783V}. The kinetic properties of $Na_V1.1$-A1783V were studied by voltage-clamp recordings of transfected tsA201 cells followed by simulation in a Hodgkin-Huxley model to predict consequences on neuronal excitability. Additionally, *ex vivo* electrophysiology, calcium imaging and single nuclei transcriptomics were performed in hippocampal and cortical regions of wildtype and heterozygous mice at PN13-15, PN20-23 and PN37-P40 to reveal vulnerable cell populations and understand seizure generation mechanisms. *SCN1A*^{A1783V} led to loss-of-function (LOF) of channel activation and slow-inactivation properties, resulting in a predicted shift of action potential (AP) rheobase and reduced firing in fast-spiking inhibitory neurons (IN). Recordings in cortex and hippocampus confirmed our predictions identifying transient LOF in fast-spiking neurons characterised by reduced firing frequency and increased AP half-width. Regular-spiking INs and pyramidal cells seemed less affected. Furthermore, network recordings and transcriptomic analysis displayed an imbalance of excitation and inhibition in various cell populations especially in postsynaptic compartments of excitatory cells. In conclusion, we extend the understanding of DS further by identifying pathophysiological changes in missense variant *SCN1A*^{A1783V} similar to other nonsense variants. Additionally, we identified multiple primary and secondary mechanisms characterizing epileptogenesis in this DS model.

Dravet Variant Impairs Interneuron Firing Predominantly by Altered Channel Activation.
Dravet syndrome (DS) is a developmental epileptic encephalopathy mainly caused by functional Na1.1 haploinsufficiency in inhibitory interneurons. Recently, a new conditional mouse model expressing the recurrent human p.(Ala1783Val) missense variant has become available. In this study, we provided an electrophysiological characterization of this variant in tsA201 cells, revealing both altered voltage-dependence of activation and slow inactivation without reduced sodium peak current density. Based on these data, simulated interneuron (IN) firing properties in a conductance-based single-compartment model suggested surprisingly similar firing deficits for Na1.1 and full haploinsufficiency as caused by heterozygous truncation variants. Impaired Na1.1 channel activation was predicted to have a significantly larger impact on channel function than altered slow inactivation and is therefore proposed as the main mechanism underlying IN dysfunction. The computational model was validated in cortical organotypic slice cultures derived from conditional mice. Pan-neuronal activation of the p.Ala1783V confirmed a predicted IN firing deficit and revealed an accompanying reduction of interneuronal input resistance while demonstrating normal excitability of pyramidal neurons. Altered input resistance was fed back into the model for further refinement. Taken together these data demonstrate that primary loss of function (LOF) gating properties accompanied by altered membrane characteristics may match effects of full haploinsufficiency on the neuronal level despite maintaining physiological peak current density, thereby causing DS.

The effect of lamotrigine and other antiepileptic drugs on respiratory rhythm generation in the pre-Bötzinger complex.
Lamotrigine and other sodium-channel blocking agents are among the most commonly used antiepileptic drugs (AEDs). Because other sodium channel blockers, such as riluzole, can severely alter respiratory rhythm generation during hypoxia, we wanted to investigate if AEDs can have similar effects. This is especially important in the context of sudden unexpected death

in epilepsy (SUDEP), the major cause of death in patients suffering from therapy-resistant epilepsy. Although the mechanism of action is not entirely understood, respiratory dysfunction after generalized tonic-clonic seizures seems to play a major role.

Human Cerebrospinal Fluid Induces Neuronal Excitability Changes in Resected Human Neocortical and Hippocampal Brain Slices.
Human cerebrospinal fluid (hCSF) has proven advantageous over conventional medium for culturing both rodent and human brain tissue. In addition, increased activity and synchrony, closer to the dynamic states exclusively recorded , were reported in rodent slices and cell cultures switching from artificial cerebrospinal fluid (aCSF) to hCSF. This indicates that hCSF possesses properties that are not matched by the aCSF, which is generally used for most electrophysiological recordings. To evaluate the possible significance of using hCSF as an electrophysiological recording medium, also for human brain tissue, we compared the network and single-cell firing properties of human brain slice cultures during perfusion with hCSF and aCSF. For measuring the overall activity from a majority of neurons within neocortical and hippocampal human slices, we used a microelectrode array (MEA) recording technique with 252 electrodes covering an area of 3.2 × 3.2 mm. A second CMOS-based MEA with 4225 sensors on a 2 × 2 mm area was used for detailed mapping of action potential waveforms and cell identification. We found that hCSF increased the number of active electrodes and neurons and the firing rate of the neurons in the slices and induced an increase in the numbers of single channel and population bursts. Interestingly, not only an increase in the overall activity in the slices was observed, but a reconfiguration of the network could also be detected with specific activation and inactivation of subpopulations of neuronal ensembles. In conclusion, hCSF is an important component to consider for future human brain slice studies, especially for experiments designed to mimic parts of physiology and disease observed .

Long-term adult human brain slice cultures as a model system to study human CNS circuitry and disease.
Most of our knowledge on human CNS circuitry and related disorders originates from model organisms. How well such data translate to the human CNS remains largely to be determined. Human brain slice cultures derived from neurosurgical resections may offer novel avenues to approach this translational gap. We now demonstrate robust preservation of the complex neuronal cytoarchitecture and electrophysiological properties of human pyramidal neurons in long-term brain slice cultures. Further experiments delineate the optimal conditions for efficient viral transduction of cultures, enabling 'high throughput' fluorescence-mediated 3D reconstruction of genetically targeted neurons at comparable quality to state-of-the-art biocytin fillings, and demonstrate feasibility of long term live cell imaging of human cells . This model system has implications toward a broad spectrum of translational studies, regarding the validation of data obtained in non-human model systems, for therapeutic screening and genetic dissection of human CNS circuitry.

Neuroprotective, Neurogenic, and Amyloid Beta Reducing Effect of a Novel Alpha 2-Adrenoblocker, Mesedin, on Astroglia and Neuronal Progenitors upon Hypoxia and Glutamate Exposure.
Locus coeruleus-noradrenergic system dysfunction is known to contribute to the progression of Alzheimer's disease (AD). Besides a variety of reports showing the involvement of norepinephrine and its receptor systems in cognition, amyloid β (Aβ) metabolism, neuroinflammation, and neurogenesis, little is known about the contribution of the specific receptors to these actions. Here, we investigated the neurogenic and neuroprotective properties of a new α2 adrenoblocker, mesedin, in astroglial primary cultures (APC) from C57BL/6 and 3×Tg-AD mice. Our results demonstrate that mesedin rescues neuronal precursors and young neurons, and reduces the lactate dehydrogenase (LDH) release from astroglia under hypoxic and normoxic conditions. Mesedin also increased choline acetyltransferase, postsynaptic density marker 95 (PSD95), and Aβ-degrading enzyme neprilysin in the wild type APC, while in the 3×Tg-AD APC exposed to glutamate, it decreased the intracellular content of Aβ and enhanced the survival of synaptophysin-positive astroglia and neurons. These effects in APC can at least partially be attributed to the mesedin's ability of increasing the expression of Interleukine(IL)-10, which is a potent anti-inflammatory, neuroprotective neurogenic, and Aβ metabolism enhancing factor. In summary, our data identify the neurogenic, neuroprotective, and anti-amyloidogenic action of mesedin in APC. Further in vivo studies are needed to estimate the therapeutic value of mesedin for AD.

Energy depletion and not ROS formation is a crucial step of glucolipotoxicity (GLTx) in pancreatic beta cells.
We have shown previously that genetic or pharmacological deletion of K channels protect against beta cell dysfunction

induced by reactive oxygen species (ROS). Since it is assumed that glucolipotoxicity (GLTx) causes ROS production, we aimed to evaluate whether suppression of K channel activity can also prevent beta cell damage evoked by GLTx. We used an in vitro model of GLTx and measured distinct parameters of stimulus-secretion coupling. GLTx gradually induced disturbances of Ca oscillations over 3 days. This impairment in Ca dynamics was partially reversed in beta cells without functional K channels (SUR1) and by the sulfonylurea gliclazide but not by tolbutamide. By contrast, the GLTx-induced suppression of glucose-induced insulin secretion could not be rescued by decreased K channel activity pointing to a direct interaction of GLTx with the secretory capacity. Accordingly, GLTx also suppressed KCl-induced insulin secretion. GLTx was not accompanied by decisively increased ROS production or enhanced apoptosis. Insulin content of beta cells was markedly reduced by GLTx, an effect not prevented by gliclazide. Since GLTx markedly diminished the mitochondrial membrane potential and cellular ATP content, lack of ATP is assumed to decrease insulin biosynthesis. The deleterious effect of GLTx is therefore caused by direct interference with the secretory capacity whereby reduction of insulin content is one important parameter. These findings deepen our understanding how GLTx damages beta cells and reveal that GLTx is disconnected from ROS formation, a notion important for targeting beta cells in the treatment of diabetes. Overall, GLTx-induced energy depletion may be a primary step in the cascade of events leading to loss of beta cell function in type-2 diabetes mellitus. Pflugers Arch, 2018; 470

UNRAVELLING THE ROLE OF THE STX1B GENE IN GENETIC EPILEPSY SYNDROMES USING AN IPSC-DERIVED AUTAPTIC CULTURE SYSTEM

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Carolin Fischer, Betül Uysal, Heidi Löffler, Niklas Schwarz, Holger Lerche
Hertie Institute for Clinical Brain Research, Dept. Of Neurology And Epileptology, Tübingen, Germany

The majority of genes implicated in epilepsy lead to ion channel dysfunction, wherefore epilepsies are often referred to as channelopathies. However, the identification of mutations in genes encoding synaptic proteins shed light on synaptopathies as another pathophysiological mechanism of epilepsy. Mutations in *STX1B*, which encodes the presynaptic protein Syntaxin-1B, have been associated with various epilepsy syndromes ranging from benign generalized febrile or afebrile seizures to severe epileptic encephalopathies. The effect of *STX1B* mutations have already been studied in different animal models like zebrafish or mouse, while data from human model systems are still missing. Moreover, most studies on synaptic transmission rely on spontaneous activity in an uncontrolled network of neurons limiting the readout of specific synaptic properties. To overcome these limitations, we use autaptic cultures of patient-specific induced pluripotent stem cells (iPSCs) to elucidate the effects of *STX1B* mutations. In that endeavour, we generated iPSC lines from patients carrying *STX1B* mutations in the regulatory H_{abc}-domain or SNARE motif. Using the advantage of autaptic cultures, we examine different synaptic properties in iPSC-derived neurons by patch clamp recordings to investigate how *STX1B* mutations affect synaptic activity on a single cell level. Understanding the pathophysiological mechanisms of synaptic dysfunction in these patients could further help to develop adequate therapies in the future.

Artemisinin-treatment in pre-symptomatic APP-PS1 mice increases gephyrin phosphorylation at Ser270: a modification regulating postsynaptic GABAR density.
Artemisinins, a group of plant-derived sesquiterpene lactones, are efficient antimalarial agents. They also share anti-inflammatory and anti-viral activities and were considered for treatment of neurodegenerative disorders like Alzheimer's disease (AD). Additionally, artemisinins bind to gephyrin, the multifunctional scaffold of GABAergic synapses, and modulate inhibitory neurotransmission . We previously reported an increased expression of gephyrin and GABA receptors in early pre-symptomatic stages of an AD mouse model (APP-PS1) and in parallel enhanced CDK5-dependent phosphorylation of gephyrin at S270. Here, we studied the effects of artemisinin on gephyrin in the brain of young APP-PS1 mice. We detected an additional increase of gephyrin protein level, elevated gephyrin phosphorylation at Ser270, and an increased amount of GABAR-γ2 subunits after artemisinin-treatment. Interestingly, the CDK5 activator p35 was also upregulated. Moreover, we demonstrate decreased density of postsynaptic gephyrin and GABAR-γ2 immunoreactivities in cultured hippocampal neurons expressing gephyrin with alanine mutations at two CDK5 phosphorylation sites. In addition, the activity-dependent modulation of synaptic protein density was abolished in neurons expressing gephyrin lacking one or both of these phosphorylation sites. Thus, our results reveal that artemisinin modulates expression as well as phosphorylation of gephyrin at sites that might have important impact on GABAergic synapses in AD.

Aim: Available anti-epileptic drugs target the epileptic effectors that set the seizure threshold, but not downstream signalling cascades that contribute to the pathogenesis and severity. In an effort to identify a new therapeutic compound with better tolerance and potency, we aimed to investigate the anti-epileptic effects of a polyphenolic derivative (PD). Methods: Pharmacological (picrotoxin) and genetic *(bang senseless[1], a gain of function mutation in sodium channel)* epileptic models of *Drosophila* and pentylenetetrazol-induced chronic kindling mouse model were used to score the anti-epileptic effects. The scoring was based on behavioural analysis that correlated with synaptic structure and function in *Drosophila* and mouse. RNA sequencing and affinity chromatography studies were performed to dissect the mechanism of action and molecular targets. Results: PD exerts both acute and chronic anti-epileptic effects by mitigating the behavioural and synaptic defects *in Drosophila.* A similar result was recapitulated in the PTZ mouse model, where reduction in basal synaptic transmission and altered excitatory-inhibitory balance was observed, but administration of PD restored these deficits. We hypothesize that PD may act by restoring homeostasis through acute activation of the JNK pathway and its complex interplay with Insulin signalling, in the context of epileptic stress. Conclusions: Identification of JNK pathway-mediated alleviation of seizures could provide unanticipated launch points for investigation into their anti-epileptic roles and identification of novel targets. Our results could pave the way for the further usage of polyphenolic compounds in combinatorial approaches against acquired and genetic refractory epilepsies.

IDENTIFICATION OF A NOVEL MISSENSE VARIANT IN A FAMILY WITH AUTOSOMAL DOMINANT SLEEP-RELATED HYPERMOTOR EPILEPSY (ADSHE)

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Chiara Villa[1], Eleonora Rivellini[1], Federica Arrigoni[2], Luca De Gioia[2], Romina Combi[1]
[1]University of Milano-Bicocca, Department Of Medicine And Surgery, Monza, Italy, [2]University of Milano-Bicocca, Department Of Biotechnology And Biosciences, Milan, Italy

Aims: autosomal dominant sleep-related hypermotor epilepsy (ADSHE) is a familial form of focal epilepsy, characterized by hyperkinetic focal seizures, mainly arising in the neocortex during non-rapid eye movements (NREM) sleep. *CHRNA2*, *CHRNA4*, *CHRNB2*, *CRH*, *KCNT1*, *DEPDC5*, and *CABP4* genes are known to be associated with ADSHE, accounting for only a small proportion of the genetically determined cases. We aimed to identify additional disease-causing genes in an Italian family affected by ADSHE and to investigate their functional effects. ***Methods***: genomic DNA was isolated from peripheral blood and trio-based whole-exome sequencing (WES) was performed on the proband and her relatives. Sanger sequencing and co-segregation analysis were used to validate candidate variants. Bioinformatic prediction of pathogenicity was carried out for further evaluation. ***Results:*** trio-based WES revealed 9 novel variants shared by the proband and her affected father but absent in her unaffected mother. Validation by Sanger sequencing confirmed the presence of a novel missense variant (p.W276G) in *MOXD1* gene, encoding monooxigenase DBH like 1 protein, detected in heterozygosity in all affected family members. This variant was predicted to be pathogenic by different *in silico* tools (SIFT, Polyphen-2 and Mutation Taster). Computational analysis of protein structure by the webserver Dynamut2 revealed a high destabilizing effect with a ΔΔG=-3.77 kcal/mol. The mutated amino acid is located near the copper binding site, suggesting an alteration of the binding pocket of the enzyme. ***Conclusions:*** our data suggest that *MOXD1* gene could be associated with ADSHE, but *in vitro* functional analyses are needed to draw definite conclusions.

STRUCTURE-FUNCTION RELATIONSHIPS IN THE INTERACTION OF PROLINE-RICH TRANSMEMBRANE PROTEIN 2 (PRRT2) WITH VOLTAGE GATED NA+ CHANNELS

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Francesca Franchi[1,2], Antonella Marte[1,3], Bruno Sterlini[1], Alexander Vogel[2], Pietro Baldelli[1,3], Anna Corradi[1,3], Pierluigi Valente[1,3], Fabio Benfenati[2,3]

Aim: Mutations in the Proline-Rich Transmembrane Protein 2 (PRRT2) gene are the causative agent for a wide spectrum of paroxysmal disorders. The neuron-specific PRRT2 protein controls the intrinsic excitability through specific interactions with voltage-gated Na^+ (Nav) 1.2 and 1.6 channels. The aim of this study is to characterize the PRRT2-Nav interaction dissecting the contribution of PRRT2 domains on Nav biophysical modulation. **Methods:** HEK293 cell-line stably expressing human Nav1.2 or Nav1.1 were sequentially transfected with (i) empty vector, (ii) wild-type full length PRRT2 (WT), (iii) the deletion mutant of PRRT2 lacking the intracellular N-terminus domain (δN-PRRT2) or (iv) the transmembrane domain (δC-PRRT2). The Nav modulation in each condition was studied by patch-clamp experiments. The biochemical interaction of Nav with PRRT2 WT with the deletion mutants was evaluated by pulldown assays. **Results:** In the presence of PRRT2 WT or δN-PRRT2, but not δC-PRRT2, Nav1.2 exhibit a reduction of current density paired by change in inactivation curves and recovery from inactivation. No functional modulation by both mutants was found on Nav1.1 under the same conditions. Pulldown experiments showed a decreased binding between the Nav1.2 and the δN-PRRT2, while δC-PRRT2 displayed an affinity similar to PRRT2 WT. **Conclusion:** Here, we formulate the tandem domain model that provides specific roles to the PRRT2 domains. We demonstrate that PRRT2 cytosolic domain exerts a binding role without modulating Nav activity, while the transmembrane domain is able to modulate the channel properties, but with a low intrinsic binding activity.

Epilepsy is a life-altering disease, affecting up to 1 million people worldwide. Although several new anti-epileptic drugs have been introduced in clinical routine in the last decades, 30% of epilepsy patients remain pharmacoresistant. Differences between fundamental properties of mouse and human neurons, as well as failures to translate therapeutic approaches from rodent models to clinical trials, highlight the need to study physiological and pathological mechanisms directly in human brain tissue. We investigated the functional and molecular properties of neuronal subpopulations in healthy and diseased human brain specimen. Using electrophysiology, Ca activity imaging and transcriptional methods (spatial transcriptomics, single nucleus RNA-seq, multiplexed FISH), we investigated the involvement of specific subpopulations of neurons in epileptic activity ex vivo. We further investigated the functional involvement of neuronal subtypes by targeted optogenetic manipulation using viral systems in human brain slice cultures. Our results provide unprecedented insight into the spatial heterogeneity of neuronal subtypes in the healthy human brain and provide detailed information on epilepsy-associated molecular transformations in the human brain. Importantly, identifying how cell types and molecular profiles are affected by epilepsy will guide development of novel therapeutic approaches for pharmacoresistant patients suffering from epilepsy.

Lithium inhibits tryptophan catabolism via the inflammation-induced kynurenine pathway in human microglia.
Despite its decades' long therapeutic use in psychiatry, the biological mechanisms underlying lithium's mood-stabilizing effects have remained largely elusive. Here, we investigated the effect of lithium on tryptophan breakdown via the kynurenine pathway using immortalized human microglia cells, primary human microglia isolated from surgical specimens, and microglia-like cells differentiated from human induced pluripotent stem cells. Interferon (IFN)-γ, but not lipopolysaccharide, was able to activate immortalized human microglia, inducing a robust increase in indoleamine-2,3-dioxygenase (IDO1) mRNA transcription, IDO1 protein expression, and activity. Further, chromatin immunoprecipitation verified enriched binding of both STAT1 and STAT3 to the IDO1 promoter. Lithium counteracted these effects, increasing inhibitory GSK3β phosphorylation and reducing STAT1 and STAT3 phosphorylation levels in IFN-γ treated cells. Studies in primary human microglia and hiPSC-derived microglia confirmed the anti-inflammatory effects of lithium, highlighting that IDO activity is reduced by GSK3 inhibitor SB-216763 and STAT inhibitor nifuroxazide via downregulation of P-STAT1 and P-STAT3 . Primary human microglia differed from immortalized human microglia and hiPSC derived microglia-like cells in their strong sensitivity to LPS, resulting in robust upregulation of IDO1 and anti-inflammatory cytokine IL-10. While lithium again decreased IDO1 activity in primary cells, it further increased release of IL-10 in response to LPS. Taken together, our study demonstrates that lithium inhibits the inflammatory kynurenine pathway in the microglia compartment of the human brain.

In vitro and in vivo anti-epileptic efficacy of eslicarbazepine acetate in a mouse model of KCNQ2-related self-limited epilepsy.
The KCNQ2 gene encodes for the K 7.2 subunit of non-inactivating potassium channels. KCNQ2-related diseases range from autosomal dominant neonatal self-limited epilepsy, often caused by KCNQ2 haploinsufficiency, to severe encephalopathies caused by KCNQ2 missense variants. In vivo and in vitro effects of the sodium channel blocker eslicarbazepine acetate (ESL) and eslicarbazepine metabolite (S-Lic) in a mouse model of self-limited neonatal epilepsy as a first attempt to assess the utility of ESL in the KCNQ2 disease spectrum was investigated.

Preparation of Acute Human Hippocampal Slices for Electrophysiological Recordings.
Epilepsy affects about 1% of the world population and leads to a severe decrease in quality of life due to ongoing seizures as well as high risk for sudden death. Despite an abundance of available treatment options, about 30% of patients are drug-resistant. Several novel therapeutics have been developed using animal models, though the rate of drug-resistant patients remains unaltered. One of probable reasons is the lack of translation between rodent models and humans, such as a weak representation of human pharmacoresistance in animal models. Resected human brain tissue as a preclinical evaluation tool has the advantage to bridge this translational gap. Described here is a method for high quality preparation of human hippocampal brain slices and subsequent stable induction of epileptiform activity. The protocol describes the induction of burst activity during application of 8 mM KCl and 4-aminopyridin. This activity is sensitive to established AED lacosamide or novel antiepileptic candidates, such as dimethylethanolamine (DMEA). In addition, the method describes induction of seizure-like events in CA1 of human hippocampal brain slices by reduction of extracellular Mg and application of bicuculline, a GABAA receptor blocker. The experimental set-up can be used to screen potential antiepileptic substances for their effects on epileptiform activity. Furthermore, mechanisms of action postulated for specific compounds can be validated using this approach in human tissue (e.g., using patch-clamp recordings). To conclude, investigation of vital human brain tissue ex vivo (here, resected hippocampus from patients suffering from temporal lobe epilepsy) will improve the current knowledge of physiological and pathological mechanisms in the human brain.

Dynorphin-based "release on demand" gene therapy for drug-resistant temporal lobe epilepsy.
Focal epilepsy represents one of the most common chronic CNS diseases. The high incidence of drug resistance, devastating comorbidities, and insufficient responsiveness to surgery pose unmet medical challenges. In the quest of novel, disease-modifying treatment strategies of neuropeptides represent promising candidates. Here, we provide the "proof of concept" that gene therapy by adeno-associated virus (AAV) vector transduction of preprodynorphin into the epileptogenic focus of well-accepted mouse and rat models for temporal lobe epilepsy leads to suppression of seizures over months. The debilitating long-term decline of spatial learning and memory is prevented. In human hippocampal slices obtained from epilepsy surgery, dynorphins suppressed seizure-like activity, suggestive of a high potential for clinical translation. AAV-delivered preprodynorphin expression is focally and neuronally restricted and release is dependent on high-frequency stimulation, as it occurs at the onset of seizures. The novel format of "release on demand" dynorphin delivery is viewed as a key to prevent habituation and to minimize the risk of adverse effects, leading to long-term suppression of seizures and of their devastating sequel.

Dimethylethanolamine Decreases Epileptiform Activity in Acute Human Hippocampal Slices .
Temporal lobe epilepsy (TLE) is the most common form of focal epilepsy with about 30% of patients developing pharmacoresistance. These patients continue to suffer from seizures despite polytherapy with antiepileptic drugs (AEDs) and have an increased risk for premature death, thus requiring further efforts for the development of new antiepileptic therapies. The molecule dimethylethanolamine (DMEA) has been tested as a potential treatment in various neurological diseases, albeit the functional mechanism of action was never fully understood. In this study, we investigated the effects of DMEA on neuronal activity in single-cell recordings of primary neuronal cultures. DMEA decreased the frequency of spontaneous synaptic events in a concentration-dependent manner with no apparent effect on resting membrane potential (RMP) or action potential (AP) threshold. We further tested whether DMEA can exert antiepileptic effects in human brain tissue . We analyzed the effect of DMEA on epileptiform activity in the CA1 region of the resected hippocampus of TLE patients by recording extracellular field potentials in the pyramidal cell layer. Epileptiform burst activity in resected hippocampal tissue from TLE patients remained stable over several hours and was pharmacologically suppressed by lacosamide, demonstrating the applicability of our platform to test antiepileptic efficacy. Similar to lacosamide, DMEA also suppressed epileptiform activity in the majority of samples, albeit with variable interindividual effects. In conclusion, DMEA might present a new approach for treatment in pharmacoresistant TLE and further studies will be required to identify its exact mechanism of action and the

involved molecular targets.

Step-by-step guide to building an inexpensive 3D printed motorized positioning stage for automated high-content screening microscopy.
High-content screening microscopy relies on automation infrastructure that is typically proprietary, non-customizable, costly and requires a high level of skill to use and maintain. The increasing availability of rapid prototyping technology makes it possible to quickly engineer alternatives to conventional automation infrastructure that are low-cost and user-friendly. Here, we describe a 3D printed inexpensive open source and scalable motorized positioning stage for automated high-content screening microscopy and provide detailed step-by-step instructions to re-building the device, including a comprehensive parts list, 3D design files in STEP (Standard for the Exchange of Product model data) and STL (Standard Tessellation Language) format, electronic circuits and wiring diagrams as well as software code. System assembly including 3D printing requires approx. 30h. The fully assembled device is light-weight (1.1kg), small (33×20×8cm) and extremely low-cost (approx. EUR 250). We describe positioning characteristics of the stage, including spatial resolution, accuracy and repeatability, compare imaging data generated with our device to data obtained using a commercially available microplate reader, demonstrate its suitability to high-content microscopy in 96-well high-throughput screening format and validate its applicability to automated functional Cl- and Ca-imaging with recombinant HEK293 cells as a model system. A time-lapse video of the stage during operation and as part of a custom assembled screening robot can be found at https://vimeo.com/158813199.

Human microglia regional heterogeneity and phenotypes determined by multiplexed single-cell mass cytometry.
Microglia, the specialized innate immune cells of the CNS, play crucial roles in neural development and function. Different phenotypes and functions have been ascribed to rodent microglia, but little is known about human microglia (huMG) heterogeneity. Difficulties in procuring huMG and their susceptibility to cryopreservation damage have limited large-scale studies. Here we applied multiplexed mass cytometry for a comprehensive characterization of postmortem huMG (10 - 10 cells). We determined expression levels of 57 markers on huMG isolated from up to five different brain regions of nine donors. We identified the phenotypic signature of huMG, which was distinct from peripheral myeloid cells but was comparable to fresh huMG. We detected microglia regional heterogeneity using a hybrid workflow combining Cytobank and R/Bioconductor for multidimensional data analysis. Together, these methodologies allowed us to perform high-dimensional, large-scale immunophenotyping of huMG at the single-cell level, which facilitates their unambiguous profiling in health and disease.

EFFICACY OF ANTI-SEIZURE MEDICATION IN A MOUSE MODEL OF HCN1 DEVELOPMENTAL AND EPILEPTIC ENCEPHALOPATHY

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Lauren Bleakley[1], Chaseley Mckenzie[1], Christopher Reid[1,2]
[1]Florey Institute of Neuroscience and Mental Health, The University Of Melbourne, PARKVILLE, Australia, [2]Epilepsy Research Centre, Department Of Medicine, University Of Melbourne, Austin Health, HEIDELBERG, Australia

Background and Aims: Understanding drug sensitivity profiles is challenging in rare diseases such as *HCN1* developmental and epileptic encephalopathy (DEE). The Hcn1 p.M294L mouse model carries the homologue of the recurrent HCN1 p.M305L pathogenic variant and recapitulates many key phenotypic elements of *HCN1* DEE. We aimed to use this mouse model to study the effect of a range of anti-seizure medications (ASMs) on excitability in *HCN1* DEE. **Methods:** Mice were instrumented with electrocorticography (ECoG) electrodes and their brain activity recorded following the administration of various ASMs. The effect of each drug on epileptiform spike frequency was quantified. ECoG spectral data was also analysed to investigate signatures of efficacy or exacerbation. **Results:** Phenytoin, lamotrigine and retigabine significantly increased ECoG spike frequency, with lamotrigine and retigabine triggering seizures in a subset of mice tested. There was also a strong trend for carbamazepine to increase spiking. Levetiracetam, diazepam, sodium valproate and ethosuximide all significantly reduced ECoG spike frequency. There were no consistent ECoG spectral changes caused by drugs that reduced spike frequency, while drugs that increased spiking all increased power in the slower delta and/or theta bands. **Conclusions:** Drugs which work predominantly through sodium channel block increased neuronal excitability in Hcn1 p.M294L mice, suggesting they should be contraindicated in *HCN1* DEE. Conversely, levetiracetam, diazepam, valproate and ethosuximide reduced excitability, so may be effective treatments for *HCN1* DEE. This pharmacoresponsiveness profile is similar to that of other epilepsies, especially Dravet Syndrome. Our data provides an initial framework for the clinical treatment of *HCN1* DEE.

Intracerebral drug delivery is a method of bypassing the blood brain barrier for targeted pharmacological intervention in specific brain regions while maintaining low systemic drug concentrations. This is an attractive alternative treatment option for systemic drug resistant epilepsies. **AIM**: To investigate the anticonvulsive potential of the broad spectrum antiseizure medication valproate when it is chronically applied to the subthalamic nucleus (STN), a key seizure-modulating structure in the epileptic network. **METHODS**: Valproate was infused chronically into the STN of adult rats (480, 720, or 960 µg/d) via surgically implanted cannulas and microinfusion pumps. The anticonvulsive effects and putative adverse effects of the convection-enhanced intrasubthalamic valproate delivery were measured via a repeatable, intravenous pentylenetetrazol seizure threshold test, and a behavioural test battery. **RESULTS**: All doses were well tolerated, and an increased proportion of responders with increasing valproate doses was observed. Responder rates were 66 %, 83 %, and 92 % for 480 µg/d, 720 µg/d, and 960 µg/d valproate, respectively. All responders receiving 720 µg/d developed tolerance, i.e., the anticonvulsive effect dropped to a threshold increase of less than 25 % in the third week, whereas only 45 % of responders receiving 960 µg/d developed tolerance. **CONCLUSION**: Our results support the STN as a viable target for intracerebral drug delivery in epilepsies. If tolerance development can be countered with discontinuous application regimes, while high responder rates are maintained, this could provide a promising approach for the future treatment of systemic drug resistant epilepsies. This project was supported by the DFG (GE1103/9-1).

CHARACTERIZATION OF A KCNA2 LOSS-OF-FUNCTION MOUSE MODEL

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Peter Mueller[1], Ahmed Eltoki[1,2], Nikolas Layer[1], Thomas Ott[3], Holger Lerche[1], Thomas Wuttke[1], Ulrike Hedrich[1]
[1]Hertie Institute for Clincal Brain Research, Dept. Of Neurology And Epileptology, Tuebingen, Germany, [2]University of Washington, Department Of Pharmacology, Seattle, United States of America, [3]University Clinics Tuebingen, Core Facility Transgenic Animals, Tuebingen, Germany

Monogenetic developmental and epileptic encephalopathies (DEE) are rare, but severe diseases that cause an immense lifelong burden on patients and their relatives. In 2015, we described several DEE causing *de novo* variants in the *KCNA2* gene encoding the voltage-gated potassium channel K_v1.2, one of them being p.Pro405Leu (P405L). This variant exhibited a loss-of-function phenotype due to a dramatic reduction in current amplitude. We therefore expected P405L to cause increased excitability of cortical neurons as correlate for increased seizure susceptibility. To study the effect of this variant on neuronal excitability as well as possible compensatory and disease-specific mechanisms, we generated *Kcna2*^{P405L} knock-in mouse models. We combined whole-cell patch-clamp recordings of pyramidal neurons and interneurons in acute slices of PN12-15 wildtype and heterozygous mice and transcriptomic analysis via single nuclei RNA sequencing of cortical and hippocampal tissue to better understand the pathomechanism of this variant. Heterozygous *Kcna2*^{P405L} mice on a C57Bl/6 background died prematurely between one and two months of age. We therefore switched to Swiss mice and found that the animals had a slight increase in survival. Surprisingly, we found that the firing frequency of pyramidal cells was similar to wildtype, and the only difference in intrinsic properties was a significant increase in the afterhyperpolarization amplitude. Our transcriptomic data indicated an explanation for this alteration in action potential shape. In conclusion, we established a new mouse model for a loss-of-function variant in *KCNA2*. Counterintuitively, the mechanism of seizure susceptibility of this model does not rely on increased pyramidal cell excitability.

Persistent sodium current modulates axonal excitability in CA1 pyramidal neurons.
Axonal excitability is an important determinant for the accuracy, direction, and velocity of neuronal signaling. The mechanisms underlying spike generation in the axonal initial segment and transmitter release from presynaptic terminals have been intensely studied and revealed a role for several specific ionic conductances, including the persistent sodium current (I). Recent evidence indicates that action potentials can also be generated at remote locations along the axonal fiber, giving rise to ectopic action potentials during physiological states (e.g., fast network oscillations) or in pathological situations (e.g., following demyelination). Here, we investigated how ectopic axonal excitability of mouse hippocampal CA1 pyramidal neurons is regulated by I . Recordings of field potentials and intracellular voltage in brain slices revealed that electrically evoked antidromic spikes were readily suppressed by two different blockers of I , riluzole and phenytoin. The effect was mediated by a reduction of the probability of ectopic spike generation while latency was unaffected. Interestingly, the contribution of I to excitability was much more pronounced in axonal branches heading toward the entorhinal cortex compared with the opposite fiber direction toward fimbria. Thus, excitability of distal CA1 pyramidal cell axons is affected by persistent sodium currents in a direction-selective manner. This mechanism may be of importance for ectopic spike generation in oscillating network states as well as in pathological situations.

DEEP LEARNING NEURAL NETWORK FOR THE DETECTION OF EPILEPTIFORM EVENTS AND SEIZURE ONSET ZONE

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Andrei Medvedev[1], Galina Agoureeva[2]
[1]Georgetown University, Center For Functional And Molecular Imaging, Washington DC, United States of America, [2]Flinders University of South Australia (Retiree), Faculty Of Science And Engineering, Bedford Park, Australia

Aims Deep Learning (DL) neural networks can be used for automated analysis of intracranial EEG (iEEG) and the detection of pathological high frequency oscillations (HFOs) and spikes which are good biomarkers of epileptogenic tissue. We used a bidirectional Long Short-Term Memory (LSTM) neural network trained to detect ripples-on-oscillation (RonO), spikes and ripple-on-spike (RonS) and analyzed the prevalence of these events in regard to the seizure onset zone (SOZ). **Methods** We used iEEG from the open access database (14 patients). Spectral features were analyzed continuously across 40-min iEEG records and the initial screening for event candidates was done with a novel thresholding algorithm. 1000 events of each class (spike, RonS, RonO and baseline) were visually verified and selected. Training of the LSTM network was performed using random selections of 500 events (per class) while other 500 events (per class) were used for testing. **Results** The network was able to detect events with sensitivity/specificity above 85-90% for all event classes. Spikes and RonS showed highly significant correlation with SOZ ($p < 0.005$) in all patients regardless of the location of SOZ. Ripples without spikes (RonO) showed significant correlation with SOZ ($p < 0.01$) within the hippocampus. **Conclusions** Deep Learning networks can be used for automated detection of HFOs and epileptic spikes within iEEG and thus can be instrumental in the delineation of seizure onset zone. The DL networks can significantly accelerate the analysis of iEEG data and increase their diagnostic value, which may improve surgical outcome in patients with localization-related refractory epilepsy.

DYNAMICS OF SEIZURE-LIKE PROPAGATION IN SPIKING NETWORK MODELS.

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Damien Depannemaecker[1], Mallory Carlu[2], Alain Destexhe[3]
[1]CNRS, Neuropsi – Institut Des Neurosciences Paris-saclay, Saclay, France, [2]CNRS, Neuropsi, Saclay, France, [3]NeuroPSI, Icn, Saclay, France

Aims: In epilepsies, seizures originating from one or various regions mays spread or not to the rest of the brain, propagating from one region to another. Into a given region receiving an incoming seizure, the underlying mechanisms that will lead to contain or propagate the perturbation remain unclear. We study these aspects through computational models at the neural network scale to understand which specific features play a role. Methods: Three different models of electrophysiological activity based on ordinary differential equations, describing the dynamics of the neuron's membrane potential are used to build networks of inhibitory and excitatory populations. These networks receive incoming perturbations mimicking the seizure input. Results: We observe two possible scenarios, either both populations exhibit paroxysmal responses, or only the inhibitory population exhibit a strong activity, thus containing the excitatory population and preventing propagation to the next regions. We found that these behaviors do not only depend on the characteristics of the inputs as the perturbation leads to dynamical heterogeneity inside the network, non-trivially related to its architecture. Conclusions: Our results show a variety of local responses to strong incoming perturbations, leading to different global network phenomenologies. We observe how the choice of single-neuron models highly condition the large-scale dynamics, which opens the way to a discussion on the very choice of model one can use in this type of study.

This work is a retrospective review of the electrocorticography of patients with an implanted RNS -Responsive neurostimulation device who received any of the three available vaccination series (Pfeizer, Johnson & Johnson, and Moderna) for providing immunity for COVID 19 in the United States. Retrospective review of such a dataset available in a cohort of such patients was IRB approved and such dataset was analyzed. Although this report identifies only a small cohort of patients, no significant differences in electrocorticography were noted after vaccine administration in this case series. Such findings may merit further study and analysis.

PHARMACOLOGY AND DESENSITIZATION PROPERTIES OF α4-CONTAING GABAA RECEPTORS

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Florian Vogel[1], Martin Krenn[2], Petra Scholze[3], Margot Ernst[1]
[1]Medizinische Universität Wien, Center For Brain Research, Department Of Pathobiology Of The Nervous System, Wien, Austria, [2]Medizinische Universtiät Wien, Department Of Neurology, Wien, Austria, [3]Medical University of Vienna, Center For Brain Research, Vienna, Austria

Aims: We recently reported a *de novo* missense variant in *GABRA4* in an individual with early-onset drug-resistant epilepsy and neurodevelopmental abnormalities. An electrophysiological characterization of the variant, located in the pore-forming domain, shows accelerated desensitization and a lack of seizure-protective neurosteroid function. Our findings represent the first genetic and functional evidence for an association between *GABRA4* and a neurodevelopmental disorder with epilepsy. To date, still little is still known about α4- containing $GABA_A$ receptor pharmacology. In this study we will perform further pharmacological analysis of this and other *GABRA4* variants in comparison to the wild type in a panel of α4- containing $GABA_A$ receptors. A pharmacological rescue of disrupted desensitization caused by specific *GABRA4* variants could provide the basis of future treatments. **Methods:** Recombinant expression is done in *Xenopus Laevis* oocytes and HEK cells. Electrophysiological characterization is performed using the two electrode voltage clamp technique and the patch clamp technique. Biochemical analysis of rodent brain samples complements the study. **Results and Conclusion:** Provided that future replications will reinforce a causal relationship, *GABRA4* may soon be added to the constantly growing list of epilepsy-related disease genes. Our preliminary data suggest a novel mechanism of interaction between so called “benzodiazepine insensitive” α4- containing $GABA_A$receptors and benzodiazepines. This novel pharmacological mechanism could pave the way for future $GABA_A$receptor targeting therapeutics.

DAILY INTERMITTENT FASTING ATTENUATES ABSENCE EPILEPSY IN MICE.

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Coline Rulhe[1], Steeve Thirard[1], Juri Aparicio Arias[1], Zoé Husson[1], Stephanie Trouche[2], Tristan Bouschet[2], Emmanuel Valjent[3], Federica Bertaso[4]
[1]Institut de Génomique Fonctionnelle, Neuroscience, Montpellier, France, [2]IGF, Univ Montpellier, CNRS, INSERM, Montpellier, France, Neuroscience, Montpellier, France, [3]IGF, Université Montpellier, CNRS, Inserm, Molecular And Neural Coding Of Behavior (mncb)lab, Montpellier, France, [4]Université de Montpellier, Institut De Génomique Fonctionnelle, Montpellier, France

Several studies have shown a tripartite link between food intake, seizures and cognitive deficits in epilepsy. Absence Epilepsy (AE) affect children during a critical phase of neurodevelopment. Limiting or even avoiding treatments based on antiepileptic drugs with strong side effects is extremely important. We investigated daily intermittent fasting (IF) as an innovative, drug-free method to improve seizure burden as well as cognitive deficits on different mouse models of AE. We implemented a 1-month daily IF regime (8 h feeding/16 h fasting) in control and epileptic mice followed by a multilevel analysis. We tracked the evolution of seizures (by electroencephalographic recordings) and behavioural comorbidities in the Grm7^{AAA} KI mouse, an isomorphic model of "pure" AE. We show that the 1-month IF regime reduced significantly the occurrence of absence seizures by ~40%, while improving social and cognitive behavioural scores. RNA-seq experiments and preliminary gene ontology analysis revealed an altered mRNA expression pattern in the thalami of epileptic animals that was reversed by IF. In particular, modifications of angiogenesis-related genes were confirmed by blood vessels tracing experiments. Similar results were obtained in a pharmacological model of atypical absence seizures, the AY9944 mouse. Thus, our results indicate that daily IF could be a simple and efficient non-invasive strategy to be proposed as an alternative to the existing, yet often ineffective, anti-epileptic drugs or strict regimes, such as the ketogenic diet.

TIME-LIMITED ALTERATIONS IN CORTICAL ACTIVITY OF A KNOCK-IN MICE MODEL OF KCNQ2-RELATED DEVELOPMENTAL AND EPILEPTIC ENCEPHALOPATHY

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Najoua Biba
AMU, Neuroscience, Marseille, France

De novo missense variants in the *KCNQ2* gene encoding the Kv7.2 subunit of Kv7/M channel are the main cause of Developmental and Epileptic Encephalopathy (DEE). *KCNQ2* related-DEE is characterized by pharmaco-resistant neonatal seizures associated with a developmental delay. While seizures usually resolve some weeks or months after birth, cognitive/behavioral deficits persist, greatly affecting the patient's quality of life. To better understand the cellular mechanisms underlying *KCNQ2-associated* network dysfunction and their progression over time, we investigated *in vivo,* using local field potential recordings of freely moving animals, the seizure susceptibility in KI mice, and *ex-vivo* in layers II/III and V of motor cortical slices, using patch-clamp recordings, the electrophysiological properties of pyramidal cells from a heterozygous knock-in (KI) mouse model carrying the p.T274M pathogenic variant during neonatal, post-weaning and juvenile developmental stages.

MEDICAL CANNABIS FOR SEVERE TREATMENT-RESISTANT EPILEPSY IN CHILDREN: A CASE-SERIES OF 10 PATIENTS

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Rayyan Zafar[1], Anne Schlag[1], Lawrence Phillips[2], David Nutt[1]
[1]Imperial College London, Brain Sciences, London, United Kingdom, [2]London School of Economics, -, AE, United Kingdom

Introduction Whole-plant medical cannabis has shown considerable anecdotal evidence for efficacy in children suffering from intractable epilepsies. In spite of this only isolated CBD is licensed as an intervention for such patients. Here we report a case series of 10 children using whole-plant extracts to demonstrate the feasibility of this intervention. **Methods** This study was conducted retrospectively through collecting clinical data from caretakers and clinicians on study outcome variables. Participants were recruited through charity patient representative groups that support children who are using medical cannabis to treat their epilepsies. Medicines were prescribed to patients by clinicians in both National Health Service and private medical practices. Ten children, 18 years old or under, with intractable epilepsies, were recruited from two charities. There were no limitations on diagnosis, sex, or ethnic origin. Participants were treated with a range of whole-plant medical cannabis oils. Individual dosing regimens were determined by clinicians. The primary outcome measure was seizure frequency. **Results** Seizure frequency across all 10 participants was reduced by 86% with no significant adverse events. Participants reduced the use of antiepileptic drugs from an average of seven to one following treatment with medical cannabis. We also noted significant financial costs of £874 per month to obtain these medicines through private prescriptions. **Conclusions** This study establishes the feasibility of whole-plant medical cannabis as an effective and well-tolerated medicine for reducing seizure frequency in children suffering from intractable epilepsies. These findings justify the potential value of further research into the reported therapeutic benefit of whole-plant medicinal cannabis products.

CESIUM CHLORIDE ACTIVATES C-TO-U RNA EDITED GLYCINE RECEPTORS

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Steffen Fricke[1], Florian Hetsch[2], Julia Leonhard[1], Anna Eylmann[1], Pina Knauff[3], Marcus Semtner[4], Jochen Meier[1]
[1]Technische Universität Braunschweig, Cell Physiology, Braunschweig, Germany, [2]Johannes Gutenberg-University of Mainz, Institute Of Pathophysiology, Mainz, Germany, [3]Charité Universitätsmedizin Berlin, Institute Of Cell Biology, Berlin, Germany, [4]Max Delbrueck Center for Molecular Medicine, Cellular Neurosciences, Berlin, Germany

Chloride salts of the alkali metals sodium and potassium play an important physiological role in virtually any cell of our body and their cations are vital for the normal function of excitable cells. Besides sodium and potassium, other cations of the alkali metal family have been shown to affect neuronal physiology, e.g. cesium and lithium. While cesium is readily used in electrophysiological approaches as a blocker of potassium channels, lithium is widely used as a mood-stabilizing drug in the treatment of bipolar disorders. Lately, our group has shown that C-to-U RNA editing plays an important role in the diversification of gene products, and discovered that C-to-U RNA-edited glycine receptors (GlyRs) play a crucial part in the progression of temporal lobe epilepsy (TLE) as facilitated activation of the RNA-edited gain-of-function GlyRs contributes – in a neuron type-specific way – to diverse neuropsychiatric symptoms of the disease. In a recent publication, we demonstrated that C-to-U RNA editing of GlyR subunits allows ammonium chloride to exert an agonistic action specifically on these edited receptors (Kankowski et al., 2018). This prompted us to investigate the effects of different chloride salts of alkali metals (e.g. sodium, potassium, cesium and lithium) on different edited and unedited GlyR subunits using whole-cell patch clamp recordings of transfected HEK293T cells. Our results identify cesium chloride as a novel agonist for C-to-U RNA-edited GlyRs that exhibits its action on these receptors in a dose-dependent and subunit-specific manner and may therefore be of importance in neuropsychiatric research of temporal lobe epilepsy.

TOWARD NOVEL THERAPEUTIC INTERVENTIONS FOR STXBP1-ASSOCIATED DISORDERS

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Wietske Van Der Ent[1], Justine Laulin[1], Zuhur Said[1], Kinga Gawel[1,2], Nancy Banono[1], Camila Esguerra[1]
[1]NCMM - University of Oslo, Chemical Neuroscience, Oslo, Norway, [2]Medical University of Lublin, Department Of Experimental And Clinical Pharmacology, Lublin, Poland

Approximately 25-30% of people suffering from epileptic seizures do not respond to available antiseizure drugs (ASDs). Additionally, ASDs tolerated well by adults may cause severe side effects in children. Thus, there is a high need for models to test novel therapeutic options. Especially rare forms of epilepsy, where evaluation of intervention may be challenging due to the limited number of subjects, will benefit from animal models suited for rapid drug screening. Focusing on STXBP1-associated disorders, we developed two drug-screening protocols for potential ASDs: one based on behavioural analysis and another based on morphological alterations. Combining these screening methods with various genetic and chemical zebrafish epilepsy models, we mean to identify novel potential ASDs from libraries of FDA-approved compounds and natural products. Top hits from these initial screens will be confirmed through EEG recordings, and evaluated for their effects on neuronal morphology and additional disease comorbidities such as Schizophrenia- and Autism Spectrum Disorder-like features.

Phenotypic Characterization of Larval Zebrafish (Danio rerio) with Partial Knockdown of the cacna1a Gene.
The CACNA1A gene encodes the pore-forming α1 subunit of voltage-gated P/Q type Ca channels (Ca2.1). Mutations in this gene, among others, have been described in patients and rodents suffering from absence seizures and episodic ataxia type 2 with/without concomitant seizures. In this study, we aimed for the first time to assess phenotypic and behavioral alterations in larval zebrafish with partial cacna1aa knockdown, placing special emphasis on changes in epileptiform-like electrographic discharges in larval brains. Whole-mount in situ hybridization analysis revealed expression of cacna1aa in the optic tectum and medulla oblongata of larval zebrafish at 4 and 5 days post-fertilization. Next, microinjection of two antisense morpholino oligomers (individually or in combination) targeting all splice variants of cacna1aa into fertilized zebrafish eggs resulted in dose-dependent mortality and decreased or absent touch response. Over 90% knockdown of cacna1aa on protein level induced epileptiform-like discharges in the optic tectum of larval zebrafish brains. Incubation of morphants with antiseizure drugs (sodium valproate, ethosuximide, lamotrigine, topiramate) significantly decreased the number and, in some cases, cumulative duration of epileptiform-like discharges. In this context, sodium valproate seemed to be the least effective. Carbamazepine did not affect the number and duration of epileptiform-like discharges. Altogether, our data indicate that cacna1aa loss-of-function zebrafish may be considered a new model of absence epilepsy and may prove useful both for the investigation of Cacna1a-mediated epileptogenesis and for in vivo drug screening.

Cell-to-cell heterogeneity of EWSR1-FLI1 activity determines proliferation/migration choices in Ewing sarcoma cells.
Ewing sarcoma is characterized by the expression of the chimeric EWSR1-FLI1 transcription factor. Proteomic analyses indicate that the decrease of EWSR1-FLI1 expression leads to major changes in effectors of the dynamics of the actin cytoskeleton and the adhesion processes with a shift from cell-to-cell to cell-matrix adhesion. These changes are associated

with a dramatic increase of in vivo cell migration and invasion potential. Importantly, EWSR1-FLI1 expression, evaluated by single-cell RT-ddPCR/immunofluorescence analyses, and activity, assessed by expression of EWSR1-FLI1 downstream targets, are heterogeneous in cell lines and in tumours and can fluctuate along time in a fully reversible process between EWSR1-FLI1 states, characterized by highly active cell proliferation, and EWSR1-FLI1 states where cells have a strong propensity to migrate, invade and metastasize. This new model of phenotypic plasticity proposes that the dynamic fluctuation of the expression level of a dominant oncogene is an intrinsic characteristic of its oncogenic potential.

The second European interdisciplinary Ewing sarcoma research summit--A joint effort to deconstructing the multiple layers of a complex disease.
Despite multimodal treatment, long term outcome for patients with Ewing sarcoma is still poor. The second "European interdisciplinary Ewing sarcoma research summit" assembled a large group of scientific experts in the field to discuss their latest unpublished findings on the way to the identification of novel therapeutic targets and strategies. Ewing sarcoma is characterized by a quiet genome with presence of an EWSR1-ETS gene rearrangement as the only and defining genetic aberration. RNA-sequencing of recently described Ewing-like sarcomas with variant translocations identified them as biologically distinct diseases. Various presentations adressed mechanisms of EWS-ETS fusion protein activities with a focus on EWS-FLI1. Data were presented shedding light on the molecular underpinnings of genetic permissiveness to this disease uncovering interaction of EWS-FLI1 with recently discovered susceptibility loci. Epigenetic context as a consequence of the interaction between the oncoprotein, cell type, developmental stage, and tissue microenvironment emerged as dominant theme in the discussion of the molecular pathogenesis and inter- and intra-tumor heterogeneity of Ewing sarcoma, and the difficulty to generate animal models faithfully recapitulating the human disease. The problem of preclinical development of biologically targeted therapeutics was discussed and promising perspectives were offered from the study of novel in vitro models. Finally, it was concluded that in order to facilitate rapid pre-clinical and clinical development of novel therapies in Ewing sarcoma, the community needs a platform to maintain knowledge of unpublished results, systems and models used in drug testing and to continue the open dialogue initiated at the first two Ewing sarcoma summits.

Automation of Technology for Cancer Research.
Zebrafish embryos can be obtained for research purposes in large numbers at low cost and embryos develop externally in limited space, making them highly suitable for high-throughput cancer studies and drug screens. Non-invasive live imaging of various processes within the larvae is possible due to their transparency during development, and a multitude of available fluorescent transgenic reporter lines.To perform high-throughput studies, handling large amounts of embryos and larvae is required. With such high number of individuals, even minute tasks may become time-consuming and arduous. In this chapter, an overview is given of the developments in the automation of various steps of large scale zebrafish cancer research for discovering important cancer pathways and drugs for the treatment of human disease. The focus lies on various tools developed for cancer cell implantation, embryo handling and sorting, microfluidic systems for imaging and drug treatment, and image acquisition and analysis. Examples will be given of employment of these technologies within the fields of toxicology research and cancer research.

Imaging of Human Cancer Cell Proliferation, Invasion, and Micrometastasis in a Zebrafish Xenogeneic Engraftment Model.
The xenograft model, using the early life stages of the zebrafish, allows imaging of tumor cell behavior both on a single cell and whole organism level, over time, within a week. This robust and reproducible assay can be used as an intermediate step between in vitro techniques and the expensive, and time consuming, murine models of cancer invasion and metastasis.In this chapter, a detailed protocol to inject human cancer cells into the blood circulation of a zebrafish embryo is described; the engraftment procedure is then followed by visualization and quantification methods of tumor cell proliferation, invasion, and micrometastasis formation during subsequent larval development. Interaction with the host microenvironment is also considered.

Embryonic Zebrafish: Different Phenotypes after Injection of Human Uveal Melanoma Cells.
Although murine xenograft models for human uveal melanoma (UM) are available, they are of limited utility for screening large compound libraries for the discovery of new drugs. We need new preclinical models which can efficiently evaluate drugs that can treat UM metastases. The zebrafish embryonic model is ideal for drug screening purposes because it allows the investigation of potential antitumor properties of drugs within 1 week. The optical transparency of the zebrafish provides unique possibilities for live imaging of fluorescence-labelled cancer cells and their behavior. In addition, the adaptive immune response, which is responsible for the rejection of transplanted material, is not yet present in the early stages of fish development, and systemic immunosuppression is therefore not required to allow growth of tumor cells. We studied the behavior of UM cells following injection into zebrafish embryos and observed different phenotypes. We also analyzed cell migration, proliferation, formation of micrometastasis and interaction with the host microenvironment. Significant differences were noted between cell lines: cells derived from metastases showed more migration and proliferation than cells derived from the primary tumors. The addition of the c-Met inhibitor crizotinib to the water in which the larvae were kept reduced the migration and proliferation of UM cells expressing c-Met. This indicates the applicability of the zebrafish xenografts for testing novel inhibitory compounds and provides a fast and sensitive in vivo vertebrate model for preclinical drug screening to combat UM.

Suppression of deacetylase SIRT1 mediates tumor-suppressive NOTCH response and offers a novel treatment option in metastatic Ewing sarcoma.
The developmental receptor NOTCH plays an important role in various human cancers as a consequence of oncogenic mutations. Here we describe a novel mechanism of NOTCH-induced tumor suppression involving modulation of the deacetylase SIRT1, providing a rationale for the use of SIRT1 inhibitors to treat cancers where this mechanism is inactivated because of SIRT1 overexpression. In Ewing sarcoma cells, NOTCH signaling is abrogated by the driver oncogene EWS-FLI1. Restoration of NOTCH signaling caused growth arrest due to activation of the NOTCH effector HEY1, directly suppressing SIRT1 and thereby activating p53. This mechanism of tumor suppression was validated in Ewing sarcoma cells, B-cell tumors, and human keratinocytes where NOTCH dysregulation has been implicated pathogenically. Notably, the SIRT1/2 inhibitor Tenovin-6 killed Ewing sarcoma cells in vitro and prohibited tumor growth and spread in an established xenograft model in zebrafish. Using immunohistochemistry to analyze primary tissue specimens, we found that high SIRT1 expression was associated with Ewing sarcoma metastasis and poor prognosis. Our findings suggest a mechanistic rationale for the use of SIRT1 inhibitors being developed to treat metastatic disease in patients with Ewing sarcoma.

Ewing sarcoma inhibition by disruption of EWSR1-FLI1 transcriptional activity and reactivation of p53.
Translocations involving ETS-transcription factors, most commonly leading to the EWSR1-FLI1 fusion protein, are the hallmark of Ewing sarcoma. Despite knowledge of this driving molecular event, an effective therapeutic strategy is lacking. To test potential treatment regimes, we established a novel Ewing sarcoma zebrafish engraftment model allowing time-effective, dynamic quantification of Ewing sarcoma progression and tumour burden in vivo, applicable for screening of single and combined compounds. In Ewing sarcoma the tumour-suppressor gene TP53 is commonly found to be wild-type, thus providing an attractive target for treatment. Here, we study TP53 wild-type (EW7, CADO-ES1 and TC32) and TP53-deleted (SK-N-MC) Ewing sarcoma cell lines to investigate the potentiating effect of p53 reactivation by Nutlin-3 on treatment with YK-4-279 to block transcriptional activity of EWSR1-FLI1 protein. Blocking EWSR1-FLI1 transcriptional activity reduced Ewing sarcoma tumour cell burden irrespective of TP53 status. We show that simultaneous YK-4-279 treatment with Nutlin-3 to stabilize p53 resulted in an additive inhibition of TP53 wild-type Ewing sarcoma cell burden, whilst not affecting TP53-deleted Ewing sarcoma cells. Improved inhibition of proliferation and migration by combinatorial treatment was confirmed in

vivo by zebrafish engraftments. Mechanistically, both compounds together additively induced apoptosis of tumour cells in vivo by engaging distinct pathways. We propose reactivation of the p53 pathway in combination with complementary targeted therapy by EWSR1-FLI1 transcriptional activity disruption as a valuable strategy against p53 wild-type Ewing sarcoma.

Temporal lobe epilepsy often manifests months or even years after an initial epileptogenic insult (e.g., stroke, trauma, status epilepticus) and, therefore, may be preventable. However, no such preventive treatment is currently available. Aim of this study was to test an antioxidant agent, 7,8-dihydroxyflavone (7,8-DHF), that is well tolerated and effective in preclinical models of many neurological disorders, as an anti-epileptogenic drug. However, 7,8-DHF also acts as a TrkB receptor agonist and, based on the literature, this effect may imply an anti- or a pro-epileptogenic effect. We found that low- (5 mg/kg), but not high-dose 7,8-DHF (10 mg/kg) can exert strong anti-epileptogenic effects in the lithium-pilocarpine model (i.e., highly significant reduction in the frequency of spontaneous seizures and in the time to first seizure after status epilepticus), and that these different effects correlate with differences in TrkB phosphorylation patterns and in activation of TrkB-dependent signaling pathways. These data support the possibility to develop drugs with desirable effects on the TrkB receptor, based on the selective activation of therapeutically relevant signaling pathways. In this respect, and also considering its excellent safety profile and antioxidant properties, 7,8-DHF represents a promising candidate for a preventive, anti-epileptogenic therapy, or at least a template for the development of effective and well-tolerated anti-epileptogenic drugs.

RESECTED HUMAN BRAIN TISSUE AS A PLATFORM TO SCREEN SMALL MOLECULE AND ANTISENSE OLIGONUCLEOTIDE THERAPIES FOR EPILEPSY

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Gareth Morris
University College London, Neuroscience, Physiology And Pharmacology, London, United Kingdom

Aims Current anti-seizure medications are often associated with substantial adverse effects and do not offer seizure-freedom to approximately one third of people with epilepsy. This creates a strong need for new therapeutic approaches, with drug discovery strategies often relying on animal-based models. Here, we describe a more translational approach, using live resected human brain tissue as a platform to probe the mechanisms and efficacy of small molecule and antisense oligonucleotide (ASO) therapies. Methods Human neocortical tissue was obtained with consent from patients undergoing resective surgery to alleviate pharmacoresistant seizures. Resected tissue specimens were transported in ice cold oxygenated sucrose artificial cerebrospinal fluid (ACSF) and sliced into 400 micron sections. For small molecule screening, acute seizure-like activity was induced in slices using standard chemoconvulsants. For ASO screening, slices were incubated at room temperature for 24 hours in a low volume of normal ACSF containing active ASO concentrations. Results Resected human neocortical slices exhibited evoked seizure-like activity, which was reduced by a putative anti-seizure small molecule. Slices incubated in ACSF for 24 hours retained robust RNA integrity, supporting their use as a screening platform for the molecular mechanisms of ASOs. As a proof of concept, we tested an ASO targeting microRNA-134, observing dose-dependent and specific knockdown. Conclusions Resected human brain tissue provides a robust platform for pre-clinical therapeutic discovery in epilepsy. The approach is highly translational, and overcomes concerns about the physiological relevance of animal-based approaches. We believe that these approaches should form a key step in therapeutic discovery pipelines for epilepsy.

Introduction. Developmental and Epileptic Encephalopathies (DEEs) are rare epilepsy syndromes that manifest with pharmacoresistant seizures and various degrees of developmental delay. Several genes are involved in DEE etiology, particularly voltage-gated potassium channels. Among them, Kv1.3 (KCNA3) channels represent the dominant component of voltage-gated K^+ currents in lymphocytes, and Kv1.3 block prompts immunosuppressive effects. Kv1.3 channels are also involved in microglia activation after status epilepticus, and are blocked by the anti-depressant drug fluoxetine. **Aims.** To identify new variants in DEE-affected patients and characterize their functional and pharmacological effects in order to propose personalized treatments. **Methods.** Next-generation sequencing approaches to identify new variants in DEE-affected patients; site-directed mutagenesis to introduce newly-identified variants in plasmids for heterologous expression; patch-clamp recordings on transfected cells. **Results.** We have identified nine individuals with a novel type of DEE, including marked speech delay with or without intellectual disability, epilepsy, and autism spectrum disorder. These patients carry distinct de novo heterozygous in KCNA3 gene. Patch-clamp recordings performed on CHO cells transiently expressing two of the KCNA3 variants revealed either loss- (G468F) or mixed loss- and gain-of-function effects (V478M) on Kv1.3 currents. Endogenous currents recorded in lymphoblasts from the unaffected, non-carrier father and the patient carrying the V478M variant revealed similar differences in biophysical properties than those observed in CHO cells. Fluoxetine dose-dependently (0.03-10 μM) blocked Kv1.3 and Kv1.3 V478M channels *in vitro*. **Conclusions.** KCNA3 is a novel DEE-causing gene, and fluoxetine could be a rational approach in patients carrying GoF variants in these channels.

DEVELOPMENT OF FUNCTIONAL IN VITRO MODEL IN DRAVET SYNDROME PATIENT HIPSC-DERIVED CORTICAL NEURONS.

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Ropafadzo Mzezewa
Tampere University, Faculty Of Medicine And Health Technology, Tampere, Finland

Intractable epilepsies that emerge in childhood, such as Dravet syndrome (DS), have limited response to current antiepileptic drugs (AEDs). DS patients are often typified by temperature sensitive seizures, along with other complexities like intellectual disability. New therapeutic drugs are therefore needed, as most patients are unresponsive to current AEDs. However, to obtain this, relevant preclinical models are needed. DS is mainly caused by a mutation in the SCN1A gene which is crucial for generating and propagating action potentials. Heterozygous mutation in SCN1A gene leads to loss of sodium currents and action potentials, resulting in reduced neural excitation and ultimately seizure formations. Mouse models and in vitro based human induced pluripotent stem cell (hiPSCs) models have shown that the reduced sodium current density and impaired excitation due to the mutation, primarily affects the GABAergic (inhibitory) interneurons. Thus far most of the electrophysiological findings have been performed using whole-cell patch clamp, and only few have studied this phenomenon at the network level. Here we investigated the functional alteration in hiPSCs of Dravet Syndrome patients using microelectrode arrays (MEAs). We generated two different subtypes of neural cultures: glutamatergic and GABAergic enriched cultures from DS patient lines. When cultured on MEAs we observe that DS neurons display a distinctive neuronal activity pattern compared to control neurons. Furthermore, preliminary data reveals that DS neurons portray more sensitivity in response to specific pharmacological treatments. This study highlights the applicability of disease modelling with hiPSCs and MEAs as a valuable platform to reveal underlying disease mechanisms.

DISEASE MECHANISMS OF EARLY ONSET EPILEPTIC ENCEPHALOPATHY CAUSED BY K556E KCNQ2 VARIANT

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Snezana Maljevic, Yafit Kushner, Lucas Teasdale, Miaomiao Mao, Nikola Jancovski, Christopher Reid, Steven Petrou
The Florey Institute of Neuroscience and Mental Health, Networks And Neurodevelopment, Melbourne, Australia

Background: Pathogenic variants in *KCNQ2* cause neonatal seizure disorders, including Early Onset Epileptic Encephalopathies (EOEE) characterised by pharmacoresistant seizures, developmental delay, and behavioural and cognitive deficits. Current therapies show limited efficacy in the treatment of seizures and fail to address the devastating comorbidities. *Aims:* To assess disease mechanisms of *KCNQ2 de novo* variant K556E identified in a patient with EOEE. *Methods:* The K556E variant was expressed in *Xenopus laevis* oocytes and analysed using two-microelectrode voltage clamp. Next, we generated patient induced pluripotent stem cells (iPSCs) and used *Neurogenin 2* overexpression to differentiate them into neuronal cultures which were studied using patch clamp electrophysiology and gene expression analysis. Lastly, a knock-in mouse model carrying the corresponding amino acid exchange in *Kcnq2* channel was generated using CRISPR/Cas9 technique. To assess the phenotype, we used video monitoring, EEG recordings,seizure susceptibility and behavioural tests. *Results:* K556E shows a moderate loss of function, reducing potassium currents by about 50 % when expressed in *Xenopus* oocytes. Patient iPSC-derived neurons exhibit several changes compared to healthy control, including increased rheobase and action potential firing rate. Both homo- and heterozygous mice develop spontaneous seizures and show increased mortality compared to littermate controls. We further observed increased susceptibility to thermally and chemically induced seizures. A battery of behavioural tests revealed heterozygous mice have reduced marble burying capabilities. *Conclusions:* K556E reduces the KCNQ-mediated currents which translates into hyperexcitability of patient iPSC-derived neurons and seizures and cognitive deficits in mice.

NEUROTRANSMITTER LEVELS ARE ALTERED IN SPECIFIC BRAIN AREAS OF DOGS AFTER ACUTE AND CHRONIC MEDIUM-CHAIN TRIGLYCERIDE ADMINISTRATION – A POSSIBLE ANTISEIZURE MECHANISM

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Sebastian Meller[1], Robert Hildebrandt[1], Franz Söbbeler[1], Martina Gramer[2], Franziska Richter[2], Holger Volk[1]
[1]University of Veterinary Medicine, Department Of Small Animal Medicine & Surgery, Hannover, Germany, [2]University of Veterinary Medicine, Department Of Pharmacology, Toxicology & Pharmacy, Hannover, Germany

Background: The positive impact of medium-chain triglycerides (MCTs) in the management of cognitive dysfunction and epilepsy in humans and dogs is currently being researched. However, the mechanisms of MCTs remain not fully elucidated. The aim of this study was to evaluate the effect of MCTs on canine neurotransmitter levels in different brain regions, in cerebrospinal fluid (CSF), serum, and urine. **Material & Methods:** Feeding of dogs was conducted in a randomised, crossover trial with a commercial diet (control). It was either supplemented with MCT-oil 2 h prior to assessment (acute) or daily for 2 weeks, with assessment conducted 10 h after last feeding (chronic). Proton Magnetic Resonance Spectroscopy with a 3-Tesla MRI scanner was used for concentration level assessment of common neurotransmitters in four brain regions (parietal, piriform, occipital, thalamic). Subsequently, CSF, blood, and urine were collected and analysed via high-performance liquid chromatography. **Results:** Paired data from eight healthy Beagle dogs were compared. Glutamine was reduced 2 h after MCT-administration in the piriform cortex [P = 0.0349] and glutamate after two weeks of MCT [P = 0.0184], respectively. Thalamic gamma-Aminobutyric acid (GABA) levels were increased 2 h after MCT-administration [P = 0.0492]. CSF, blood, and urine analysis did not show any significant intergroup changes. **Conclusion:** MCT-enriched diets have a direct impact on canine brain neurotransmitter levels in areas that may be crucial for seizure generation and propagation. Glutamate reduction and GABA increase might represent one possible anti-seizure mechanism of MCTs. However, those alterations are not present in CSF or other biological fluids.

Scent dog identification of samples from COVID-19 patients - a pilot study.
As the COVID-19 pandemic continues to spread, early, ideally real-time, identification of SARS-CoV-2 infected individuals is pivotal in interrupting infection chains. Volatile organic compounds produced during respiratory infections can cause specific scent imprints, which can be detected by trained dogs with a high rate of precision.

A combination of NMDA and AMPA receptor antagonists retards granule cell dispersion and epileptogenesis in a model of acquired epilepsy.
Epilepsy may arise following acute brain insults, but no treatments exist that prevent epilepsy in patients at risk. Here we examined whether a combination of two glutamate receptor antagonists, NBQX and ifenprodil, acting at different receptor subtypes, exerts antiepileptogenic effects in the intrahippocampal kainate mouse model of epilepsy. These drugs were administered over 5 days following kainate. Spontaneous seizures were recorded by video/EEG at different intervals up to 3 months. Initial trials showed that drug treatment during the latent period led to higher mortality than treatment after onset of epilepsy, and further, that combined therapy with both drugs caused higher mortality at doses that appear safe when used singly. We therefore refined the combined-drug protocol, using lower doses. Two weeks after kainate, significantly less mice of the NBQX/ifenprodil group exhibited electroclinical seizures compared to vehicle controls, but this effect was lost at subsequent weeks. The disease modifying effect of the treatment was associated with a transient prevention of granule cell dispersion and less neuronal degeneration in the dentate hilus. These data substantiate the involvement of altered glutamatergic transmission in the early phase of epileptogenesis. Longer treatment with NBQX and ifenprodil may shed further light on the apparent temporal relationship between dentate gyrus reorganization and development of spontaneous seizures.

Commonalities and differences in extracellular levels of hippocampal acetylcholine and amino acid neurotransmitters during status epilepticus and subsequent epileptogenesis in two rat models of temporal lobe epilepsy.
Chemically or electrically induced status epilepticus (SE) in rodents is a commonly used method for induction of epilepsy. Structural and functional changes in the hippocampus play a pivotal role in epileptogenesis induced by SE. Although cholinergic mechanisms have long been thought to play an important role in the onset and propagation of epileptic seizures, not much is known about the potential role of acetylcholine (ACh) in ictogenesis and epileptogenesis in SE models of temporal lobe epilepsy. Here we used in vivo microdialysis to determine extracellular levels of ACh and, for comparison, several amino acid transmitters in the ventral hippocampus during SE, epileptogenesis, and the chronic epileptic state in two rat models of SE-induced epilepsy. SE was either induced by lithium-pilocarpine or by sustained electrical stimulation of the basolateral amygdala (BLA). ACh increased during SE in both models. Pretreatment with the muscarinic receptor antagonist scopolamine before BLA stimulation reduced SE severity and duration. In contrast to ACh, no consistent changes in amino acid levels were found during SE in the two models. During epileptogenesis and the chronic epileptic state, the only commonalities found in both models were a decrease in ACh in epileptic rats during the chronic epileptic state and a decrease in aspartate during epileptogenesis. The data demonstrate complex, model-dependent alterations in extracellular levels of ACh and amino acid neurotransmitters and only few commonalities. Thus, data originating from only one model of post-SE epilepsy should not be generalized but may have a limited translational value for understanding ictogenesis or epileptogenesis.

Case Report: Embedding "Digital Chronotherapy" Into Medical Devices-A Canine Validation for Controlling Status Epilepticus Through Multi-Scale Rhythmic Brain Stimulation.
Circadian and other physiological rhythms play a key role in both normal homeostasis and disease processes. Such is the case of circadian and infradian seizure patterns observed in epilepsy. However, these rhythms are not fully exploited in the design of active implantable medical devices. In this paper we explore a new implantable stimulator that implements chronotherapy as a feedforward input to supplement both open-loop and closed-loop methods. This integrated algorithm allows for stimulation to be adjusted to the ultradian, circadian and infradian patterns observed in patients through slowly-varying temporal adjustments of stimulation and algorithm sub-components, while also enabling adaption of stimulation based on immediate physiological needs such as a breakthrough seizure or change of posture. Embedded physiological sensors in the stimulator can be used to refine the baseline stimulation circadian pattern as a "digital zeitgeber," i.e., a source of stimulus that entrains or synchronizes the subject's natural rhythms. This algorithmic approach is tested on a canine with severe drug-resistant idiopathic generalized epilepsy exhibiting a characteristic diurnal pattern correlated with sleep-wake cycles. Prior to implantation, the canine's cluster seizures evolved to status epilepticus (SE) and required emergency pharmacological intervention. The cranially-mounted system was fully-implanted bilaterally into the centromedian nucleus of the thalamus. Using combinations of time-based modulation, thalamocortical rhythm-specific tuning of frequency parameters as well as fast-adaptive modes based on activity, the canine experienced no further SE events post-implant as of the time of writing (7 months). Importantly, no significant cluster seizures have been observed either, allowing the reduction of rescue medication. The use of digitally-enabled chronotherapy as a feedforward signal to augment adaptive neurostimulators could prove a useful algorithmic method in conditions where sensitivity to temporal patterns are characteristics of the disease state, providing a novel mechanism for tailoring a more patient-specific therapy approach.

Discrimination of SARS-CoV-2 Infections From Other Viral Respiratory Infections by Scent Detection Dogs.
Testing of possibly infected individuals remains cornerstone of containing the spread of SARS-CoV-2. Detection dogs could contribute to mass screening. Previous research demonstrated canines' ability to detect SARS-CoV-2-infections but has not investigated if dogs can differentiate between COVID-19 and other virus infections. Twelve dogs were trained to detect SARS-CoV-2 positive samples. Three test scenarios were performed to evaluate their ability to discriminate SARS-CoV-2-infections from viral infections of a different aetiology. Naso- and oropharyngeal swab samples from individuals and samples from cell culture both infected with one of 15 viruses that may cause COVID-19-like symptoms were presented as distractors in a randomised, double-blind study. Dogs were either trained with SARS-CoV-2 positive saliva samples (test scenario I and II) or with supernatant from cell cultures (test scenario III). When using swab samples from individuals infected with viruses other than SARS-CoV-2 as distractors (test scenario I), dogs detected swab samples from SARS-CoV-2-infected individuals with a mean diagnostic sensitivity of 73.8% (95% CI: 66.0-81.7%) and a specificity of 95.1% (95% CI: 92.6-97.7%). In test scenario II and III cell culture supernatant from cells infected with SARS-CoV-2, cells infected with other coronaviruses and non-infected cells were presented. Dogs achieved mean diagnostic sensitivities of 61.2% (95% CI: 50.7-71.6%, test scenario II) and 75.8% (95% CI: 53.0-98.5%, test scenario III), respectively. The diagnostic specificities were 90.9% (95% CI: 87.3-94.6%, test scenario II) and 90.2% (95% CI: 81.1-99.4%, test scenario III), respectively. In all three test scenarios the mean specificities were above 90% which indicates that dogs can distinguish SARS-CoV-2-infections from other viral infections. However, compared to earlier studies our scent dogs achieved lower diagnostic sensitivities. To deploy COVID-19 detection dogs as a reliable screening method it is therefore mandatory to include a variety of samples from different viral respiratory tract infections in dog training to ensure a successful discrimination process.

OV329, a novel highly potent γ-aminobutyric acid aminotransferase inactivator, induces pronounced anticonvulsant effects in the pentylenetetrazole seizure threshold test and in amygdala-kindled rats.
An attractive target to interfere with epileptic brain hyperexcitability is the enhancement of γ-aminobutyric acidergic (GABAergic) inhibition by inactivation of the GABA-metabolizing enzyme GABA aminotransferase (GABA-AT). GABA-AT inactivators were designed to control seizures by raising brain GABA levels. OV329, a novel drug candidate for the treatment of epilepsy and addiction, has been shown in vitro to be substantially more potent as a GABA-AT inactivator than vigabatrin, an antiseizure drug approved as an add-on therapy for adult patients with refractory complex partial seizures and monotherapy for pediatric patients with infantile spasms. Thus, we hypothesized that OV329 should produce pronounced anticonvulsant effects in two different rat seizure models.

Canine olfactory detection and its relevance to medical detection.
The extraordinary olfactory sense of canines combined with the possibility to learn by operant conditioning enables dogs for their use in medical detection in a wide range of applications. Research on the ability of medical detection dogs for the identification of individuals with infectious or non-infectious diseases has been promising, but compared to the well-established and-accepted use of sniffer dogs by the police, army and customs for substances such as money, explosives or drugs, the deployment of medical detection dogs is still in its infancy. There are several factors to be considered for standardisation prior to deployment of canine scent detection dogs. Individual odours in disease consist of different volatile organic molecules that differ in magnitude, volatility and concentration. Olfaction can be influenced by various parameters like genetics, environmental conditions, age, hydration, nutrition, microbiome, conditioning, training, management factors, diseases and pharmaceuticals. This review discusses current knowledge on the function and importance of canines' olfaction and evaluates its limitations and the potential role of the dog as a biomedical detector for infectious and non-infectious diseases.

Scopolamine prevents aberrant mossy fiber sprouting and facilitates remission of epilepsy after brain injury.
Prevention or modification of acquired epilepsy in patients at risk is an urgent, yet unmet, clinical need. Following acute brain insults, there is an increased risk of mesial temporal lobe epilepsy (mTLE), which is often associated with debilitating comorbidities and reduced life expectancy. The latent period between brain injury and the onset of epilepsy may offer a therapeutic window for interfering with epileptogenesis. The pilocarpine model of mTLE is widely used in the search for novel

antiepileptogenic treatments. Recent biochemical studies indicated that cholinergic mechanisms play a role in the epileptogenic alterations induced by status epilepticus (SE) in this and other models of mTLE, which prompted us to evaluate whether treatment with the muscarinic antagonist scopolamine during the latent period after SE is capable of preventing or modifying epilepsy and associated behavioral and cognitive alterations in female Sprague-Dawley rats. First, in silico pharmacokinetic modeling was used to select a dosing protocol by which M-receptor inhibitory brain levels of scopolamine are maintained during prolonged treatment. This protocol was verified by drug analysis in vivo. Rats were then treated twice daily with scopolamine over 17 days after SE, followed by drug wash-out and behavioral and video/EEG monitoring up to ~6 months after SE. Compared to vehicle controls, rats that were treated with scopolamine during the latent period exhibited a significantly lower incidence of spontaneous recurrent seizures during periods of intermittent recording in the chronic phase of epilepsy, less behavioral excitability, less cognitive impairment, and significantly reduced aberrant mossy fiber sprouting in the hippocampus. The present data may indicate that scopolamine exerts antiepileptogenic/disease-modifying activity in the lithium-pilocarpine rat model, possibly involving increased remission of epilepsy as a new mechanism of disease-modification. For evaluating the rigor of the present data, we envision a study that more thoroughly addresses the gender bias and video-EEG recording limitations of the present study.

RETROSPECTIVE STUDY OF THE SERUM LEVEL OF LEVETIRACETAM IN FOCAL AND GENERALIZED EPILEPSY RELATED TO SEIZURE FREQUENCY AND SIDE EFFECTS IN A SINGLE CENTER

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Hyoshin Son[1], Inyoung Hwang[2], Ahwon Kim[1], Kyung-Il Park[1], Ki-Young Jung[1], Sang Kun Lee[1]
[1]Seoul National University Hospital, Neurology, Seoul, Korea, Republic of, [2]Seoul National University Hospital, Clinical Pharmacology And Therapeutics, Seoul, Korea, Republic of

Antiepileptic drugs (AEDs) are the basic treatment for epilepsy. Levetiracetam is known to affect the synaptic vesicle protein Sv2A. Considering the variability in clinical situations of each patient, or center-dependent, affecting seizure-free rate or adverse drug reactions, the subdivided therapeutic range of levetiracetam in epilepsy patients in a single center and their clinical characteristics were retrospectively analyzed in this study. Data were collected and retrospectively reviewed for patients who were diagnosed with focal (mainly temporal lobe epilepsy) and generalized epilepsy and visited the neurology outpatient center or were admitted to the Seoul National University Hospital from January 19, 2016 (when laboratory results for the concentration of levetiracetam began) to December 31, 2020. In this study, seizure freedom was achieved in >60% of all three groups in each focal and generalized epilepsy group with levetiracetam. In the cases of focal epilepsy, seizure-free rates tended to be higher with increasing levetiracetam concentrations; however, the statistical significance was not clear. In the cases of generalized epilepsy, seizure-free rates did not show significant change according to the serum level. The frequency of adverse drug reactions tended to be higher in the moderate- and high-dose groups than in the low-dose group in focal epilepsy, although this difference was not statistically significant. There was no case of adverse drug reactions in generalized epilepsy group. Further studies with multiple factors with a larger number of patients will guarantee the detailed implications of levetiracetam concentration related to drug efficacy and adverse drug reactions in real clinical situations.

RETINAL DYSFUNCTION IN A MOUSE MODEL OF HCN1 DEVELOPMENTAL EPILEPTIC ENCEPHALOPATHY

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Christopher Reid[1], Bang Bui[2], Da Zhao[2], Paulo Pinares-Garcia[1], Ian Forster[1], Chaseley Mckenzie[1], Vickie Wong[2], Lauren Bleakley[1]
[1]Florey Institute of Neuroscience and Mental Health, Neurophysiology Of Excitable Networks Laboratory, PARKVILLE, Australia, [2]University of Melbourne, Vision, Parkville, Australia

Pathogenic variants in *HCN1* are associated with a range of epilepsy syndromes including developmental epileptic encephalopathies (DEE). As HCN1 channels are highly expressed in rod and cone photoreceptor inner segments, mutated HCN1 channels are likely to impact visual function in HCN1 DEE. The recurrent *de novo* HCN1 (M305L) pathogenic variant results in a gain-of-function allowing the flux of excitatory ions at depolarised potentials. The $Hcn1^{M294L}$ mouse recapitulates the seizure and behavioral phenotypes seen in patients. Electroretinogram (ERG) recordings from $Hcn1^{M294L}$ mice revealed a significant decrease in the photoreceptor sensitivity to light, as well as attenuated bipolar cell and retinal ganglion cell response amplitudes. $Hcn1^{M294L}$ mice were also unable to respond to high rates of flicker light. There was no impact of the variant on the structure of the eye or the expression of the Hcn1 protein in the retina. *In silico* modelling of photoreceptors revealed that the mutated HCN1 channel dramatically reduced light-induced hyperpolarision, decreasing the Ca^{2+} current amplitude change in response to light. Given the tight relationship between Ca^{2+} and transmitter release the dynamic range of the change of glutamate released from photoreceptors during a light stimulus will be significantly blunting. Patients with HCN1 pathogenic variants are likely to have a dramatically reduced sensitivity to light and a limited ability to process temporal information. Our results provide insights into the role HCN1 channels play in retinal function, as well as highlighting the need to consider retinal dysfunction in disease caused by HCN1 variants.

ABSENCE-SEIZURE BLOCKADE RESCUES REM SLEEP IMPAIRMENT IN A RAT MODEL OF SYNGAP1 HAPLOINSUFFICIENCY

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Ingrid Buller-Peralta[1], Katerina Hristova[1], Alejandro Bassi[2], Adrian Ocampo[2], Melissa Fasol[1], Sally Till[1], Peter Kind[1], Alfredo Gonzalez-Sulser[1]
[1]University of Edinburgh Centre for Discovery Brain Sciences, Simons Initaitive For The Developing Brain, Edinburgh, United Kingdom, [2]Universidad de Chile, Laboratorio De Sueño Y Cronobiología, Santiago, Chile

SYNGAP1 haploinsufficiency is one of the primary genetic causes of paediatric epilepsy and neurodevelopmental disorders, resulting in absence seizures, severe intellectual disability, autism and sleep disturbances. We previously found that a novel SYNGAP1 rat model replicates the primary epilepsy type in patients, absence seizures. Spontaneous spike and wave discharges (SWDs), the electrophysiological correlate of absence seizures were also blocked in *Syngap*$^{+/\Delta Gap}$ rats by acute treatment with the anti-epileptic drug ethosuximide (ETX). Here we assessed sleep impairments in *Syngap*$^{+/\Delta Gap}$ rats and tested whether seizure blockade rescued sleep abnormalities. *Syngap*$^{+/\Delta Gap}$ rats and wildtype littermates were implanted with a skull surface EEG array with neck EMG electrodes and chronically recorded through a wireless acquisition system. Circadian recordings were performed and animals were given acute ETX or saline.
Syngap$^{+/\Delta Gap}$ rats showed an increased number of SWDs through the whole circadian cycle coupled with shortened rapid eye movement (REM) sleep bouts, resulting in an overall REM decrease. *Syngap*$^{+/\Delta Gap}$ rats displayed less and longer wake and non-REM sleep bouts, although total minutes were equivalent between genotypes. ETX blocked SWDs in *Syngap*$^{+/\Delta Gap}$ rats during the estimated drug half-life time and reverted the REM sleep deficit by increasing the number of REM bouts. Non-REM sleep bout number and durations were also normalized although no effect was observed in wake. Our results suggest that seizure activity impairs sleep, although ETX may have a direct effect on sleep independent of SWDs. In future we will assess how seizures and decreased REM may contribute to social cognitive deficits in *SYNGAP1* haploinsufficiency.

IMPACT OF AGING ON PENTYLENETETRAZOLE-INDUCED EPILEPSY IN RATS: POSSIBLE ROLE OF OXIDATIVE STRESS AND NRF2/HO-1 PATHWAY

POSTER SESSION 07 - SECTION: CLINICAL AND EXPERIMENTAL EPILEPSY MODELS

Abdelaziz Hussein, Walaa Obydah, Asmaa Yehia, Somaya Saad
Mansoura faculty of Medicine, Medical Physiology, Mansoura, Egypt

Aim: To examine the impact of aging on the response of rats to PTZ-induced epilepsy and the possible role of oxidative stress and Nrf2/HO-1 pathway in this response. **Methods**: forty male albino rats were allocated into 4 equal groups; 1) normal young control (YC) group, aged 8-12 weeks, 2) normal old control (OC) group, aged 24 months, 3) PTZ-Young group: young rats received PTZ (50 mg/Kg, i.p. every other day) for 2 weeks and 4) PTZ-Old group: as group 3 but old rats. The latency for the first jerk and the seizure score were assessed in rats as well as markers of oxidative stress (MDA, catalase and total antioxidant capacity (TAC)) and the relative expression of Nrf2 and HO-1 at the level of mRNA in brain tissues were done at the end of experiment. **Results:** old rats showed early and significant increase in seizure score with PTZ administration and significant decrease in seizure latency compared to young rats (p<0.01). Also, the concentration of MDA was significantly higher, while TAC and catalase activity were significantly lower in old rats than young rats (p<0.01). Moreover, the expression of Nrf2 and HO-1 was significantly decreased in old normal rats compared to normal young rats with PTZ administration (p< 0.01). **Conclusion**: aging increases the vulnerabilities of rats to PTZ-induced epilepsy. This might be due to upregulation of oxidative stress and down regulation of the antioxidant genes including Nrf2 and HO-1.

BEHAVIORAL ASSESSMENT OF THE PARKINSON'S DISEASE MOUSE MODEL OF HUMAN TYROSINASE OVEREXPRESSION IN THE LOCUS COERULEUS

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Andres Jaramillo[1], Csilla Novák[2], Frank Angestein[3], Matthew Betts[4], Constanze Seidenbecher[5], Matthias Prigge[2]
[1]Leibniz Institute for Neurobiology, Team Prigge, Magdeburg, Germany, [2]Leibniz Institute for Neurobiology, Neuromodulatory Networks, Magdeburg, Germany, [3]German Center for Neurodegenerative Disease, Functional Neuroimaging, Magdeburg, Germany, [4]Institute of Cognitive Neurology and Dementia Research (IKND), Imaging Subcortical Systems In Aging And Disease, Magdeburg, Germany, [5]Leibniz Institute for Neurobiology, Department Of Behavioral Neurology, Magdeburg, Germany

The function of the locus coeruleus (LC) becomes impaired before the more prototypical degeneration of substantia nigra pars compacta during the pathogenesis of Parkinson's disease (PD). Despite the identification of some indicative symptoms during the early, prodromal stage of PD, such as REM sleep behavior disorder or anosmia, these are not sufficient for accurate diagnosis. Therefore, PD can only be diagnosed when the typical motor symptoms appear. At that stage, neuroprotective interventions are limited, since several dopaminergic neurons have already suffered irreversible damage or they are apoptotic. Our work was set out to develop early diagnostic functional biomarkers inspired by early circuit dysfunction of the LC network. We use the human tyrosinase overexpression mouse model as a proxy for progressive neuromelanin-induced neurodegeneration of the LC in mice. We present a behavioral evaluation of physiological fitness of the LC using a battery that includes the open field, marble burying, elevated plus maze and free locomotion tests. We implemented a hypothesis-free motif detection program (Variational Animal Motion Embedding / VAME) that detects subtle changes in locomotion that are otherwise extremely difficult to observe. We observed differences in locomotor activity between the tyrosinase-expressing group and the control group. We believe that neuronal circuit-derived psychophysical and behavioral tests implemented in slow progression mouse models of PD can contribute to the discovery of novel non-motor symptoms in human PD patients, which in turn will help to diagnose Parkinson's disease in early stages and expand the therapeutic window.

Background: Parkinson's disease (PD) is characterized by the formation of proteinaceous aggregates of α-synuclein (α-syn) in cell bodies and neurites of *Substantia Nigra pars compacta* (SNpc) dopaminergic neurons, eventually causing cell death. Interestingly, defective activity or mutations in GBA1, the gene coding for lysosomal enzyme Glucocerebrosidase (GCase), are the strongest risk factor to develop PD. Based on this evidence, GCase may represent a new therapeutic target to oppose α-syn accumulation in PD. **Aim**: To evaluate the therapeutic potential of the novel GCase enhancer CF30 against the accumulation of toxic A53T α-syn species with *in vitro* and *in vivo* PD models. **Methods**: Chaperone-induced GCase enhancement was assayed in SHSY cell cultures and in the striatum of mice. To assess the impact of molecular chaperones on motor skills, neurochemical content and cellular pathology, behavioural, biochemical and histological analyses were performed after 3 weeks of a chronic treatment with CF30 in C57Bl6 mice following unilateral injection of a AAV1/2 α-synA53T into the SNpc. **Results:** CF30 is well tolerated at effective concentration/dosage in cell lines and in vivo. GCase activity is enhanced by, respectively, 40 and 18%. Plasma and brain kinetics indicate good oral availability and brain penetrance. Preliminary efficacy test on the A53T α-syn mouse model indicate that the compound does not reduce total α-syn accumulation in the striatum or in the SNpc. However, CF30 seems to reduce the ratio between pSer129 α-syn and total α-syn, suggesting that the compound may be effective to prevent deposition of α-syn aggregates.

Moderate ethanol drinking is sufficient to alter Ventral Tegmental Area dopamine neurons activity via functional and structural remodeling of GABAergic transmission.
Earlier studies have shown a major involvement of Ventral Tegmental Area (VTA) dopamine (DA) neurons in mediating the rewarding effects of ethanol (EtOH). Much less is known on the role of this system in mediating the transition from moderate to excessive drinking and abuse. Here we sought to explore the hypothesis that early stage drinking in rodents, resembling recreational EtOH use in humans, is sufficient to dysregulate VTA DA transmission thus increasing the propensity to use over time. To this purpose, midbrain slice recordings in mice previously exposed to an escalating (3, 6 and 12%) 18-day voluntary EtOH drinking paradigm was used. By recording from DA and γ-aminobutyric acid (GABA) VTA neurons in midbrain slices, we found that moderate EtOH drinking leads to a significant suppression of the spontaneous activity of VTA DA neurons, while increasing their response to acute EtOH application. We also found that chronic EtOH leads to the enhancement of GABA input frequency onto a subset of DA neurons. Structurally, chronic EtOH induced a significant increase in the number of GABA axonal boutons contacting DA neurons, suggesting deep rewiring of the GABA network. This scenario is consistent with a downmodulation of the reward DA system induced by moderate EtOH drinking, a neurochemical state defined as "hypodopaminergic" and previously associated with advanced stages of drug use in humans. In this context, increased sensitivity of DA neurons towards acute EtOH may represent the neurophysiological correlate of increased unitary rewarding value, possibly driving progression to addiction.

ALTERED RESTING-STATE FUNCTIONAL BRAIN NETWORK IN PARKINSON'S DISEASE WITH MAJOR AND MINOR VISUAL HALLUCINATION

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Yae Ji Kim[1], Yong Jeong[2]
[1]Korea Advanced Institute of Science and Technology, Brain And Cognitive Engineering, Daejeon-si, Korea, Republic of, [2]Korea Advanced Institute of Science and Technology, Bio And Brain Engineering, Daejeon-si, Korea, Republic of

Visual hallucination (VH) is the most common psychosis in Parkinson’s disease (PD). Based on the symptoms, VH is categorized into major hallucination (MH) and minor hallucination (mH). Previous studies have reported alterations in resting-state networks (RSNs) underlying VH mechanisms, but differences between MH and mH are still elusive. In this regard, this study aims to investigate different RSNs in MH and mH in PD. 69 PD patients (23 MH, 22 mH, 24 without VH (nH)) were enrolled in this study. Seeds were selected for RSNs: LPC/PCC for default mode (DMN); TPJ for ventral and FEF/IPS for dorsal attention (VAN, DAN); V1 for visual (VN). Seed-to-voxel analysis is then conducted to examine intra-network relationships between the groups. To investigate inter-network among the groups, we performed ROI-to-ROI analysis for each pair of networks. In seed-based analysis, compared to nH, MH and mH patients demonstrated greater connectivity between the right LPC of DMN and the left frontal orbital cortex; decreased connectivity between right TPJ of VAN and precuneus cortex; between right FEF of DAN and posterior middle temporal gyrus and precuneus cortex. Inter-network of DMN-VAN connectivity exhibited significant increases in MH than mH. Moreover, DAN-VAN connectivity showed significant decreases in MH compared to nH. The present study demonstrated the disrupted attention networks, but the aberrant pattern in DMN in both MH and mH compared to controls. The result also indicates DMN and VAN are strongly wired in MH than mH. This study provides novel insights into the different mechanisms of major and minor hallucination.

PROTEOMIC AND STEREOLOGICAL STUDY: SYNAPTIC INVOLVEMENT OF HUMAN AMYGDALA IN PARKINSON'S DISEASE

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Sandra Villar-Conde[1], Melania Gonzalez-Rodriguez[1], Veronica Astillero-Lopez[1], Daniel Saiz-Sanchez[1], Isabel Ubeda-Banon[1], Alino Martinez-Marcos[2], Alicia Flores-Cuadrado[1]
[1]UNIV. CASTILLA-LA MANCHA, Facultad De Medicina De Ciudad Real, CIUDAD REAL, Spain, [2]UNIVERSIDAD DE CASTILLA-LA MANCHA, Facultad De Medicina De Ciudad Real, CIUDAD REAL, Spain

Emotional deficits are common symptoms in Parkinson's disease (PD). The amygdala involvement by α-synuclein (Braak stage 3) could constitute neural substrates underlying these manifestations. Differential α-synucleinopathy between amygdaloid nuclei has been described. MRI and VBM studies have revealed volumetric changes with conflicting results. Only one stereological study has analyzed neuronal population, but glial populations have been neglected. Likewise, proteomic analyses focused on amygdala in PD are lacking. The present work analyzed the area fraction occupied by Lewy bodies (LB), volumetric and glial changes and proteomic alterations in the amygdala in PD. Brains from 18 PD (Braak 5-6) and 18 non-PD age-matched subjects were obtained from Spanish Biobank network. Area fraction occupied by LB was analyzed by Area Fraction Fractionator. Cavalieri's method was used for volume estimation. Microglial and astroglial populations were estimated by Optical Fractionator. Dia-PASEF and MALDI were used for the proteomic study. No volumetric changes were detected and a homogeneous distribution of LB in the different amygdaloid nuclei were reported. No changes in the Iba-1 and GFAP density were either observed. Proteomic data revealed 17 up- and 24 downregulated proteins in the amygdala with PD. Although changes in cell populations have not been detected, functional impairment related to the amygdala in PD may be due to alterations at the proteomic level likely related to synapses, mitochondrial damage, and the immune response. This work is sponsored by the UCLM/ERDF (2021-GRIN-31233to NPND), the Spanish MEC/ERDF (SAF2016-75768-R) and MCI (PID2019-108659RB-I00) and the JCCM/ERDF (SBPLY/17/180501/000430). SVC and MGR held a fellowship UCLM/ESF.

The Human Hippocampus in Parkinson's Disease: An Integrative Stereological and Proteomic Study.
Parkinson's disease (PD) is a prevalent neurodegenerative disease that is pathologically described as a six-stage α-synucleinopathy. In stage 4, α-synuclein reaches the hippocampus, inducing cognitive deficits, from which it progresses to the isocortex, leading to dementia. Among hippocampal fields, cornu ammonis 2 is particularly affected by this α-synucleinopathy and critical for cognitive decline. Volumetric studies using magnetic resonance imaging have produced controversial results, with only some reporting volume loss, whereas stereological data obtained using nonspecific markers do not reveal volume changes, neural or glial loss. Proteomic analysis has not been carried out in the hippocampus of patients with PD.

O-CYCLIC PHYTOSPHINGOSINE-1-PHOSPHATE PROTECTS AGAINST NEURODEGENERATION IN THE PARKINSON'S DISEASE MOUSE MODEL

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Myeong Ok Kim[1,2], Hyeon Jin Lee[1], Jun Sung Park[1], Min Woo Kim[1], Kyong Hwan Choe[1,3], Bart Rutten[3]
[1]Gyeongsang National University, Division Of Life Science And Applied Life Science, Jinju, Korea, Republic of, [2]Alz-Dementia Korea Co, Alz-dementia Korea Co, Jinju, Korea, Republic of, [3]Maastricht University, Department Of Psychiatry And Neuropsychology, Maastricht, Netherlands

The present study was undertaken to unveil the potential neuroprotective effects of O-cyclic phytosphingosine-1-phosphate (cPS1P) against mouse models of Parkinson's disease (PD). cPS1P is a novel and chemically synthesized sphingosine metabolite derived from phytosphingosine-1-phosphate (PS1P). To unveil the protective effects of cPS1P against Parkinson's disease, we used MPTP and NSE-hαSyn Korl transgenic mice, MPTP was injected at a dose of 30mg/Kg/per day for 5 days, and the cPS1P 1mg/Kg/day intraperitoneally. We have used behavioral, biochemical, and immunofluorescence stainings for the analysis. We have used the open field test, wire hanging test, pole test, and rotarod test. The behavioral results suggested that in the PD-models there was a significant loss in the motor functions, which were reversed with the administration of cPS1P. Similarly, as hypothesized, in the MPTP and NSE-hαSyn Korl transgenic mice, the expression of the S1P1 receptor was significantly reduced, compared to the control group, which was enhanced in the cPS1P injected mice. Similarly, we checked the expression of inflammatory cytokines in the experimental mice brains, which suggested that in the MPTP and NSE-hαSyn Korl transgenic mice, the expression of these markers was significantly enhanced, compared to the control group. Interestingly, these markers were reversed in the cPS1P co-injected mice brains. The overall studies supported the notion that cPS1P may act as a specific agonist of S1PR1 which reduces the PD-associated symptoms in the preliminary animal's studies. DETERMINATION OF THE NUMBER OF CNVS IN THE SNCA GENE BY DDPCR

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Mélanie Ferrien[1], Christelle Tesson[1], Agnes Rastetter[1], Suzanne Lesage[1], Jean-Christophe Corvol[2], Alexis Brice[3]
[1]Sorbonne University, Brain Institute - Paris Brain Institute - ICM, Inserm, CNRS, APHP, Pitié Salpêtrière Hospital, PARIS, France, [2]APHP, Hôpital de la Pitié Salpêtrière, Department Of Neurology, PARIS, France, [3]Sorbonne Université, Institut du Cerveau - Paris Brain Institute - ICM, Inserm, CNRS, APHP, Hopital De La Pitie Salpetriere, Paris, France

Digital droplet PCR (ddPCR) is an assay that combines state-of-the-art microfluidics technology with TaqMan-based PCR to achieve precise target DNA quantification. Point mutations and exon rearrangements (deletions, duplications and triplications) in PRKN, PINK1, DJ-1, LRRK2, and SNCA are the main causes of rare monogenic forms of Parkinson's disease (PD). Herein, we applied this technology 1) to validate screened copy number variations (CNVs) detected either by Multiplex Ligation Probe Assay (MLPA) or by targeted Next Generation Sequencing (NGS) technique and where available to conduct segregation analysis; 2) to accurately phase genomic variants in carriers of double heterozygous variants, in absence of familial co-segregation. We tested five PD patients with heterozygous SNCA multiplications detected either by MLPA (n = 2) or by custom gene panel (n = 3) and one patient without SNCA multiplications as a negative internal control. ddPPCR analysis revealed four patients with whole SNCA gene duplications and one patient with gene triplication, suggesting this technique rapid, reliable and sensitive. Phasing PRKN double heterozygous mutations carried by single PD patients using this ddPCR technique is under progress.

THE ROLE OF ETHNO-RACIAL FACTORS IN ASSESSING RISK FOR PARKINSON'S DISEASE

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Sara Siddiqi[1], Juan Li[2], Kamaya Lawrence[1], Abigail Morris[1], Kim Matheson[1], Paul Villeneuve[1,3], Julianna Tomlinson[2], Michael Schlossmacher[2], Natalina Salmaso[1]
[1]Carleton University, Neuroscience, Ottawa, Canada, [2]University of Ottawa, Brain And Mind Research Institute, Ottawa, Canada, [3]Carleton University, School Of Mathematics And Statistics, Ottawa, Canada

Aims: Parkinson's Disease (PD) risk research includes factors from genetics to the environment. To date, there is a lack of large-scale multifactorial studies that investigate a definitive link between race/ethnicity and PD risk. We conducted a targeted literature review to quantify the inclusion of ethno-racial factors in the context of PD risk. Furthermore, we employed a dataset of human PD incidences to validate trends observed in the literature. **Methods:** We conducted a PubMed search including articles published in 2000-2020 with the following MeSH terms: PD/diagnosis/risk factors/incidence/epidemiology. Data visualizations of variables related to PD risk factors and race were completed using the *Fox Insight* database (https://foxinsight-info.michaeljfox.org/insight/explore/insight.jsp) on 04/07/2021. For up-to-date information on the study, visit https://foxinsight-info.michaeljfox.org/insight/explore/insight.jsp. **Results:** Out of 410 total articles, only 5% accounted for ethno-racial factors as an integral part of analysis. A few studies identified significant differences in PD incidence whereby African Americans are less likely to be diagnosed with PD than Caucasian individuals. Data analyses indicated PD diagnosis was associated with race, and male sex was associated with an increased risk of PD, regardless of race. **Conclusions:** Differences in PD incidence across race/ethnicity may be related to a combination of factors including access to health care, genetics and environmental factors. These findings highlight the need for further PD studies with diverse cohorts. **Acknowledgements:** The Fox Insight Study (FI) is funded by The Michael J. Fox Foundation for Parkinson's Research. We would like to thank the Parkinson's community for participating in this study to make this research possible.

ESTABLISHING THE VALIDITY OF A NOVEL PERCEPTUAL TASK FOR PARKINSON DISEASE

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Brenda Hanna-Pladdy[1], Kelly Lyons[2]
[1]University of Maryland School of Medicine, Center For Advanced Imaging Research (cair), Department Of Diagnostic Radiology & Nuclear Medicine,, Baltimore, United States of America, [2]University of Kansas Medical Center, Parkinson's Disease And Movement Disorder Center, Department Of Neurology, Kansas City, United States of America

Aims: This study aimed to establish the validity of a novel perceptual paradigm designed to optimize detection of spatial deficits in Parkinson disease (PD) segregated from movement deficits. Discriminant analyses determined which perceptual tasks best differentiated between PD patients and healthy controls. **Methods:** Study participants (n=141; mean age=66) included non-demented PD patients (n=99; H&Y<2.5; RMO=53, LMO=46) and healthy controls (n=42) with similar male to female ratios (PD 70/29; C 25/17). Perceptual accuracy of interval spaces of three horizontal lines (width interval) and two line lengths in vertical and horizontal orientations (length equivalence) were quantified through verbal responses of the same or different. A custom program (Neurobehavioral systems) presented 4 second stimulus pairs for comparison across 48 trials randomized for line lengths (4, 8, 12 cm) and discrimination difficulty. **Results:** Discriminant function analyses revealed that perceptual accuracy correctly classified 85.9% of PD patients based on length equivalence (p=.036) for 4 (p=.037) and 12 cm lines (p=.002), and 4 cm width interval estimations (p<.001). Conversely, 84.9% of RMO PD patients were correctly classified by width interval estimations (p=.029) at 4 and 12 cm (p<.02), and length equivalence at 12 cm (p=.006). In contrast, perceptual accuracy was not reliable in classifying LMO patients and healthy controls. **Conclusions:** Overall, the findings confirm the presence of visuoperceptual impairment early in the disease process separate from movement deficits, and highlights the need to validate sensitive tests of spatial accuracy specifically tailored to capture PD heterogeneity and improve prediction of risk for cognitive decline.

PARKINSON´S DISEASE AND DBS: THE INFLUENCE OF GENDER IN COGNITIVE OUTPUTS

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Cristina Nombela Otero[1], Jennifer Jiménez[2], Gustavo Fernández Pajarín[3], Ángel Sesar[3], Isabel Jimenez[3], Juan Martín-Rodriguez[4], Fernando Alonso-Frech[5]
[1]Universidad Autónoma de Madrid, Biological And Health Psychology, Madrid, Spain, [2]Asociación Parkinson Madrid, Innovation And Research, Madrid, Spain, [3]Complejo Hospitalario de Santiago, Neurología, Santiago de Compostela, Spain, [4]Instituto de Biomedicina de Sevilla, Trastornos Del Movimiento, Sevilla, Spain, [5]Hospital Clínico San Carlos, Neurología, Madrid, Spain

Aims. The action mechanism of Deep Brain Stimulation (DBS) points at restoring the dysbalanced neuronal networks in Basal Ganglia. In general terms, patients with Parkinson´s disease (PD) may impair cognitive performance after surgery. Recent gender studies on PD indicate that the preliminary symptoms and subsequent ones may vary between genders. Most PD patients undergoing DBS (PD-DBS) are male, and retrospective studies showed a differential effect on cognition outputs after DBS. We hypothesize that women will benefit from DBS more than men on a cognitive basis, whereas males may increase the cognitive deficits assessed at baseline. Methods. A sample of 20 DBS-PD patients (6 female and fourteen male) underwent DBS surgery at the Hospital Clínico San Carlos. We conducted a retrospective analysis of published data (Avecillas-Chasín et al., 2019), including the gender variable with baseline (presurgery) and two years after surgery data (follow-up). Results Data showed that female patients benefit more than men from the therapy, presenting higher scores in general cognitive assessments questionnaires (MEC -Mini Examen Cognoscitivo-, and Mattis Dementia Rating Scale) at follow-up. Male scored lower on specific neuropsychological scales (Verbal free recall of The Hopkins Verbal Learning Test, and speed processing of TMT-A test, among others. In the following months, new data will be added to the sample. Conclusions. Gender may be mediating the differential effect described in DBS outputs. The analysis of these differences would shed some light on understanding the disorder and how to treat it.

Fibromyalgia Detection Based on EEG Connectivity Patterns.
The identification of a complementary test to confirm the diagnosis of FM. The diagnosis of fibromyalgia (FM) is based on clinical features, but there is still no consensus, so patients and clinicians might benefit from such a test. Recent findings showed that pain lies in neuronal bases (pain matrices) and, in the long term, chronic pain modifies the activity and dynamics of brain structures. Our hypothesis is that patients with FM present lower levels of brain activity and therefore less connectivity than controls.

Women Neuroscientist Disciples of Pío del Río-Hortega: the Cajal School Spreads in Europe and South America.
Pio del Rio-Hortega was not only the discoverer of the microglia and oligodendroglia but also possibly the most prolific mentor of all Santiago Ramon y Cajal's disciples (Nobel awardee in Physiology or Medicine 1906 and considered as the father of modern Neuroscience). Among Río-Hortega's mentees, three exceptional women are frequently forgotten, chronologically: Pio's niece Asunción Amo del Río who worked with Río-Hortega at Madrid, Paris, and Oxford; the distinguished British neuropathologist Dorothy Russell who also worked with Pío at Oxford; and Amanda Pellegrino de Iraldi, the last mentee in his career. Our present work analyzes the figures of these three women who were in contact and collaborated with Pío del Río-Hortega, describing the influences received and the impact on their careers and the History of Neuroscience. The present work completes the contribution of women neuroscientists who worked with Cajal and his main disciples of the Spanish Neurological School both in Spain (previous work) and in other countries (present work).

The Women Neuroscientists in the Cajal School.
At the beginning of the 20th century, in view of the growing international recognition of Santiago Ramón y Cajal, the Spanish

authorities took some important steps to support Cajal's scientific work. This recognition peaked in 1906, when Camillo Golgi and Santiago Ramón y Cajal shared the Nobel Prize in Physiology or Medicine. The Spanish government provided Cajal a state-of-the-art laboratory in Madrid to allow him to continue with his research and they funded salaries to pay his first tenured collaborators, the number of which increased further after the creation of the . The was an organism set up to help promising researchers develop their careers in different ways, thereby contributing to the development of science in Spain. Although largely forgotten or relatively unknown, there has been a recent revival in the recognition of the school that developed around Cajal, collectively referred to as the Spanish Neurological School (or colloquially, as the Cajal School or School of Madrid). Almost all Cajal's collaborators were men, although a limited number of female scientists spent part of their careers at the heart of the Cajal School. Here we discuss these women and their work in the laboratory in Madrid. We have tracked the careers of Laura Forster (from Australia/United Kingdom), Manuela Serra, María Soledad Ruiz-Capillas and María Luisa Herreros (all Spanish), through their scientific publications, both in the journal founded by Cajal and elsewhere, and from other documentary sources. To complete the picture, we also outline the careers of other secondary figures that contributed to the production and running of Cajal's laboratory in Madrid. We show here that the dawn of Spanish neuroscience included a number of contributions from female researchers who to date, have received little recognition.

Hypothalamic volume loss is associated with reduced melatonin output in Parkinson's disease.
Recent studies have suggested that melatonin-a hormone produced by the pineal gland under circadian control-contributes to PD-related sleep dysfunction. We hypothesized that degenerative changes to the neural structures controlling pineal function (especially the suprachiasmatic nuclei of the anterior hypothalamus) may be responsible for reduced melatonin output in these patients. We compared hypothalamic volumes in PD patients with matched controls and determined whether volume loss correlated with reduced melatonin output in the PD group.

Genetic impact on cognition and brain function in newly diagnosed Parkinson's disease: ICICLE-PD study.
Parkinson's disease is associated with multiple cognitive impairments and increased risk of dementia, but the extent of these deficits varies widely among patients. The ICICLE-PD study was established to define the characteristics and prevalence of cognitive change soon after diagnosis, in a representative cohort of patients, using a multimodal approach. Specifically, we tested the 'Dual Syndrome' hypothesis for cognitive impairment in Parkinson's disease, which distinguishes an executive syndrome (affecting the frontostriatal regions due to dopaminergic deficits) from a posterior cortical syndrome (affecting visuospatial, mnemonic and semantic functions related to Lewy body pathology and secondary cholinergic loss). An incident Parkinson's disease cohort (n = 168, median 8 months from diagnosis to participation) and matched control group (n = 85) were recruited to a neuroimaging study at two sites in the UK. All participants underwent clinical, neuropsychological and functional magnetic resonance imaging assessments. The three neuroimaging tasks (Tower of London, Spatial Rotations and Memory Encoding Tasks) were designed to probe executive, visuospatial and memory encoding domains, respectively. Patients were also genotyped for three polymorphisms associated with cognitive change in Parkinson's disease and related disorders: (i) rs4680 for COMT Val158Met polymorphism; (ii) rs9468 for MAPT H1 versus H2 haplotype; and (iii) rs429358 for APOE-ε2, 3, 4. We identified performance deficits in all three cognitive domains, which were associated with regionally specific changes in cortical activation. Task-specific regional activations in Parkinson's disease were linked with genetic variation: the rs4680 polymorphism modulated the effect of levodopa therapy on planning-related activations in the frontoparietal network; the MAPT haplotype modulated parietal activations associated with spatial rotations; and APOE allelic variation influenced the magnitude of activation associated with memory encoding. This study demonstrates that neurocognitive deficits are common even in recently diagnosed patients with Parkinson's disease, and that the associated regional brain activations are influenced by genotype. These data further support the dual syndrome hypothesis of cognitive change in Parkinson's disease. Longitudinal data will confirm the extent to which these early neurocognitive changes, and their genetic factors, influence the long-term risk of dementia in Parkinson's disease. The combination of genetics and functional neuroimaging provides a potentially useful method for stratification and identification of candidate markers, in future clinical trials against cognitive decline in Parkinson's disease.

Alpha-theta effects associated with ageing during the Stroop test.
The Stroop effect is considered as a standard attentional measure to study conflict resolution in humans. The response of the brain to conflict is supposed to change over time and it is impaired in certain pathological conditions. Neuropsychological Stroop test measures have been complemented with electroencephalography (EEG) techniques to evaluate the mechanisms

in the brain that underlie conflict resolution from the age of 20 to 70. To study the changes in EEG activity during life, we recruited a large sample of healthy subjects of different ages that included 90 healthy individuals, divided by age into decade intervals, which performed the Stroop test while recording a 14 channel EEG. The results highlighted an interaction between age and stimulus that was focused on the prefrontal (Alpha and Theta band) and Occipital (Alpha band) areas. We concluded that behavioural Stroop interference is directly influenced by opposing Alpha and Theta activity and evolves across the decades of life.

Multiple modes of impulsivity in Parkinson's disease.
Cognitive problems are a major factor determining quality of life of patients with Parkinson's disease. These include deficits in inhibitory control, ranging from subclinical alterations in decision-making to severe impulse control disorders. Based on preclinical studies, we proposed that Parkinson's disease does not cause a unified disorder of inhibitory control, but rather a set of impulsivity factors with distinct psychological profiles, anatomy and pharmacology. We assessed a broad set of measures of the cognitive, behavioural and temperamental/trait aspects of impulsivity. Sixty adults, including 30 idiopathic Parkinson's disease patients (Hoehn and Yahr stage I-III) and 30 healthy controls, completed a neuropsychological battery, objective behavioural measures and self-report questionnaires. Univariate analyses of variance confirmed group differences in nine out of eleven metrics. We then used factor analysis (principal components method) to identify the structure of impulsivity in Parkinson's disease. Four principal factors were identified, consistent with four different mechanisms of impulsivity, explaining 60% of variance. The factors were related to (1) tests of response conflict, interference and self assessment of impulsive behaviours on the Barrett Impulsivity Scale, (2) tests of motor inhibitory control, and the self-report behavioural approach system, (3) time estimation and delay aversion, and (4) reflection in hypothetical scenarios including temporal discounting. The different test profiles of these four factors were consistent with human and comparative studies of the pharmacology and functional anatomy of impulsivity. Relationships between each factor and clinical and demographic features were examined by regression against factor loadings. Levodopa dose equivalent was associated only with factors (2) and (3). The results confirm that impulsivity is common in Parkinson's disease, even in the absence of impulse control disorders, and that it is not a unitary phenomenon. A better understanding of the structure of impulsivity in Parkinson's disease will support more evidence-based and effective strategies to treat impulsivity.

Into the groove: can rhythm influence Parkinson's disease?
Previous research has noted that music can improve gait in several pathological conditions, including Parkinson's disease, Huntington's disease and stroke. Current research into auditory-motor interactions and the neural bases of musical rhythm perception has provided important insights for developing potential movement therapies. Specifically, neuroimaging studies show that rhythm perception activates structures within key motor networks, such as premotor and supplementary motor areas, basal ganglia and the cerebellum - many of which are compromised to varying degrees in Parkinson's disease. It thus seems likely that automatic engagement of motor areas during rhythm perception may be the connecting link between music and motor improvements in Parkinson's disease. This review seeks to describe the link, address core questions about its underlying mechanisms, and examine whether it can be utilized as a compensatory mechanism.

EXAMINATION OF PITUITARY ADENYLATE CYCLASE-ACTIVATING POLYPEPTIDE IN PARKINSON'S DISEASE FOCUSING ON CORRELATIONS WITH MOTOR SYMPTOMS

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Andrea Dr. Tamas[1], Daniel Pham[1], Beata Polgar[2], Tunde Toth[1], Adel Jungling[1], Balazs Daniel Fulop[1], Norbert Kovacs[3], Endre Pal[3], Istvan Balas[4], Dora Szabo[1], Robert Herczeg[5], Attila Gyenesei[5], Zalan Szanto[6], Dora Reglodi[1]
[1]Medical School, University of Pecs, Department Of Anatomy, Mta-pte Pacap Research Team, Centre For Neuroscience, Pecs, Hungary, [2]Medical School, Clinical Centre, University of Pecs, Department Of Medical Microbiology And Immunology, Pecs, Hungary, [3]Medical School, Clinical Centre, University of Pecs, Department Of Neurology, Pecs, Hungary, [4]Medical School, Clinical Centre, University of Pecs, Department Of Neurosurgery, Pecs, Hungary, [5]University of Pecs, Szentagothai Research Centre, Pecs, Hungary, [6]Medical School, Clinical Centre, University of Pecs, Department Of Surgery, Pecs, Hungary

The neuroprotective effects of pituitary adenylate cyclase-activating polypeptide (PACAP) have been shown in numerous in vitro and in vivo models of Parkinson's disease (PD) supporting the theory that PACAP could have an important role in the pathomechanism of the disorder affecting mostly older patients. Earlier studies found changes in PACAP levels in neurological disorders, therefore, the aim of our study was to examine PACAP in plasma samples of PD patients. Peptide levels were measured with ELISA and correlated with clinical parameters, age, stage of the disorder based on the Hoehn and Yahr (HY) scale, subtype of the disease, treatment and specific scores measuring motor and non-motor symptoms, such as movement disorder society-unified Parkinson's disease rating scale(MDS-UPDRS), Epworth sleepiness scale(ESS), Parkinson's disease sleep scale(PDSS-2) and Beck-depression inventory(BDI). Our results showed significantly decreased PACAP levels in PD patients without deep brain stimulation (DBS) therapy and in akinetic-rigid subtype, additionally we also described further decrease in the HY stage 3 and 4. Elevated PACAP levels were found in patients with DBS. There were no significant correlations in PACAP level with MDS-UPDRS, type of pharmacological treatment, PDSS-2 sleepiness and depression (BDI) scales, but we found increased PACAP level in patients with more severe sleepiness problems based on the ESS scale. Based on these results we suggest that following the alterations of PACAP with other frequently used clinical biomarkers in PD patients might improve strategic planning of further therapeutic interventions and help to provide a clearer prognosis regarding the future perspective of the disease.

SERUM MYELOPEROXIDASE, BUT NOT THE CEREBROSPINAL-FLUID ENZYME, IS CLOSELY LINKED TO CLINICAL FEATURES AND NEURONAL DAMAGE IN IDIOPATHIC PARKINSON´S DISEASE

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Emilio Fernández Espejo[1], Antonio Córdoba-Fernández[2], Angel Martín De Pablos[3]
[1]Reial Academia de Medicina de Catalunya, Medicine, Barcelona, Spain, [2]Universidad de Sevilla, Podologia, Sevilla, Spain, [3]Hospital Macarena, Cirugía, Sevilla, Spain

Introduction. Myeloperoxidase (MPO) has been implicated in the development of Parkinson´s disease. To date, no study has examined how MPO level in biofluids relates to motor and non-motor features of idiopathic PD. The objective of this study was to look at the relationship of MPO concentration in serum and cerebrospinal fluid (CSF) with clinical variables of the disease. Methods. MPO concentration and activity were measured. The degree of nigrostriatal dopaminergic cell loss was evaluated with single-photon emission computed tomography (SPECT) with ^{123}I-Ioflupane, specific radioligand of the dopamine transporter (DAT). Results. MPO is active in serum, not in the CSF. Serum MPO concentration, not CSF one, was significantly higher in the patients ($p<.0001$ vs controls). Significant correlation values were found between serum MPO concentration and rating scales of motor severity (Hoehn-Yahr staging; motor MDS-UPDRS part III), and percentage reduction of DAT binding on basal ganglia ($p<.0001$). Conclusions. Serum myeloperoxidase, but not CSF MPO, is active and is increased in PD patients. Serum MPO level, not CSF one, correlates with motor severity degree and loss of dopamine-transporter binding on basal ganglia, an indirect measure of neuronal death in the *substantia nigra*. These results would allow improving diagnosis of PD, and it opens new avenues for treatment based on serum myeloperoxidase..

BLAMING NEUROMELANIN FOR PARKINSON'S DISEASE: TIME-DEPENDENT TYROSINASE OVEREXPRESSION DRIVES ENDOGENOUS SYNUCLEINOPATHY IN NONHUMAN PRIMATES

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Jose Lanciego[1], Julia Chocarro[1], Ana Fajardo-Serrano[1], Alfonso Vazquez[2], Ana Rodríguez-Pérez[3], Jose Labandeira-Garcia[3], Miquel Vila[4], Alberto Rico[1]
[1]Center for Applied Medical Research (CIMA), University of Navarra, Neurosciences, Pamplona, Spain, [2]Hospital Universitario de Navarra, Neurosurgery, Pamplona, Spain, [3]Research Center for Molecular Medicine and Chronic Diseases (CIMUS), University of Santiago de Compostela, Neuroanatomy, La Coruña, Spain, [4]Vall d'Hebron Research Institute (VHIR), Neurodegenerative Diseases Research Group, Barcelona, Spain

Although neuromelanin (NMel) is a dark pigment characteristic of dopaminergic neurons in the human substantia nigra pars compacta (SNpc), its potential role in the pathogenesis of Parkinson's disease (PD) has been neglected since most commonly used laboratory animals lack NMel. Here we took advantage of AAVs encoding tyrosinase for driving a time-dependent NMel accumulation within the SNpc in macaques up to similar levels as observed in elderly humans. Furthermore, NMel accumulation induced (i) an endogenous synucleinopathy mimicking intracellular inclusions typically observed in PD, (ii) a progressive degeneration of NMel-expressing dopaminergic neurons, and (iii) a pro-inflammatory phenotype mediated by activated microglial cells and perivascular macrophages. Moreover, Lewy body-like intracellular inclusions were observed in brain areas receiving dopaminergic innervation, supporting a prionoid spread of endogenous synucleinopathy by permissive trans-synaptic templating. In summary, the conducted strategy resulted in the characterization and validation of a new macaque model of PD matching the known neuropathology of this disorder with unprecedented accuracy. Finally, evidence was provided showing that intracellular aggregation of endogenous alpha-synuclein is triggered by NMel accumulation, therefore any therapeutic approach intended to decrease NMel levels may provide appealing choices for the successful implementation of novel PD therapeutics.

ETHANOL EXTRACT FROM WITHERINGIA COCCOLOBOIDES DECREASES α-SYNUCLEIN AGGREGATE IN CAENORHABDITIS ELEGANS STRAIN NL5901

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Ruth Melida Sanchez Mora[1], Johanna González Devia[1], Alejandra Mantilla Galindo[2]
[1]Universidad Colegio Mayor de Cundinamarca, Cundinamarca, Bogotá, D.C., Colombia, [2]Universidad del Rosario, Cundinamarca, Bogotá, D.C., Colombia

Neurodegenerative diseases (ND) are a public health problem worldwide, these cause loss of healthy years, are permanent incapacitating and generate high costs in health systems. People affected with Parkinson´s disease have protein deposits of α- synuclein (α-syn) in brain cells. The use of biological models such as Caenorhabditis elegans (C. elegans) can answer questions that arise every day for the development of new therapeutic targets. Witheringia coccoloboides (W.coccoloboides) has been described as a promising plant in the palliative treatment of ND due to its neuroprotective action. Therefore, the main **objective** of this study was to evaluate the effect of the ethanolic extract of W. coccoloboides on protein aggregates of α-syn in the transgenic strain NL5901 of C. elegans, what it is characterized by the presence of α-syn aggregates labeled with yellow fluorescent protein (YFP), which allows evaluating the effect of compounds on phenotypic properties and the protein aggregates of α-syn. The **results** show that the ethanolic extract of W.coccoloboides leaves, has a reducing effect in α-syn protein aggregates, improving the physiological characteristics of reproduction and motility, decreasing the levels of ROS in the strain NL 5901. Therefore, it is possible to suggest that ethanolic extract of W. coccoloboides leaves has a protective effect on strain NL 5901, probably attributed to the presence of flavonoids and terpenes, which in turn generates a recovery of the muscular activity in the egg laying and locomotion, all probably related to the synergistic interaction of phytocompounds such as sterols and/or terpenes, flavonoids and alkaloids.

FLUORESCENCE LIFETIME IMAGING OF PATHOLOGICAL CHANGES ASSOCIATED WITH PARKINSON'S DISEASE IN MOUSE DUODENAL WHOLEMOUNT TISSUES

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Jana Harsanyiova[1,2], Alzbeta Kralova Trancikova[1,3]
[1]Comenius University in Bratislava, Jessenius Faculty of Medicine in Martin, Biomedical Centre Martin, Martin, Slovak Republic, [2]Comenius University in Bratislava, Jessenius Faculty of Medicine in Martin, Department Of Pathophysiology, Martin, Slovak Republic, [3]Slovak Academy of Sciences, Institute Of Neuroimmunology, Bratislava, Slovak Republic

AIMS: The onset of Parkinson's disease (PD) is believed to be localized to peripheral organs up to 10-15 years before the involvement in the central nervous system (CNS). This wide "time window" provides us the opportunity to identify pathological changes, for example in the gastrointestinal tract (GIT) tissues, even before they reach CNS. We focused on optimizing a combination of two advanced microscopic methods: fluorescence lifetime imaging (FLIM) analysis and wholemount tissue staining to detect early alpha-synuclein-related pathology in the GIT, and identifying specific structures (mucosal, submucosal or muscle layers) in which these changes occur. METHODS: We focused on an early detection of the pathologically aggregated proteins in GIT tissues. PD-related pathology in a mouse model was induced by oral administration of rotenone. Duodenal tissues were collected after 0,4,6,8,10,12-week of rotenone treatment. Wholemount tissues were stained with Thioflavin S (ThS), a routinely used fluorescent probe to detect aggregated proteins and analysed by FLIM. RESULTS: Our experiments showed a gradual increase in ThS fluorescence in the range of 800-1000ps in mouse duodenal tissues depending on the length of rotenone application. We recorded a slight increase in ThS fluorescence in this interval after 6 weeks of rotenone application and this effect increased after 10 weeks. Similar effects in controls were not observed. CONCLUSIONS: Based on our results, FLIM analysis appears to be suitable even for complex samples as wholemount GIT tissue, as well as to be sufficiently sensitive and appropriate to detect gradual pathological changes associated with the formation of aggregated protein structures.

Parkinson's Disease and the Gut: Future Perspectives for Early Diagnosis.
Parkinson's disease (PD) is a neurodegenerative disease characterized by progressive degeneration of dopaminergic neurons, and at the cellular level by the formation of Lewy bodies in the central nervous system (CNS). However, the onset of the disease is believed to be localized to peripheral organs, particularly the gastrointestinal tract (GIT) and the olfactory bulb sooner before neuropathological changes occur in the CNS. Patients already in the pre-motor stage of PD suffer from various digestive problems and/or due to significant changes in the composition of the intestinal microbiome in this early stage of the disease. Detailed analyses of patient biopsies and autopsies as well as animal models of neuropathological changes characteristic of PD provided important information on the pathology or treatment of PD symptoms. However, presently is not clarified where the pathological processes associated with PD is initiated; (by which these processes are disseminated to the CNS or other tissues within the GIT; and (which neuropathological changes could also serve as a , or (would be the most appropriate choice for routine examination of patient biopsies.

Alpha-Synuclein in the Gastrointestinal Tract as a Potential Biomarker for Early Detection of Parkinson's Disease.
The primary pathogenesis associated with Parkinson's disease (PD) occurs in peripheral tissues several years before the onset of typical motor symptoms. Early and reliable diagnosis of PD could provide new treatment options for PD patients and improve their quality of life. At present, however, diagnosis relies mainly on clinical symptoms, and definitive diagnosis is still based on postmortem pathological confirmation of dopaminergic neuronal degeneration. In addition, the similarity of the clinical, cognitive, and neuropathological features of PD with other neurodegenerative diseases calls for new biomarkers, suitable for differential diagnosis. Alpha-synuclein (α-Syn) is a potential PD biomarker, due to its close connection with the pathogenesis of the disease. Here we summarize the currently available information on the possible use of α-Syn as a biomarker of early stages of PD in gastrointestinal (GI) tissues, highlight its potential to distinguish PD and other

neurodegenerative diseases, and suggest alternative methods (primarily developed for other tissue analysis) that could improve α-Syn detection procedures or diagnostic methods in general.

Extracellular DNA Correlates with Intestinal Inflammation in Chemically Induced Colitis in Mice.
Circulating extracellular DNA (ecDNA) is known to worsen the outcome of many diseases. ecDNA released from neutrophils during infection or inflammation is present in the form of neutrophil extracellular traps (NETs). It has been shown that higher ecDNA concentration occurs in a number of inflammatory diseases including inflammatory bowel disease (IBD). Enzymes such as peptidyl arginine deiminases (PADs) are crucial for NET formation. We sought to describe the dynamics of ecDNA concentrations and fragmentation, along with NETosis during a mouse model of chemically induced colitis. Plasma ecDNA concentration was highest on day seven of dextran sulfate sodium (DSS) intake and the increase was time-dependent. This increase correlated with the percentage of cells undergoing NETosis and other markers of disease activity. Relative proportion of nuclear ecDNA increased towards more severe colitis; however, absolute amount decreased. In colon explant medium, the highest concentration of ecDNA was on day three of DSS consumption. Early administration of PAD4 inhibitors did not alleviate disease activity, but lowered the ecDNA concentration. These results uncover the biological characteristics of ecDNA in IBD and support the role of ecDNA in intestinal inflammation. The therapeutic intervention aimed at NETs and/or nuclear ecDNA has yet to be fully investigated.

Structure of vagal afferent nerve terminal fibers in the mouse trachea.
The structure of primary afferent nerve terminals profoundly influences their function. While the complex vagal airway nerve terminals (stretch receptors, cough receptors and neuroepithelial bodies) were thoroughly characterized, much less is known about the structure of airway nerves that do not form distinct complex terminals (often termed free nerve fibers). We selectively induced expression of GFP in vagal afferent nerves in the mouse by transfection with AAV-GFP virus vector and visualized nerve terminals in the trachea by whole organ confocal imaging. Based on structural characteristics we identified four types of vagal afferent nerve fiber terminals in the trachea. Importantly, we found that distinct compartments of tracheal tissue are innervated by distinct nerve fiber terminal types in a non-overlapping manner. Thus, separate terminal types innervate tracheal epithelium vs. anterolateral tracheal wall containing cartilaginous rings and ligaments vs. dorsal wall containing smooth muscle. Our results will aid the study of structure-function relationships in vagal airway afferent nerves and regulation of respiratory reflexes.

Various aspects of sex and gender bias in biomedical research.
The main role of research in medicine is to provide relevant knowledge which, after successful translation to clinical practice, improves the quality of healthcare. The sex bias which is still present in the majority of research disciplines prefers male subjects despite legislation changes in the US grant agencies and European research programme Horizon 2020. Male subjects (cells, animals) still dominate in preclinical research and it has detrimental consequences for women's health and the quality of science. Opposite bias exists for data obtained mainly in animal models utilizing female subjects (e.g. research in multiple sclerosis, osteoporosis) with skewed outcomes for men affected by these diseases. Either way, scientists are producing results which compromise half of the population. Assumptions that females as cohorts are more variable and another assumption that the oestrous cycle should be tracked in case the females are enrolled in preclinical studies were proven wrong. Variability of male versus female cohorts are comparable and do not only stem from hormonal levels. The widespread prevalence of sex differences in human diseases ultimately requires detailed experiments performed on both sexes, unless the studies are specifically addressing reproduction or sex-related behaviors.

Vagus Nerves Provide a Robust Afferent Innervation of the Mucosa Throughout the Body of the Esophagus in the Mouse.
The vagal afferent nerves regulate swallowing and esophageal motor reflexes. However, there are still gaps in the understanding of vagal afferent innervation of the esophageal mucosa. Anatomical studies found that the vagal afferent mucosal innervation is dense in the upper esophageal sphincter area but rare in more distal segments of the esophagus. In contrast, electrophysiological studies concluded that the vagal afferent nerve fibers also densely innervate mucosa in more distal esophagus. We hypothesized that the transfection of vagal afferent neurons with adeno-associated virus vector encoding green fluorescent protein (AAV-GFP) allows to visualize vagal afferent nerve fibers in the esophageal mucosa in the mouse. AAV-GFP was injected into the vagal jugular/nodose ganglia in vivo to sparsely label vagal afferent nerve fibers.

The esophageal tissue was harvested 4-6 weeks later, the GFP signal was amplified by immunostaining, and confocal optical sections of the entire esophagi were obtained. We found numerous GFP-labeled fibers in the mucosa throughout the whole body of the esophagus. The GFP-labeled mucosal fibers were located just beneath the epithelium, branched repeatedly, had mostly longitudinal orientation, and terminated abruptly without forming terminal structures. The GFP-labeled mucosal fibers were concentrated in random areas of various sizes in which many fibers could be traced to a single parental axon. We conclude that the vagus nerves provide a robust afferent innervation of the mucosa throughout the whole body of the esophagus in the mouse. Vagal mucosal fibers may contribute to the sensing of intraluminal content and regulation of swallowing and other reflexes.

ORAL NANO-DELIVERY OF NASCO POMACES EXTRACT EXERTS ANTI-INFLAMMATORY EFFECTS IN THE 1-METHYL-4-PHENYL-1,2,3,6-TETRAHYDROPYRIDINE (MPTP) MOUSE MODEL OF PARKINSON'S DISEASE.

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Marcello Serra[1], Pathik Hiteshbhai Parekh[1], Mohamad Allaw[2], Maria Manconi[2], Micaela Morelli[1]
[1]University of Cagliari, Department Of Biomedical Sciences, Monserrato, Italy, [2]University of Cagliari, Department Of Scienze Della Vita E Dell'ambiente, Cagliari, Italy

Persistent neuroinflammation is considered a main event implicated in the neuropathology of Parkinson's Disease (PD). Grape pomaces, a waste by-products of wine production, are rich in polyphenols and have demonstrated antioxidant properties both *in vitro* and *in vivo* animal models of neurodegenerative diseases. Nonetheless, their oral use is limited by their low brain bioavailability and extensive first-passage metabolism. To overcome these limitations, in the present study we incorporated grape pomaces extract from *Vitis vinifera* Nasco into nutriosome (Nasco nutriosome), a novel nanovesicle system composed of the S75 phospholipid and the maltodextrin Nutriose® FM06. To investigate the anti-inflammatory properties of Nasco nutriosome in the 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) mouse model of PD, we administrated Nasco nutriosome intragastrically in mice that were treated repeatedly with MPTP. Then, we evaluated in the Caudate-Putamen (CPu) and the substantia nigra compacta (SNc), two brain areas highly affected in PD, the immunoreactivity for the glial fibrillary acidic protein (GFAP), as marker of astroglia, and for the ionized calcium-binding adaptor molecule 1 (IBA1), as marker of microglia. Additionally, we co-localize the pro-inflammatory interleukin (IL)-1β with IBA1, to gain additional information about the microglia phenotype. Immunohistochemical analyses revealed that administration Nasco nutriosome significantly counteracted both microgliosis in the CPu, and the astrogliosis in the SNc and CPu, in mice receiving repeated MPTP treatment. Additionally, in the CPu, Nasco nutriosome treatment effectively reduced the production of IL-1β in IBA1 (+) cells. Altogether, these results highlight the promising anti-inflammatory effects exerted by Nasco nutriosome treatment in the preclinical MPTP-mouse model of PD.

Effects of docosanyl ferulate, a constituent of Withania somnifera, on ethanol- and morphine-elicited conditioned place preference and ERK phosphorylation in the accumbens shell of CD1 mice.
Docosanyl ferulate (DF) is a behaviourally active GABA receptor complex (GABAR) agonist, recently isolated from the standardized methanolic extract of Withania somnifera Dunal (WSE) root. Previous studies have shown that WSE prevents both ethanol- and morphine-dependent acquisition and expression of conditioned place preference (CPP) and stimulation of dopamine release in the nucleus accumbens shell (AcbSh).

Activation of Antioxidant and Proteolytic Pathways in the Nigrostriatal Dopaminergic System After 3,4-Methylenedioxymethamphetamine Administration: Sex-Related Differences.
3,4-Methylenedioxymethamphetamine (MDMA, "ecstasy") is an amphetamine-related drug that may damage the dopaminergic nigrostriatal system. To investigate the mechanisms that sustain this toxic effect and ascertain their sex-dependence, we evaluated in the nigrostriatal system of MDMA-treated (4 × 20 mg/kg, 2 h apart) male and female mice the activity of superoxide dismutase (SOD), the gene expression of SOD type 1 and 2, together with SOD1/2 co-localization with tyrosine hydroxylase (TH)-positive neurons. In the same mice and brain areas, activity of glutathione peroxidase (GPx) and of β2/β5 subunits of the ubiquitin-proteasome system (UPS) were also evaluated. After MDMA, SOD1 increased in striatal TH-positive terminals, but not nigral neurons, of males and females, while SOD2 increased in striatal TH-positive terminals and nigral neurons of males only. Moreover, after MDMA, SOD1 gene expression increased in the midbrain of males and females, whereas SOD2 increased only in males. Finally, MDMA increased the SOD activity in the midbrain of females, without affecting GPx activity, decreased the β2/β5 activities in the striatum of males and the β2 activity in the midbrain of females. These results suggest that the mechanisms of MDMA-induced neurotoxic effects are sex-dependent and

dopaminergic neurons of males could be more sensitive to SOD2- and UPS-mediated toxic effects.

Association between Novel Object Recognition/Spontaneous Alternation Behavior and Emission of Ultrasonic Vocalizations in Rats: Possible Relevance to the Study of Memory.
Rats emit ultrasonic vocalizations (USVs) in situations with emotional valence, and USVs have also been proposed as a marker for memories conditioned to those situations. This study investigated whether USV emissions can predict and/or be associated with the behavior of rats in tests that evaluate unconditioned memory. To this end, rats were subjected to "tickling", a procedure of heterospecific play that has emotional valence and elicits the emission of USVs, and afterwards evaluated in the novel object recognition test (NOR) and in the single trial continuous spontaneous alternation behavior (SAB) test in a Y maze. The number of 22-kHz USVs (aversive) and 50-kHz USVs (appetitive) emitted in response to tickling and during NOR and SAB tests were scored, and the correlations among them and with rats' behavior evaluated. Rats emitted 50-kHz USVs, but not 22-kHz USVs, during the NOR and SAB tests, and such calling behavior was not linked with the behavioral readouts indicative of memory function in either test. However, rats that prevalently emitted 22-kHz USVs in response to tickling displayed an impaired NOR performance. These findings suggest that measuring the emission of USVs could be of interest in studies of unconditioned memory, at least with regard to 22-kHz USVs.

Neuroinflammation and L-dopa-induced abnormal involuntary movements in 6-hydroxydopamine-lesioned rat model of Parkinson's disease are counteracted by combined administration of a 5-HT receptor agonist and A receptor antagonist.
Several lines of evidence have strongly implicated neuroinflammation in Parkinson's disease (PD) progression and l-dopa-induced dyskinesia. The present study investigated whether early subchronic pretreatment with the serotonin 5-HT receptor agonist eltoprazine plus the adenosine A receptor antagonist preladenant counteracted l-dopa-induced abnormal involuntary movements (AIMs, index of dyskinesia), and neuroinflammation, in unilateral 6-hydroxydopamine(6-OHDA)-lesioned rat model of PD. The immunoreactivity of glial fibrillary acidic protein (GFAP), and the colocalization of ionized calcium binding adaptor molecule-1 (IBA-1), with interleukin (IL)-1β, tumor-necrosis-factor-α (TNF-α) and IL-10 were evaluated in the denervated caudate-putamen (CPu) and substantia nigra pars-compacta (SNc). The combined subchronic pretreatment with l-dopa plus eltoprazine and preladenant reduced AIMs induced by acute l-dopa challenge in these rats and decreased GFAP and IBA-1 immunoreactivity induced by the drug in both CPu and SNc, with reduction in IL-1β in IBA-1-positive cells in both CPu and SNc, and in TNF-α in IBA-1-positive cells in SNc. Moreover, a significant increase in IL-10 in IBA-1-positive cells was observed in SNc. Evaluation of immediate early-gene zif-268 (index of neuronal activation) after l-dopa challenge, showed an increase in its expression in denervated CPu of rats pretreated with l-dopa or l-dopa plus preladenant compared with vehicle, whereas rats pretreated with eltoprazine, with or without preladenant, had lower zif-268 expression. Finally, tyrosine hydroxylase and dopamine transporter examined to evaluate neurodegeneration, showed a significant equal decrease in all experimental groups. The present findings suggest that combination of l-dopa with eltoprazine and preladenant may be promising therapeutic strategy for delaying the onset of dyskinesia, preserving l-dopa efficacy and reducing neuroinflammation markers in nigrostriatal system of 6-OHDA-lesioned rats.

Involvement of the Protein Ras Homolog Enriched in the Striatum, Rhes, in Dopaminergic Neurons' Degeneration: Link to Parkinson's Disease.
is one of the most interesting genes regulated by thyroid hormones that, through the inhibition of the striatal cAMP/PKA pathway, acts as a modulator of dopamine neurotransmission. is expressed at high levels in the dorsal striatum, with a medial-to-lateral expression gradient reflecting that of both dopamine D and adenosine A receptors. transcript is also present in the hippocampus, cerebral cortex, olfactory tubercle and bulb, substantia nigra pars compacta (SNc) and ventral tegmental area of the rodent brain. In line with -dependent regulation of dopaminergic transmission, data showed that lack of enhanced cocaine- and amphetamine-induced motor stimulation in mice. Previous studies showed that pharmacological depletion of dopamine significantly reduces mRNA levels in rodents, non-human primates and Parkinson's disease (PD) patients, suggesting a link between dopaminergic innervation and physiological mRNA expression. Rhes protein binds to and activates striatal mTORC1, and modulates L-DOPA-induced dyskinesia in PD rodent models. Finally, Rhes is involved in the survival of mouse midbrain dopaminergic neurons of SNc, thus pointing towards a Rhes-dependent modulation of autophagy and mitophagy processes, and encouraging further investigations about mechanisms underlying dysfunctions of the nigrostriatal system.

Lack of drug- and cue-stimulated emissions of ultrasonic vocalizations in C57BL/6J mice repeatedly treated with amphetamine.
The emission of ultrasonic vocalizations (USVs) is thought to communicate the behavioral and emotional states elicited in rodents by social and non-social stimuli. On this basis, studies of psychopharmacology in rats are increasingly utilizing USVs as a behavioral marker to evaluate the effects of drugs on the emotional state. Conversely, very limited information is available as to whether psychoactive drugs influence USV emissions in mice. To provide new insights in this respect, we evaluated the emission of USVs in C57BL/6J mice subjected to repeated treatment with the dopaminergic psychostimulant of abuse amphetamine. Mice were first allowed to perform social contacts in dyads, and 2 days later they received amphetamine (1-4 mg/kg, i.p.) in a test cage (× 5 administrations) on alternate days. Seven days after treatment discontinuation, mice were re-exposed to the test cage to evaluate whether the presentation of drug-paired environmental cues elicited calling behavior, and thereafter received an amphetamine challenge. An additional group of animals received the dopamine receptor agonist apomorphine (1-4 mg/kg, i.p.), to further clarify the role of dopamine transmission in calling behavior of mice. C57BL/6J mice emitted USVs during social contacts, but did not significantly vocalize after amphetamine administration, in response to amphetamine-paired environmental cues, and after apomorphine administration. These results indicate that C57BL/6J mice may respond differently to social and pharmacological stimuli in terms of USV emissions, and may lay the foundation for future studies aimed at clarifying whether USVs may be a useful behavioral marker in studies of psychopharmacology in mice.

Pharmacological interactions between adenosine A receptor antagonists and different neurotransmitter systems.
While Parkinson's disease (PD) is traditionally characterized by dopaminergic neuron degeneration, several neurotransmitters and neuromodulators besides dopamine are also involved in the onset and progression of the disease and its symptoms. The other principal neurotransmitters/neuromodulators known to control basal ganglia functions and, in particular, motor functions, are GABA, glutamate, serotonin (5-HT), noradrenaline, acetylcholine, adenosine and endocannabinoids. Among these, adenosine is the most relevant, acting through its adenosine A receptor. Work in experimental models of PD has established the effects of A receptor antagonists, including the alleviation of disrupted dopamine functions and improved efficacy of dopamine replacement therapy. Moreover, positive interactions between A receptor antagonists and both D and D receptor agonists have been described in vitro at the receptor-receptor level or in more complex in vivo models of PD, respectively. In addition, the interactions between A receptor antagonists and glutamate ionotropic GluN-containing N-Methyl-d-aspartic acid receptors, or metabotropic glutamate (mGlu) receptors, including both mGlu receptor inhibitors and mGlu receptor activators, have been reported in both in vitro and in vivo animal models of PD, as have positive interactions between A and endocannabinoid CB receptor antagonists. At the same time, a combination of A receptor antagonists and 5-HT-5-HT receptor agonists have been described to modulate the expression of dyskinesia induced by chronic dopamine replacement therapy.

Increased emissions of 50-kHz ultrasonic vocalizations in hemiparkinsonian rats repeatedly treated with dopaminomimetic drugs: A potential preclinical model for studying the affective properties of dopamine replacement therapy in Parkinson's disease.
Dopamine replacement therapy used in Parkinson's disease (PD) may induce alterations in the emotional state that can underlie the manifestation of iatrogenic psychiatric-like disturbances. The preclinical investigation of these disturbances is limited, also because few reliable paradigms are available to study the affective properties of dopaminomimetic drugs in parkinsonian animals. To provide a relevant experimental tool in this respect, we evaluated whether dopaminomimetic drugs modified the emission of 50-kHz ultrasonic vocalizations (USVs), a behavioral marker of positive affect, in rats bearing a unilateral lesion with 6-hydroxydopamine in the medial forebrain bundle. Apomorphine (2 or 4 mg/kg, i.p.), L-3,4-dihydroxyphenilalanine (L-DOPA, 6 or 12 mg/kg, i.p.), or pramipexole (2 or 4 mg/kg, i.p.) were administered in a test cage (× 5 administrations) on alternate days. Seven days after treatment discontinuation, rats were re-exposed to the test cage to measure conditioned calling behavior and thereafter received a drug challenge. Hemiparkinsonian rats treated with either apomorphine or L-DOPA, but not pramipexole, markedly vocalized during repeated treatment and after challenge, and showed conditioned calling behavior. Moreover, apomorphine, L-DOPA and pramipexole elicited different patterns of 50-kHz USV emissions and rotational behavior, indicating that calling behavior in hemiparkinsonian rats treated with dopaminomimetic drugs is not a byproduct of motor activation. Taken together, these results suggest that measuring 50-kHz USV emissions may be a relevant experimental tool for studying how dopaminomimetic drugs modify the affective state in parkinsonian rats, with possible implications for the preclinical investigation of iatrogenic psychiatric-like disturbances in PD.

Gender Differences in Neurodegeneration, Neuroinflammation and Na-Ca Exchangers in the Female A53T Transgenic Mouse Model of Parkinson's Disease.
Twelve-month-old male mice expressing the human A53T variant of α-synuclein (A53T) develop dopamine neuron degeneration, neuroinflammation, and motor deficits, along with dysfunctions of the mitochondrial Na-Ca exchanger (NCX) isoforms 1 (NCX1) and 3 (NCX3) in the nigrostriatal system. Since gender is thought to play a role in the etiology of Parkinson's disease (PD), we characterized neurochemical and behavioral alterations in 12-month-old female A53T transgenic mice. We investigated the presence of dopaminergic degeneration, astrogliosis and microgliosis using immunohistochemistry for tyrosine hydroxylase (TH), glial fibrillary acidic protein (GFAP) and ionized calcium-binding adaptor molecule-1 (IBA-1) in both the substantia nigra pars compacta (SNc) and striatum. In the same regions, we also evaluated the co-localization of NCX1 in cells positive for IBA-1 and the co-localization of NCX3 in TH-positive neurons and fibers. Furthermore, in both male and female mice, we performed motor (beam walking and pole tests) and memory [novel object recognition (NOR) and spontaneous alternation] tasks, together with tests to evaluate peripheral deficits (olfactory and stool collection tests). Female A53T transgenic mice displayed degeneration of nigral dopaminergic neurons, but neither microgliosis nor astrogliosis in the SNc and striatum. Moreover, female A53T transgenic mice displayed co-localization between NCX1 and IBA-1 positive cells in the striatum but not SNc, whereas NCX3 did not co-localize with either TH-positive terminals or neuronal bodies in the nigrostriatal system. Furthermore, female A53T transgenic mice showed increased crossing time in the beam walking test, but no impairments in the pole or memory tests, and in tests that evaluated peripheral deficits, whereas male A53T transgenic mice displayed motor, memory and peripheral deficits. Immunohistochemical and behavioral results obtained here in the female mice differ from those previously observed in males, and suggest a dissimilar influence of NCX1 and NCX3 on dopaminergic function in female and male A53T transgenic mice, strengthening the validity of these mice as a model for studying the etiological factors of PD.

Dopaminergic Control of Striatal Cholinergic Interneurons Underlies Cocaine-Induced Psychostimulation.
Cocaine drastically elevates dopamine (DA) levels in the striatum, a brain region that is critical to the psychomotor and rewarding properties of the drug. DA signaling regulates intrastriatal circuits connecting medium spiny neurons (MSNs) with afferent fibers and interneurons. While the cocaine-mediated increase in DA signaling on MSNs is well documented, that on cholinergic interneurons (ChIs) has been more difficult to assess. Using combined pharmacological, chemogenetic, and cell-specific ablation approaches, we reveal that the D2R-dependent inhibition of acetylcholine (ACh) signaling is fundamental to cocaine-induced changes in behavior and the striatal genomic response. We show that the D2R-dependent control of striatal ChIs enables the motor, sensitized, and reinforcing properties of cocaine. This study highlights the importance of the DA- and D2R-mediated inhibitory control of ChIs activity in the normal functioning of striatal networks.

EFFECTS OF INFLAMMATION IN THE PROGRESSION OF PARKINSON'S DISEASE IN A RAT MODEL OVEREXPRESSING HUMAN α-SYNUCLEIN

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Mariangela Massaro Cenere[1,2], Marta Tiberi[1,3], Emanuela Paldino[4], Francesca Cossa[1,2], Francesca Fusco[4], Valerio Chiurchiù[3,5], Nicola Mercuri[1,2]
[1]University of Rome 'Tor Vergata', Systems Medicine, Rome, Italy, [2]IRCCS Santa Lucia Foundation, Experimental Neurology, Rome, Italy, [3]IRCCS Santa Lucia Foundation, Resolution Of Neuroinflammation, Rome, Italy, [4]IRCCS Santa Lucia Foundation, Neuroanatomy, Rome, Italy, [5]CNR, Institute Of Translational Farmacology, Rome, Italy

Aim: Parkinson's disease (PD) is characterized by the aggregation and accumulation of α-synuclein, the main component of Lewy bodies and neurites, the loss of dopaminergic neurons in the *substantia nigra*, reduction of striatal dopaminergic fibers, and neuroinflammation. Mechanisms through which α-synuclein and inflammation interactions mediate neurodegenerative processes in PD are still unclear. In this study, a two-hit animal model of PD was created to investigate mechanisms through which overexpression of α-synuclein and inflammation accelerate the progression of PD neurodegeneration. **Methods**: Rats overexpressing human α-synuclein, at 2-months old, were administered with a single intraperitoneal injection of the inflammogen lipopolysaccharide (LPS; 5 mg/kg). At 3 months after injection, nigral dopaminergic neurodegeneration, α-synuclein pathology, and neuroinflammation were evaluated by immunohistochemistry, immunofluorescence, and high dimensional flow cytometry analyses. **Results**: The acute injection of LPS in rats caused long-lasting neuroinflammation with microgliosis and increased T-lymphocytes infiltration in the striatum and in the *substantia nigra*. This was leading to loss of dopaminergic neurons, increased accumulation of phospho-S129 α-synuclein, and altered dendritic arborization of dopaminergic neurons in the *substantia nigra*. Furthermore, an increase of Th1 and Th17 CD4 T-cells and a concomitant reduction of regulatory T-cells were observed in the peripheral blood. **Conclusions**: Our two-hit animal model involving both a genetic lesion and an inflammatory factor reproduced key features of PD, thus it could be a valid model for the study of mechanisms of PD progression. **Acknowledgment:** RF-2018-12365509 to N.B.M. and V.C.

Identification of Ultrastructural Signatures of Sleep and Wake in the Fly Brain.
The cellular consequences of sleep loss are poorly characterized. In the pyramidal neurons of mouse frontal cortex we found that mitochondria and secondary lysosomes occupy a larger proportion of the cytoplasm after chronic sleep restriction compared to sleep, consistent with increased cellular burden due to extended wake. For each morphological parameter the within-animal variance was high, suggesting that the effects of sleep and sleep loss vary greatly among neurons. However, the analysis was based on 4-5 mice/group and a single section/cell. Here, we applied serial block-face scanning electron microscopy to identify signatures of sleep and sleep loss in the Drosophila brain. Stacks of images were acquired and used to obtain full 3D reconstructions of the cytoplasm and nucleus of 263 Kenyon cells from adult flies collected after a night of sleep (S) or after 11 hours (SD11) or 35 hours (SD35) of sleep deprivation (9 flies/group). Relative to S flies, SD35 flies showed increased density of dark clusters of chromatin and of Golgi apparata and a trend increase in the percent of cell volume occupied by mitochondria, consistent with increased need for energy and protein supply during extended wake. Logistic regression models could assign each neuron to the correct experimental group with good accuracy, but in each cell nuclear and cytoplasmic changes were poorly correlated, and within-fly variance was substantial in all experimental groups. Together, these results support the presence of ultrastructural signatures of sleep and sleep loss but underscore the complexity of their effects at the single-cell level.

POTENTIAL OF EXERCISE TO MODIFY THE PROGRESSION OF PRODROMAL PARKINSON'S DISEASE

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Leonie Baldauf[1], Malte Feja[1,2], Eva Schäffer[3], Daniela Berg[3], Franziska Richter[1,2]
[1]University of Veterinary Medicine Hannover, Foundation, Department Of Pharmacology, Toxicology And Pharmacy, Hannover, Germany, [2]Hannover Graduate School For Neuroscience, Infection Medicine And Veterinary Science (HGNI), Center For Systems Neurocience (zsn), Hannover, Germany, [3]University Hospital Schleswig-Holstein, Christian-Albrecht Universitys, Department Of Neurology, Kiel, Germany

Aims: Subtle motor and non-motor dysfunctions indicative of beginning Parkinson's disease (PD) progression are evident before clinical disease diagnosis, requiring a disease-modifying treatment to start during early prodromal stage. Persons of risk would be willing to determine their risk of developing PD and change their lifestyle in case of a concrete beneficial approach. Growing evidence indicates the potential of exercise in reducing components of PD-related pathology. We hypothesized that early intervention by exercise has a disease-modifying effect during prodromal phase in our PD mouse model and can be applied as a non-pharmacological preventive strategy for early-stage PD. **Methods:** We examined exercise in transgenic mice that overexpress human wild-type alpha-synuclein (Thy1-aSyn mice) and replicate PD hallmarks by developing robust fine motor deficits at two months of age. Six-week-old male wild-type and Thy1-aSyn mice were assigned to three groups receiving different intensity levels of exercise on a treadmill. Motor performance was assessed in the challenging beam and vertical pole test. Fecal pellets of mice are processed for microbiome sequencing, and brains and plasma taken for in-depths post-mortem analysis of PD-related pathology. **Results:** Transgenic mice showed motor impairment on challenging beam and vertical pole, reflecting the expected progression of aSyn pathology at this age. Improved vertical pole performance under exercise in wildtypes suggests symptomatic effects, while slight improvements in beam performance might indicate a disease-modifying potential of exercise. **Conclusions:** These results suggest that exercise is able to alleviate early sensorimotor deficits in Thy1-aSyn mice and demonstrate its potential as an early PD-modifying treatment.

Alpha-synuclein pathology, microgliosis, and parvalbumin neuron loss in the amygdala associated with enhanced fear in the Thy1-aSyn model of Parkinson's disease.
In Parkinson's disease (PD), the second most common neurodegenerative disorder, non-motor symptoms often precede the development of debilitating motor symptoms and present a severe impact on the quality of life. Lewy bodies containing misfolded α-synuclein progressively develop in neurons throughout the peripheral and central nervous system, which may be correlated with the early development of non-motor symptoms. Among those, increased fear and anxiety is frequent in PD and thought to result from pathology outside the dopaminergic system, which has been the focus of symptomatic treatment to alleviate motor symptoms. Alpha-synuclein accumulation has been reported in the amygdala of PD patients, a brain region critically involved in fear and anxiety. Here we asked whether α-synuclein overexpression alone is sufficient to induce an enhanced fear phenotype in vivo and which pathological mechanisms are involved. Transgenic mice expressing human wild-type α-synuclein (Thy1-aSyn), a well-established model of PD, were subjected to fear conditioning followed by extinction and then tested for extinction memory retention followed by histopathological analysis. Thy1-aSyn mice showed enhanced tone fear across acquisition and extinction compared to wild-type littermates, as well as a trend to less retention of fear extinction. Immunohistochemical analysis of the basolateral nucleus of the amygdala, a nucleus critically involved in tone fear learning, revealed extensive α-synuclein pathology, with accumulation, phosphorylation, and aggregation of α-synuclein in transgenic mice. This pathology was accompanied by microgliosis and parvalbumin neuron loss in this nucleus, which could explain the enhanced fear phenotype. Importantly, this non-motor phenotype was detected in the pre-clinical phase, prior to dopamine loss in Thy1-aSyn mice, thus replicating observations in patients. Results obtained in this study suggest a possible mechanism by which increased anxiety and maladaptive fear processing may occur in PD, opening a door for therapeutic

options and further early biomarker research.

THE INTERPLAY OF LIPOPOLYSACCHARIDE AND ALPHA-SYNUCLEIN TO MODEL GUT-BRAIN PATHOPHYSIOLOGY IN PARKINSON´S DISEASE

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Anna-Sophia Hartke[1,2], Inken Waltl[3], Ulrich Kalinke[1,3], Franziska Richter[1,2], Christopher Käufer[2]
[1]Hannover Graduate School For Neuroscience, Infection Medicine And Veterinary Science (HGNI), Center For Systems Neurocience (zsn), Hannover, Germany, [2]University of Veterinary Medicine Hannover, Department Of Pharmacology, Toxicology And Pharmacy, Hannover, Germany, [3]TWINCORE, Centre for Experimental and Clinical Infection Research, Institute For Experimental Infection Research, Hannover, Germany

Aims: Although Parkinson's disease (PD) is the second most common neurodegenerative disease, we lack better understanding of the pathologic pathways leading to the disease and its progression. Increasing evidence points to infectious diseases and a role of the gut-brain axis as environmental risk factors. Lipopolysaccharide (LPS) producing gram-negative bacteria are more frequent in the gut-microbiome of PD patients. We hypothesize that LPS, an activator of various immune pathways, could contribute to disease progression via neuroinflammation and up-regulation of neuronal alpha-Synuclein (αSyn). **Methods:** To test this hypothesis, the role of LPS in the progression of PD was evaluated in a human αSyn overexpression model (Thy1- αSyn "Line 61" Mouse). Two low doses of LPS (0.3 and 0.8 mg/kg) were intraperitoneally injected into αSyn mice and wild-type littermates. Afterwards various examinations including clinical score, blood flow cytometry, and brain immunohistology were performed. **Results:** Both dosages only induced transient symptoms and mild weight loss in mice, with full recovery after 7 days. A single injection of 0.8 mg/kg LPS was sufficient to influence the number of immune cells in the blood at 7 days post injection as previously described after LPS exposure. Furthermore, LPS injected mice developed brain region specific microgliosis. In **conclusion**, an LPS dosage of 0.8 mg/kg was sufficient to induce a transient disease phenotype in wild-type and PD model mice while showing measurable neuroinflammation. Therefore, this model will be used to assess the progression of PD symptoms and the interplay with neuroinflammation in sensitive motoric and cognitive behavior experiments.

Current Evidence for a Bidirectional Loop Between the Lysosome and Alpha-Synuclein Proteoforms.
Cumulative evidence collected in recent decades suggests that lysosomal dysfunction contributes to neurodegenerative diseases, especially if amyloid proteins are involved. Among these, alpha-synuclein (aSyn) that progressively accumulates and aggregates in Lewy bodies is undisputedly a main culprit in Parkinson disease (PD) pathogenesis. Lysosomal dysfunction is evident in brains of PD patients, and mutations in lysosomal enzymes are a major risk factor of PD. At first glance, the role of protein-degrading lysosomes in a disease with pathological protein accumulation seems obvious and should guide the development of straightforward and rational therapeutic targets. However, our review demonstrates that the story is more complicated for aSyn. The protein can possess diverse posttranslational modifications, aggregate formations, and truncations, all of which contribute to a growing known set of proteoforms. These interfere directly or indirectly with lysosome function, reducing their own degradation, and thereby accelerating the protein aggregation and disease process. Conversely, unbalanced lysosomal enzymatic processes can produce truncated aSyn proteoforms that may be more toxic and prone to aggregation. This highlights the possibility of enhancing lysosomal function as a treatment for PD, if it can be confirmed that this approach effectively reduces harmful aSyn proteoforms and does not produce novel, toxic proteoforms.

DEVELOPING ZEBRAFISH CRISPR/CAS9 KNOCKOUT MODELS OF PARKINSON'S DISEASE TO IDENTIFY NOVEL THERAPEUTIC TARGETS.

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Jessica Garcia-Fernandez[1], Laura Lopez-Blanch[2], Manuel Irimia[2], Flavia De Santis[1], Javier Terriente[1]
[1]ZeClinics, Institut De Recerca Germans Trias I Pujol (igtp), Badalona, Spain, [2]Parc Recerca Biomedica de Barcelona, Centro De Regulación Genómica (crg), Barcelona, Spain

Parkinson's disease (PD) is the second most common neurodegenerative disorder. Commonly, it affects people over 60 years old. However, the disease can be manifested early in life. Most of the cases are of sporadic etiology and 10 to 20 % of genetic cause, with mutations occurring in only one gene following a Mendelian's inheritance pattern. Patients experience motor and no motor symptoms that escalate as disease progresses. As human patients present punctual mutations and/or small deletions in *park1*, *park2*, *park6*, *park7*, and *park8*, we targeted the zebrafish exon counterparts. Here, the aim is to generate CRISPR/Cas9 loss-of-function alleles of the aforementioned PD-associated genes in zebrafish to discover novel therapeutic targets. We have observed high conservation with expression patterns in the central nervous system of zebrafish. Validation of these models at the cellular/molecular level shows a striking reduction of tyrosine hydroxylase (*th1*) mRNA and protein levels, suggesting that zebrafish dopaminergic neurons are affected by our genetic disruption. Additionally, preliminary results show some differences in the locomotion behaviour of mutants compared to wild type. Lastly, on-going transcriptomic analysis of postmitotic neurons of our models could show genes differentially expressed, which could help us identify novel molecular targets and altered pathways. Overall, phenotypic characterisation and a molecular signature identification could pave the ground for future development of new therapeutic strategies and drugs for Parkinson's Disease.

Neuro-sys, ., Gardanne, France

Aims : Parkinson's disease (PD) is characterized by dopaminergic neuron loss in the *substantia nigra* (SN), alpha-synuclein (α-Syn) aggregation and motor dysfunctions. Toxic species of α-Syn contributes to the physiopathology of PD. Loss of function of GBA, a lysosomal glucocerebrosidase, due to gene mutations, is a strong risk factor for PD. Here we aimed to develop a novel *in vivo* model of PD, combining α-Syn toxicity and inhibition of GBA. **Methods** : α-Syn solution, containing oligomers and protofibrils, was bilaterally injected in the SN of aged male C57BL/6J mice. Mice were chronically treated with conduritol-B-epoxide (CBE, 50 mg/kg, ip), a GBA inhibitor. Neuropathology was assessed by histology and confocal imaging. Locomotor activity of the mice was investigated with the bar and the grid walking test. **Results** : Loss of dopaminergic neurons in the SN was observed 2 weeks after α-Syn injection and GBA inhibition, and progressed over time (up to 6 weeks). The neuronal death was associated with inflammation and α-Syn aggregation. In addition, α-Syn/CBE-treated mice showed locomotor deficits 3 weeks after the surgery as they made step errors on the grid walking test and had reduced speed on the bar test. These locomotor dysfunctions also seemed to be progressive over time. **Conclusions** : Intra-nigral injections of α-Syn, combined to chronic inhibition of GBA triggered a loss of dopaminergic neurons in the SN and motor dysfunctions, in aged mice. This new animal model of PD shares the main pathological features observed in PD patients.

Parkinson's disease (PD) is a neurodegenerative process characterized by the presence of Lewy bodies in different brain regions, affection of many neurotransmitter systems and manifestation of motor and non-motor symptoms. These latter ones often appear before the motor symptomatology and highly impact on the life quality of the patients. Already in the presymptomatic phase, the noradrenergic nucleus locus coeruleus (LC) shows Lewy bodies and PD-like pathology, being one of the first nuclei that undergoes neurodegeneration. This nucleus has a critical role in stress response, emotional memory and control of motor, sensory and autonomic function and can even modulate dopamine homeostasis. The aim of this study is to investigate how the LC participates in PD pathogenesis and symptomatology. For that, we studied the impact of alpha-synuclein overexpression in the LC at molecular and behavioral levels in a pre-symptomatic rodent model of PD. These preliminary data will contribute to better understanding the role of the noradrenergic system in the early phases of the disease, and to identify novel therapeutic strategies to dampen PD progression. JR holds a PhD grant from the University of the Basque Country. This project is financed by the Basque Government (PIBA19-0038; PUE21-03) and the University of the Basque Country (COLAB20/07; GIU19/339). This research was conducted in the scope of the Transborder Joint Laboratory (LTC) "non-motor CoMorbidities in Parkinson's Disease (CoMorPD)". No conflict of interest. **Keywords**: Locus coeruleus, Parkinson's disease, α- synuclein, noradrenergic neurons.

REDUCED INTERACTION OF AGGREGATED α-SYNUCLEIN AND VAMP2 BY ENVIRONMENTAL ENRICHMENT ALLEVIATES HYPERACTIVITY AND ANXIETY IN A MODEL OF PARKINSON'S DISEASE

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Soohyun Wi[1], Kyungri Kim[2], Sung-Rae Cho[2]
[1]Seoul National University Hospital, Department Of Rehabilitation Medicine, Seoul, Korea, Republic of, [2]Yonsei University College of Medicine, Department And Research Institute Of Rehabilitation Medicine, Seoul, Korea, Democratic People's Republic of

Parkinson's disease (PD) is a prevalent motor disease caused by the accumulation of mutated α-synuclein (α-Syn); however, its early stages are also characterized by non-motor symptoms, such as olfactory loss, cognitive decline, depression, and anxiety. The therapeutic effects of
environmental enrichment (EE) on motor recovery have been reported, but its effects on non-motor symptoms remain unclear. Herein, we reveal the beneficial effects of EE on PD-related non-motor symptoms and changes in synaptic plasticity in the nucleus accumbens. To investigate its therapeutic effects in the early phase of PD, we randomly assigned eight-month-old mice overexpressing human A53T (hA53T) α-Syn to either the EE or standard condition groups for two months. Next, we performed behavioral tests and biochemical and histological analyses at 10 months of age. EE significantly alleviated locomotor hyperactivity and anxiety during the early stages of PD. It normalized the levels of tyrosine hydroxylase, phosphorylated and oligomeric α-Syn, and soluble N-ethylmaleimide-sensitive factor attachment protein receptor complex-forming proteins, including synaptosomal-associated protein, 25 kDa, syntaxin1, and vesicle-associated membrane protein 2 (VAMP2). Moreover, the interactions between VAMP2 and pSer129 α-Syn were markedly reduced following EE. The restoration of synaptic vesicle transportation status may underlie the neuroprotective effects of EE in hA53T α-Syn mice.

Background: Grape pomaces, a waste by-product of wine production, have received great attention for their richness in polyphenols, compounds known to exert anti-inflammatory and antioxidant effects in animal models of neurodegenerative diseases. These pomaces, however, have low brain bioavailability upon oral administration due to their extensive degradation in the gastrointestinal tract. **Aims:** To overcome the above-mentioned problems, Nasco pomaces extract was incorporated into a novel nanovesicle system, nutriosomes, composed of phospholipid (S75) and maltodextrin (Nutriose® FM06), to investigate the neuroprotective effect of Nasco pomaces in the 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) mouse model of Parkinson's Disease (PD). **Methods:** Biocompatibility of nutriosomes was assessed on intestinal epithelial cells (Caco-2). Nasco nutriosomes or Nasco suspension were administered intragastrically and their neuroprotective effects were evaluated in MPTP-treated mice. Degeneration of nigrostriatal dopaminergic neurons was assessed through immunohistochemical evaluation of tyrosine hydroxylase (TH) in the caudate-putamen (CPu) and substantia nigra pars compacta (SNc), along with the dopamine transporter (DAT) in the CPu. **Results:** The obtained nutriosomes were highly biocompatible towards Caco-2 cells. Nasco pomaces extract resulted rich in polyphenols, i.e. gallic acid, (+)-catechin, (-)-epicatechin, procyanidin-B2, and quercetin. Immunohistochemical analysis revealed that Nasco nutriosomes but not Nasco suspension significantly contrasted the MPTP-mediated reduction of TH and DAT-positive fibres in the CPu and the number of TH-positive cells in SNc. **Conclusion:** These results highlight the promising therapeutic effects of Nasco pomace extracts when administered in a nutriosome in the MPTP-mouse model of PD, and validate the effectiveness of the nutriosome preparation over suspension as an innovative nano-drug delivery system.

Protective effect of alpha mangostin on rotenone induced toxicity in rat model of Parkinson's disease.
Parkinson's disease (PD) is a progressive, late-onset, and degenerative disorder that affects the central nervous system with an unknown etiology. Due to its incredible complexity in disease nature, many of the existing treatment approaches show a vain recovery in Parkinson's patients. Therefore, an in search of disease-modifying therapeutics for an effective recovery is essential. Alpha mangostin is an important polyphenolic xanthone reported for its neuroprotective effect against rotenone-induced α-synuclein aggregation and loss of tyrosine hydroxylase positive (TH)-neurons in SH-SY5Y cells. Hence, the current study aims to test its protective effect in managing the in-vivo rat model of PD. To justify this aim, adult male Sprague Dawley rats (250 ± 20 g) were subjected to chronic treatment of rotenone (2 mg/kg/day, s.c.) for 21 days. In parallel alpha mangostin treatment (10 mg/kg, i.p) was administered along with rotenone for 21 days. Chronic rotenone treatment for 21 days increased lipid peroxidation, nitrite concentration, and decreased glutathione levels. Further, depletion of TH-dopaminergic neuron expression in substantia nigra pars compacta (SNc), and the development of motor and behavioral deficits in rotenone treated animals like cognitive impairment, muscle incoordination, and neuromuscular weakness were observed. Moreover, western blot studies ascertained the reduced normal alpha-synuclein levels and increased phosphorylated α-synuclein levels in comparison to the vehicle-treated group. Treatment with alpha mangostin significantly restored the locomotor activity, memory deficits, and improved the levels of antioxidant enzymes. It also significantly reduced the levels of phosphorylated α-synuclein which in turn gave protection against TH-dopaminergic neuronal loss in SNc, suggesting it's anti-oxidant and anti-aggregatory potential against α-synuclein. In conclusion through our current results, we could suggest that alpha mangostin has a potential neuroprotective effect against rotenone-induced PD and might be used as a neuroprotective agent. Further mechanistic studies on preclinical and clinical levels are required to be conducted with alpha mangostin to

avail and foresee it as a potential agent in the treatment and management of PD.

A Cleaning Crew: The Pursuit of Autophagy in Parkinson's Disease.
Parkinson's disease (PD) is the second-most common neurodegenerative disorder, neuropathologically characterized by the aggregation of misfolded α-synuclein (α-syn) protein, which appears to be central to the onset and progression of PD pathology. Evidence from pioneering studies has highly advocated the existence of impaired autophagy pathways in the brains of PD patients. Autophagy is an evolutionarily conserved, homeostatic mechanism for minimizing abnormal protein aggregates and facilitating organelle turnover. Any aberration in constitutive autophagy activity results in the aggregation of misfolded α-syn, which, in turn, may further inhibit their own degradation-leading to a vicious cycle of neuronal death. Despite the plethora of available literature, there are still lacunas existing in our understanding of the exact cellular interplay between autophagy impairment and α-syn accumulation-mediated neurotoxicity. In this context, clearance of aggregated α-syn via up-regulation of the autophagy-lysosomal pathway could provide a pharmacologically viable approach to the treatment of PD. The present Review highlights the basics of autophagy and detrimental cross-talk between α-syn and chaperone-mediated autophagy, and α-syn and macroautophagy. It also depicts the interaction between α-syn and novel targets, LRRK2 and mTOR, followed by the role of autophagy in PD from a therapeutic perspective. More importantly, it further updates the reader's understanding of various newer therapeutic avenues that may accomplish disease modification via promoting clearance of toxic α-syn through activation of autophagy.

NEUROBEHAVIORAL ASSESSMENT OF VANILLIN IN MPTP-INDUCED MOUSE MODEL OF PARKINSON'S DISEASE

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Linchi Rani, Amal Mondal
Jawaharlal Nehru University, School Of Life Science, Delhi, India

Aim Drugs currently available for the treatment of Parkinson's disease (PD) either have adverse effects or have suboptimal efficacy. Flavonoids are strong antioxidants with minimal damage with long-term usage. Vanillin (Van) is one such flavonoid that has been found to have antioxidant and neuroprotective characteristics in a variety of neurological disorders. Because there has been limited research on the neuroprotective role of Van in PD, the current study looked at its potential impact on MPTP-induced neurobehavioral deficits in a mouse model of PD. *Methods* To determine the potential neuroprotective effects of Van on motor balance and coordination, we performed the pole test, narrow beam test, and forced swim test at the end of the experiment. Five groups of animals were studied for behavioural changes after the induction of PD and treatment with Van for 21 days. *Results* In the current study, Van successfully alleviated the deficits of MPTP-induced motor function. MPTP-intoxicated mice showed motor dysfunctions, including taking longer time to descend in the pole test and taking longer time to cross the beam, with more foot slips and more immobility time as compared to the control group. There was a significant reduction in motor impairment in the pole test, which showed decreased time spent crossing and foot slip numbers and also reduced immobility time in the Van, MPTP + Van, and L-DOPA treated groups when compared with the MPTP-intoxicated group. *Conclusion* Thus, the current study indicates that Van treatment ameliorates MPTP-induced motor dysfunction in a mouse model of PD.

Unravelling the role of gut microbiota in Parkinson's disease progression: Pathogenic and therapeutic implications.
In recent years, researchers have shown interest in bi-directional interaction between the brain and gut, called "gut-brain axis". Emerging pieces of evidence indicate that disturbances in this axis is found to be associated with the Parkinson's disease (PD). Several clinical investigations revealed the crucial role of gut microbiota in the pathogenesis of PD. It has been suggested that aggregation of misfolded protein α-syn, the neuropathological hallmark of PD, might begin in gut and propagates to the CNS via vagus nerve and olfactory bulb. Emerging evidences also suggest that initiation and progression of PD may be due to inflammation originating from gut. It has been shown that microbial gut dysbiosis causes the production of various pathogenic microbial metabolites which elevates pro-inflammatory environment in the gut that promotes neuroinflammation in the CNS. These observations raise the intriguing question - how gut microbial dysbiosis could contribute to PD progression. In this context, various microbiota-targeted therapies are under consideration that can re-establish the intestinal homeostasis which may have greater promise in the prevention and treatment of PD. This review focuses on the role of the gut microbiota in the initiation, progression of PD and current therapeutic intervention to deplete the severity of the disease.

Emerging concepts of mitochondrial dysfunction in Parkinson's disease progression: Pathogenic and therapeutic implications.
Mitochondria are very dynamic organelle which plays a multifactorial role for a broad range of physiological processes inside the cell to maintain neural circuit integrity. They are required for the generation of cellular energy, regulation of calcium homeostasis and controlling programmed cell death. Defective mitochondrial homeostasis is frequently reported in a broad range of neurological disorders. Many lines of evidence suggest that it plays an essential role in aging and neurodegeneration. Parkinson's disease (PD), the second most prevalent neurodegenerative disorder and its aetiology is still largely unexplored. Overwhelming evidences indicate that mitochondrial dysfunction plays a central role in PD pathogenesis. Various genes involved in maintaining the mitochondrial homeostasis are also associated with the PD pathophysiology. Alterations in mitochondrial functions such as generation of reactive oxygen species (ROS), impaired mitophagy, altered mitochondrial dynamics, impaired mitochondrial biogenesis and Ca buffering may precede the development of PD pathology. In addition, recent studies have also shown the involvement of gut microbiota in the pathogenesis of several

neurodegenerative diseases including PD. In this context, mitochondria-targeted therapies that can ameliorate the mitochondrial abnormalities may have great promise in the prevention and treatment of PD. This review aims to discuss the mitochondrial dysfunction associated with PD pathogenesis, influence of microbiome on mitochondrial regulation and various mitochondrial targeted therapies that can improve the mitochondrial function and deplete the severity of the disease. AIMS Anxiety/depression are the most prevalent neuropsychiatric disorders in Parkinson's disease (PD) patients (~50%), occurring at different stages. Neuropathological and functional changes in the serotonin (5-HT) system are involved in the PD prodromal phase and contribute to non-motor symptoms. Using a mouse model of human α-synuclein (h-α-Syn) overexpression in 5-HT neurons, we aim to evaluate: 1- behavioral phenotype, 2- endoplasmic reticulum (ER) stress and unfolded protein response (UPR) activation and 3- possible sex differences. **METHODS** Recombinant AAV vector serotype 5 (AAV5) encoding wild-type h-α-Syn was used to overexpress h-α-Syn in raphe 5-HT neurons of male and female mice. The behavioral phenotype was examined at 4- and 8-weeks post-infusion. Immunohistochemistry was performed for h-α-Syn, TPH and BIP proteins. Protein levels of UPR pathway markers (BIP, GRP94, p-eIF2α, and p-eEF2) and BDNF were assessed by Western-blot. Statistical significance was ascertained by t-tests or one-way ANOVA, as appropriate. **RESULTS** In male mice, raphe h-α-Syn overexpression induced a depressive-like phenotype in tail suspension and forced swim tests, and reduced raphe BDNF levels. In parallel, significant increases in BIP and GRP94 levels were detected indicating UPR pathway activation. ER stress also increased p-eIF2α and p-eEF2 levels, suggesting PERK pathway activation. However, female mice exhibited anhedonia in the sucrose preference test and an anxiety-like phenotype in the dark-light box test, along with a different UPR activation response. **CONCLUSIONS** Overexpression of h-α-Syn in the mouse 5-HT system induces a sex-specific behavioral phenotype and UPR activation, suggesting that different brain circuits may be affected.

(1) Introduction COVID-19 leads to neurological symptoms in up to 76% of the patients. Persisting symptoms far beyond recovery are common in many patients and point towards a progression of neurological impairment. Neuroinflammation post viral infection is a potential risk factor for the development of neurodegenerative diseases such as Parkinson's Disease (PD) and Alzheimer's Disease (AD). **(2) Aims** We examined the impact of COVID-19 on neuroinflammatory and neurodegenerative processes in hamster brains during and post SARS-CoV-2 infection. Hamsters showed mild to moderate symptoms, representing the clinical symptoms of most human patients. Our aim was to investigate whether a SARS-CoV-2 infection could lead to processes associated with neurodegenerative diseases such as PD or AD. **(3) Methods** 8 to 10 weeks old hamsters were intranasally infected with 10^5 PFU SARS-CoV-2 solved in PBS (mock-infected: only PBS) under BSL-3 conditions. The animals were euthanized 3 and 14 days post infection via Pentobarbital injection. Afterwards, brain sections were analyzed via immunohistochemistry. **(4) Results:** Although, we found no viral proteins in the brain parenchyma, there was persisting microgliosis after viral clearance (14 dpi). This finding is of special interest due to the fact, that viral infections and progressive neuroinflammation are risk factors for PD and AD. Histological evaluation indicated alterations of the neuronal homeostasis, which are associated with neurodegenerative diseases. **(5) Conclusions** The results indicate that a SARS-CoV-2 infection is a potential risk factor for neurodegenerative diseases such as AD and PD.

Sorbonne University, Brain Institute - Paris Brain Institute - ICM, Inserm, CNRS, APHP, Pitié Salpêtrière Hospital, PARIS, France

Parkinson's disease (PD) is a neurodegenerative disease characterized by the loss of dopaminergic neurons leading to a triad of motor symptoms. Only 40% of early-onset recessive forms are explained by mutations in known PD-associated genes. To look for novel recessively inherited PD-genes, we performed homozygosity mapping and exome sequencing in 91 families with consanguinity. We identified homozygous pathogenic variants in 10 potential candidate genes for recessively inherited PD. We aimed at functionally validate these novel candidate genes, using the Caenorhabditis elegans models. Transgenic strains of C.elegans expressing Green Fluorescent Protein (GFP) specifically in the dopaminergic neurons were used with a reverse genetic approach, via RNAi mediated genes. Behavioral tests involving the dopaminergic system have been carried out, including the Slow Basal Response, the Speed After Swimming and the Trash Test. Each test was performed at Day3 and Day9. The positive control is a C.elegans dopamine-deficient Cat-2 line. C.elegans orthologue of the human recessive PD-associated *PARK7* gene, *djr-1.2,* was used to validate the tests. Of the three behavioral tests, only the Slow Basal Response showed a significant basal slowing of the Cat-2 and RNAi-*djr-1.2* worms at Day3 compared with the negative control, that was rescued by the levodopa. These data will be validated using other genes known to be involved in recessive forms of PD (*PRKN*, *PINK1*, *VPS13C*) before screening potential candidate genes to validate/invalidate their involvement in PD.

Background: Parkinson's disease (PD) is a chronic, progressive neurodegenerative condition; characterized with the degeneration of the nigrostriatal dopaminergic pathway and neuroinflammation. During PD progression, microglia, the resident immune cells in the central nervous system (CNS) display altered activity, but their role in maintaining PD development has remained unclear to date. Aims: The purinergic $P2Y_{12}$ receptor ($P2Y_{12}R$), which is expressed on the microglia in the CNS has been shown to regulate microglial activity and responses; however, the function of the $P2Y_{12}R$ in PD is unknown. Results: We have found that MPTP-induced PD-symptoms in mice are associated with marked neuroinflammatory changes and $P2Y_{12}R$ contribute to the activation of microglia and progression of the disease. Surprisingly, while pharmacological or genetic targeting of the $P2Y_{12}R$ augments acute mortality in MPTP-treated mice, these interventions protect against the neurodegenerative cell loss and the development of neuroinflammation in vivo. Pharmacological inhibition of receptors during disease development reverses the symptoms of PD and halts disease progression. We found that $P2Y_{12}R$ regulates ROCK and p38 MAPK activity and control cytokine production. Conclusions: Our conclusion is that the receptor has a dualistic role in PD: functional $P2Y_{12}Rs$ are essential to initiate a protective inflammatory response, since the lack of the receptor leads to reduced survival; however, at later stages of neurodegeneration, $P2Y_{12}Rs$ are apparently responsible for maintaining the activated state of microglia and stimulating pro-inflammatory cytokine response. Improved understanding of the $P2Y_{12}R$-mediated actions in the CNS may reveal novel approaches to control neuroinflammation and modify disease progression in PD.

Aims Advanced methods in neuroimaging analysis are providing new insights into the mechanisms underlying Parkinson's Disease (PD). They have shown predictive abilities in detecting early changes in the brain, and correlating them with different disease related symptoms. By using preclinical models of the disease, this work aims to decipher the tissular signatures of these imaging changes by establishing correlation with histological findings. Methods Rats receive a double bilateral intranigral injection of the AAV alpha-synuclein, then undergo several behavioral tests to evaluate motor and cognitive functions over a 4-month period. Three MRI acquisitions are held at 2-,10- and 18-weeks post-injection, including a whole-brain T2w and T2*w. Histological studies are led to evaluate dopaminergic degeneration, iron accumulation and alpha synuclein deposits in the brain. Results This PD model shows a moderate and progressive dopaminergic neurodegeneration, with 30% loss of TH+ neurons in the nigrostriatal pathway at 4-months post-injection. It also exhibits diffuse synucleinopathy in the brain. Behavioral tests reveal deficits in sensori-motricity, attention and visuo-spatial learning. Whole-brain VBM analysis show hypointense signals between MRI sessions 2 and 3, in the nigrostriatal pathway, the hippocampus, the fimbria, as well as the limbic, insular, and prefrontal cortex. Indeed, these regions are directly related to the motor and executive functions impaired. Conclusion Spatial and functional correlations between imaging analysis and behavioral & histological profiles of established PD animal models, has the potential to explain the changes observed in imaging on a cellular and molecular level, and to help better understand the physiopathology of the disease.

EFFECTS OF DIRECTIONAL SUBTHALAMIC DEEP BRAIN STIMULATION ON GAIT AND BALANCE IN PARKINSON DISEASE PATIENTS

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Marie-Laure Welter[1], Saoussen Cherif[1], Julie Bourilhon[2], Claire Olivier[1], Dorian Bannier[2], David Maltête[3], Stéphane Derrey[4], Carine Karachi[1]
[1]Brain Institute, U1127, Paris, France, [2]Rouen University Hospital, Neurophysiology Department, Rouen, France, [3]Rouen University Hospital, Neurology Department, Rouen, France, [4]Rouen University Hospital, Neurosurgery Department, Rouen, France

The effects of subthalamic deep brain stimulation (STN-DBS) on freezing of gait (FOG) and falls are variable across individual patients. The possibility to use directional STN-DBS with specific shaping of the volume of tissue activated represents a new therapeutic option. In this pilot study, we included 10 PD patients with FOG Off-dopa and tested the effects of directional STN-DBS versus single-ring STN-DBS on gait and balance disorders using gait recordings and validated clinical scales. Patients were assessed before surgery (Off/On-dopa) and after surgery with a randomized cross-over double-blind design with: 1) single-ring, 2) directional STN-DBS with current shaping including the central part of the STN (gait 'hot-spot'), 3) dorsolateral part of the STN (sensorimotor 'hot-spot'), 4) ventral part of the STN, or 5) outside and 5) Off STN-DBS. Up to now, 8 patients were assessed 6 months after surgery. In these patients, all active STN-DBS conditions improved motor disability, axial and GABS scores relative to Off STN-DBS condition. The clinical gait and balance disorders were significantly lower with the gait 'hot-spot' directional STN-DBS relative to the directional sensorimotor, ventral and outside conditions, with no significant difference with the single-ring condition. We also found better gait parameters with single-ring and directional gait 'hot-spot' STN-DBS relative to dorsolateral-sensorimotor directional STN-DBS, with lower number of FOG episodes and gait asymmetry during straight-forward gait, and higher step length. These preliminary result suggest that directional central-gait 'hot-spot' STN-DBS is more efficient than dorsolateral-sensorimotor STN-DBS to improve gait and balance disorders in PD patients.

CORTICAL ACTIVITY RELATED TO SENSORIMOTOR SYNCHRONIZATION GUIDED BY DIFFERENT TYPES OF EXTERNAL CUES

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Janne Heijs[1], Silvana Huertas-Penen[1], Richard Van Wezel[2], Tjitske Heida[1]
[1]University of Twente, Biomedical Signals And Systems, Enschede, Netherlands, [2]Donders Institute for Brain, Cognition and Behaviour, Biophysics, Nijmegen, Netherlands

Sensorimotor synchronization (SMS) is a frequently used therapy in Parkinson's disease (PD). SMS involves the adaptation of automatic, repetitive movements (i.e. gait), to external, sensory stimuli, called cues. Its effectivity depends on the characteristics of the cue, for example, some patients benefit from visual cues (e.g. bars on the floor), while others prefer auditory cues (e.g. metronome beat). The aim of the current study is to evaluate the cortical activity related to different types of external cues, to assess the effect of the type, frequency and rhythmicity of cues. We hypothesize that the effects of different cues are related to the synchronization of different neuronal networks: the Basal Ganglia-Thalamo-Cortical (BGTC)-network (e.g. (pre-)frontal and sensorimotor cortex), and the Cerebellum-Thalamo-Cortical (CTC)-network (e.g. premotor and parietal cortex). Twenty-one healthy subjects performed a finger tapping experiment, guided by different cues in a 2x2x2-design, to evaluate the effect of: 1) cueing type: visual cues (flickering circle) vs. auditory cues (repetitive tones); 2) cueing frequency: discrete cues (1Hz) vs. continuous cues (3.2Hz); and 3) cueing rhythmicity: isorhythmic cues (one rhythm) vs. polyrhythmic cues (two rhythms in a [2:3]-relationship). A 32-channel EEG system recorded the electrocortical activity. Preliminary results show increased synchronization in cortical areas associated to the BGTC-network when using continuous or isorhythmic cues, and in areas associated to the CTC-network when using discrete or polyrhythmic cues. No differences are found between visual and auditory cues. The preliminary results show that the use of discrete and polyrhythmic cues may effectively bypass the defective BGTC-network in PD.

NARINGENIN MODULATES PARAQUAT-INDUCED OXIDATIVE STRESS AND MITOCHONDRIAL DYSFUNCTION IN A CELLULAR MODEL OF PARKINSON'S DISEASE (SH-SY5Y CELLS)

POSTER SESSION 07 - SECTION: PARKINSON'S DISEASE

Mir Ahmad[1], Amal Mondal[1,2], Moshahid M Rizvi[3]
[1]Jawaharlal Nehru University (JNU), School Of Life Sciences (sls), New-Delhi, India, [2]Jawaharlal Nehru University, School Of Life Sciences,, New Delhi, India, [3]Jamia Millia Islamia (JMI), Department Of Biosciences, Jamia Millia New Delhi, India

Parkinson's disease (PD), a common neurodegenerative disease is characterized by the progressive loss of dopaminergic neurons in the substantia nigra. The cause of PD onset remains unknown for a long time. However, recent reports suggest oxidative stress and mitochondrial dysfunction play key roles in the pathogenesis of PD. The drugs used for the treatment of PD show suboptimal results, and those that have shown some kind of neuroprotection in the animal models have failed to show any significant efficacy in clinical trials. Flavonoids are naturally occurring polyphenolic compounds that exhibit therapeutic properties in PD and do not show any side effects even in extended use. Naringenin (NAR), one such natural flavonoid, also has been reported to show neuroprotection against PD-related pathology. However, studies on its neuroprotective role and the underlying mechanisms are scarce, therefore the present study will explore the potential neuroprotective role of NAR in paraquat (PQ)-induced parkinsonism in SH-SY5Y cells. The present study determined the effect of NAR on PQ-induced cellular toxicity by measuring cell viability, oxidative stress, mitochondria membrane potential ($\Delta\Psi m$) and ATP levels in SH-SY5Y cells. Our results show that NAR treatment in SH-SY5Y cells resulted in increased cell viability, decreased oxidative stress, reduced the PQ-induced dysregulations in $\Delta\Psi m$ and increased mitochondrial ATP levels. In conclusion, NAR exhibits neuroprotection against PQ-induced neurotoxicity in SH-SY5Y cells indicating its therapeutic potential against PD. The development and identification of selective inhibitors based on these parameters will provide approaches for treating PD progression.

Naringenin alleviates paraquat-induced dopaminergic neuronal loss in SH-SY5Y cells and a rat model of Parkinson's disease.
Parkinson's disease (PD), a common neurodegenerative disease is characterized by the progressive loss of dopaminergic neurons in the substantia nigra. The cause of dopaminergic loss in PD remains unknown for a long time, however, recent reports suggest oxidative stress plays a key role in the pathogenesis of PD. Paraquat (PQ), a widely used herbicide is an oxidative stress inducer that has been implicated as a potential risk factor for the development of PD. Flavonoids are naturally occurring polyphenolic compounds that display a variety of therapeutic properties against oxidative stress. Naringenin (NAR), a natural flavonoid, exhibits neuroprotection against PD-related pathology. However, studies on its neuroprotective role and the underlying mechanisms are scarce, therefore the present study explored the potential neuroprotective role of NAR in PQ-induced parkinsonism in SH-SY5Y cells and rat model. The effect of NAR on PQ-induced cellular toxicity was determined by measuring cell viability, oxidative stress, ATP levels and the same effect was determined by assessing behavioral, biochemical, immunohistochemical, qRT-PCR and Western blot in rat model. NAR treatment in SH-SY5Y cells resulted in increased cell viability, reduced oxidative stress, elevated mitochondrial membrane potential, and higher cellular ATP levels. In rats, NAR treatment resulted in significant neuroprotection against PQ-induced behavioral deficits, oxidative stress, mitochondrial dysfunction, and astrocytosis. NAR treatment significantly modulated PQ-induced mRNA expressions of DRD2, DAT, LRRK2, SNCA, β-catenin, caspase-3, BDNF genes. NAR treatment increased TH protein expression and modulated its immunoreactivity in rat striatum. Also, GFAP decreased in response to NAR treatment. So, in the present study, NAR exhibits neuroprotection against PQ-induced neurotoxicity and neurodegeneration indicating its novel therapeutic potential against PD.

Pathophysiological implications of neuroinflammation mediated HPA axis dysregulation in the prognosis of cancer and depression.
Cancer patients are more likely to develop depressive symptoms and show a poor prognosis compared to the normal healthy

individuals. Cancer occurrence and the anticancer treatments result in the pro-inflammatory cytokines-mediated inflammation, which dysregulates the HPA-axis activity that may result in depression-like behaviour. Conversely, depression causes the activation of the HPA-axis that results in the downstream release of endogenous glucocorticoids which may result in depressive signs and symptoms in some cancer patients. Depression may also result in non-adherence to treatment and increased mortality in cancer patients. In this review, we have focused on the role of neuroimmune axis and hyperactive HPA-axis in case of both cancer and depression. Therefore, therapeutics targeting the HPA-axis dysregulation could be effective in ameliorating symptoms of depression in cancer patients.
Mol Cell Endocrinol, 2021; 520

A selective D2 dopamine receptor agonist alleviates depression through up-regulation of tyrosine hydroxylase and increased neurogenesis in hippocampus of the prenatally stressed rats.
Prenatal stress (PNS) has its negative impact on both the infant hippocampal neurogenesis and pregnancy outcomes in the neonates that serves as a risk factor for postnatal depression in adult offsprings. Therefore, main objectives of the present study were to evaluate the effect of maternal chronic unpredictable mild stress (CUMS) on behavioural changes, levels of oxidative stress, changes in selective developmental signaling genes and neurogenesis in the adult brain of Wistar rats and its reversal through a selective non-ergoline D2 type dopamine receptor (D2R) agonist Ropinirole (ROPI). Effects of ROPI treatment on CUMS induced adult rats offspring were measured by assessment of behavioural tests (sucrose preference test and forced swim test), biomarkers of oxidative stress, protein expression of tyrosine hydroxylase (TH), mRNA expression of SHH, GSK-3β, β-catenin, Notch, brain-derived neurotrophic factor (BDNF), Dopamine receptor 2 (Drd2) and bromodeoxyuridine (BrdU) cell proliferation assay. The oxidative stress, protein and mRNA expression were determined in the hippocampus and prefrontal cortex while the BrdU cell proliferation was observed in the hippocampus of rat brain. PNS induced changes resulted in depression validated by the depression-like behaviours, increased oxidative stress, decreased TH expression, altered expression of selective developmental genes, along with the reduced hippocampal neurogenesis and BDNF expression in the brain of adult offsprings. Chronic ROPI treatment reversed those effects and was equally effective like Imipramine (IMI) treatment. So, the present study suggested that ROPI can be used as an antidepressant drug for the treatment of depressive disorders.
Neurochem Int, 2020; 136
30718708: Fatima M, Srivastav S, Ahmad MH, Mondal AC
Effects of chronic unpredictable mild stress induced prenatal stress on neurodevelopment of neonates: Role of GSK-3β.
Prenatal stress (PNS) has gained attention with regard to its impact on hippocampal neurogenesis in neonates which serves as a risk factor for postnatal neurodevelopmental deficits. Evidences from animal models have suggested that depression responsive hypothalamic-pituitary-adrenal (HPA) axis and its hormonal response via cortisol, is responsible for critical neurodevelopmental deficits in the offspring which is transduced due to gestational stress. But knowledge in the area of assessing the effects of maternal chronic unpredictable mild stress (CUMS) on neurogenesis and expression of some key signaling molecules in the offsprings are limited. We have used Wistar rats to induce PNS in offsprings by maternal CUMS during pregnancy. Prefrontal cortex (PFC) and hippocampus were assessed for biomarkers of oxidative stress, neurogenesis, neurodevelopmental signaling molecules and DNA damage in the male Wister offsprings. Our investigations resulted in sufficient evidences which prove how maternal psychological stress has widespread effect on the fetal outcomes via major physiological alteration in the antioxidant levels, neurogenesis, signaling molecules and DNA damage. PNS leads to the upregulation of GSK-3β which in turn inhibited mRNA and protein expressions of sonic hedgehog (SHH), β-catenin, Notch and brain derived neurotrophic factor (BDNF). The study explored multifaceted signaling molecules especially, GSK-3β responsible for crosstalks between different neurodevelopmental molecules like SHH, Notch, BDNF and β-catenin affecting neurodevelopment of the offsprings due to PNS.
Sci Rep, 2019; 9

Role of Hypothalamic-Pituitary-Adrenal Axis, Hypothalamic-Pituitary-Gonadal Axis and Insulin Signaling in the Pathophysiology of Alzheimer's Disease.
Alzheimer's disease (AD), the commonest progressive neurodegenerative disorder of the brain, is clinically characterized by the formation of extracellular amyloid plaques and intracellular neurofibrillary tangles. Recent studies suggest a relationship between the endocrinal dysregulation and the neuronal loss during the AD pathology. Dysregulation of the hypothalamic-pituitary-adrenal (HPA) axis and hypothalamic-pituitary-gonadal (HPG) axis regulating circulating levels of glucocorticoid hormones has been implicated in the pathophysiology of AD. Likewise, dysregulated insulin signaling, impaired glucose uptake and insulin resistance are some of the prime factors in the onset/progression of AD. In this review, we have discussed the changes in HPA and HPG axes, implicated insulin resistance/signaling and glucose regulation during the onset/progression of AD. Therefore, simultaneous detection of these endocrinal markers in the early or presymptomatic

stages may help in the early diagnosis of AD. This evidence for implicated endocrinal functions supports the fact that modulation of endocrinal pathways can be used as therapeutic targets for AD. Future studies need to determine how the induction or inhibition of endocrinal targets could be used for predictable neuroprotection in AD therapies.

Evaluation of naproxen-induced oxidative stress, hepatotoxicity and genotoxicity in male Wistar rats.

Naproxen (NP), a nonsteroidal anti-inflammatory drug (NSAID), is used for the treatment of common pain, inflammation and tissue damage. Genotoxicity testing of NP is of prime importance as it represents the largest group of drugs to which humans are exposed. Not many genotoxic studies are reported on NP; therefore, the present study investigated the detailed genotoxic and oxidative stress properties of NP. Male Wistar rats were administered NP orally at the doses of 38.91 and 65.78 mg/kg body weight for 14 days. Reduced glutathione (GSH), superoxide dismutase (SOD), catalase (CAT) and lipid peroxidation (LPO) activities/levels were measured in the liver, kidney and brain tissues. The aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP) activities, and total bilirubin (TBIL) levels were measured in the liver tissues. Micronucleus frequency (micronucleus test MNT) and DNA damage (comet assay) were performed in the bone marrow cells and leukocytes, respectively. The results showed that NP treatment decreased the GSH levels and increased the SOD, CAT, LPO, ALT, AST, ALP and TBIL activities/levels compared to the control (0.05). Results of MNT showed an increased micronucleus induction and comet assay showed a significant increase in DNA damage in the NP treated animals (0.05). Treatment of NP resulted in the biochemical imbalance and induced oxidative stress that deteriorated the integrity of the cells, which caused significant damage to the genetic material and affected liver function in male Wistar rats. Therefore, NP is a potential genotoxic agent that induces genotoxicity and oxidative stress.

Influence of microglia and astrocyte activation in the neuroinflammatory pathogenesis of Alzheimer's disease: Rational insights for the therapeutic approaches.

Alzheimer's disease (AD), the most common progressive neurodegenerative disorder is characterized by the formation of extracellular amyloid plaques and intracellular neurofibrillary tangles (NFTs). Increasing evidences suggest a link between neuroinflammation and neuronal dysfunction in AD, orchestrated by the progressive activation of microglial cells and astrocytes with the consequent overproduction of proinflammatory molecules. The concomitant release of anti-inflammatory mediators antagonizes the inflammatory processes and leading to the severity of the AD pathology. The simultaneous detection of these inflammatory molecules in the pre-symptomatic stage may help in the early diagnosis of the AD. We have discussed the impact of microglia and astrocytic cells, the principal agents in the neuroinflammation process, in relation to the progression of the AD. Modulation of the risk factors and targeting of these immune mechanisms could lead to better therapeutic or preventive strategies for the AD. Further studies need to determine, how the inhibition of inflammatory factors could be used for the AD alternative therapies.

Determination of potential oxidative damage, hepatotoxicity, and cytogenotoxicity in male Wistar rats: Role of indomethacin.

The present study demonstrated the indomethacin (INDO) induced oxidative stress, hepatotoxicity, and genotoxicity in male Wistar rats. Animals were orally administrated INDO at doses of 0.302 and 0.605 (mg/kg b.w.) for 2 weeks. Reduced glutathione (GSH), superoxide dismutase (SOD), catalase (CAT), and lipid peroxidation (LPO) activities/levels were measured in the liver, kidney, and brain tissues. The aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP) activities, total bilirubin (TBIL) levels, and histopathological changes were determined in the liver tissues. Micronucleus frequency (micronucleus test) and DNA damage (comet assay) tests were performed in the bone marrow cells and leukocytes, respectively. Results show that INDO treatment decreased the GSH, SOD, and CAT levels/activities and increased the LPO, ALT, AST, ALP, and TBIL activities/levels. INDO induced significant hepatic injury and micronucleus and DNA damage. Thus, the current investigations confirm the oxidative stress, hepatotoxic, and genotoxic properties of INDO in the male Wistar rats.

In vivo induction of antioxidant response and oxidative stress associated with genotoxicity and histopathological alteration in two commercial fish species due to heavy metals exposure in northern India (Kali) river.

Heavy metals can significantly bioaccumulate in fish tissues. The step wise mechanism of heavy metal toxicities on fish health is still limited. The present study assessed the tissue-specific antioxidant response and oxidative stress biomarkers of commercially important fish species namely, Channa striatus and Heteropneustes fossilis inhabiting Kali River of northern

India where heavy-metal load is beyond the World Health Organisation - maximum permissible limits. Heavy metals chromium (Cr), nickel (Ni), lead (Pb) and cadmium (Cd) were elevated in both fish species compared to recommended values of the Federal Environmental Protection Agency (FEPA), 1999 for edible fishes. Reduced glutathione (GSH), superoxide dismutase (SOD) and catalase (CATA) activities in all tissues (brachial, neural, renal and hepatic) were altered. Cellular lipid and protein compromisation in both fishes induced by heavy metals was determined by lipid peroxidation (LPO) and protein carbonylation (PC) assays. Micronucleus (MN) test of erythrocytes and comet assay of liver cells confirmed genotoxicity. Histopathology of the liver, kidney and brain of affected fishes was distorted significantly with its reference fishes thereby affecting the quality and quantity of these fish stocks. This raises a serious concern as these fishes are consumed by the local population which would ultimately affect human health.

In Parkinson's Disease (PD), the management of motor fluctuations aims at prolonging the effect of dopaminergic stimulation while reducing total levodopa (L-DOPA) load to avoid dyskinesia. Catechol-*O*-methyl transferase (COMT) inhibition reduces degradation of L-DOPA to 3-OMD and could prolong L-DOPA effectiveness by reducing both L-DOPA and dopamine metabolism. However, some COMT inhibitors like tolcapone and entacapone show hepatotoxicity and a real necessity to develop new drugs with a better toxic profile is highly desired. By studying the chemical constituents of a plant, *M. pruriens*, several tetrahydroisoquinoline compounds (THIQ) derived from L-DOPA were characterized and tested on several L-DOPA enzymes metabolism enzymes including COMT (BioCIS). Some compounds have shown an absence of toxicity and a COMT inhibitory activity similar to tolcapone. Firstly, we tested the COMT BioCIS inhibitors in an MPP+ *in vivo C. elegans* model, presenting partial loss of dopaminergic (DA) neurons and a dysfunctional specific dopamine-associated behavior. We evaluated the behavioral effect of COMT BioCIS inhibitors, comparing with tolcapone as a reference drug. After, we evaluated the different COMT inhibitors to observe if they could potentiate low doses of L-DOPA. Finally, we studied the most effective compound in an *in vivo* 6-OHDA rat model of Parkinson's disease. We were able to restore the behavioral deficit in the MPP^{+}*C. elegans* model not only with L-DOPA but also with tolcapone and COMT inhibitors. COMT inhibitors could potentiate L-DOPA effect and the most effective BioCIS drug had similar results to tolcapone. The administration of the selected drug in the 6-OHDA rat model could confirm our results by potentiating the effect of L-DOPA. Our results pave the way for the use of COMT inhibitors on L-DOPA-treated parkinsonian patients.

After unilateral lesion of the medial forebrain bundle (MFB) by 6-Hydroxydopamine (6-OHDA) rats exhibit lateralized deficits in spontaneous behavior or apomorphine-induced rotations. We investigated whether such lateralization is attenuated by either 30 Hz deep brain stimulation (DBS) or glutamatergic neurotransmission in the inferior colliculus (IC) of Wistar rats. For that, hemiparkinsonian rats were created by injecting 6-OHDA in the right MFB. Immediately after that injection, the same rats were also implanted with electrode or microinjection guide-cannula in the IC. One week later, rotatory behavior was assessed immediately after each rat had received apomorphine (s.c.). Intracollicular DBS did not affect spontaneous lateralization but attenuated apomorphine-induced rotations. Spontaneous lateralization disappeared after both glutamatergic antagonist MK-801 or the agonist NMDA microinjected in the IC. Apomorphine-induced rotations were potentiated by MK-801 but were not affected by NMDA intracollicular microinjection. Importantly, the side of the IC microinjection regarding the lesion (ipsi- or contralateral) is particularly important. Taken together, the present results support our hypothesis that the hypersensitivity caused by neurochemical lesion of nigro-striatal dopaminergic pathway can be influenced by IC 30 Hz DBS or glutamatergic intracollicular neurotransmission.

Introduction. Parkinson's disease (PD) is a common neurodegenerative disorder. G2019S mutation in leucine-rich repeat kinase 2 (*LRRK2*) is common genetic risk factor for PD. However, molecular mechanisms of PD associated with mutation in the *LRRK2 gene* remain unknown. Earlier, it was shown that the most common mutation in the *LRRK2* gene, G2019S, was associated with activity of glucoceresobridase (GCase) enzyme, encoded by the *GBA* gene, mutations in which are also common genetic risk factors for PD. **Aim.** To evaluate whether the alteration of lysosomal activites may play role in PD associated with mutation G2019S in the *LRRK2 gene* (*LRRK2*-G2019S-PD). **Materials and methods.** Blood samples of 6 patients with *LRRK2*-G2019S-PD, 180 sPD patients and 168 controls were generated. The enzymatic activities of GCase and also alpha-L-Iduronidase (IDUA), galactosylceramidase (GALC), alpha-galactosidase (GLA), acid sphingomyelinase (ASMase) and their substrates concentrations (hexosylsphingosine (HexSph), globotriaosylsphingosine (LysoGb3), lysosphingomyelin (LysoSM)) were measured by liquid chromatography tandem-mass spectrometry in blood. **Results**. No differences in enzyme activity of GCase, GLA, GAA, ASMase, IDUA, GALC in *LRRK2*-G2019S-PD patients with sPD and controls ($p>0.05$). However, GALC activity was elevated in sPD compared to controls ($p=0.009$). LysoSM concentration was decreased in sPD compared to controls ($p=0.0002$). While HexSph concentration was increased in LRRK2-G2019S-PD patients compared to sPD patients ($p=0.040$) and LysoGb3 concentration was increased in LRRK2-G2019S-PD patients than in sPD patients and controls ($p<0.05$). **Conclusion**s. Our results first demonstrated alteration of lysosphingolipid concentrations in LRRK2-G2019S-PD patients with increase of HexSph and LysoGb3 concentrations in LRRK2-G2019S-PD.

FUNCTIONAL REORGANIZATION OF THE PERI-INFARCT CORTEX PROMOTING RECOVERY OF SKILLED MOTOR FUNCTIONS AFTER STROKE

POSTER SESSION 07 - SECTION: STROKE

Jithin Nambiar[1,2], Matteo Panzeri[1,2], Mark-Aurel Augath[3], Fritjof Helmchen[1,2], Anna-Sophia Wahl[1,2,4]
[1]University of Zürich, Neuroscience Center Zürich, Zürich, Switzerland, [2]University of Zürich, Brain Research Institute, Zürich, Switzerland, [3]ETH Zürich, Institute Of Biomedical Engineering, Zürich, Switzerland, [4]University of Heidelberg, Central Institute Of Mental Health, Mannheim, Germany

Once a stroke occurs, victims suffer from lifelong disabilities including the impairment of speech, vision and motor control. No pharmacological therapy is currently available to stimulate the restoration of function. However, forms of spontaneous recovery exist even without a therapeutic intervention. The principles underlying such increased plasticity, which can promote map-shifts and rewiring of neuronal circuitry, are not well understood. The brain region adjacent to stroke damage, the 'penumbra' zone, is critical for stroke rehabilitation. Thus, understanding the reorganization of neuronal circuits in the peri-infarct tissue around cortical strokes and its contribution to functional recovery with cellular resolution is crucial to develop new therapies. Whereas clinical trials are limited in resolution, chronic 2-photon calcium imaging in a mouse model of stroke opens new avenues to study cellular responses to the injury in relation to the functional deficit over time. We trained mice to run on an irregularly spaced ladder wheel, a task that demands flexible limb movements to successfully execute grasping actions (*Omlor et al, Nat Commun* ***10,*** *4812 (2019),* and simultaneously applied chronic 2-photon calcium imaging of motor cortex activity during learning and after a motor cortex stroke. Our preliminary data show how individual surviving neurons and whole neuronal populations reorganize and remap in the peri-infarct region and how they form new circuits to provide a neurobiological prerequisite for the restoration of lost motor function. Our results may enable the identification of key principles of neuronal repair and may thus lead to improved future rehabilitative strategies.

Adaptive Whisking in Mice.
Rodents generate rhythmic whisking movements to explore their environment. Whisking trajectories, for one, appear as a fixed pattern of whisk cycles at 5-10 Hz driven by a brain stem central pattern generator. In contrast, whisking behavior is thought to be versatile and adaptable to behavioral goals. To begin to systematically investigate such behavioral adaptation, we established a whisking task, in which mice altered the trajectories of whisking in a goal-oriented fashion to gain rewards. Mice were trained to set the whisker to a defined starting position and generate a protraction movement across a virtual target (no touch-related tactile feedback). By ramping up target distance based on reward history, we observed that mice are able to generate highly specific whisking patterns suited to keep reward probability constant. On a sensorimotor level, the behavioral adaptation was realized by adjusting whisker kinematics: more distant locations were targeted using higher velocities (i.e., pointing to longer force generation), rather than by generating higher acceleration (i.e., pointing to stronger forces). We tested the suitability of the paradigm of tracking subtle alteration in whisking motor commands using small lesions in the rhythmic whisking subfield (RW) of the whisking-related primary motor cortex. Small contralateral RW lesions generated the deterioration of whisking kinematics with a latency of 12 days post-lesion, a change that was readily discriminated from changes in the behavioral adaptation by the paradigm.

FIBRINOGEN REGULATES LESION BORDER-FORMING REACTIVE ASTROCYTE PROPERTIES AFTER VASCULAR DAMAGE

POSTER SESSION 07 - SECTION: STROKE

Pasquale Conforti[1,2], Szilvia Mezey[2], Suvra Nath[1,2], Yu-Hsuan Chu[1,2], Subash C. Malik[1,2], Jose C. Martínez Santamaría[1,2], Sachin S. Deshpande[1,2], Lauriane Pous[1,2], Barbara Zieger[3], Christian Schachtrup[2,4]

Reactive astrocytes at the border of damaged neuronal tissue organize into a barrier surrounding the fibrotic lesion core, separating this central region of inflammation and fibrosis from healthy tissue. Astrocytes are essential to form the border and for wound repair but interfere with neuronal regeneration. However, the mechanisms driving these astrocytes during CNS disease are unknown. Here we show that blood-derived fibrinogen is enriched at the interface of lesion border-forming elongated astrocytes after cortical brain injury. Anticoagulant treatment depleting fibrinogen reduces astrocyte reactivity, extracellular matrix deposition and inflammation with no change in the spread of inflammation, whereas inhibiting fibrinogen conversion into fibrin did not significantly alter astrocyte reactivity, but changed the deposition of astrocyte extracellular matrix. RNA sequencing of FACS-isolated astrocytes of fibrinogen-depleted mice after cortical injury revealed repressed gene expression signatures associated with astrocyte reactivity, extracellular matrix deposition and immune-response regulation, as well as increased gene expression signatures associated with astrocyte metabolism and astrocyte-neuron communication. Systemic pharmacologic depletion of fibrinogen resulted in the absence of elongated, border-forming astrocytes and increased the survival of neurons in the lesion core after cortical injury. These results identify fibrinogen as a critical trigger for lesion border-forming astrocyte properties in CNS disease.

P75 neurotrophin receptor controls subventricular zone neural stem cell migration after stroke.
Stroke is the leading cause of adult disability. Endogenous neural stem/progenitor cells (NSPCs) originating from the subventricular zone (SVZ) contribute to the brain repair process. However, molecular mechanisms underlying CNS disease-induced SVZ NSPC-redirected migration to the lesion area are poorly understood. Here, we show that genetic depletion of the p75 neurotrophin receptor (p75) in mice reduced SVZ NSPC migration towards the lesion area after cortical injury and that p75 NSPCs failed to migrate upon BDNF stimulation in vitro. Cortical injury rapidly increased p75 abundance in SVZ NSPCs via bone morphogenetic protein (BMP) receptor signaling. SVZ-derived p75 NSPCs revealed an altered cytoskeletal network- and small GTPase family-related gene and protein expression. In accordance, BMP-treated non-migrating p75 NSPCs revealed an altered morphology and α-tubulin expression compared to BMP-treated migrating wild-type NSPCs. We propose that BMP-induced p75 abundance in NSPCs is a regulator of SVZ NSPC migration to the lesion area via regulation of the cytoskeleton following cortical injury.

Intestinal differentiation involves cleavage of histone H3 N-terminal tails by multiple proteases.
The proteolytic cleavage of histone tails, also termed histone clipping, has been described as a mechanism for permanent removal of post-translational modifications (PTMs) from histone proteins. Such activity has been ascribed to ensure regulatory function in key cellular processes such as differentiation, senescence and transcriptional control, for which different histone-specific proteases have been described. However, all these studies were exclusively performed using cell lines cultured in vitro and no clear evidence that histone clipping is regulated in vivo has been reported. Here we show that histone H3 N-terminal tails undergo extensive cleavage in the differentiated cells of the villi in mouse intestinal epithelium. Combining

biochemical methods, 3D organoid cultures and in vivo approaches, we demonstrate that intestinal H3 clipping is the result of multiple proteolytic activities. We identified Trypsins and Cathepsin L as specific H3 tail proteases active in small intestinal differentiated cells and showed that their proteolytic activity is differentially affected by the PTM pattern of histone H3 tails. Together, our findings provide in vivo evidence of H3 tail proteolysis in mammalian tissues, directly linking H3 clipping to cell differentiation.

Neonatal cerebral hypoxia-ischemia (HI) is the leading cause of death and disability in newborns with the only current treatment being hypothermia. An increased understanding of the pathways that facilitate tissue repair after HI may aid the development of better treatments. Here we study the role of lactate receptor HCAR1 in tissue repair after HI in mice. We show that HCAR1 knockout mice have reduced tissue regeneration compared with wildtype mice. Proliferation of neural progenitor cells and glial cells, as well as microglial activation were impaired. Transcriptome analysis showed a strong transcriptional response to HI in the subventricular zone of wildtype mice involving about 7300 genes. In contrast, the HCAR1 knockout mice showed a modest response, involving about 750 genes. Notably, fundamental processes in tissue repair such as cell cycle and innate immunity were dysregulated in HCAR1 knockout. Our data suggest that HCAR1 is a key transcriptional regulator of pathways that promote tissue regeneration after HI.

A SUBCOMMISSURAL ORGAN-SPONDIN-DERIVED PEPTIDE (NX210C) IMPROVES RECOVERY OF SYNAPTIC TRANSMISSION AFTER CEREBRAL ISCHEMIA IN VITRO

POSTER SESSION 07 - SECTION: STROKE

Mélissa Sourioux[1], Sighild Lemarchant[1], Juliette Le Douce[1], Sandrine Hugues[2], Mélissa Farinelli[2], Yann Godfrin[1,3]
[1]Axoltis Pharma, Preclinical R&d, Lyon, France, [2]E-Phy-Science, -, Biot, France, [3]Godfrin Life-Sciences, -, Caluire-et-Cuire, France

Aim: Cerebral ischemia is characterized by a transient deprivation of oxygen and nutrients to the brain leading to neuronal dysfunction, cell death, and subsequent motor and cognitive impairments. Hence, there is a substantial need for solutions to prevent this condition or treat its consequences. The aim of this study was thus to evaluate the efficacy of a subcommissural organ-spondin-derived peptide (NX210c) to restore synaptic transmission following cerebral ischemia *in vitro*. **Methods:** Mouse hippocampal brain slices were submitted to oxygen-glucose deprivation (OGD) to mimic ischemia. NX210c (250 µg/mL) or vehicle was bath-applied either from the beginning or the end of OGD exposure. Functional recovery was assessed by recording field excitatory postsynaptic potentials (fEPSPs) evoked at Schaffer collateral-CA1 synapses. **Results/Conclusions:** While OGD causes synaptic depression, concurrent administration of NX210c improves recovery. Indeed, fEPSP slopes were significantly higher in NX210c-treated than in vehicle-treated slices within 30-60 minutes from OGD induction (fEPSP slope expressed as a % of baseline: 47.2±4.5 and 61.7±5.0 for vehicle and NX210c respectively, $p<0.05$) and this beneficial effect persisted for 80-90 minutes post-OGD (72.4±2.9 and 92.6±2.4 for vehicle and NX210c respectively, $p<0.001$). Staggeringly, NX210c was efficient even if added after OGD exposure (77.1±2.7 and 88.0±1.9 for vehicle and NX210c respectively, 90-120 minutes post-OGD, $p<0.01$). According to complementary studies, this beneficial effect of NX210c on the restoration of synaptic transmission could be explained by its preferential action on GluN2A-containing NMDA receptors. Finally, NX210c is a promising drug-candidate to improve neurological outcomes after ischemic insult.

IMPACT OF TEMPORAL OXYGEN AND GLUCOSE DEPRIVATION ON NEONATAL ASTROCYTES CULTURED ON THE SELECTED BIOMATERIALS

POSTER SESSION 07 - SECTION: STROKE

Justyna Gargas, Justyna Janowska, Malgorzata Ziemka-Nalecz, Joanna Sypecka
Mossakowski Medical Research Institute Polish Academy of Sciences, Neurorepair Department, Warszawa, Poland

Aim: As the cells responsible for maintaining local homeostasis, astrocytes are very sensitive to any changes in their microenvironment. Temporary limitation of oxygen and glucose affects developing brain and is associated with perinatal asphyxia, which is one of the leading causes of child deaths under the age of 5-years. In this context, an *in vitro* model of perinatal asphyxia was used to determine the survival and morphology of neonatal astrocytes after transient oxygen and glucose deprivation (OGD). **Methods:** The primary mixed glial cultures were established from the neonatal rat brains, followed by cell culturing for 12 days prior to astrocyte isolation. The cells were then subjected to OGD procedure and cultured for the following 24h in physiologically normoxic condition (5% oxygen) on surfaces coated with poly-L-lysine or selected biomaterials: fibronectin, laminin and Matrigel. The cells were immunolabelled with lineage-specific markers and their expression was quantified in regard to applied biomaterials. **Results:** Cell adhesion to tested biomaterials had significant effects on astrocyte morphology, proliferation and expression of markers associated with cytoskeleton (GFAP), excitatory amino-acid transport (EAAT1) and glycogen synthesis and use (GS). The highest increase in the marker expression (by 362% for GFAP, 237% for GS) were observed when the OGD-subjected astrocytes were cultured on fibronectin. **Conclusions:** Culturing astrocytes on various biomaterials after OGD exerts strong impact on their morphology and proliferation. This observation could be especially useful when aiming at mimicking in vitro physiological conditions or creating selected disease-in-a-dish models for both basic research and pre-clinical studies.

Stroke is the second most common cause of death and major cause of disability worldwide. Oligodendrocytes (OLs) are one of the most vulnerable cell populations in response to ischemia. Its death leads to demyelination of axons and neuronal disfunction leading to long-term sensorimotor and cognitive deficits. Here we aim to generate patient-specific OLs from skin cells and use them to repair demyelinated axons due to cerebral ischemia. For that, human fibroblast-derived induced pluripotent stem cells (iPSCs) primed to neural phenotype are transplanted into, first, the somatosensory cortex adjacent to an ischemic lesion in a rat stroke model, and second, human adult cortical organotypic slices. Characterization of grafted-derived OLs and axonal myelination was performed using immunohistochemistry followed by confocal and immuno-electron microscopy. In both, *human-to-rat* and *human-to-human* models, iPSCs-derived progenitors were able to generate OLs in different stages of differentiation. In rats, part of the human-derived OLs became mature in the core of the transplantation and in the corpus callosum. Also, transplantation increased endogenous oligodendrogenesis. Most importantly, iPSC-derived progenitors gave rise to mature OLs in a human-to-human grafted situation. We also observed graft-derived myelin surrounding axons of host neurons. In conclusion, iPSC-derived progenitors transplanted into an *in vivo* rat stroke model as well as *ex vivo* human system give rise to mature OLs which are involved in axonal myelination. This strategy will allow us to better understand the mechanisms of remyelination of damaged axons after ischemic stroke and to improve functional recovery after stroke recovery by means of stem cell-based approach.

Stroke is one of the major causes of long-term disability and death in adult humans worldwide. Ischemic stroke is characterized by a shortage of glucose and oxygen to a specific area of the brain causing neuronal death, which leads to motor and cognitive impairments. The replacement of these neurons is essential for the functional recovery of patients. In this study, we aim to transplant human embryonic stem cells-induced neurons (hES-iNs) in an animal model of cortical stroke. hES-iNs are generated by ESCs programming inducing overexpression of NGN2 transcription factor. After 7 days of programming, cells were transplanted into the somatosensory cortex adjacent to a cortical ischemic lesion in rats subjected to cortical stroke. Characterization of the grafted neurons, their axonal myelination and synaptic inputs to them were performed using immunohistochemistry and immunoelectron microscopy (iEM). NGN2-programmed hESCs do not give rise to teratomas. Three months after transplantation ES-iN express markers of immature and mature neurons as well as markers for both, upper and deep cortical layers. We observed that programmed neurons send widespread axonal projections to the cortex of both hemispheres of stroke-subjected. More importantly, iEM data showed that ES-iNs receive functional synaptic inputs from host cortical neurons and their axons are myelinated by host-derived oligodendrocytes. In conclusion, hES-iNs transplanted into stroke-injured rat cortex survive, give rise to immature and mature neurons, express cortical layer markers, send widespread projections, and integrate in the host brain.

FUNCTIONAL CHARACTERIZATION OF A NOVEL DUAL A2A/A2B ADENOSINE RECEPTOR ANTAGONIST ON CA1 SYNAPTIC PLASTICITY OR DURING OXYGEN GLUCOSE DEPRIVATION

POSTER SESSION 07 - SECTION: STROKE

Martina Venturini[1], Federica Cherchi[1], Clara Santalmasi[1], Lucia Frulloni[1], Daniela Catarzi[2], Vittoria Colotta[2], Flavia Varano[2], Felicita Pedata[1], Elisabetta Coppi[1], Anna Maria Pugliese[1]

Background: Adenosine is a neuromodulator exerting its functions *via* four receptor subtypes, A_1, A_{2A}, A_{2B}, and A_3. The A_{2A} and A_{2B} receptors (A_{2A}Rs, A_{2B}Rs) are both coupled to Gs-protein and expressed at hippocampal level where they are known to inhibit paired-pulse facilitation (PPF), an electrophysiological paradigm whose reduction reflects an increase in presynaptic glutamate release. The selective antagonism of A_{2A}R or A_{2B}R protects from the irreversible synaptic failure induced by severe oxygen glucose deprivation (OGD) in the CA1 hippocampus and prevents or delays anoxic depolarization (AD) appearance, an unequivocal sign of neuronal injury, also counteracting CA1 neuronal loss, astrocyte activation and cytochrome C release. A multi-target pharmacological approach, which has become an increasingly pursued strategy for the cure of complex pathologies, included cerebral ischemia, could be advantageous for the treatment of stroke by blocking both A_{2A}Rs and A_{2B}Rs. **Aim**: We studied the effects of the newly synthesized multitarget A_{2A}R/A_{2B}R antagonist, P626, on PPF and AD development induced by severe OGD. **Methods**: Electrophysiological recordings were performed to monitor synaptic transmission and plasticity in the CA1 region of acutely isolated rat hippocampal slices. **Results**: The appearance of AD during a 30 minute OGD was significantly delayed by P626 (400 nM). Furthermore, P626 (200 nM) completely antagonized PPF reduction induced by the selective A_{2A}R agonist CGS21680 (50 nM) or the selective A_{2B}R agonist BAY60-6583 (200 nM). **Conclusions**: Data demonstrated the beneficial effect of P626, a multitarget antagonist of A_{2A}R/A_{2B}R, in preventing OGD-induced CA1 damage and in modulating glutamate release in this brain area.

THE CONNECTION BETWEEN PRIMARY CILIA AND THE HYPOXIA-INDUCIBLE FACTOR-2ALPHA PROMOTES THE MEK/ERK SIGNALING PATHWAY

POSTER SESSION 07 - SECTION: STROKE

Tristan Leu, Jannik Denda, Anna Wrobeln, Joachim Fandrey
University of Duisburg-Essen, Institute Of Physiology, Essen, Germany

Cell communication is essential for processes like proliferation, apoptosis, and differentiation. Primary cilia, which are antennae-like structures on the cell surface of most mammalian cells, including neural tissue, are necessary for these processes. Cilia are fundamental for cellular signaling and the realization of signaling pathways, such as Hedgehog, Wnt and TGF-β. Disruption of this signal transmission leads to a multitude of deadly human diseases, like the Joubert syndrome (JBTS), the Meckel–Gruber syndrome (MKS), or the Bardet–Biedl syndrome (BBS). This often involves deformations of the central nervous system, such as forebrain disorders, hydrocephalus or exencephaly. Especially in situations without suitable oxygen supply, it is necessary to provide relevant signals for counter-regulations quickly. One of the most important factors in such critical situations are hypoxia-inducible factors (HIFs). Especially HIF-2 is promoting neurogenesis and has a protective effect on neuronal stem cells. We showed by Co-Immunoprecipitation that intraflagellar transport protein 88 homolog (IFT88) directly interacts with HIF-2α, in neuronal cells. Furthermore, we have detected by immunofluorescence staining that HIF-2α accumulates under hypoxia in the ciliary axoneme and promotes ciliary elongation. qPCR analysis have proved that HIF-2α affects ciliary signaling by promoting the MEK/ERK signaling pathway. Neuronal cells without HIF-2α decrease transcription of *Mek1/2* and *Erk1/2*, and thus target genes of the MEK/ERK signaling pathway, such as *Fos* and *Jun*, are significantly decreased. These results suggest that under hypoxic conditions HIF-2α influences ciliary signaling by interacting with IFT88. This implies an unexpected and far more extensive function of HIF-2α than described before.

EFFECTS OF UROGUANYLIN'S SIGNALLING PATHWAY ON ISCHEMIC STROKE

POSTER SESSION 07 - SECTION: STROKE

Martina Ratko[1,2], Nikola Habek[1,2,3], Marina Dobrivojević Radmilović[1], Siniša Škokić[1], Helena Justić[1], Anja Barić[1], Aleksandra Dugandžić[1,2,3]
[1]School of Medicine, University of Zagreb, Croatian Institute For Brain Research, Zagreb, Croatia, [2]School of Medicine, University of Zagreb, Centre Of Excellence For Basic, Clinical And Translational Neuroscience, Zagreb, Croatia, [3]School of Medicine, University of Zagreb, Department Of Physiology, Zagreb, Croatia

Activation of guanylate cyclase (GC) A after ischemic stroke is neuroprotective. The aim is to investigate the effect of GC-C activation by uroguanylin (UGN) on ischemic stroke. MCAO was performed on GC-C knock out (GC-C KO), UGN KO mice and their WT littermates. MR images were acquired before and 24h after stroke. Ca^{2+} response was recorded in astrocytes 48h after MCAO. Systolic (SP), diastolic (DP) and mean arterial blood pressure (MAP) were recorded. GC-C KO develop significantly smaller ischemic lesions. Though they have higher SP, DP and MAP, blood flow or its reduction during MCAO did not differ between KO and WT. Unlike GC-C KO, UGN KO and WT have stronger Ca^{2+} response to UGN stimulation in peri-ischemic astrocytes and this difference may result in smaller lesions in GC-C KO. Stronger activation was explained when immunohistochemical staining showed GC-C expression in peri-ischemic astrocytes, while under normoxic conditions it is limited to neurons. GC-C activation leads to development of larger lesions. Its expression in peri-ischemic astrocytes causes stronger activation of the Ca^{2+}-dependent signalling pathway which could stimulate the Na^{+}/H^{+} exchanger causing tissue acidification and neuronal death. ACKNOWLEDGEMENTS: Research was funded by the Scientific Centre of Excellence for Basic, Clinical and Translational Neuroscience (project “Experimental and clinical research of hypoxic-ischemic damage in perinatal and adult brain”; GAKK01.1.1.01.0007 funded by the European Union through the European Regional Development Fund), “Young researchers' career development project – training of doctoral students” and BRADISCHEMIA (UIP-2017-05-8082) of Croatian Science Foundation funded by European Union’s European Social Fund.

IN VIVO MESOSCALE IMAGING OF CONTRALESIONAL MOTOR CORTEX ACTIVITY DURING A GRASPING TASK IN MICE FOLLOWING STROKE

POSTER SESSION 07 - SECTION: STROKE

Matteo Panzeri[1,2], Jithin Nambiar[1,2], Mark-Aurel Augath[3], Fritjof Helmchen[1,2], Anna-Sophia Wahl[1,2,4]
[1]University of Zürich, Brain Research Institute, Zürich, Switzerland, [2]University of Zurich / ETH Zurich, Neuroscience Center Zurich, Zurich, Switzerland, [3]ETH Zürich, Institute Of Biomedical Engineering, Zürich, Switzerland, [4]University of Heidelberg, Central Institute Of Mental Health, Mannheim, Germany

Stroke lesion size and location are major factors influencing the degree of sensorimotor impairment and the capacity for restoration of lost functions. While it is well established that the tissue immediately surrounding the stroke core undergoes functional reorganization and takes over part of the functionality lost to the stroke, the role of the contralesional, healthy motor cortex remains a matter of debate. Changes in neuronal activity on the contralesional side have been reported both in humans and in rodent stroke models. However, it remains unclear whether post-stroke functional modifications in contralesional motor cortex merely reflect maladaptation in functional connectivity, or whether spontaneous re-mapping of lost motor function takes place. To investigate this question, we developed a skilled reach-to-grasp task, in which mice manipulate a joystick with their right forelimb to receive a reward. Once mice are experts in the task, they receive a large photothrombotic stroke to the left sensorimotor cortex, followed by weekly testing in the task up to 8 weeks post-stroke. We perform bilateral recordings of layer 2/3 pyramidal neuron activity across the dorsal cortex using wide-field calcium imaging, while tracking forelimb trajectories with high-speed cameras. The goals of this pilot project are to characterize changes of grasp-related global L2/3 cortical activity patterns, to track the evolution of these changes over a critical post-stroke plasticity period of up to 2 months, and to evaluate how these changes relate to adjustments in grasping dynamics. The results gained here may reveal principles that could serve future refinements of rehabilitative strategies.

THE PROTEIN KINASE C SIGNALING PATHWAY REGULATES HYPOXIA-INDUCED LTP OF NMDA NEUROTRANSMISSION IN VISUAL RETINOCOLLICULAR PATHWAY

POSTER SESSION 07 - SECTION: STROKE

Hanna Dumanska, Nickolai Veselovsky
Bogomoletz Institute Of Physiology National Academy Of Science Of Ukraine, Department Of Neuronal Network Physiology, Kyiv, Ukraine

Hypoxia is the main accompanying factor of numerous diseases. Identification of the mechanisms underlying *the* early stage of hypoxic injury of the retinocollicular pathway will benefit the future treatment of the navigation, orientation, and visual attention impairments. We have previously reported that hypoxia-induced long-term potentiation (LTP) of NMDA retinocollicular transmission is associated with a decrease of the current decay time - an increase in NR2A/NR2B ratio. In this study, we tested the role of protein kinase C (PKC) signaling pathway in hypoxia-induced LTP. We developed the unique coculture of dissociated retinal cells and superficial superior colliculus neurons. Using paired patch-clamp technique, we recorded pharmacologically isolated NMDA neurotransmission under normal and hypoxic conditions *in vitro*. The presence of chelerythrine chloride (5 µM ChC - an inhibitor of PKC) completely blocked LTP of NMDA transmission induced by hypoxia. The ChC also abolished the hypoxia-induced increase of spontaneous NMDA currents amplitudes but did not affect the increased occurrence frequency. Moreover, we observed that ChC blocked the decrease of the decay time of evoked and spontaneous currents (control 48.2 ± 4.6ms; hypoxia 13.5 ± 5.4ms; reoxygenation in presence of ChC 46.2± 4.8ms; hypoxia in presence of ChC 45.8 ± 5.5 ms; reoxygenation 43.8 ± 5.6ms). Inhibition of PKC signaling pathway completely blocked LTP of NMDA retinocollicular transmission and lead to the offset of associated changes in NMDAR subunit composition. The revealed electrophysiological basis of LTP in response to hypoxic injury might be targeted to prevent lesions of the retinocollicular pathway.

BRAIN-WIDE MICROLESIONS AFFECT THE DEGENERATION OF MEMORY CIRCUITS IN THE HIPPOCAMPUS

POSTER SESSION 07 - SECTION: STROKE

Hendrik Heiser[1], Adrian Hoffmann[1], Victor Ibanez[1], Martin Wieckhorst[1], Fritjof Helmchen[1], Anna-Sophia Wahl[1,2]

While our memory determines our thinking and decisions, the deterioration of memory indicates a loss of self-concept and self-determination. 20% of stroke survivors exhibit cognitive decline and dementia-like symptoms, an impairment that is often misdiagnosed and under-researched. A typical early symptom of this vascular form of dementia is impaired spatial orientation. We here present a mouse model where we can study within the same mouse the formation of memory engrams for spatial orientation in the healthy condition and after induction of microlesions. Mice were trained to navigate in a virtual corridor while we performed 2photon calcium imaging in the CA1 region of the hippocampus. We tracked the activity of individual neurons and neuronal populations during the spatial navigation task in the healthy and in the pathological condition: After inducing brain-wide microinfarcts, we observed responses to the injury on a cellular and network level. We show that these distributed microlesions cause cognitive symptoms, while sparing motor function. Depending on their size and location, these lesions appear to impair spatial memory and induce substantial recoding and reorganization of surviving neurons to restore lost memory engrams. With our approach, we aim to elucidate how surviving neurons in the hippocampus rewire to compensate for the loss of others. An improved understanding of causal relationships between neural rewiring and recovery of cognitive features may open new options for novel therapeutic approaches or optimized cognitive rehabilitation strategies to treat patients with vascular dementia as a long-term consequence of ischemic insults.

THE EFFECTS OF SHORT-TERM HYPOXIA ON CA CURRENTS IN RETINAL GANGLION CELLS

POSTER SESSION 07 - SECTION: STROKE

Mariia Telka, Hanna Dumanska, Nickolai Veselovsky
Bogomoletz Institute Of Physiology National Academy Of Science Of Ukraine, Department Of Neuronal Network Physiology, Kyiv, Ukraine

Hypoxia is a common factor of numerous ocular diseases such as glaucoma, diabetic retinopathy, age-related macular degeneration. These pathologies lead to damage of retinal ganglion cells (RGC) and optic nerve head to subsequent vision loss. It has been shown previously that short-term hypoxia induces bidirectional long-term plasticity in retinocollicular projections. Voltage-gated calcium channels (VGCC) are an important component of synaptic transmission. They also play a central role in different signaling processes, like enzyme activation, gene transcription, and the onset of apoptosis. The aim of this work was to identify and evaluate the effect of an early stage of hypoxia injury on VGCC in cultured RGC. Calcium currents were recorded in cultured rat RGCs using the whole-cell patch-clamp technique in voltage-clamp mode. The fast local superfusion was used for application (45 - 180 sec) of the hypoxic solution to simulate the short-term hypoxic states. The hypoxia effect induced a fast decrease of Ca current amplitude without kinetic changes in the majority of RGC (88%; 28 from 32). The level of inhibition was 25 ± 3% (from 8% to 67%) The repeated application of hypoxic solution did not lead to adaptation (rate of inhibition remained unchanged). We found that the reversibility of decrease depended on the duration of the hypoxia state. Our results show the inhibitory effect of hypoxia on VGCC in RGC. Thus, the hypoxia-induced reduction of calcium influx is a protective mechanism, on the other hand, it may affect the transmission of visual signals through presynaptic mechanisms in RGC projections.

EXCITABILITY PROPERTIES OF TRIGEMINAL GANGLION NEURONS.
The firing properties of small neurons (with diameters of soma less than 25 μm) were investigated using patch-clamp technique in whole-cell configuration in primary culture of trigeminal ganglia (TG) of postnatal rats. TG neurons were divided into three groups according to their firing responses to long-lasting depolarizing pulses: adaptive neurons (AN) characterized by a strongly adaptive responses; tonic neurons (TN) characterized by a multiple tonic firing; neurons with a delay before initiation of AP generation, namely, NDG. AN, TN and NDG also differed in AP electrophysiological and pharmacological characteristics. TN was distinguished by responses to hyperpolarization and the greatest value of input resistance. TN, AN and NDG were characterized by different active properties (amplitude of action potential and afterhyperpolarization, reobase, threshold). Each group of neurons was characterized by heterogeneity of AP duration and of frequency properties for TN. The application of tetrodotoxin (TTX) (250 nM) resulted in full or partial inhibition of AP generation and some neurons had TTX – insensitive firing responses. Neurons that were not affected by TTX had markedly longer AP. TTX had no effect on electrical activity of some AN and NDG. Based on sensitivity to TTX and their electrophysiological properties, AN and NDG seem to be C-fiber nococeptors.

MULTIPARAMETRIC EVALUATION OF FUNCTIONAL OUTCOMES IN STROKE PATIENTS USING CONNECTOMICS

POSTER SESSION 07 - SECTION: STROKE

Esin Avci[1], Gitta Rohweder[2], Axel Sandvig[3], Ioanna Sandvig[3]
[1]Norwegian University of Science and Technology, Department Of Medicine And Health Sciences, Institute For Neuromedicine And Movement Science, Trondheim, Norway, [2]St. Olav's Hospital, Stroke Unit, Trondheim, Norway, [3]Norwegian University of Science and Technology (NTNU), Department Of Neuromedicine And Movement Science (inb), Trondheim, Norway

Despite technological advances in medicine, stroke is still one of the leading causes of disability worldwide. The underlying physiology, extent of changes in neural network and recovery patterns are not fully understood. This ongoing longitudinal clinical study aims to provide a connectomics perspective on stroke recovery using multimodal quantitative tools to assess the rewiring of the functional and structural network and the correlates of motor function improvement. The study sample includes 25 ischemic and hemorrhagic stroke patients with upper extremity motor deficits, examined within 5 days, at 1 month and at 3 months after stroke onset. The control group consists of 25 age- and gender-matched healthy subjects. To quantify the surviving neural network, we use advanced high-resolution 7T MRI neuroimaging and 64-channel EEG. fMRI and DTI are used to estimate lesion volume and remaining nerve fiber connections. EEG is applied to assess cortical activation patterns. Degree of motor function damage and restoration are quantified via kinematic tools with 3D motion capture systems and EMG. Blood samples are collected to examine pro and anti-inflammatory responses and the regulation of specific microRNA transcriptional factors. Data will be stratified based on age, lesion volume and surviving neural network. We aim to provide links between biomarkers, functional motor outcomes and connectivity states to demonstrate adaptive or maladaptive responses. We endeavor to explain how neural network responses to stroke-induced changes and are modulated with restored function. With this knowledge, better rehabilitation strategies can be developed to maximize recovery for individual stroke patients.

THE ROLE OF MITOCHONDRIA IN THE MAINTENANCE OF HIPPOCAMPAL CELLS VIABILITY DURING THE POST-ISCHEMIC PERIOD

POSTER SESSION 07 - SECTION: STROKE

Nadia Kravchenko, Yelyzaveta Nikandrova, Galyna Skibo, Iryna Lushnikova
Bogomoletz Institute of Physiology, Department Of Cytology, Kyiv, Ukraine

Ischemic stroke is a major cause of disability and death worldwide, reflecting the extreme vulnerability of the brain to even brief disruption of blood flow. The brain sensitivity to oxygen-glucose deficiency is not identical in different cells and regions, thus the degree of damage varies. This study aimed to investigate the mitochondrial patterns of basic hippocampal cell types in the modelling of post-ischemic damage using slice cultures and transient oxygen-glucose deprivation (OGD) with subsequent normoxia. The changes were assessed at initial (reactive, 1h), intermediate (adaptive, 4h), and delayed (destructive, 24h) stages. The mitochondrial activity (MA) in pyramidal neurons, interneurons, astroglia, oligodendroglia and microglia were assessed using combined immunohistochemistry/MitoTrackerOrange staining. It was shown that at the reactive stage MA in all types of cells increased, which might indicate the activation of their metabolism. During the next two stages, the level of MA in pyramidal neurons and oligodendrocytes was significantly dropping while in interneurons, astroglia and microglia it was considerably increasing. There was a direct strong correlation between MA dynamics and cell viability. The electron microscopic analyses showed that under extreme conditions, direct intercellular interactions, including the exchange of cellular contents, were to a certain extent able to stabilize the state of the nervous tissue, which can be considered as emergency endogenous neuroprotection. Studying cellular responses induced by OGD is important for enhancing the effectiveness of neuroprotective strategies.

SEROTONIN MODULATION OF MOTOR RECOVERY AFTER STROKE IN MICE

POSTER SESSION 07 - SECTION: STROKE

Rafael De Sa, Matej Skrobot, Christoph Harms, Nikolaus Wenger
Charité – Universitätsmedizin Berlin, Experimental Neurology, Berlin, Germany

Globally, one in four adults will suffer from a stroke during their lifetime. Among stroke survivors, there is a high prevalence of motor deficits. Despite best medical care, motor recovery remains often incomplete. One important repair mechanism, following hemiparesis, is the reorganization of spinal circuits that attract new synaptic innervation from supraspinal brain areas. However, little is known, how these rewiring processes are mediated at the circuit level, and how these processes can be enhanced therapeutically. Can pharmacogenetic up- or downregulation of spinal serotonin release modulate motor recovery in animal models of stroke? To answer these questions, we are using TPH2iCre mice combined with spinal cord AAV injections allowing the inhibition of the serotonin neurons in the raphe nucleus. After phototrombosis, the effect of serotonin inhibition will be assessed on motor recovery through different behavioral tasks such as the staircase and rotarod. These results will be able to generate novel insights towards the design of circuit specific neuromodulation strategies to improve motor recovery after stroke.

Mechanisms Underlying Adaptation of Respiratory Network Activity to Modulatory Stimuli in the Mouse Embryo.
Breathing is a rhythmic behavior that requires organized contractions of respiratory effector muscles. This behavior must adapt to constantly changing conditions in order to ensure homeostasis, proper body oxygenation, and CO2/pH regulation. Respiratory rhythmogenesis is controlled by neural networks located in the brainstem. One area considered to be essential for generating the inspiratory phase of the respiratory rhythm is the preBötzinger complex (preBötC). Rhythmogenesis emerges from this network through the interplay between the activation of intrinsic cellular properties (pacemaker properties) and intercellular synaptic connections. Respiratory activity continuously changes under the impact of numerous modulatory substances depending on organismal needs and environmental conditions. The preBötC network has been shown to become active during the last third of gestation. But only little is known regarding the modulation of inspiratory rhythmicity at embryonic stages and even less on a possible role of pacemaker neurons in this functional flexibility during the prenatal period. By combining electrophysiology and calcium imaging performed on embryonic brainstem slice preparations, we provide evidence showing that embryonic inspiratory pacemaker neurons are already intrinsically sensitive to neuromodulation and external conditions (i.e., temperature) affecting respiratory network activity, suggesting a potential role of pacemaker neurons in mediating rhythm adaptation to modulatory stimuli in the embryo.

NEURONAL-SPECIFIC CLEAVAGE OF SINGLE-CHAIN TPA: MECHANISMS AND CONSEQUENCES ON CELLULAR FATE.

POSTER SESSION 07 - SECTION: STROKE

Hortense Triniac, Denis Vivien, Benoît Roussel
Inserm U1237, University Of Caen Bb@c, Caen, France

Aims: Tissue-type plasminogen activator (tPA) is a serine protease of the central nervous system that exhibits both neurotrophic and neurotoxic effects. tPA is secreted under its single-chain form (sc-tPA) and can be cleaved by plasmin or kallikrein in a two-chain form (tc-tPA). sc-tPA promotes *N*-Methyl-D-Aspartate receptors (NMDARs)'s calcium Influx under NMDA stimulation (Bertrand et al., 2015; Parcq et al., 2012), while tc-tPA, by activating the MET receptor, leads to the phosphorylation and internalization of NMDARs containing the GluN2B subunit (Hedou et al., 2021) and a decrease of NMDAR-signalling. Interestingly, .in a NMDA model of excitotoxicity, sc- and tc-tPA display bot pro-excitotoxicity and neuroprotection respectively. Methods: Pure mouse cortical neurons were treated with alexa-conjugated sc-tPA And the proportion of sc- and tc-tPA was evaluated by electrophoresis. Results: On 12 days in vitro (DIV) neurons, a time dependent cleavage of sc-tPA into tc-tPA is observed.. This phenomenon is inhibited by aprotinin and α2-antiplasmin, and enhanced by the lysine analogues epsilon-aminocaproic acid (EACA) and tranexamic acid (TXA). Almost No cleavage was observed with 7 DIV cortical neurons; and no cleavage at all was observed in astrocytes, HEK or PC12 cells, making this mechanism neuron-specific. Conclusions: These results indicate a cleavage mechanism that requires an activation surface specific to 12 DIV cortical neurons and dependant on the conversion of plasminogen into plasmin.

BETA-ALANINE PROTECTS THE CEREBELLAR NEURONS FROM ISCHEMIC CELL DEATH

POSTER SESSION 07 - SECTION: STROKE

Olga Kopach[1], Dmitri Rusakov[1], Sergiy Sylantyev[2]
[1]Queen Square Institute of Neurology, University College London, Clinical And Experimental Epilepsy, London, United Kingdom, [2]University of Aberdeen, Rowett Institute, Aberdeen, United Kingdom

Ischemia-induced neuronal cell death is the cause of the high mortality attributed to stroke globally. Amongst multiple mechanisms contributing to neuronal cell death upon oxygen-glucose deprivation (OGD) that takes place in ischemia, glutamate-induced excitotoxicity is prevalent, causing neuronal hyperexcitation accompanied by disinhibition across various regions of the brain. Strategies to halt the ischemia-induced cell death include targeting unbalanced activation of glutamate receptors, i.e. NMDA receptors (NMDAR), or impaired function of inhibitory receptors, e.g. $GABA_A$ receptors ($GABA_AR$); however, it often leads to numerous side-effects. Thus, searching for a medicine that would counteract glutamate-induced excitotoxicity via different receptor types remains a focus of many studies. Here, we investigated potential therapeutic effects of the FDA-approved compound β-Alanine (β-Ala) that possesses the ability to suppress NMDAR while activating inhibitory receptors, both glycine and $GABA_AR$. For this, we have modelled the OGD-induced impairments in the cerebellum tissue to find that β-Ala protects cerebellar neurons upon OGD. Two-photon excitation imaging was used to quantify cell death for the two neuronal types in the cerebellum: granule cell (GC) layer and Purkinje cells (PC); electrophysiology was implemented to record membrane depolarization in both cell types in acute cerebellar slices. Our data revealed that β-Ala (1 mM) has reduced the magnitude of cell depolarization following OGD (GC: from ~12.0 mV to ~7.6, $p<0.001$; PC: from ~39 mV to ~24, $p<0.001$). β-Ala also prevented the OGD-induced neuronal cell death for both cell types. Together this demonstrates a strong neuroprotective effect of β-Ala during cerebral ischemia.

Genetically engineered MAPT 10+16 mutation causes pathophysiological excitability of human iPSC-derived neurons related to 4R tau-induced dementia.
Human iPSC lines represent a powerful translational model of tauopathies. We have recently described a pathophysiological phenotype of neuronal excitability of human cells derived from the patients with familial frontotemporal dementia and parkinsonism (FTDP-17) caused by the MAPT 10+16 splice-site mutation. This mutation leads to the increased splicing of 4R tau isoforms. However, the role of different isoforms of tau protein in initiating neuronal dementia-related dysfunction, and the causality between the MAPT 10+16 mutation and altered neuronal activity have remained unclear. Here, we employed genetically engineered cells, in which the IVS10+16 mutation was introduced into healthy donor iPSCs to increase the expression of 4R tau isoform in exon 10, aiming to explore key physiological traits of iPSC-derived MAPT IVS10+16 neurons using patch-clamp electrophysiology and multiphoton fluorescent imaging techniques. We found that during late in vitro neurogenesis (from ~180 to 230 days) iPSC-derived cortical neurons of the control group (parental wild-type tau) exhibited membrane properties compatible with "mature" neurons. In contrast, MAPT IVS10+16 neurons displayed impaired excitability, as reflected by a depolarized resting membrane potential, an increased input resistance, and reduced voltage-gated Na- and K-channel-mediated currents. The mutation changed the channel properties of fast-inactivating Na and decreased the Na1.6 protein level. MAPT IVS10+16 neurons exhibited reduced firing accompanied by a changed action potential waveform and severely disturbed intracellular Ca dynamics, both in the soma and dendrites, upon neuronal depolarization. These results unveil a causal link between the MAPT 10+16 mutation, hence overproduction of 4R tau, and a dysfunction of human cells, identifying a biophysical basis of changed neuronal activity in 4R tau-triggered dementia. Our study lends further support to using iPSC lines as a suitable platform for modelling tau-induced human neuropathology in vitro.

Mitochondrial ROS control neuronal excitability and cell fate in frontotemporal dementia.

The second most common form of early-onset dementia-frontotemporal dementia (FTD)-is often characterized by the aggregation of the microtubule-associated protein tau. Here we studied the mechanism of tau-induced neuronal dysfunction in neurons with the FTD-related 10+16 MAPT mutation.

Biodegradable Microcapsules Loaded with Nerve Growth Factor Enable Neurite Guidance and Synapse Formation.
Neurological disorders and traumas often involve loss of specific neuronal connections, which would require intervention with high spatial precision. We have previously demonstrated the biocompatibility and therapeutic potential of the layer-by-layer (LbL)-fabricated microcapsules aimed at the localized delivery of specific channel blockers to peripheral nerves. Here, we explore the potential of LbL-microcapsules to enable site-specific, directional action of neurotrophins to stimulate neuronal morphogenesis and synaptic circuit formation. We find that nanoengineered biodegradable microcapsules loaded with nerve growth factor (NGF) can guide the morphological development of hippocampal neurons in vitro. The presence of NGF-loaded microcapsules or their clusters increases the neurite outgrowth rate while boosting neurite branching. Microcapsule clusters appear to guide the trajectory of developing individual axons leading to the formation of functional synapses. Our observations highlight the potential of NGF-loaded, biodegradable LbL-microcapsules to help guide axonal development and possibly circuit regeneration in neuropathology.

LTP Induction Boosts Glutamate Spillover by Driving Withdrawal of Perisynaptic Astroglia.
Extrasynaptic actions of glutamate are limited by high-affinity transporters expressed by perisynaptic astroglial processes (PAPs): this helps maintain point-to-point transmission in excitatory circuits. Memory formation in the brain is associated with synaptic remodeling, but how this affects PAPs and therefore extrasynaptic glutamate actions is poorly understood. Here, we used advanced imaging methods, in situ and in vivo, to find that a classical synaptic memory mechanism, long-term potentiation (LTP), triggers withdrawal of PAPs from potentiated synapses. Optical glutamate sensors combined with patch-clamp and 3D molecular localization reveal that LTP induction thus prompts spatial retreat of astroglial glutamate transporters, boosting glutamate spillover and NMDA-receptor-mediated inter-synaptic cross-talk. The LTP-triggered PAP withdrawal involves NKCC1 transporters and the actin-controlling protein cofilin but does not depend on major Ca-dependent cascades in astrocytes. We have therefore uncovered a mechanism by which a memory trace at one synapse could alter signal handling by multiple neighboring connections.

Maturation and phenotype of pathophysiological neuronal excitability of human cells in tau-related dementia.
Frontotemporal dementia and parkinsonism (FTDP-17) caused by the 10+16 splice-site mutation in the gene encoding microtubule-associated protein tau () provides an established platform to model tau-related dementia Neurons derived from human induced pluripotent stem cells (iPSCs) have been shown to recapitulate the neurodevelopmental profile of tau pathology during corticogenesis, as in the adult human brain. However, the neurophysiological phenotype of these cells has remained unknown, leaving unanswered questions regarding the functional relevance and the gnostic power of this disease model. In this study, we used electrophysiology to explore the membrane properties and intrinsic excitability of the generated neurons and found that human cells mature by ~150 days of neurogenesis to become compatible with matured cortical neurons. In earlier FTDP-17, however, neurons exhibited a depolarized resting membrane potential associated with increased resistance and reduced voltage-gated Na- and K-channel-mediated conductance. Expression of the Na1.6 protein was reduced in FTDP-17. These effects led to reduced cell capability of induced firing and changed the action potential waveform in FTDP-17. The revealed neuropathology might thus contribute to the clinicopathological profile of the disease. This sheds new light on the significance of human models of dementia.

Optical monitoring of glutamate release at multiple synapses in situ detects changes following LTP induction.
Information processing and memory formation in the brain relies on release of the main excitatory neurotransmitter glutamate from presynaptic axonal specialisations. The classical Hebbian paradigm of synaptic memory, long-term potentiation (LTP) of transmission, has been widely associated with an increase in the postsynaptic receptor current. Whether and to what degree LTP induction also enhances presynaptic glutamate release has been the subject of debate. Here, we took advantage of the recently developed genetically encoded optical sensors of glutamate (iGluSnFR) to monitor its release at CA3-CA1 synapses in acute hippocampal slices, before and after the induction of LTP. We attempted to trace release events at multiple

synapses simultaneously, by using two-photon excitation imaging in fast frame-scanning mode. We thus detected a significant increase in the average iGluSnFR signal during potentiation, which lasted for up to 90 min. This increase may reflect an increased amount of released glutamate or, alternatively, reduced glutamate binding to high-affinity glutamate transporters that compete with iGluSnFR.

Maturation of neural stem cells and integration into hippocampal circuits - a functional study in an model of cerebral ischemia.
The hippocampus is the region of the brain that is most susceptible to ischemic lesion because it contains pyramidal neurons that are highly vulnerable to ischemic cell death. A restricted brain neurogenesis limits the possibility of reversing massive cell death after stroke and, hence, endorses cell-based therapies for neuronal replacement strategies following cerebral ischemia. Neurons differentiated from neural stem/progenitor cells (NSPCs) can mature and integrate into host circuitry, improving recovery after stroke. However, how the host environment regulates the NSPC behavior in post-ischemic tissue remains unknown. Here, we studied functional maturation of NSPCs in control and post-ischemic hippocampal tissue after modelling cerebral ischemia We traced the maturation of electrophysiological properties and integration of the NSPC-derived neurons into the host circuits, with these cells developing appropriate activity 3 weeks or less after engraftment. In the tissue subjected to ischemia, the NSPC-derived neurons exhibited functional deficits, and differentiation of embryonic NSPCs to glial types - oligodendrocytes and astrocytes - was boosted. Our findings of the delayed neuronal maturation in post-ischemic conditions, while the NSPC differentiation was promoted towards glial cell types, provide new insights that could be applicable to stem cell therapy replacement strategies used after cerebral ischemia.

Optimized Model of Cerebral Ischemia for the Long-Lasting Assessment of Hippocampal Cell Death.
Among all the brain, the hippocampus is the most susceptible region to ischemic lesion, with the highest vulnerability of CA1 pyramidal neurons to ischemic damage. This damage may cause either prompt neuronal death (within hours) or with a delayed appearance (over days), providing a window for applying potential therapies to reduce or prevent ischemic impairments. However, the time course when ischemic damage turns to neuronal death strictly depends on experimental modeling of cerebral ischemia and, up to now, studies were predominantly focused on a short time-window-from hours to up to a few days post-lesion. Using different schemes of oxygen-glucose deprivation (OGD), the conditions taking place upon cerebral ischemia, we optimized a model of mimicking ischemic conditions in organotypical hippocampal slices for the long-lasting assessment of CA1 neuronal death (at least 3 weeks). By combining morphology and electrophysiology, we show that prolonged (30-min duration) OGD results in a massive neuronal death and overwhelmed astrogliosis within a week post-OGD whereas OGD of a shorter duration (10-min) triggered programmed CA1 neuronal death with a significant delay-within 2 weeks-accompanied with drastically impaired CA1 neuron functions. Our results provide a rationale toward optimized modeling of cerebral ischemia for reliable examination of potential treatments for brain neuroprotection, neuro-regeneration, or testing neuroprotective compounds .

Release probability increases towards distal dendrites boosting high-frequency signal transfer in the rodent hippocampus.
Dendritic integration of synaptic inputs involves their increased electrotonic attenuation at distal dendrites, which can be counterbalanced by the increased synaptic receptor density. However, during network activity, the influence of individual synapses depends on their release fidelity, the dendritic distribution of which remains poorly understood. Here, we employed classical optical quantal analyses and a genetically encoded optical glutamate sensor in acute hippocampal slices of rats and mice to monitor glutamate release at CA3-CA1 synapses. We find that their release probability increases with greater distances from the soma. Similar-fidelity synapses tend to group together, whereas release probability shows no trends regarding the branch ends. Simulations with a realistic CA1 pyramidal cell hosting stochastic synapses suggest that the observed trends boost signal transfer fidelity, particularly at higher input frequencies. Because high-frequency bursting has been associated with learning, the release probability pattern we have found may play a key role in memory trace formation.

DISCOVERING NEW THERAPEUTIC STRATEGIES IN STROKE THROUGH APC/C-CDH1-ROCK2 SIGNALLING PATHWAY

POSTER SESSION 07 - SECTION: STROKE

Jesus Agulla[1,2], Rebeca Lapresa[1,2], Angeles Almeida[1,2]

Aims Stroke is a leading cause of long-term adult disability and death in developed countries. Therefore, it is essential to establish new therapeutic strategies aimed at limiting and/or repairing ischemic neuronal damage. APC/C-Cdh1 is essential for neuronal survival. Previously, we described that Cdh1 regulates the balance between proliferation, neurogenesis and apoptosis. Neuronal reorganization after stroke determines the recovery of the lost brain function. ROCK2 regulates the morphology, elongation and retraction of neurites, making it an essential pathway in synaptic plasticity. Recently, we demonstrated that Cdh1 regulates ROCK2 levels and activity in cortical neurons, which modulates the stability of dendrites and synapses. However, whether Cdh1 plays a role in stroke remains unknown. Methods To assess this issue, we used both, an *in vitro* model of ischemia/reoxygenation (I/R) and an *in vivo* middle cerebral artery occlusion (MCAO) model in Cdh1-cKO and WT mice. Results We found that Cdh1 modulates neuronal susceptibility through RhoA-ROCK2 signalling pathway, since ROCK2 inhibition and knock-down reduced neuronal apoptosis induced by I/R. In vivo, we showed that Cdh1 was involved in the functional recovery after MCAO, enhancing neuronal survival and favouring infarct reduction and the recovery of neurological functions. Conclusions These results demonstrate that APC/C-Cdh1 actively modulates the neuronal response to I/R damage, enhancing neuronal survival through ROCK2 regulation, making them potential molecular targets for stroke treatment. INVESTIGATING THE MECHANISMS INVOLVED IN AUTOSIS-MEDIATED NEURONAL DEATH

POSTER SESSION 07 - SECTION: STROKE

Pauline Depierre[1], Vanessa Ginet[2], Anita Truttmann[2], Julien Puyal[1,3]
[1]University of Lausanne, Dept Of Fundamental Neurosciences, Lausanne, Switzerland, [2]University Hospital Center of Vaud, Clinic Of Neonatology, Department Of Women, Mother And Child, Lausanne, Switzerland, [3]Lausanne University Hospital, Curml, University Center Of Legal Medicine, Lausanne, Switzerland

We previously provided evidence that autophagy (a physiological process of degradation of organelles and proteins) could be overactivated and involved in neuronal death in rodent models of perinatal cerebral hypoxia/ischemia (HI). We also reported the presence of autosis, a Na^+/K^+ ATPase-dependent type of autophagic cell death, in dying CA3 neurons of the hippocampus following perinatal cerebral HI. Aim: Since neuronal autosis could occur in dying neurons, we are now aiming to understand the mechanisms by which autosis leads to neuronal death. We here investigated two main hypotheses: 1) is-it due to an over degradation of specific proteins and/or organelles? or 2) is-it due to an excessive membrane recruitment for the formation of autophagosomes? Methods: We used neurotoxic doses of the pro-autophagy inducer Tat-BECN1 peptide and hypoxic/excitotoxic (KaHx) (6% O_2/kainate 30µM) stimulations to induce autosis in primary cortical neuronal cultures. Results: Our data suggests that the degradation step of autophagy is not involved in neuronal autosis because the inhibition of the lysosomal activity or the fusion between the autophagosome/lysosome with pharmacological (E64d/PepstatinA and Bafilomycin A1) and genetical (shRNA *stx17*) tools were not neuroprotective. Focusing on autophagosome membrane sources, we identified mitochondria and Golgi Apparatus as potent candidates as both organelles were significantly affected by Tat-BECN1 treatment. However, we also found that neuronal autosis is associated with an increased in golgiphagy but not mitophagy. Conclusion: Our results suggest that elucidating the precise mechanisms by which neuronal autosis is affecting mitochondria could lead to new neuroprotective targets for the treatment of perinatal asphyxia.

Introduction: Thalamic vascular syndromes result in a wide variety of clinical outcomes that may depend on the thalamic territory affected by the lesions. However, the contribution of each thalamic nucleus to the different sleep clinical outcomes is still not clear. Here we sought to investigate the relationship between the topography of the lesion, sleep-wake regulation and oscillatory activity in humans and mice. **Methods.** 15 thalamic stroke patients with age/gender-matched controls and o*ptical mini-stroke (OPTO-Stroke)* with SHAM control mice were included. Diffusion-weighted images were used for the categorization of thalamic lesions. High-density and frontal-parietal EEG recordings were used in humans and mice respectively to characterize sleep-wake architecture and oscillations. Anatomical thalamocortical connectivity in OPTO-stroke mice was performed. **Results:** Intralaminar (IL) or mediodorsal (MD) nuclei stroke patients showed increased sleepiness ($p<0.001$), NREM1 percentage and number of NREM2-NREM1 or NREM1-wake transitions ($p<0.01$) compared to controls, but not in lateral thalamic lesions. Remarkably, a frontal derivation decrease in spindle power was found in both humans and mice ($p<0.001$). Interestingly, medial thalamic strokes in mice showed decreased IL-prefrontal cortex connectivity that correlated with deficits in sleep, spindling and working memory and pain. **Conclusion:** These results suggest that IL/MD lesions, but not lateral thalamic lesions, resulting in sleep fragmentation and reduced frontal spindles. Based on the mouse model data, sleep, topography of spindles and working memory alterations may be due to changes in thalamocortical connectivity. Our work provides novel insights into thalamic sub-networks responsible for sleep-wake control and potentially identifies specific targets for sleep-related therapies.

GAMMA OSCILLATIONS DEFICIT IN THE RECOVERING PERILESIONAL CORTEX : ORIGIN AND CORRECTION

POSTER SESSION 07 - SECTION: STROKE

Michael Alasoadura[1,2,3], Juliette Leclerc[2], Mahmoud Hazime[1], Jérôme Leprince[1,3], David Vaudry[1,3,4], Julien Chuquet[2,3]
[1]Normandie Univ, UNIROUEN, Neuronal And Neuroendocrine Differenciation And Communication Laboratory, Inserm U1239, ROUEN, France, [2]Normandie Univ, UNIROUEN, Neurological And Ventilatory Handicap Research Group, Ur3830-grhvn, ROUEN, France, [3]UNIROUEN, Institute For Research And Innovation In Biomedicine (irib), ROUEN, France, [4]Normandie Univ, UNIROUEN, Genomic And Personalized Medicine In Cancer And Neurological Disorders Laboratory, Inserm U1245, ROUEN, France

In the chronic phase following a cortical focal ischemia, recovery of lost functions involves timely remodelling of neuronal networks adjacent to the lesion. Due to an excessive GABA-mediated tonic inhibition, the perilesional region exhibits reduced excitability accounting for sub-optimal functional recovery. This peri-infarct zone also displays a prolonged deficit of low-gamma oscillation power (LG-power, 30-50Hz), a rhythm thought to synchronize neuronal activity and organize information processing. To optimize functional recovery, we hypothesized that peri-infarct LG-power should be normalized. AIM : Study the link between GABA-mediated hypoexcitability, LG-power and the ensuing subpar recovery. METHOD **:** While evaluating recovery of dexterous forepaw function and GABA-like immunoreactivity, we probed in vivo, the local field potential activity in the peri-infarct cortex of mice subjected to a focal cortical ischaemia at 7-, 21- and 4-months post stroke. RESULTS : LG-power was diminished in the peri-infarct zone at 7- and 21-days post-stroke. Interestingly, recovery of skilled forepaw use, positively correlated with LG-power. GABA-like immunoreactivity confirmed an excess of signal extending from lesion border paralleling a gradient of astrocyte reactivity. Local micro-infusion of GABA into the cortex, dampens LG-power while the pharmacological blockade of GABAergic tonic inhibition boosted them. Four months after stroke, GABA-like immunoreactivity, astrocyte reactivity and LG-power returned to sham-like levels. Overall, our observations suggest that the excess of tonic inhibition is involved in the collapse of LG-power in the peri-infarct cortex. Thus, neurostimulation interventions able to correct peri-infarct gamma-power, may boost post-stroke functional recovery.

[1]VIB–NERF, Neuroelectronics Research Flanders, Leuven, Belgium, [2]KU Leuven, Department Of Neuroscience, Leuven Brain Institute, Leuven, Belgium, [3]imec, Imec, Leuven, Belgium

Ipsilateral thalamocortical diaschisis describes the reduction of thalamic function, metabolism, and perfusion resulting from a distant lesion of the ipsilateral hemisphere. We aimed to evaluate the perfusion characteristics and effect on cortico-thalamic activity in chronic middle cerebral artery stroke, not directly affecting the thalamus. Functional ultrasound imaging (fUSI) was used to monitor variations in relative cerebral blood volume (rCBV) compared to baseline. rCBV levels were analyzed brain-wide and continuously at high spatiotemporal resolution (100µm, 2Hz) until 3hrs after stroke onset in awake head-fixed rats. The occlusion of the middle cerebral artery was induced under awake conditions using $FeCl_3$, a chemothrombotic agent suited for permanently occluding the distal branch. Cortico-thalamic evoked responses were imaged during ipsi- and contra-lesional whisker stimulation. First, we characterized the features of both the ischemia and spreading depolarizations with fUSI under awake conditions. Second, we described how the thalamo-cortical pathway was functionally altered immediately after the stroke onset. We observed a secondary and delayed alteration of cortico-thalamic evoked responses a few days after the initial injury. Our procedure aims at early, continuous, and chronic evaluations of hemodynamics and brain functions after stroke toward the development of clinically relevant therapeutic strategies.

CHARACTERIZATION OF A MOUSE MODEL OF POST-STROKE SPASTICITY

POSTER SESSION 07 - SECTION: STROKE

Frederique Wieters, Prisca Kuhnhäuser, Jule Ullert, Franziska Ziolkowski, Gereon Fink, Markus Aswendt
University Hospital Cologne, Neurology, Cologne, Germany

Aims Spasticity develops in 35% of patients after stroke and is one of the most common causes of motor disability worldwide, its precise definition and pathophysiology remain elusive, which to date renders its experimental targeting tricky (Wieters et al. 2020). The aim was to develop a reliable mouse model of post-stroke spasticity. **Methods** Adult C57Bl/6 mice underwent an 8-week long experimental paradigm including repetitive Hoffmann reflex (H-reflex) recordings in the forepaw and behavioral testing (cylinder, grid walk, rotating beam test). Stroke was induced by photothrombosis (Aswendt et al. 2020) in various cortical sensory and motor areas as well as in combination with an implanted optical fiber in the internal capsule. For quantitative evaluation of microscopy data AIDAhisto was used (Pallast et al. 2019). Kinematic analysis was performed using Deeplabcut (Mathis et al. 2018). The H-reflex was quantified with the H/M ratio, which is known to be increased in spasticity. **Results** A classical spasticity phenotype was not detected. In primary and secondary motor cortex lesions there was no or only a moderate increase in H/M ratio. Highest H/M ratio developed in mice with internal capsular stroke. The kinematic analysis and random forest classification revealed a specific set of features for mice with increased H/M ratio independent on lesion type. Histological quantification confirmed expected patterns of reactive astrocytes and neuroinflammation surrounding the stroke lesions. **Conclusions** We here provide a reliable mouse model for post-stroke spasticity for future translational studies. Viral tracing and optogenetic dissection of neural circuits underlying the pathology are ongoing.

Microglia are key players in mayor neurological disorders such as stroke, but they have been largely analyzed at the gene expression level, focusing on inflammatory polarization. In contrast, here we study a critical but widely overlooked microglial function: apoptotic cell phagocytosis, which prevents the spillover of cytotoxic contents from dying neurons and limits the inflammatory response. To analyze apoptotic cell phagocytosis in situ, we use as a model the neurogenic niche of the hippocampus, wherein we can establish baseline phagocytosis levels of naturally dying newborn cells by microglia. We show that microglial phagocytic function was impaired after ischemic stroke using an in vivo rodent model of transient medial cerebral artery occlusion (tMCAo) as well as an in vitro oxygen and nutrient deprivation model (OND) in hippocampal organotypic slices and primary microglia. We identified several mechanisms as drivers of the microglial phagocytic blockade after OND, including impaired microglial process motility, lysosomal alterations and the induction of an adaptive autophagy response. Autophagy inhibition had a deleterious effect on microglial phagocytosis and viability, determined using pharmacological (ULK1/2 inhibitor MRT68921) and genetic (ATG4B KO) approaches. In contrast, the autophagy inducer rapamycin prevented to some extent the microglial phagocytic blockade induced by tMCAo in vivo, although it did not significantly affect microglial phagocytosis in vitro. These results suggest that rapamycin partially prevents stroke-induced microglial phagocytic impairment possibly through an indirect, non-cell autonomous mechanism and pave the way to develop more specific strategies for the modulation of microglial phagocytosis.

IMPACT OF FERRITIN LEVELS ON OUTCOMES AFTER ENDOVASCULAR THROMBECTOMY

POSTER SESSION 07 - SECTION: STROKE

Kangho Choi[1], Jahae Kim[2], Jihye Kim[1], Dooyoung Kim[1], Jina Hong[1]
[1]Chonnam National University Hospital, Neurology, Gwangju, Korea, Republic of, [2]Chonnam National University Hospital, Nuclear Medicine, Gwangju, Korea, Republic of

Background: In patients with large vessel occlusion (LVO) stroke treated with mechanical thrombectomy (MT), ferritin levels have not been explored thus far to assess clinical outcomes. We investigated the predictive value of serum ferritin levels in assessing clinical outcomes in acute stroke patients with LVO treated with MT. **Methods:** A total of 747 patients with LVO treated with MT were enrolled in this study. The primary outcome measure was a poor outcome at 3 months, defined as a modified Rankin Scale score of 3−6. Ferritin levels were analyzed as both categorical (in quartiles) and continuous (using a 2-log transformation) variables. **Results:** As the serum ferritin quartile increased, the number of patients having a poor outcome increased (46.5% vs. 57.2% vs. 58.3% vs. 65.1%; $P_{trend} = 0.004$). In multivariable regression analyses, the ferritin quartile had a significant association with a poor outcome ($P_{trend} < 0.001$). The highest ferritin quartile, Q4, was associated with a poor outcome compared to the Q1 group (odds ratio [OR] = 2.74, 95% confidence interval [CI]: 1.70−4.43, $p < 0.001$). When ferritin was analyzed as a continuous variable, a high ferritin level was also significantly associated with a poor outcome (OR = 1.50, 95% CI: 1.21−1.86, $p < 0.001$). **Conclusion:** High serum ferritin level is associated with a poor outcome at 3 months after MT in patients with LVO. Baseline ferritin level can be an independent predictor of functional outcome after MT.

OPTIMISE DOSAGE AND EFFECT SIZE IN VIRTUAL REALITY-BASED INTERVENTION FOR POST-STROKE SURVIVORS WITH COEXISTENCE OF LANGUAGE AND MOTOR DYSFUNCTIONS

POSTER SESSION 07 - SECTION: STROKE

Biao Zeng
University of South Wales, School Of Psychology And Therapeutic Studies, Pontypridd, United Kingdom

In the last two decades, virtual reality (VR) techniques are emerging in post-stroke rehabilitation. Post-stroke patients suffer from impairments in verbal communication and motor. A wide co-existence of aphasia and motor dysfunction indicates that the two deficits could derive from similar brain lesions, specifically Broca's and motor cortex (Anderlini, Wallis & Marinovic, 2019). Motor rehabilitation could help the recovery of language function. This study examines the association between dose, intensity, and effect size in randomised controlled studies focusing on interventions aiming to improve language, speech, motor function respectively, or co-existence impairment. The study adopts the framework suggested by Baker (2012) and Warren et al. (2007) and referred dosage to the effect size of a study, reports and summarises dosage characteristics. Our analysis shows that "teaching episodes" and "dose form" are rarely reported in the included VR-based intervention studies. Specifically taking co-existing language and motor dysfunctions together, the dosage components are not related to the intervention effects size and the association is not statistically significant. This study concludes that future study needs to be able to relate dosage to an outcome, asking questions about the relationship between the different dosage characteristics and the intervention effect size. Furthermore, we propose that post-stroke survivors adopt nonverbal communication (NVC) to play as both a motor rehabilitator and as a facilitator of language recovery. NVC is the transmission of messages or signals through nonverbal behaviour such as eye contact, facial expressions, gestures, and posture.

Aims: Paralysis of the upper limbs after a stroke is extremely detrimental for daily life and rehabilitation in chronic conditions is very challenging. Yet, active robotic assistive devices relying on biological signals appear promising for late rehabilitation. We aimed here to try a rehabilitation training using the newly developed EMG-triggered and intention-based shoulder Hybrid Assistive Limb (HAL) assistive exoskeleton in a chronic stroke patient. **Methods:** A 54 year-old woman suffering from right hemiparesis after a cerebral infarction in the left middle cerebral artery region underwent 10 sessions of HAL-assisted rehabilitation 2 years after onset. Each session consisted of performance evaluation and deltoid-triggered arm elevation training in the scapular plane with the HAL. Muscle activity was recorded with EMG and kinematics were recorded with 3D motion capture. **Results:** We report a lasting motor progression shown by an increase of range of motion (33.5° before rehabilitation, 57.3° after, and 64.3° at a 6 months follow-up) and of MMT scores (2 to 4). Muscle synergy analysis showed a better coordination of shoulder muscles and a more defined synergy distinction during arm raising/arm lowering (Fig. 1). **Conclusion:** The findings hint toward the efficiency of shoulder HAL therapy for rehabilitation of chronic stroke patients with hemiparetic shoulder dysfunctions. The presented analyses of motion and muscle activity suggest the changed

synergetic muscle control as a possible mechanism behind the

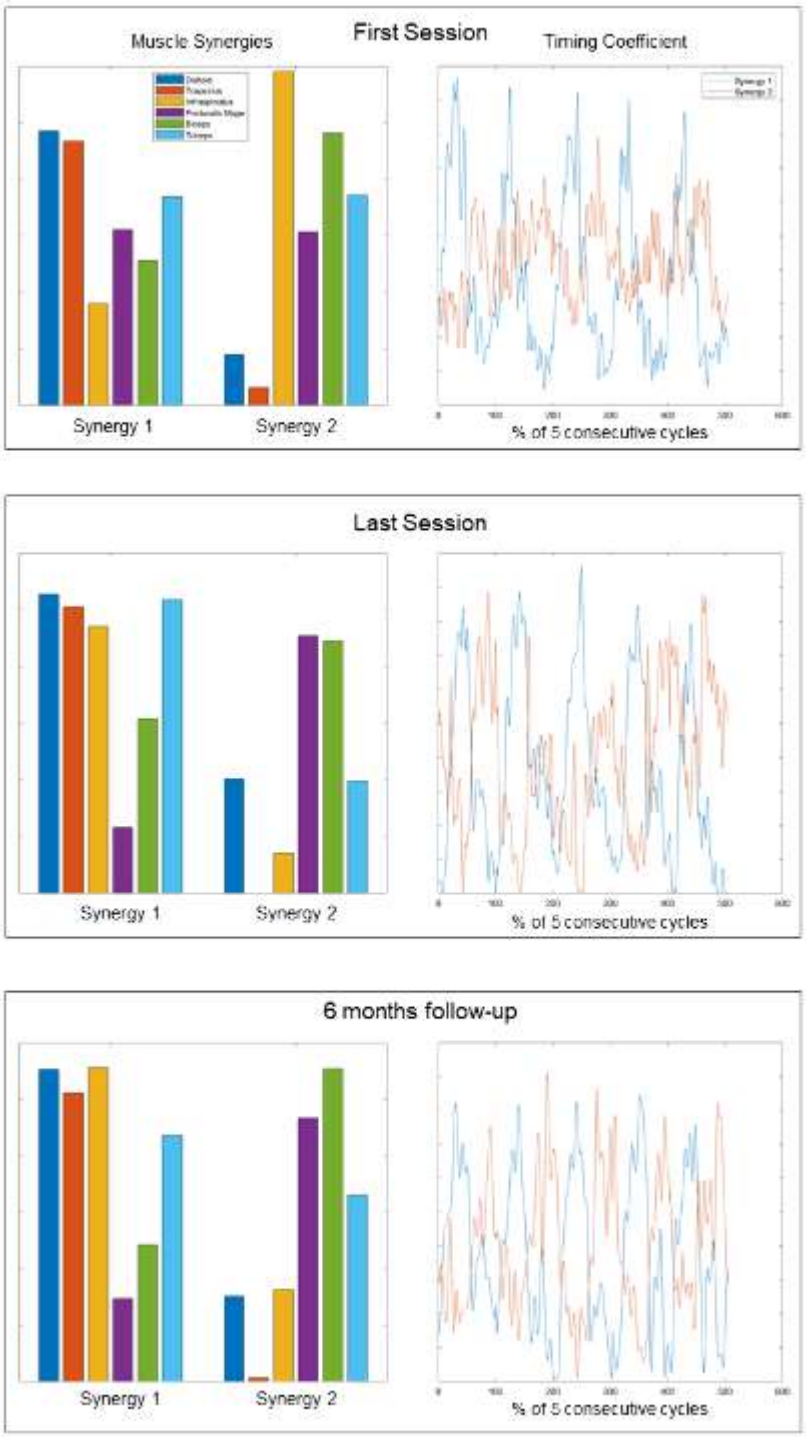

Figure 1: Muscle synergies and timing coefficients for the first session, last session, and 6 months follow-up.

improvement.

DORSAL MENINGEAL LYMPHATIC VESSELS ARE INVOLVED IN RESOLUTION AND FUNCTIONAL CONNECTIVITY RECOVERY AFTER INTRACEREBRAL HEMORRHAGE

POSTER SESSION 07 - SECTION: STROKE

Anais Virenque[1], Salli Antila[2], Raz Balin[1], Kari Alitalo[2], Francesco Noe[1]
[1]University of Helsinki, Neuroscience Center, Helsinki Institute Of Life Science, Helsinki, Finland, [2]University of Helsinki, Wihuri Research Institute And Translational Cancer Medicine Program, Helsinki, Finland

Aims: Early intracranial hematoma drainage is crucial for the treatment of intracerebral hemorrhage (ICH). Currently, there are no available non-invasive strategies, which have been clinically approved as an aid in ICH resolution. The identification of novel therapeutic targets is therefore essential to develop safe and effective therapeutic strategies. Methods: Here we investigated the possible function of the meningeal lymphatic vessels (mLVs) in ICH resolution. To better identify the role of the mLVs we used two preclinical mouse models of ICH, mimicking focal cortical ischemic hemorrhage and subcortical extended hemorrhage, and characterized the dynamics of blood drainage through the dorsal mLVs. We also analyzed the effect of mLV drainage on the functional recovery after subcortical ICH, in mice presenting an acquired mLV deficit. Results: After ICH induction, we observed a specific flow of blood-derived components within the mLVs, suggesting that the meningeal lymphatics can play a role in facilitating the hemorrhage drainage. We also found that local formation of new mLVs is directly correlated with ICH-related neuroinflammation levels. Mice presenting acquired mLV dysfunction showed a delayed recovery after ICH and a drop of functional connectivity in the areas affected by the intracranial hematoma. Conclusion: These findings suggest that meningeal lymphatics are involved in the resolution of ICH and could provide a valuable therapeutic target.

Blocking TNFα-driven astrocyte purinergic signaling restores normal synaptic activity during epileptogenesis.
Epilepsy is characterized by unpredictable recurrent seizures resulting from abnormal neuronal excitability. Increasing evidence indicates that aberrant astrocyte signaling to neurons plays an important role in driving the network hyperexcitability, but the underlying mechanism that alters glial signaling in epilepsy remains unknown. Increase in glutamate release by astrocytes participates in the onset and progression of seizures. Epileptic seizures are also accompanied by increase of tumor necrosis factor alpha (TNFα), a cytokine involved in the regulation of astrocyte glutamate release. Here we tested whether TNFα controls abnormal astrocyte glutamate signaling in epilepsy and through which mechanism. Combining Ca imaging, optogenetics, and electrophysiology, we report that TNFα triggers a Ca -dependent glutamate release from astrocytes that boosts excitatory synaptic activity in the hippocampus through a mechanism involving autocrine activation of P2Y1 receptors by astrocyte-derived ATP/ADP. In a mouse model of temporal lobe epilepsy, such TNFα-driven astrocytic purinergic signaling is permanently active, promotes glial glutamate release, and drives abnormal synaptic activity in the hippocampus. Blocking this pathway by inhibiting P2Y1 receptors restores normal excitatory synaptic activity in the inflamed hippocampus. Our findings indicate that targeting the coupling of TNFα with astrocyte purinergic signaling may be a therapeutic strategy for reducing glial glutamate release and normalizing synaptic activity in epilepsy.

MIM-Deficient Mice Exhibit Anatomical Changes in Dendritic Spines, Cortex Volume and Brain Ventricles, and Functional Changes in Motor Coordination and Learning.
In this study, we performed a comprehensive behavioral and anatomical analysis of the Missing in Metastasis (Mtss1/MIM) knockout (KO) mouse brain. We also analyzed the expression of MIM in different brain regions at different ages. MIM is an I-BAR containing membrane curving protein, shown to be involved in dendritic spine initiation and dendritic branching in Purkinje cells in the cerebellum. Behavioral analysis of MIM KO mice revealed defects in both learning and reverse-learning, alterations in anxiety levels and reduced dominant behavior, and confirmed the previously described deficiency in motor coordination and pre-pulse inhibition. Anatomically, we observed enlarged brain ventricles and decreased cortical volume.

Although MIM expression was relatively low in hippocampus after early development, hippocampal pyramidal neurons exhibited reduced density of thin and stubby dendritic spines. Learning deficiencies can be connected to all detected anatomical changes. Both behavioral and anatomical findings are typical for schizophrenia mouse models.

Modeling a Nociceptive Neuro-Immune Synapse Activated by ATP and 5-HT in Meninges: Novel Clues on Transduction of Chemical Signals Into Persistent or Rhythmic Neuronal Firing.
Extracellular ATP and serotonin (5-HT) are powerful triggers of nociceptive firing in the meninges, a process supporting headache and whose cellular mechanisms are incompletely understood. The current study aimed to develop, with the neurosimulator NEURON, a novel approach to explore in silico the molecular determinants of the long-lasting, pulsatile nature of migraine attacks. The present model included ATP and 5-HT release, ATP diffusion and hydrolysis, 5-HT uptake, differential activation of ATP P2X or 5-HT3 receptors, and receptor subtype-specific desensitization. The model also tested the role of branched meningeal fibers with multiple release sites. Spike generation and propagation were simulated using variable contribution by potassium and sodium channels in a multi-compartment fiber environment. Multiple factors appeared important to ensure prolonged nociceptive firing potentially relevant to long-lasting pain. Crucial roles were observed in: (i) co-expression of ATP P2X2 and P2X3 receptor subunits; (ii) intrinsic activation/inactivation properties of sodium Nav1.8 channels; and (iii) temporal and spatial distribution of ATP/5-HT release sites along the branches of trigeminal nerve fibers. Based on these factors we could obtain either persistent activation of nociceptive firing or its periodic bursting mimicking the pulsating nature of pain. In summary, our model proposes a novel tool for the exploration of peripheral nociception to test the contribution of clinically relevant factors to headache including migraine pain.

Developmental Dysfunction of the Central Nervous System Lymphatics Modulates the Adaptive Neuro-Immune Response in the Perilesional Cortex in a Mouse Model of Traumatic Brain Injury.
The recently discovered meningeal lymphatic vessels (mLVs) have been proposed to be the missing link between the immune and the central nervous system. The role of mLVs in modulating the neuro-immune response following a traumatic brain injury (TBI), however, has not been analyzed. Parenchymal T lymphocyte infiltration has been previously reported as part of secondary events after TBI, suggestive of an adaptive neuro-immune response. The phenotype of these cells has remained mostly uncharacterized. In this study, we identified subpopulations of T cells infiltrating the perilesional areas 30 days post-injury (an early-chronic time point). Furthermore, we analyzed how the lack of mLVs affects the magnitude and the type of T cell response in the brain after TBI.

Cytotoxic CD8 T lymphocytes expressing ALS-causing SOD1 mutant selectively trigger death of spinal motoneurons.
Adaptive immune response is part of the dynamic changes that accompany motoneuron loss in amyotrophic lateral sclerosis (ALS). CD4 T cells that regulate a protective immunity during the neurodegenerative process have received the most attention. CD8 T cells are also observed in the spinal cord of patients and ALS mice although their contribution to the disease still remains elusive. Here, we found that activated CD8 T lymphocytes infiltrate the central nervous system (CNS) of a mouse model of ALS at the symptomatic stage. Selective ablation of CD8 T cells in mice expressing the ALS-associated superoxide dismutase-1 (SOD1) mutant decreased spinal motoneuron loss. Using motoneuron-CD8 T cell coculture systems, we found that mutant SOD1-expressing CD8 T lymphocytes selectively kill motoneurons. This cytotoxicity activity requires the recognition of the peptide-MHC-I complex (where MHC-I represents major histocompatibility complex class I). Measurement of interaction strength by atomic force microscopy-based single-cell force spectroscopy demonstrated a specific MHC-I-dependent interaction between motoneuron and CD8 T cells. Activated mutant SOD1 CD8 T cells produce interferon-γ, which elicits the expression of the MHC-I complex in motoneurons and exerts their cytotoxic function through Fas and granzyme pathways. In addition, analysis of the clonal diversity of CD8 T cells in the periphery and CNS of ALS mice identified an antigen-restricted repertoire of their T cell receptor in the CNS. Our results suggest that self-directed immune response takes place during the course of the disease, contributing to the selective elimination of a subset of motoneurons in ALS.

PLASMA LEVELS OF BDNF AND EGF ARE REDUCED IN ACUTE STROKE PATIENTS COMPARED TO HEALTHY AGE AND GENDER MATCHED CONTROLS.

POSTER SESSION 07 - SECTION: STROKE

Linda Øverberg[1], Cecilie Morland[2]
[1]Oslo Metropolitan Universityy, Behavioral Sciences, Oslo, Norway, [2]Oslo Metropolitan University, Behavioral Sciences, Oslo, Norway

Annualy, stroke affects almost 14 million people worldwide. It is the second leading cause of death, and a major cause of acquired disability. Nearly 50 % of stroke survivers end up being chronically disabled. The degree of initial impairment in cognitive and motor functions affects the recovery, but other factors also contribute. These are largely unidentified, making precise prediction of recovery demanding. The variation in the balance of soluble regulators of neurotoxicity, neuroprotection and repair are presumably essential. Identifying blood biomarkers is a hot topic these days, and finding good predictive biomarkers for stroke outcome can ultimately be used to tailor treatment and follow-up of each stroke patient. Here we measure plasma levels of known regulators of neuroprotection and repair in acute ischemic stroke patients and compare them to the plasma levels in healthy age and gender matched controls. We found that the levels of BDNF and EGF were considerably lower in stroke patients than in healthy controls. These may be interesting biomarkers to predict stroke outcome. The levels of bFGF and irisin did not vary between the groups. The lower levels of growth factors emphasize that during the acute phase of stroke, there is a mismatch between the need for neuroprotection and repair, and the brain's ability to induce these processes. Large individual differences in growth factor levels were seen between the stroke patients in the acute phase, but whether these can be used to explain the individual differences in longterm post-stroke recovery and prognosis remain to be investigated.

THE TRANSCRIPTION FACTOR SP1 MODULATES ROS-INDUCED ACCUMULATION OF WRAP53 AND NEUROPROTECTION AFTER ISCHEMIA

POSTER SESSION 07 - SECTION: STROKE

Sandra Martínez-Peralta[1,2], Irene Sánchez-Morán[1,2], Cristina Rodríguez[1,2], Angeles Almeida[1,2]
[1]University Hospital of Salamanca, University of Salamanca, CSIC, Institute Of Biomedical Research Of Salamanca (ibsal), Salamanca, Spain, [2]CSIC, University of Salamanca, Institute Of Functional Biology And Genomics (ibfg), Salamanca, Spain

Aims Reactive oxygen species (ROS) generated after ischemia promote DNA repair and neuronal survival by inducing the expression of WRAP53 (WD40 encoding RNA antisense to p53) [1]. The transcription factor Sp1 acts as a pleiotropic oxidative stress response protein in neurons and promotes neuroprotection against ischemia [2]. Interestingly, Wrap53 promoter contains putative consensus sequences (GC boxes) for Sp1. Hence, Sp1 might be a good candidate to modulate WRAP53-mediated DNA repair and neuronal survival after stroke. **Methods** Primary cortical neurons were subjected to *in vitro* ischemia (oxygen and glucose deprivation) and WRAP53 and Sp1 levels were modulated by lipotransfection. Protein detection was analyzed by confocal microscopy and WB. RT-PCR and CHIP analysis were also performed. Middle cerebral artery occlusion was used as an *in vivo* ischemic stroke model. **Results** Ischemia rapidly induced mRNA and protein Sp1 expression in neurons, which preceded WRAP53 upregulation. ROS-induced nuclear accumulation of Sp1 was observed both in primary cultured neurons and ischemic mouse brain (ipsilateral hemisphere). Wrap53 promoter region co-immunoprecipitated with anti-Sp1, suggesting Sp1 as a modulator of WRAP53 expression. Moreover, Sp1 downregulation by siRNA prevented WRAP53 accumulation. **Conclusions** Sp1 modulates ROS-induced WRAP53 expression after ischemia. This new ROS-Sp1-WRAP53 signaling pathway poses Sp1 and WRAP53 as attractive targets for neuroprotective strategies in ischemic stroke. Acute ischemic stroke is a debilitating disorder with no effective treatments apart from the thrombolytic recombinant tissue plasminogen activator, which can be administered in a limited category of stroke patients. Following ischemic stroke, the ischemic core and the penumbra (peri-infarct area) experience progressive tissue damage and repair characterized by neuroinflammatory events. These include the recruitment and accumulation of activated GFAP+ astrocytes, which influence the penumbra by secreting factors and form a glial scar. Previously, we have shown that under physiological conditions autotaxin (ATX) is expressed by astrocytic processes at excitatory synapses regulating the bioactive phospholipid synthesis at the synaptic cleft (Thalman et al., Molecular Psychiatry, 2018). We therefore analyzed the role of the phospholipid lysophosphatidic acid (LPA) in the regulation of stroke-related cortical excitability and disease outcome. Using a mouse line with an astrocytic ATX-deletion and pharmacologically inhibiting ATX on one side and an animal model with a pre-existing LPA-related cortical excitability on the other, we could show that a dysregulation of synaptic LPA signaling exacerbates stroke pathology (Bitar et al., Sci Transl Med, 2022). Moreover, an animal model expressing a human single nucleotide polymorphism leading to an LPA-related cortical excitability (PRG-1^{R346T}) exhibited an overall unfavorable stroke outcome. Importantly, ATX levels remained elevated up to 14 days following stroke in patients. Our data suggest a critical importance of astrocytic secreted factors in stroke pathophysiology and inhibition of synaptic LPA signaling as a novel therapeutic target in stroke patients.

POTENTIAL TARGETING OF STROKE BY MEANS OF LAYERED NANO- AND MICRO- PARTICLES

POSTER SESSION 07 - SECTION: STROKE

Kristine Danielyan, Nelli Ohanyan, Samvel Chailyan
Institute of Biochemistry named after H Buniatian, Nas Ra, Yerevan, Armenia

Background. Targeted delivery of the medicines is the most effective way to treat diseased tissues. We propose, in experimental settings the efficient delivery of Proline Rich Peptide (PRP; novel compound, serving for the neuroprotection), PP (general activator of Phosphoribosyl Pyrophosphate Synthase -1 (PRPS-1; EC=2.7.6.1), regulative enzyme of purines and pyrimidines syntheses) as well as allopurinol, inhibitor of Xanthine Oxidoreductase (XOR, which includes Xanthine Oxidase; XO (EC=1.17.1.4) and Xanthine Dehydrogenase XDH (EC 1.17.1.4), the regulative enzyme of purine catabolism) by means of PEG-ilated and not PEG-ilated albumin nanoparticles will possibly stimulate fast regeneration and protection of the brain tissue in the experimental stroke settings. **Methods.** For determination of the size of the particles it was used electron transmission microscopy technique (Philips CM-100 TM, USA). The loading and the controlled release of the medicines was evaluated by the colorimetric methods (Cary 60, Agilent, USA). Circulation abilities of loaded albumin particles were compared with PEG-ilated particles. Effect of the particles was evaluated in animals injected intracranially with paticles. **Results.** We created particles from <100 nm to < 2 microns diameter.. PEG-ilated particles are more stable in water as well as in the trypsin environment. Release of most of the medicines predominantly occurred during day 3th; the effect was stronger in not PEG-ilated partciles. It was detected BBB protection in case of utility of PEG-ilated and loaded with medicines particles. **Conclusion.** We created layered with the different medicines PEG-ilated and not PEG-ilated particles, which might target different pathological stages of experimental stroke development.

TOWARDS IPS-BASED CELL THERAPY FOR BRAIN REGENERATION

POSTER SESSION 07 - SECTION: STROKE

Rebecca Weber[1], Patrick Perron[1], Chantal Bodenmann[1], Daniela Uhr[1], Debora Wanner[1], Kathrin Zürcher[1], Hirohide Saito[2], Simon Hoerstrup[1], Roger Nitsch[1], Christian Tackenberg[1], Ruslan Rust[1]

Stroke is a leading cause of disability and death worldwide. This is largely due to the lack of effective medical therapy that promotes long-term recovery. Cell-based therapy is an emerging treatment paradigm and is considered a potential regenerative strategy for stroke patients with remaining neurologic deficits. Despite promising preclinical results in animal stroke models, the efficacy of cell therapies has not been confirmed beyond doubt in a clinical setting. Here, we generate good manufacturing practice (GMP)-compatible neural progenitor cells (NPCs) from transgene- and xeno-free induced pluripotent stem cells (iPSCs) that can be smoothly adapted for clinical applications. The produced NPCs have a stable gene-expression over at least 15 passages and can be scaled for up to 10^{18} cells per initially seeded 10^{6} cells. To ensure a pure NPC population for *in vivo* applications, we reduce risks of iPSC contamination using micro RNA-switch technology as a safety checkpoint. The generated NPCs were transduced with a fluorescent and bioluminescent dual reporter-construct and locally transplanted into a photothrombotic mouse model of stroke. We confirmed long-term survival and migration of transplanted cells using non-invasive *in vivo* bioluminescence imaging over a month. Repeated deep learning-based functional assessments of animals was performed to evaluate the functional recovery following stroke compared to a control group. In-depth histological analysis revealed that the majority transplanted cells differentiate into mature neurons without any sign of pluripotent residuals. Animals receiving the cell therapy had a reduced stroke volume, increased recovery-associated tissue responses and higher recovery of motor function.

ELECTROPHYSIOLOGICAL FINGERPRINTING OF THE ABNORMAL BRAIN CAVITY

POSTER SESSION 07 - SECTION: STROKE

Ugur Kilic
KU Leuven, Research Group Experimental Neurosurgery And Neuroanatomy, Leuven, Belgium

Stroke is a highly debilitating neurological disorder affecting brain modalities such as vision, speech, and motor function. It remains the leading cause of chronic disability, and state-of-the-art therapies often fail to offer full recovery. In ischemic-stroke rodents, Ramanathan et al. (DOI: 10.1038/s41591-018-0058-y) showed decreased motor task-related delta oscillations correlated with functional recovery. However, much remains unclear about the altered neural activity of stroke and the abnormal brain cavity (aBC), the leftover lesion caused by stroke. A better understanding of altered neural activity following stroke is essential for novel therapy development. Here we investigated altered motor cortex (MC) dynamics in the aBC over time. In five male Sprague-Dawley rats, we mimicked the aBC by aspirating parts of the fore-limb MC. We performed acute and chronic *in-vivo* electrophysiological recordings in the peri-lesional cortex and aBC wall. In the acute setting, our results show a sudden loss in delta power compared to the healthy cortex. In the chronic setting, some regions recovered and resembled pre-lesion activity while others retained acute-stroke activity or deteriorated further. Our study reveals complex changes in neural activity after aBC formation in rodents. The heterogeneity of these findings needs to be addressed to deepen our knowledge of the complex nature of the stroke-related disability. Further targeting these changes in neural activity could pave the way for the development of novel therapies.

Aims: The continuous addition of new neurons to the hippocampus through life (or adult hippocampal neurogenesis (AHN)) plays a crucial role in hippocampal functions, including mood regulation and pattern separation. AHN has been extensively studied in rodents and Old-World primates; however, this phenomenon remains less characterized in humans.Our group demonstrated the presence of immature dentate granule cells (DGCs) in the human hippocampus. However, the presence of neural stem cells (NSCs) in this structure remained elusive. **Methods:** We applied state-of-the-art tissue preservation and staining methodologies to reconstruct the stages encompassed by human AHN in 15 neurologically healthy control subjects. **Results:** Our results demonstrate the existence of a population of Nestin^{+} S100β^{-} radial glia-like cells with phenotypic and morphological NSCs properties in the human DG. We also observe proliferative cells and neuroblasts. The use of widely validated cell markers, and the application of stereological cell counts allowed reconstruction of the maturation trajectory of immature DGCs. Our work also provides a thorough analysis of all the elements that constitute the human hippocampal neurogenic niche, such as astrocytes, microglia, and blood vessels. Importantly, microglial function is impaired in aged subjects, which parallels with decreased AHN rates. **Conclusions:** Our results reveal the maintenance of the human NSC pool during adulthood. We have interrogated all the stages encompassed by human AHN, thereby shedding light on the cellular composition and age-driven remodeling of the human hippocampal neurogenic

niche.

Impact of neurodegenerative diseases on human adult hippocampal neurogenesis.
Disrupted hippocampal performance underlies psychiatric comorbidities and cognitive impairments in patients with neurodegenerative disorders. To understand the contribution of adult hippocampal neurogenesis (AHN) to amyotrophic lateral sclerosis, Huntington's disease, Parkinson's disease, dementia with Lewy bodies, and frontotemporal dementia, we studied postmortem human samples. We found that adult-born dentate granule cells showed abnormal morphological development and changes in the expression of differentiation markers. The ratio of quiescent to proliferating hippocampal neural stem cells shifted, and the homeostasis of the neurogenic niche was altered. Aging and neurodegenerative diseases reduced the phagocytic capacity of microglia, triggered astrogliosis, and altered the microvasculature of the dentate gyrus. Thus, enhanced vulnerability of AHN to neurodegeneration might underlie hippocampal dysfunction during physiological and pathological aging in humans.

GSK-3β S9A overexpression leads murine hippocampal neural precursors to acquire an astroglial phenotype in vivo.
The addition of new neurons to the existing hippocampal circuitry persists in the adult dentate gyrus (DG). During this process, named adult hippocampal neurogenesis (AHN), adult hippocampal progenitor cells (AHPs) give rise to newborn dentate granule cells (DGCs). The acquisition of a neuronal lineage by AHPs is tightly regulated by numerous signaling molecules and transcription factors. In this regard, glycogen synthase kinase 3β (GSK-3β) is a master regulator of the maturation of AHPs in vitro. Here we analyzed the cell-autonomous effects of overexpressing a constitutively active form of GSK-3β (GSK-3β S9A) in AHPs in vivo. To this end, we stereotaxically injected a GSK-3β S9A-encoding retrovirus (GSK-3β-V5) into the DG of young adult C57BL6/J Ola Hsd female mice and studied the cell lineage acquisition, migratory and marker expression patterns, and the morphological maturation of the infected cells over time. Strikingly, GSK-3β S9A-transduced cells expressed glial fibrillary acidic protein (GFAP) and NG2, thereby acquiring an immature astroglial phenotype, which differed markedly from the neuronal phenotype observed in cells transduced with a control retrovirus that encoded GFP.

Accordingly, the morphology and migration patterns of cells transduced by the two retroviruses are remarkably divergent. These observations support the role of GSK-3β as a cornerstone that regulates the balance between new astocytes/neurons generated in the adult murine DG.

Evidences for Adult Hippocampal Neurogenesis in Humans.
The rodent hippocampus generates new neurons throughout life. This process, named adult hippocampal neurogenesis (AHN), is a striking form of neural plasticity that occurs in the brains of numerous mammalian species. Direct evidence of adult neurogenesis in humans has remained elusive, although the occurrence of this phenomenon in the human dentate gyrus has been demonstrated in seminal studies and recent research that have applied distinct approaches to birthdate newly generated neurons and to validate markers of adult-born neurons. Our data point to the persistence of AHN until the 10th decade of human life, as well as to marked impairments in this process in patients with Alzheimer's disease. Moreover, our work demonstrates that the methods used to process and analyze postmortem human brain samples can limit the detection of various markers of AHN to the point of making them undetectable. In this Dual Perspectives article, we highlight the critical methodological aspects that should be strictly controlled in human studies and the robust evidence that supports the occurrence of AHN in humans. We also put forward reasons that may account for current discrepancies on this topic. Finally, the unresolved questions and future challenges awaiting the field are highlighted.

Unraveling human adult hippocampal neurogenesis.
Adult neurogenesis occurs in a few selected regions of the mammalian brain. One such region is the hippocampus, the so-called gateway to memory, where adult hippocampal neurogenesis (AHN) occurs. Here, we provide a comprehensive description of the methods used in our laboratory to unambiguously detect a population of immature neurons in the human hippocampus until the 10th decade of life. The criteria used to refine and develop the current protocol include obtaining post-mortem human samples of remarkable quality and under tightly controlled conditions for immunohistochemistry (IHC) studies, optimizing tissue processing and histological procedures, establishing criteria to reliably validate antibody signal and performing unbiased stereological cell counts. Moreover, we provide a detailed description of the parameters that, in our view, should be reported in human AHN studies. The opposing results obtained by introducing slight variations in the methodological conditions should be considered by future studies that seek to increase our knowledge of this fascinating process. By applying simple and inexpensive tissue pre-treatments, this protocol, which can be completed in 7 days, might be applicable to a variety of IHC studies performed on other tissues of human (or animal) origin.

Activity-Dependent Reconnection of Adult-Born Dentate Granule Cells in a Mouse Model of Frontotemporal Dementia.
Frontotemporal dementia (FTD) is characterized by neuronal loss in the frontal and temporal lobes of the brain. Here, we provide the first evidence of striking morphological alterations in dentate granule cells (DGCs) of FTD patients and in a mouse model of the disease, Tau mice. Taking advantage of the fact that the hippocampal dentate gyrus (DG) gives rise to newborn DGCs throughout the lifetime in rodents, we used RGB retroviruses to study the temporary course of these alterations in newborn DGCs of female Tau mice. In addition, retroviruses that encode either PSD95:GFP or Syn:GFP revealed striking alterations in the afferent and efferent connectivity of newborn Tau DGCs, and monosynaptic retrograde rabies virus tracing showed that these cells are disconnected from distal brain regions and local sources of excitatory innervation. However, the same cells exhibited a predominance of local inhibitory innervation. Accordingly, the expression of presynaptic and postsynaptic markers of inhibitory synapses was markedly increased in the DG of Tau mice and FTD patients. Moreover, an increased number of neuropeptide Y-positive interneurons in the DG correlated with a reduced number of activated egr-1 DGCs in Tau mice. Finally, we tested the therapeutic potential of environmental enrichment and chemoactivation to reverse these alterations in mice. Both strategies reversed the morphological alterations of newborn DGCs and partially restored their connectivity in a mouse model of the disease. Moreover, our data point to remarkable morphological similarities between the DGCs of Tau mice and FTD patients. We show, for the first time to our knowledge, that the population of dentate granule cells is disconnected from other regions of the brain in the neurodegenerative disease frontotemporal dementia (FTD). These alterations were observed in FTD patients and in a mouse model of this disease. Moreover, we tested the therapeutic potential of two strategies, environmental enrichment and chemoactivation, to stimulate the activity of these neurons in mice. We found that some of the alterations were reversed by these therapeutic interventions.

Adult hippocampal neurogenesis is abundant in neurologically healthy subjects and drops sharply in patients with Alzheimer's disease.
The hippocampus is one of the most affected areas in Alzheimer's disease (AD). Moreover, this structure hosts one of the most unique phenomena of the adult mammalian brain, namely, the addition of new neurons throughout life. This process, called adult hippocampal neurogenesis (AHN), confers an unparalleled degree of plasticity to the entire hippocampal circuitry. Nonetheless, direct evidence of AHN in humans has remained elusive. Thus, determining whether new neurons are continuously incorporated into the human dentate gyrus (DG) during physiological and pathological aging is a crucial question with outstanding therapeutic potential. By combining human brain samples obtained under tightly controlled conditions and state-of-the-art tissue processing methods, we identified thousands of immature neurons in the DG of neurologically healthy human subjects up to the ninth decade of life. These neurons exhibited variable degrees of maturation along differentiation stages of AHN. In sharp contrast, the number and maturation of these neurons progressively declined as AD advanced. These results demonstrate the persistence of AHN during both physiological and pathological aging in humans and provide evidence for impaired neurogenesis as a potentially relevant mechanism underlying memory deficits in AD that might be amenable to novel therapeutic strategies.

Spheroids Spontaneously Generated In Vitro from Sheep Ovarian Cortical Cells Contain Integrating Cells That Exhibit Hallmarks of Neural Stem/Progenitor Cells.
Cell spheroids are inducible or spontaneously generated cell aggregates produced in vitro that can provide a valuable model for developmental biology, stem cell biology, and cancer therapy research. This investigation aimed to define the cellular identity of spheroids spontaneously generated in vitro from sheep ovarian cortical cells cultured under specific serum-free conditions. Spheroids were characterized during 21 days of culture by morphometric evaluation, detection of alkaline phosphatase (AP) activity, gene expression analyses of stemness transcription factors and several lineage markers, immunolocalization analyses, as well as assessment of self-renewal and differentiation potential. Cell aggregation, evidenced from day 3 of culture onward, resulted in efficient generation of 65-75 spheroids for every 500,000 cells seeded. The spheroids reached maximum diameter (187 ± 15.9 μm) during the second week of culture and exhibited AP activity. Sox2, Oct4, and Nanog were expressed throughout the culture period, with upregulation of Sox2. Neural lineage specification genes (eg, nestin, vimentin, Pax6, and p75NTR) were expressed from day 10 onward at levels above that of Oct4, Nanog and those for endoderm [alpha-fetoprotein (AFP)], and mesoderm (brachyury) specification. Neural stem cell (NSC)/neural progenitor cell (NPC) markers, nestin, Pax6, p75NTR, and vimentin, were extensively localized in cells on day 10, 15 (44.75% ± 5.84%; 93.54% ± 1.35%; 78.90% ± 4.80%; 73.82% ± 3.40%, respectively), and 21 (49.98% ± 5.30%; 91.84% ± 1.9%; 76.74% ± 11.0%; 95.80% ± 3.60%, respectively). Spheroid cell self-renewal was evidenced by cell proliferation and the generation of new spheroids during two consecutive expansion periods. Culture of spheroid cells under differentiation conditions gave rise to cells showing immunolocalization of the neuron-specific antigen NeuN and the astroglial antigen GFAP (glial fibrillary acidic protein). Our results indicate that spheroids spontaneously generated in this culture system were comprised of cells with molecular characteristics of NSC/NPC that can self-renew and differentiate into neurons and glia, supporting the identity of spheroids as neurospheres.

DEVELOPMENTAL ORIGIN OF ADULT NEUROGENESIS: ANALYSIS OF THE POSTNATAL HIPOCAMPAL NEUROGENIC NICHE IN SOX5 CONDITIONAL MUTANTS.

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Cristina Medina Menéndez, Lingling Li, Elena Melgarejo, Mario Diaz, María Valdés, Rafael Lopez, Inés Colmena, Véronique Lefebvre, Aixa V. Morales
Cajal Institute, Department Of Molecular, Cellular And Developmental Neurobiology, Madrid, Spain

During embryonic and postnatal development of the dentate gyrus (DG), neural stem cells (NSCs) proliferate, migrate and generate mature granule neurons. In the DG a subpopulation of NSCs, are set aside in the subgranular zone (SGZ) and continues generating new granular neurons throughout adult life. One of the characteristics that distinguish adult NSCs most clearly from their embryonic counterparts is the acquisition of quiescence. While most of NSCs will remain in a dormant state of deep quiescence throughout life, the transitions back and forward from an active /proliferative state to a temporal shallow quiescence or resting state, ensure the lifelong maintenance of stem cell population. We have recently determined that SoxD transcription factors are required for the transition from quiescence to activation in NSCs and for the generation of new neurons in the adult SGZ (Li, Medina-Menéndez et al., 2022). Now, we have determined that abolishing Sox5 expression in DG during development (*Sox5*^{Nestin} mice) provokes a drastic decrease in NSCs proliferation during the first postnatal weeks and a decrease in neurogenesis. Surprisingly, by P30, *Sox5*^{Nestin} mice show an enhancement of NSCs proliferation, a reduction in NSCs quiescence and an increase in neurogenesis. Moreover, we have established that at P30 the transitions between a resting/superficial quiescence and active/proliferative state are severely altered in NSCs from Sox5^{Nestin} mice. Finally, by P150, the pool of NSCs and that of new neurons are reduced, indicating that in the absence of Sox5 the life-long maintenance of the adult neurogenic niche is compromised.

SoxD genes are required for adult neural stem cell activation.
The adult neurogenic niche in the hippocampus is maintained through activation of reversibly quiescent neural stem cells (NSCs) with radial glia-like morphology (RGLs). Here, we show that the expression of SoxD transcription factors Sox5 and Sox6 is enriched in activated RGLs. Using inducible deletion of Sox5 or Sox6 in the adult mouse brain, we show that both genes are required for RGL activation and the generation of new neurons. Conversely, Sox5 overexpression in cultured NSCs interferes with entry in quiescence. Mechanistically, expression of the proneural protein Ascl1 (a key RGL regulator) is severely downregulated in SoxD-deficient RGLs, and Ascl1 transcription relies on conserved Sox motifs. Additionally, loss of Sox5 hinders the RGL activation driven by neurogenic stimuli such as environmental enrichment. Altogether, our data suggest that SoxD genes are key mediators in the transition of adult RGLs from quiescence to an activated mitotic state under physiological situations.

Benzothiazole-Based LRRK2 Inhibitors as Wnt Enhancers and Promoters of Oligodendrocytic Fate.
Leucine rich repeat kinase 2 (LRRK2) is an enigmatic enzyme and a relevant target for Parkinson's disease (PD). However, despite the significant amount of research done in the past decade, the precise function of LRRK2 remains largely unknown. Moreover, the therapeutic potential of its inhibitors is in its infancy with the first clinical trial having just started. In the present work, the molecular mechanism of LRRK2 in the control of neurogenesis or gliogenesis was investigated. We designed and synthesized novel benzothiazole-based LRRK2 inhibitors and showed that they can modulate the Wnt/β-catenin signaling pathway. Furthermore, compounds and were able to promote neural progenitors proliferation and drive their differentiation toward neuronal and oligodendrocytic cell fates. These results suggest potential new avenues for the application of LRRK2 inhibitors in demyelinating diseases in which oligodendrocyte cell-death is one of the pathological features.

GROWTH/DIFFERENTIATION FACTOR 15 INFLUENCES PRIMARY CILIA IN NEURAL STEM CELLS IN THE VENTRICULAR-SUBVENTRICULAR ZONE BUT NOT IN THE SUBGRANULAR ZONE

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Katja Baur, Şeydanur Şan, Francesca Ciccolini
Universität Heidelberg, Neurobiology, Heidelberg, Germany

Neural stem cells (NSCs) are vital for adult neurogenesis throughout adulthood and are located in the two neurogenic niches in the mammalian brain: the ventricular-subventricular zone (V-SVZ) and in the subgranular zone (SGZ) in the hippocampus. The proliferation of adult NSCs is tightly regulated by environmental signals and primary cilia play a fundamental role in sensing and transducing signals governing NSC maintenance, activation and quiescence. However, niche components regulating cilia morphology and function are less known. Here we found that constitutive ablation of growth/differentiation factor 15 (GDF15) leads to more, shorter, and thicker primary cilia in NSCs of the embryonic and adult V-SVZ, but not in the age-matched hippocampal counterpart. Although GDF15 is present in both germinal niches, its receptor, the GDNF-Family Receptor Alpha-Like (GFRAL), is localized in primary cilia of NSCs in the V-SVZ but not in the SGZ. Notably, inhibition of C-X-C chemokine receptor (CXCR) 4, also expressed in primary cilia in V-SVZ progenitors, did not affect morphology of primary cilia, showing that GFRAL but not CXCR4 can affect cilia morphology. Finally, changes in morphology were partly alleviated by application of exogenous GDF15. Taken together, these results imply a direct of ciliary activation of ciliary GFRAL on primary cilia morphology.

FGF18 – A NEW PLAYER IN THE REGULATION OF ADULT SUBVENTRICULAR ZONE (SVZ) NEUROGENESIS

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Mohammad K. Hajihosseini[1], Giada Vanacore[1], Tianqi Li[1], Mette Mogensen[1], David Ornitz[2]

Introduction: Every day, neural stem cells (NSC) of the adult rodent subventricular zone (SVZ) generate new olfactory bulbs (OB) neurons, with important modulatory roles in odour-detection and behaviour. SVZ neurogenesis is compartmentalized and requires the activation of quiescent NSC, but the precise cohort of such activators remains unknown. Fibroblast Growth Factors (FGFs) regulate diverse aspects of embryonic brain development, but little is known about their roles in adult brain neurogenesis. We have analysed the expression and fate of FGF18-expressing cells in the rodent brain. **Methods & Sample size:** We used FGF18-creERT2::Rosa26-Tomato-dsred double transgenic mice (DTG) of either sex. For lineage tracing, 3-month-old mice were tamoxifen-pulsed for two consecutive days and analysed either 2 or 12 days later. To detect an effect size of 0.6-0.9 with alpha level of 0.05 and power of 0.8 in two-way ANOVA tests, n=6 was analysed per time-point. Serial sections of brain were immunolabelled with anti-dsred antibodies in conjunction with cell type-specific markers, and the rostro-caudal distribution and abundance of dsred+ cells was recorded. **Results & Conclusions:** After short chase, dsred+ cells were largely confined to dorsal and medial aspects of SVZ, whilst after long chase, dsred+ cells were additionally evident in the rostral migratory stream, and as NeuN+ neurons in periglomerular OB. In the SVZ a subset of dsred+ cells expressed GFAP. Our findings indicate that FGF18-expressing dorsal SVZ cells supply new neurons to OB. Moreover, as FGF18's receptors are expressed by quiescent NSC in the lateral SVZ, our results now identify FGF18 a potential regulator of NSC quiescence/ activation.

ROLE OF BDNF, ADENOSINE A2AR AND CANNABINOID RECEPTORS ON POSTNATAL OLIGODENDROGENESIS FROM SVZ-DERIVED NEURAL STEM CELL CULTURES

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Joana Mateus[1,2], João Moreira[1,2], Diogo Lourenço[1,2], Ana M. Sebastião[1,2], Sara Xapelli[1,2]
[1]Instituto de Farmacologia e Neurociências, Faculdade De Medicina, Universidade De Lisboa, Lisboa, Portugal, [2]Instituto de Medicina Molecular João Lobo Antunes, Faculdade De Medicina, Universidade De Lisboa, Lisboa, Portugal

Oligodendrocytes (OLs) are the myelin-forming cells in the Central Nervous System of vertebrates. The role of modulators such as brain-derived neurotrophic factor (BDNF), cannabinoid receptors type 1 and 2 (CBRs) and adenosine A2A receptors (A2ARs) on adult oligodendrogenesis from subventricular zone neural stem cells (SVZ-NSCs) remains unknown. Hence, we aimed at studying how these modulators and the putative crosstalk between them can influence OL differentiation from postnatal SVZ-NSCs. Results obtained using SVZ-NSCs cultures pharmacologically treated with adenosine A2ARs modulators, CBR ligands or BDNF, show that treatment with BDNF tends to increase oligodendrocyte precursor cell (OPC) formation (NG2/PDGFRα-positive cells) after 4 days *in vitro* (DIV) (n=3; CTRL set to 100%, BDNF 203.8±27.59; p=0.0548), whilst significantly increasing the number of OPCs at DIV7 (n=7-8; CTRL set to 100%, BDNF 210.2±21.87; p<0.0001) without affecting OL maturation (MBP-positive cells). Importantly, BDNF effects on OPC formation at DIV7 were partially abrogated by the A2AR antagonist (n=4-8; CTRL set to 100%, BDNF+ZM 174.0±8.951; p<0.01), while the antagonist by itself had no effect when comparing with control (ZM 117.6±15.47; p>0.05). No changes were observed after treatment with the A2AR agonist at these timepoints in both OPC formation and OL maturation. This work outlined the role of BDNF in promoting the formation of OPCs from SVZ-NSCs. Now we are addressing if the effect of BDNF is dependent of A2ARs, and if a simultaneous activation of CBRs is required to potentiate adult oligodendrogenesis, which will ultimately contribute to the development of alternative therapeutic targets for OL formation and remyelination.

Cannabinoid Actions on Neural Stem Cells: Implications for Pathophysiology.
With the increase of life expectancy, neurodegenerative disorders are becoming not only a health but also a social burden worldwide. However, due to the multitude of pathophysiological disease states, current treatments fail to meet the desired outcomes. Therefore, there is a need for new therapeutic strategies focusing on more integrated, personalized and effective approaches. The prospect of using neural stem cells (NSC) as regenerative therapies is very promising, however several issues still need to be addressed. In particular, the potential actions of pharmacological agents used to modulate NSC activity are highly relevant. With the ongoing discussion of cannabinoid usage for medical purposes and reports drawing attention to the effects of cannabinoids on NSC regulation, there is an enormous, and yet, uncovered potential for cannabinoids as treatment options for several neurological disorders, specifically when combined with stem cell therapy. In this manuscript, we review in detail how cannabinoids act as potent regulators of NSC biology and their potential to modulate several neurogenic features in the context of pathophysiology.

SIMULATED MICROGRAVITY TRANSIENTLY ALTERS ADULT NEUROGENESIS IN RATS

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Alexandra Gros, Fandilla Furlan, Bruno Bontempi, Jean-Luc Morel
Université de Bordeaux, Incia - Cnrs - Umr 5287, Bordeaux, France

Memory deficits have been reported in astronauts during space flights and documented in models of simulated microgravity (SMG) in humans and animals. However, the physiological causes of these behavioral effects remain largely unknown. We explored whether adult neurogenesis, known to be a crucial plasticity mechanism supporting memory processes, is altered by SMG. Adult male Long Evans rats were submitted to hindlimb suspension which simulates the body fluid reorganization and mechanical unloading encountered in space. To track the proliferation, survival and maturation of newborn cells in neurogenic niches such that the subventricular zone (SVZ), the olfactory bulb (OB) and the subgranular zone (SGZ) of the dentate gyrus (DG) of the hippocampus, rats were administered the birth dating markers 5-Ethynyl-2'-deoxyuridine and 5-Bromo-2'-deoxyuridine either immediately prior to, or at different delays following the SMG exposure period. While unaffected immediately after SMG exposure, newborn cell proliferation was decreased in the DG after 7 days of exposure. SMG also induced a decrease in short-term (7 days), but not long-term (21 days) survival of newborn cells in the DG and SVZ. Moreover, 3-weeks of physical exercise used as a countermeasure was able to reverse the decrease in newborn cell survival observed in the DG and SVZ. These findings highlight the sensitivity of adult neurogenesis to gravitational environmental factors during a transient period, possibly indicating a period of adaptation of physiological systems to this new environment. Alterations in the dynamics of adult neurogenesis may contribute, at least in part, to the cognitive deficits observed following SMG exposure.

DECIPHERING THE ROLE OF P75 NEUROTROPHIN RECEPTOR IN ADULT NEUROGENESIS: A POTENTIAL PHARMACOLOGICAL TARGET AGAINST ALZHEIMER'S DISEASE.

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Maria Anna Papadopoulou[1], Konstantina Chanoumidou[2], Ioannis Charalampopoulos[1,2]
[1]University of Crete, Medical School, Heraklion, Greece, [2]Institute of Molecular Biology & Biotechnology, Foundation Of Research & Technology, Heraklion, Greece

The pan-neurotrophin p75 receptor ($p75^{NTR}$) is a member of the TNF death receptor superfamily widely expressed in many cell types among the neural tissue, including adult neural stem cells (aNSCs). Its remarkable up regulation during neurodegeneration and its controversial signaling, ranging from survival to cell death, have attracted a special interest on this receptor as a potential pharmacological target. $p75^{NTR}$ has been extensively linked with Alzheimer's Disease (AD) by serving as a receptor for Amyloid-beta (Aβ), the major component of the plaques, found in the brain of AD patients. Additionally, recent studies are highlighting the importance of this receptor on the adult hippocampal neurogenesis – a process that seems to drop sharply in AD- although its role has not been clarified yet. We focus on revealing the $p75^{NTR}$ pleiotropic functions, by examining adult neurogenesis levels on $p75^{NTR}$ knock-out mouse lines and identifying the aNSCs proliferation and survival. Moreover, we investigate the p75NTR effects in human iPSC-derived NSCs, depicting receptor's signaling under physiological conditions and its dysregulation in NSCs derived from AD patients bearing the ApoE4 mutation. Finally, we show that $p75^{NTR}$ regulates human iPSC-derived NSCs survival in the presence of Aβ toxic oligomers, as well as primary mouse hippocampal aNSCs proliferation and differentiation, indicating its involvement in both AD progress and neurogenesis. Deciphering the specific signaling pathways necessary to mediate the actions of $p75^{NTR}$ on aNSCs' properties, we aim to reinforce endogenous ability of neurogenesis and thus strengthening its repairing capacity against AD-induced neuronal loss.

Cyclin D2 (D2) is one out of three homologous D-cyclins involved in cell cycle progression. Our previous studies suggest that D2 is a key regulator of adult hippocampal neurogenesis by controlling the proliferation of adult neural stem (aNSCs) and progenitor cells. However, available evidence is mainly based on conventional D2 knockout mice (D2KO), which have several limitations including an impaired development of the aNSC pool. To bypass these limitations, we engineered a mouse line in which exons I and II of *ccnd2* are flanked by *loxP* sites (*ccnd2flox*), and bred them to inducible Cre driver lines (Nestin-CreER^{T2}, Rosa26-CreER^{T2} or Glast-CreER^{T2}), enabling a spatiotemporally controlled deletion of D2. The knockout was induced by administration of tamoxifen at an age of 6-7 weeks and newborn cells were labelled with bromodeoxyuridine. Acute and long-term effects were assessed using multiple immunofluorescences at 2, 28 and 150 days post injection (dpi). Conditional null mutants generated with the intention of validating the *ccnd2flox* line displayed exactly the same phenotype as conventional D2KO mice. As expected, the conditional D2KO induced in young adults had less impact on adult hippocampal neurogenesis. Depending on the Cre driver, we found a 50-60% reduction of bromodeoxyuridine-positive cells accompanied by a similar reduction in neuroblasts and newborn neurons, whereas neuronal differentiation was unaffected. Taken together, these data corroborate the importance of D2 for constitutive neurogenesis. Whether D2 exerts this role through controlling the division of aNSCs or of their progeny is currently under investigation.

Detrimental effects of the 'bath salt' methylenedioxypyrovalerone on social play behavior in male rats.
Methylenedioxypyrovalerone (MDPV) is the most popular synthetic cathinone found in products marketed as 'bath salts', widely abused among teenagers and young adults. Synthetic cathinones have pharmacological effects resembling those of psychostimulants, which are known to disrupt a variety of social behaviors. However, despite the popular use of MDPV by young people in social contexts, information about its effects on social behavior is scarce. To investigate the impact of MDPV on social behavior at young age, and the underlying neurobehavioral mechanisms, we focused on social play behavior. Social play behavior is the most characteristic social behavior displayed by young mammals and it is crucial for neurobehavioral development. Treatment with MDPV reduced social play behavior in both juvenile and young adult male rats, and its play-suppressant effect was subject to tolerance but not sensitization. As the behavioral effects of MDPV have been ascribed to dopaminergic and noradrenergic neurotransmission, and given the role of these neurotransmitters in social play, we investigated the involvement of dopamine and noradrenaline in the play-suppressant effects of MDPV. The effects of MDPV on social play were blocked by either the α2 adrenoceptor antagonist RX821002 or the dopamine receptor antagonist flupenthixol, given alone or together at sub-effective doses. In sum, MDPV selectively suppresses the most vigorous social behavior of developing rats through both noradrenergic and dopaminergic mechanisms. This study provides important preclinical evidence of the deleterious effects of MDPV on social behavior, and as such increases our understanding of the neurobehavioral effects of this popular cathinone.

AXON ARCHITECTURE OF DENTATE GRANULE NEURONS IS DICTATED BY THEIR ONTOGENETIC ORIGIN IN THE MOUSE HIPPOCAMPUS

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Pierre Mortessagne[1], Thomas Kerloch[1], Fanny Farrugia[2], Djoher Nora Abrous[1], Emilie Pacary[1]

In the dentate gyrus (DG) of the hippocampus, the generation of dentate granule neurons (DGNs) starts during late embryogenesis, peaks around birth and continues at low levels during adulthood. The DG is therefore a peculiar brain structure composed of DGNs of different ontogenetic origins constituting subpopulations of DGNs that might play different roles in hippocampal physiology. Surprisingly, this hypothesis has received little attention and, although the morpho-functional properties of adult-born DGNs (Adu-DGNs) have been extensively studied, very little is known about the developmentally-generated ones. In this context, we have undertaken to analyse the morphological characteristics of these different subpopulations of DGNs. For this purpose, we targeted DGNs generated at E14.5 and P0 using in vivo electroporation and Adu-DGNs using retrovirus transduction. Using this strategy, we have already shown that developmentally-born DGNs (Dev-DGNs), especially embryonically-born cells, and Adu-DGNs display distinct dendritic arbors once mature (Kerloch et al., 2019). Interestingly, we have also found lower spine density in Dev-DGNs compared to Adu-DGNs and striking differences at the axonal level. Indeed, in the hilus and CA3 we observed that the later DGNs are generated, the bigger their mossy fiber boutons and the more filipodia they have. Furthermore, our preliminary data suggest that the projection sites of their axons in CA3/CA2 as well as the length and position of their axonal initial segment are also dependent on their ontogenetic origin. Altogether our data demonstrate that the temporal origin of DGNs dictates their morphological properties and thus potentially their functions in the hippocampal network.

Adult neurogenesis persists in the neurogenic zones where new neurons are incorporated into existing neuronal circuits to preserve and improve learning and memory tasks. Relevant structural elements of the neurogenic niches include the family of Cell Adhesion Molecules (CAM), which participate in signal transduction and regulate radial glial progenitor's (RGPs) survival, division and differentiation. The Neural Cell Ahesion Molecule 2 (NCAM2) is important for neuronal morphogenesis, dendritic arborization and synaptogenesis. However, their implications in the regulation of RGPs are poorly investigated. The aim of this study is to unravel the role of NCAM2 in adult neurogenesis. To study the implications of NCAM2 in the regulation of RGPs during hippocampal adult neurogenesis *in vivo,* we characterized the expression of NCAM2 in the dentate gyrus by immunofluorescence. In addition, 8 week-old mice were injected with NCAM2 expression modulating vectors and the transduced hippocampus were analyzed at different time points. Finally, the effects of NCAM2 in the regulation of RGPs were complemented *in vitro* analyzing the proliferation of SGZ derived neurospheres infected with NCAM2 overexpressing vectors. The characterization of the expression of NCAM2 among the main actors of the neurogenic process revealed different levels of NCAM2 amid the progression of RGPs and the formation of neurons. Further, our results indicate that the modulation of NCAM2 expression arrest cells in a RGP-like state affecting the normal course of the neurogenic events. Together, our data suggest a significant implication of NCAM2 in the regulation of RGPs during adult neurogenesis in the hippocampus.

The Hidden Side of NCAM Family: NCAM2, a Key Cytoskeleton Organization Molecule Regulating Multiple Neural Functions. Although it has been over 20 years since Neural Cell Adhesion Molecule 2 (NCAM2) was identified as the second member of the NCAM family with a high expression in the nervous system, the knowledge of NCAM2 is still eclipsed by NCAM1. The first studies with NCAM2 focused on the olfactory bulb, where this protein has a key role in axonal projection and axonal/dendritic compartmentalization. In contrast to NCAM1, NCAM2's functions and partners in the brain during development and adulthood have remained largely unknown until not long ago. Recent studies have revealed the importance of NCAM2 in nervous system development. NCAM2 governs neuronal morphogenesis and axodendritic architecture, and controls important neuron-specific processes such as neuronal differentiation, synaptogenesis and memory formation. In the adult brain, NCAM2 is highly expressed in dendritic spines, and it regulates synaptic plasticity and learning processes. NCAM2's functions are related to its ability to adapt to the external inputs of the cell and to modify the cytoskeleton accordingly. Different studies show that NCAM2 interacts with proteins involved in cytoskeleton stability and proteins that regulate calcium influx, which could also modify the cytoskeleton. In this review, we examine the evidence that points to NCAM2 as a crucial cytoskeleton regulation protein during brain development and adulthood. This key function of NCAM2 may offer promising new therapeutic approaches for the treatment of neurodevelopmental diseases and neurodegenerative disorders.

New Partners Identified by Mass Spectrometry Assay Reveal Functions of NCAM2 in Neural Cytoskeleton Organization. Neuronal cell adhesion molecule 2 (NCAM2) is a membrane protein with an important role in the morphological development of neurons. In the cortex and the hippocampus, NCAM2 is essential for proper neuronal differentiation, dendritic and axonal

outgrowth and synapse formation. However, little is known about NCAM2 functional mechanisms and its interactive partners during brain development. Here we used mass spectrometry to study the molecular interactome of NCAM2 in the second postnatal week of the mouse cerebral cortex. We found that NCAM2 interacts with >100 proteins involved in numerous processes, including neuronal morphogenesis and synaptogenesis. We validated the most relevant interactors, including Neurofilaments (NEFs), Microtubule-associated protein 2 (MAP2), Calcium/calmodulin kinase II alpha (CaMKIIα), Actin and Nogo. An in silico analysis of the cytosolic tail of the NCAM2.1 isoform revealed specific phosphorylation site motifs with a putative affinity for some of these interactors. Our results expand the knowledge of NCAM2 interactome and confirm the key role of NCAM2 in cytoskeleton organization, neuronal morphogenesis and synaptogenesis. These findings are of interest in explaining the phenotypes observed in different pathologies with alterations in the NCAM2 gene.

NCAM2 Regulates Dendritic and Axonal Differentiation through the Cytoskeletal Proteins MAP2 and 14-3-3.
Neural cell adhesion molecule 2 (NCAM2) is involved in the development and plasticity of the olfactory system. Genetic data have implicated the NCAM2 gene in neurodevelopmental disorders including Down syndrome and autism, although its role in cortical development is unknown. Here, we show that while overexpression of NCAM2 in hippocampal neurons leads to minor alterations, its downregulation severely compromises dendritic architecture, leading to an aberrant phenotype including shorter dendritic trees, retraction of dendrites, and emergence of numerous somatic neurites. Further, our data reveal alterations in the axonal tree and deficits in neuronal polarization. In vivo studies confirm the phenotype and reveal an unexpected role for NCAM2 in cortical migration. Proteomic and cell biology experiments show that NCAM2 molecules exert their functions through a protein complex with the cytoskeletal-associated proteins MAP2 and 14-3-3γ and ζ. We provide evidence that NCAM2 depletion results in destabilization of the microtubular network and reduced MAP2 signal. Our results demonstrate a role for NCAM2 in dendritic formation and maintenance, and in neural polarization and migration, through interaction of NCAM2 with microtubule-associated proteins.

In mammals, adult hippocampal neurogenesis (AHN) is necessary for memory, learning and adaptation to the environment. In human brain we showed persistent AHN into the eighth decade of life, despite a smaller multipotent progenitor pool in the aging dentate gyrus (DG) stem cell niche. Although, other studies failed to detect doublecortin (DCX) and other immature neuron markers in adult DG. We reported DCX expression in co-localization with other neuronal proteins and RNAs in the human DG neurogenic niche of the subgranular zone (SGZ). The existence of adult hippocampal neurogenesis (AHN) in human brain is largely debated. To investigate human hippocampus neurogenic niche molecular features, we applied single nuclei (sn) RNA sequencing (seq), snATAC-seq, Visium (10X Genomics) and slide-seq using deterministic barcoding in intact tissue (DBiT-seq) for spatial omics sequencing. Subgranular zone cell clusters highly expressed genes involved in: cell mitosis and differentiation (PTPRT, p=6.44*E-95); embryonic development and cell fate determination (SOX1, p=4.72*E-11); neuron migration and differentiation (L1CAM, p=1.56*E-05); involved in cell migration and adhesion (RELN, p=1.38*E-46); and neurite extension (NRSN,1p=1.73*E-65). Granule cell layer cell clusters highly expressed genes involved in: cell fate determination and neurogenesis (PROX1, p=1.65*E-149); the switch to adult-like connectivity during neurogenesis (CALB1, p=1.18*E-52); stabilizing dendritic shape during neuron development (MAP2, p=9.13*E-30). Single nucleus and spatial multiomics identified canonical cell clusters localized in the expected hippocampus subfields, and support the existence of a hippocampus neurogenic niche in the subgranular zone.

Obesity is one of the most serious and costly health challenges facing the modern world. Increasing evidence suggests that the risk of developing a metabolic syndrome or obesity may be influenced very early in the development, especially through inappropriate fetal and/or neonatal nutrition. Outcomes from epidemiological studies indicate that maternal nutrition during pregnancy and lactation periods has a profound impact on adult neurogenesis in the offspring. In this study, an intergenerational dietary model based on overfeeding of experimental mice during prenatal and early postnatal development was used to produce mice with various body conditions. The aim of the present study was to experimentally investigate the impact of the maternal high-energy diet during pregnancy and lactation periods on adult neurogenesis in the olfactory neurogenic region involving the subventricular zone (SVZ) and rostral migratory stream (RMS). Our findings indicate that, under the influence of a maternal high-energy diet administered during pregnancy and lactation, SVZ/RMS neurogenesis is altered as indicated by decreased proliferation of neural precursors, increased cell degeneration, and by changes in the number of nitrergic cells. The major finding of this study is that maternal high-energy diet affects individual processes of SVZ/RMS neurogenesis only in mice where extreme phenotype, such as significant overweight/adiposity or obesity is manifested. EXERCISING ON CANNABINOIDS: A COMBINED EFFORT IN REGULATING POSTNATAL NEUROGENESIS

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

João Moreira[1,2], Rui Rodrigues[1,2], Ana M. Sebastião[1,2], Sara Xapelli[1,2]
[1]Instituto de Farmacologia e Neurociências, Faculdade De Medicina, Universidade De Lisboa, Lisboa, Portugal, [2]Instituto de Medicina Molecular João Lobo Antunes, Faculdade De Medicina, Universidade De Lisboa, Lisboa, Portugal

Neurogenesis, the formation of new neurons from neural stem cells (NSCs), occurs mainly within the subventricular zone (SVZ) and the hippocampal dentate gyrus (DG). Cannabinoids, which activate primarily type 1 and 2 receptors (CB_1R and CB_2R), modulate this process whereas physical exercise has been shown to potentiate neurogenesis. While CB_1R signaling is required for exercise-mediated effects on hippocampal NSC proliferation, much less is known about the effects of CB2R. Recent data suggests an interaction between CB_2R and BDNF, a major neurotrophin upregulated with physical exercise, in regulating postnatal neurogenesis. Therefore, this work aimed to study whether exercise-regulated neurotrophic factors combined with CB_2R modulation play an impactful role on postnatal neurogenesis, using SVZ- and DG-derived neurospheres pharmacologically treated with different CB_2R ligands and neurotrophic factors (BDNF, VEGF and IGF-1). No significant alterations in cell survival were observed in both niches in response to any treatment. BDNF significantly enhanced cell proliferation in DG-derived neurospheres. Concerning neuronal differentiation, all neurotrophic factors stimulated neuronal differentiation in DG whereas only BDNF promoted an increase in the number of mature neurons in SVZ. Interestingly, the co-incubation of neurotrophic factors with the CB_2R agonist potentiated the effects observed with the independent treatments in neuronal differentiation. In DG, the antagonism of CB_2R blocked the effects promoted by the neurotrophic factors on neuronal differentiation suggesting that the activation of this receptor is crucial for their effects. This study sheds light on the potential synergism between physical exercise and endocannabinoid signaling in regulating postnatal neurogenesis.

The Mitochondrial Antioxidant Sirtuin3 Cooperates with Lipid Metabolism to Safeguard Neurogenesis in Aging and Depression.
Neural stem cells (NSCs), crucial for memory in the adult brain, are also pivotal to buffer depressive behavior. However, the mechanisms underlying the boost in NSC activity throughout life are still largely undiscovered. Here, we aimed to explore the role of deacetylase Sirtuin 3 (SIRT3), a central player in mitochondrial metabolism and oxidative protection, in the fate of NSC under aging and depression-like contexts. We showed that chronic treatment with tert-butyl hydroperoxide induces NSC aging, markedly reducing SIRT3 protein. SIRT3 overexpression, in turn, restored mitochondrial oxidative stress and the differentiation potential of aged NSCs. Notably, SIRT3 was also shown to physically interact with the long chain acyl-CoA dehydrogenase (LCAD) in NSCs and to require its activation to prevent age-impaired neurogenesis. Finally, the SIRT3 regulatory network was investigated in vivo using the unpredictable chronic mild stress (uCMS) paradigm to mimic depressive-like behavior in mice. Interestingly, uCMS mice presented lower levels of neurogenesis and LCAD expression in the same neurogenic niches, being significantly rescued by physical exercise, a well-known upregulator of SIRT3 and lipid metabolism. Our results suggest that targeting NSC metabolism, namely through SIRT3, might be a suitable promising strategy to delay NSC aging and confer stress resilience.

Adult Neural Stem Cells as Promising Targets in Psychiatric Disorders.
The development of new therapies for psychiatric disorders is of utmost importance, given the enormous toll these disorders pose to society nowadays. This should be based on the identification of neural substrates and mechanisms that underlie disease etiopathophysiology. Adult neural stem cells (NSCs) have been emerging as a promising platform to counteract brain damage. In this perspective article, we put forth a detailed view of how NSCs operate in the adult brain and influence brain

homeostasis, having profound implications at both behavioral and functional levels. We appraise evidence suggesting that adult NSCs play important roles in regulating several forms of brain plasticity, particularly emotional and cognitive flexibility, and that NSC dynamics are altered upon brain pathology. Furthermore, we discuss the potential therapeutic value of utilizing adult endogenous NSCs as vessels for regeneration, highlighting their importance as targets for the treatment of multiple mental illnesses, such as affective disorders, schizophrenia, and addiction. Finally, we speculate on strategies to surpass current challenges in neuropsychiatric disease modeling and brain repair.

Isolation and Expansion of Neurospheres from Postnatal (P1-3) Mouse Neurogenic Niches.
The neurosphere assay is an extremely useful in vitro technique for studying the inherent properties of neural stem/progenitor cells (NSPCs) including proliferation, self-renewal and multipotency. In the postnatal and adult brain, NSPCs are mainly present in two neurogenic niches: the subventricular zone (SVZ) lining the lateral ventricles and the subgranular zone of the hippocampal dentate gyrus (DG). The isolation of the neurogenic niches from postnatal brain allows obtaining a higher amount of NSPCs in culture with a consequent advantage of higher yields. The close contact between cells within each neurosphere creates a microenvironment that may resemble neurogenic niches. Here, we describe, in detail, how to generate SVZ- and DG-derived neurosphere cultures from 1-3-day-old (P1-3) mice, as well as passaging, for neurosphere expansion. This is an advantageous approach since the neurosphere assay allows a fast generation of NSPC clones (6-12 days) and contributes to a significant reduction in the number of animal usage. By plating neurospheres in differentiative conditions, we can obtain a pseudomonolayer of cells composed of NSPCs and differentiated cells of different neural lineages (neurons, astrocytes and oligodendrocytes) allowing the study of the actions of intrinsic or extrinsic factors on NSPC proliferation, differentiation, cell survival and neuritogenesis.

Cannabinoid Actions on Neural Stem Cells: Implications for Pathophysiology.
With the increase of life expectancy, neurodegenerative disorders are becoming not only a health but also a social burden worldwide. However, due to the multitude of pathophysiological disease states, current treatments fail to meet the desired outcomes. Therefore, there is a need for new therapeutic strategies focusing on more integrated, personalized and effective approaches. The prospect of using neural stem cells (NSC) as regenerative therapies is very promising, however several issues still need to be addressed. In particular, the potential actions of pharmacological agents used to modulate NSC activity are highly relevant. With the ongoing discussion of cannabinoid usage for medical purposes and reports drawing attention to the effects of cannabinoids on NSC regulation, there is an enormous, and yet, uncovered potential for cannabinoids as treatment options for several neurological disorders, specifically when combined with stem cell therapy. In this manuscript, we review in detail how cannabinoids act as potent regulators of NSC biology and their potential to modulate several neurogenic features in the context of pathophysiology.

"MILKING": AN INNOVATIVE APPROACH TO INVESTIGATE THE PROPERTIES OF POSTNATAL BRAIN NEURAL STEM CELLS AND TO OBTAIN OLIGODENDROCYTE PROGENITOR CELLS FROM LIVE EXPERIMENTAL ANIMALS

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Dimitris Dimitrakopoulos[1], Robin J. Franklin[2], Ilias Kazanis[1,2]
[1]University of Patras, Laboratory Of Developmental Biology, Department Of Biology, Patras, Greece, [2]University of Cambridge, Wellcome Trust – Mrc Cambridge Stem Cell Institute, Cambridge, United Kingdom

Aims: Postnatal brain neural stem and progenitor cells (NSPCs) cluster in anatomically defined stem cell niches, such as the subependymal zone (SEZ) and are characterized by self-renewal and quiescence. Oligodendrocyte progenitor cells (OPCs) give rise to myelinating oligodendrocytes and also exhibit self-renewing potential. Here, we refine our method of “milking” the ventricular system in order to collect OPCs from the corpus callosum and to investigate the basic properties of SEZ-resident NSPCs. **Methods:** Milking consists of an intracerebroventricular injection of a release cocktail containing neuraminidase, β1-integrin blocking antibody and Fibroblast Growth Factor-2 in order to induce the controlled flow of NSPCs and OPCs in the cerebrospinal fluid. At a second “collection” step, liquid biopsies of CSF are performed from the cisterna magna of anesthetized experimental animals without the need of an incision. Liquid biopsies after milking caudal ventricular areas resulted in the isolation of cells expressing typical OPC markers. Cells isolated after milking of the SEZ, were cultured in three different growth media. The typical NSPC medium and two media known to favor the expansion of neural stem cells without enhancing their progress towards differentiation. **Results:** Our results showed significant differences in the morphology of grown cells and in their colony-formation characteristics that we investigate further using a range of NSPC markers in order to directly assess the profile of endogenous SEZ. **Conclusions:** This novel approach paves the way for performing longitudinal studies in experimental animals, for more in vivo relevant cell culture assays, and for future clinical neuro-regenerative applications.

Isolation of neural stem and oligodendrocyte progenitor cells from the brain of live rats.
Postnatal brain neural stem and progenitor cells (NSPCs) cluster in anatomically inaccessible stem cell niches, such as the subependymal zone (SEZ). Here, we describe a method for the isolation of NSPCs from live animals, which we term "milking." The intracerebroventricular injection of a release cocktail, containing neuraminidase, integrin-β1-blocking antibody, and fibroblast growth factor 2, induces the controlled flow of NSPCs in the cerebrospinal fluid, where they are collected via liquid biopsies. Isolated cells retain key in vivo self-renewal properties and their cell-type profile reflects the cell composition of their source area, while the function of the niche is sustained even 8 months post-milking. By changing the target area more caudally, we also isolate oligodendrocyte progenitor cells (OPCs) from the corpus callosum. This novel approach for sampling NSPCs and OPCs paves the way for performing longitudinal studies in experimental animals, for more in vivo relevant cell culture assays, and for future clinical neuro-regenerative applications.

Characterization of substantia nigra neurogenesis in homeostasis and dopaminergic degeneration: beneficial effects of the microneurotrophin BNN-20.
Loss of dopaminergic neurons in the substantia nigra pars compacta (SNpc) underlines much of the pathology of Parkinson's disease (PD), but the existence of an endogenous neurogenic system that could be targeted as a therapeutic strategy has been controversial. BNN-20 is a synthetic, BDNF-mimicking, microneurotrophin that we previously showed to exhibit a pleiotropic neuroprotective effect on the dopaminergic neurons of the SNpc in the "weaver" mouse model of PD. Here, we assessed its potential effects on neurogenesis.

ROLE OF TET2 IN NEURAL STEM CELL MAINTENANCE AND DIFFERENTIATION

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Laura Lázaro-Carot, Esteban Jiménez-Villalba, Sacri Ferrón
Institute of Biotechnology and Biomedicine/ University of Valencia, Department Of Cell Biology, Burjassot, Valencia, Spain

Neurogenesis throughout lifespan in mammalian brain is supported by multipotent neural stem cells (NSCs), characterized by their abilities of self-renewal and differentiation into the three lineages of the central nervous system: neurons, astrocytes and oligodendrocytes. Both capabilities are maintained by specific intracellular and extracellular factors. One of these intrinsic factors is the epigenetic process of genomic imprinting (GI). GI causes genes to be expressed depending on their parental origin, causing a monoallelic expression of a subset of genes called *imprinted genes*. It has been shown that this process is implicated in the control of gene dosage in NSCs, regulating their maintenance and differentiation. GI is regulated by differentially methylated regions (DMRs) in maternal and paternal chromosomes. Ten-eleven-translocation (TET) enzymes catalyze DNA demethylation, giving rise to the 5-hydroxymethylcytosine (5hmC) epigenetic mark. However, although hydroxymethylation levels are high in the mouse brain, the potential role of TET proteins regulating GI in adult neurogenesis is not described. This work characterizes the expression of *Tet2* gene and it is coding protein, TET2, both *in vivo* and *in vitro*, focusing on NSCs of the adult subventricular zone (SVZ) neurogenic niche. In addition, the role of *Tet2* is also studied by the generation of a conditional mouse model deficient in *Tet2* specifically in NSCs. Our data reveal that TET2 is essentially required for terminal differentiation of adult NSCs into non-neurogenic astrocytes. Morever, an RNASeq analysis in *Tet2* deficient NSCs identify candidate imprinted genes that might be implicated in this process.

Aims
Adult hippocampal neurogenesis (AHN) encompasses the addition of new neurons to the hippocampus throughout life. This process significantly enhances hippocampal plasticity, and it is implicated in mood regulation and pattern separation. To address whether AHN and the neurogenic niche are compromised by distinct forms of neurodegeneration we compared a cohort of patients with Amyotrophic lateral sclerosis (ALS) and Huntington's disease (HD) with neurologically healthy control subjects. **Methods**
High-quality postmortem human samples obtained from 15 control subjects and 12 patients with ALS and, 6 with HD were subjected to state-of-the-art tissue preservation methodologies, which allowed visualization of neural stem cells (NSCs), immature dentate granule cells (DGCs), and specific components of the dentate gyrus (DG) neurogenic niche. **Results**
Compared to control subjects, patients with ALS and HD showed increased densities of NSCs and immature DGCs. The morphological maturation of immature DGCs is altered in ALS. These cells showed early maturation impairments in HD, which suggests a maturation delay. We observed DG astrogliosis, microglial alterations, and thickening of capillaries. These alterations point to the vulnerability of AHN and the human DG neurogenic niche to neurodegenerative diseases. **Conclusions**
Despite the hippocampus is not the brain area primarily affected by ALS and HD, our data reveal that these diseases severely impact AHN. These conditions disturbed the homeostasis of the neurogenic niche, thereby impairing DGCs maturation. Our data provide fundamental insights into the pathophysiology of neurodegenerative diseases and are expected to contribute to the future design of novel therapeutic strategies for these yet incurable conditions.

Impact of neurodegenerative diseases on human adult hippocampal neurogenesis.
Disrupted hippocampal performance underlies psychiatric comorbidities and cognitive impairments in patients with neurodegenerative disorders. To understand the contribution of adult hippocampal neurogenesis (AHN) to amyotrophic lateral sclerosis, Huntington's disease, Parkinson's disease, dementia with Lewy bodies, and frontotemporal dementia, we studied postmortem human samples. We found that adult-born dentate granule cells showed abnormal morphological development and changes in the expression of differentiation markers. The ratio of quiescent to proliferating hippocampal neural stem cells shifted, and the homeostasis of the neurogenic niche was altered. Aging and neurodegenerative diseases reduced the phagocytic capacity of microglia, triggered astrogliosis, and altered the microvasculature of the dentate gyrus. Thus, enhanced vulnerability of AHN to neurodegeneration might underlie hippocampal dysfunction during physiological and pathological aging in humans.

Evidences for Adult Hippocampal Neurogenesis in Humans.
The rodent hippocampus generates new neurons throughout life. This process, named adult hippocampal neurogenesis (AHN), is a striking form of neural plasticity that occurs in the brains of numerous mammalian species. Direct evidence of adult neurogenesis in humans has remained elusive, although the occurrence of this phenomenon in the human dentate gyrus has been demonstrated in seminal studies and recent research that have applied distinct approaches to birthdate newly generated neurons and to validate markers of adult-born neurons. Our data point to the persistence of AHN until the 10th decade of human life, as well as to marked impairments in this process in patients with Alzheimer's disease. Moreover, our work demonstrates that the methods used to process and analyze postmortem human brain samples can limit the detection of various markers of AHN to the point of making them undetectable. In this Dual Perspectives article, we highlight the critical methodological aspects that should be strictly controlled in human studies and the robust evidence that supports the occurrence of AHN in humans. We also put forward reasons that may account for current discrepancies on this topic. Finally, the unresolved questions and future challenges awaiting the field are highlighted.

Unraveling human adult hippocampal neurogenesis.
Adult neurogenesis occurs in a few selected regions of the mammalian brain. One such region is the hippocampus, the so-called gateway to memory, where adult hippocampal neurogenesis (AHN) occurs. Here, we provide a comprehensive description of the methods used in our laboratory to unambiguously detect a population of immature neurons in the human hippocampus until the 10th decade of life. The criteria used to refine and develop the current protocol include obtaining post-mortem human samples of remarkable quality and under tightly controlled conditions for immunohistochemistry (IHC) studies, optimizing tissue processing and histological procedures, establishing criteria to reliably validate antibody signal and performing unbiased stereological cell counts. Moreover, we provide a detailed description of the parameters that, in our view, should be reported in human AHN studies. The opposing results obtained by introducing slight variations in the methodological conditions should be considered by future studies that seek to increase our knowledge of this fascinating process. By applying simple and inexpensive tissue pre-treatments, this protocol, which can be completed in 7 days, might be applicable to a variety of IHC studies performed on other tissues of human (or animal) origin.

Activity-Dependent Reconnection of Adult-Born Dentate Granule Cells in a Mouse Model of Frontotemporal Dementia.
Frontotemporal dementia (FTD) is characterized by neuronal loss in the frontal and temporal lobes of the brain. Here, we provide the first evidence of striking morphological alterations in dentate granule cells (DGCs) of FTD patients and in a mouse model of the disease, Tau mice. Taking advantage of the fact that the hippocampal dentate gyrus (DG) gives rise to newborn DGCs throughout the lifetime in rodents, we used RGB retroviruses to study the temporary course of these alterations in newborn DGCs of female Tau mice. In addition, retroviruses that encode either PSD95:GFP or Syn:GFP revealed striking alterations in the afferent and efferent connectivity of newborn Tau DGCs, and monosynaptic retrograde rabies virus tracing showed that these cells are disconnected from distal brain regions and local sources of excitatory innervation. However, the same cells exhibited a predominance of local inhibitory innervation. Accordingly, the expression of presynaptic and postsynaptic markers of inhibitory synapses was markedly increased in the DG of Tau mice and FTD patients. Moreover, an increased number of neuropeptide Y-positive interneurons in the DG correlated with a reduced number of activated egr-1

DGCs in Tau mice. Finally, we tested the therapeutic potential of environmental enrichment and chemoactivation to reverse these alterations in mice. Both strategies reversed the morphological alterations of newborn DGCs and partially restored their connectivity in a mouse model of the disease. Moreover, our data point to remarkable morphological similarities between the DGCs of Tau mice and FTD patients. We show, for the first time to our knowledge, that the population of dentate granule cells is disconnected from other regions of the brain in the neurodegenerative disease frontotemporal dementia (FTD). These alterations were observed in FTD patients and in a mouse model of this disease. Moreover, we tested the therapeutic potential of two strategies, environmental enrichment and chemoactivation, to stimulate the activity of these neurons in mice. We found that some of the alterations were reversed by these therapeutic interventions.

Adult hippocampal neurogenesis is abundant in neurologically healthy subjects and drops sharply in patients with Alzheimer's disease.
The hippocampus is one of the most affected areas in Alzheimer's disease (AD). Moreover, this structure hosts one of the most unique phenomena of the adult mammalian brain, namely, the addition of new neurons throughout life. This process, called adult hippocampal neurogenesis (AHN), confers an unparalleled degree of plasticity to the entire hippocampal circuitry. Nonetheless, direct evidence of AHN in humans has remained elusive. Thus, determining whether new neurons are continuously incorporated into the human dentate gyrus (DG) during physiological and pathological aging is a crucial question with outstanding therapeutic potential. By combining human brain samples obtained under tightly controlled conditions and state-of-the-art tissue processing methods, we identified thousands of immature neurons in the DG of neurologically healthy human subjects up to the ninth decade of life. These neurons exhibited variable degrees of maturation along differentiation stages of AHN. In sharp contrast, the number and maturation of these neurons progressively declined as AD advanced. These results demonstrate the persistence of AHN during both physiological and pathological aging in humans and provide evidence for impaired neurogenesis as a potentially relevant mechanism underlying memory deficits in AD that might be amenable to novel therapeutic strategies.

Maturation Dynamics of the Axon Initial Segment (AIS) of Newborn Dentate Granule Cells in Young Adult C57BL/6J Mice.
Newborn dentate granule cells (DGCs) are generated in the hippocampal dentate gyrus (DG) of rodents through a process called adult hippocampal neurogenesis, which is subjected to tight intrinsic and extrinsic regulation. The use of retroviruses encoding fluorescent proteins has allowed the characterization of the maturation dynamics of newborn DGCs, including their morphological development and the establishment and maturation of their afferent and efferent synaptic connections. However, the study of a crucial cellular compartment of these cells, namely, the axon initial segment (AIS), has remained unexplored to date. The AIS is not only the site of action potential initiation, but it also has a unique molecular identity that makes it one of the master regulators of neural plasticity and excitability. Here we examined the dynamics of AIS formation in newborn DGCs of young female adult C57BL/6J mice Our data reveal notable changes in AIS length and thickness throughout cell maturation under physiological conditions and show that the most remarkable structural changes coincide with periods of intense morphological and functional remodeling. Moreover, we demonstrate that AIS development can be modulated extrinsically by both neuroprotective (environmental enrichment) and detrimental (lipopolysaccharide from) stimuli. The hippocampal dentate gyrus (DG) of rodents generates newborn dentate granule cells (DGCs) throughout life. This process, named adult hippocampal neurogenesis, confers a unique degree of plasticity to the hippocampal circuit, and it is crucial for learning and memory. Here we studied, for the first time, the formation of a key cellular compartment of newborn DGCs, namely, the axon initial segment (AIS) Our data reveal remarkable AIS structural remodeling throughout the maturation of these cells under physiological conditions. Moreover, AIS development can be modulated extrinsically by both neuroprotective (environmental enrichment) and detrimental (lipopolysaccharide from) stimuli.

Untold New Beginnings: Adult Hippocampal Neurogenesis and Alzheimer's Disease.
Neurogenesis occurs in a limited number of brain regions during adulthood. Of these, the hippocampus has attracted great interest due to its involvement in memory processing. Moreover, both the hippocampus and the main area that innervates this structure, namely the entorhinal cortex, show remarkable atrophy in patients with Alzheimer's disease (AD). Adult hippocampal neurogenesis is a process that continuously gives rise to newborn granule neurons in the dentate gyrus. These cells coexist with developmentally generated granule neurons in this structure, and both cooperative and competition phenomena regulate the communication between these two types of cells. Importantly, it has been revealed that GSK-3β and tau proteins, which are two of the main players driving AD pathology, are cornerstones of adult hippocampal neurogenesis

regulation. We have shown that alterations either promoting or impeding the actions of these two proteins have detrimental effects on the structural plasticity of granule neurons. Of note, these impairments occur both under basal conditions and in response to detrimental and neuroprotective stimuli. Thus, in order to achieve the full effectiveness of future therapies for AD, we propose that attention be turned toward identifying the pathological and physiological actions of the proteins involved in the pathogenesis of this condition.

Soluble Tau has devastating effects on the structural plasticity of hippocampal granule neurons.
Tau is a neuronal microtubule-associated protein with countless physiological functions. Although the detrimental effects of insoluble aggregated Tau have been widely studied, recent evidence supports the notion that soluble Tau (composed mostly of monomers and dimers) is also toxic for neurons. Here we evaluated the long-term impact of a single stereotaxic injection of human soluble Tau on hippocampal granule neurons in mice. At the ultrastructural level, soluble Tau reduced the number of afferent synapses and caused a dramatic depletion of synaptic vesicles both in afferent and efferent synapses. Furthermore, the use of an RFP-expressing retrovirus revealed that soluble Tau altered the morphology of newborn granule neurons and reduced their afferent (dendritic spines) and efferent (mossy fiber terminals) connectivity. Finally, soluble Tau caused specific impairment of behavioral pattern separation capacity. Our results thus demonstrate for the first time that soluble Tau causes long-term detrimental effects on the morphology and connectivity of newborn granule neurons and that these effects correlate with impaired behavioral pattern separation skills. These data might be relevant for the field of neurodegenerative disorders, since they contribute to reinforcing the pathological roles played by distinct Tau species in vivo.

Absence of microglial CX3CR1 impairs the synaptic integration of adult-born hippocampal granule neurons.
Microglia are immune cells that play a crucial role in maintaining brain homeostasis. Among the mechanisms of communication between microglia and neurons, the CX3CL1/CX3CR1 axis exerts a central modulatory role. Animals lacking CX3CR1 microglial receptor (CX3CR1-/- mice) exhibit marked alterations not only in microglia but also in neurons located in various regions of the brain. Here we show that microglial depletion of CX3CR1 leads to the deficient synaptic integration of adult-born granule neurons in the dentate gyrus (DG), both at the afferent and efferent level. Regarding the alterations in the former level, these cells show a reduced number of dendritic spines, which also exhibit morphological changes, namely enlargement and shortening. With respect to changes at the efferent level, these cells show a reduced area of axonal terminals. Both at the afferent and efferent level, synapses show ultrastructural enlargement, but they are depleted of synaptic vesicles, which suggests impaired functionality. We also show that selective increased microglial activation and extracellular matrix deposition in the zones in which the afferent synaptic contacts of these cells occur, namely in the molecular and the granule layer of the DG. In order to evaluate the impact of these structural alterations from a functional point of view, we performed a battery of behavioral tests related to hippocampal-dependent emotional behavior. We observed that female CX3CR1-/- mice exhibit a hyperactive, anxiolytic-like and depressive-like phenotype. These data shed light on novel aspects of the regulation of adult hippocampal neurogenesis by microglia that could be highly relevant for research into mood disorders.

INVESTIGATING THE DYNAMICS OF ACTIVATION OF POSTNATAL NEURAL STEM CELLS

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Isabel Mateos White[1], Carmen Mateos Martínez[1], Jaime Fabra Beser[1], David De Agustín Durán[1], Isabel Fariñas[1,2], Cristina Gil Sanz[1]
[1]University of Valencia, Cellular Biology, Functional Biology And Physical Anthropology Department, Biotecmed Institute, Burjassot, Spain, [2]CIBERNED, Centro De Investigación Biomédica En Red Sobre Enfermedades Neurodegenerativas,, Madrid, Spain

The subventricular zone (SVZ) of the lateral ventricles is one of the neurogenic niches of the adult mammalian brain. Neural stem cells (NSCs) populating this niche are pre-specified since embryonic ages and remain quiescent during long periods of time, until they reactivate giving rise to different types of olfactory-bulb interneurons throughout life.
Recently, many studies have been performed to clarify the behavior of NSCs and the molecular mechanisms regulating quiescence exit to produce new cells. Some of them are related to extrinsic signals perceived by NSCs, including interactions with the environment and the neighboring cells via adhesion molecules (CAMs). However, the mechanisms regulating the activation pattern of NSCs before the adult niche establishment are still unknown. Building on the embryonic specification of NSCs, we can target them using in vivo electroporation, at embryonic or early postnatal ages.
Here, we display some approaches using electroporation is this neurogenic niche including the study of the postnatal activation dynamics of NSCs utilizing lineage-tracing strategies and functional experiments employing conditional knock-out mice. Both strategies relay in the use of plasmids containing a tamoxifen inducible CRE recombinase (CRE-ERT2) to allow temporal control of the recombination in NSCs. Lineage tracing experiments using different promoters to drive the expression of CRE in CRE-reporter mice revealed diverse patterns of NSCs activation. Functional experiments employing conditional knock-out mice for a gene involved in the regulation of NSCs quiescence, the CAM Cdh2, enabled us to analyze the consequences of its deletion in such NSCs only at postnatal ages.

ZBTB20 is crucial for the specification of a subset of callosal projection neurons and astrocytes in the mammalian neocortex. Neocortical progenitor cells generate subtypes of excitatory projection neurons in sequential order followed by the generation of astrocytes. The transcription factor zinc finger and BTB domain-containing protein 20 (ZBTB20) has been implicated in regulation of cell specification during neocortical development. Here, we show that ZBTB20 instructs the generation of a subset of callosal projections neurons in cortical layers II/III in mouse. Conditional deletion of Zbtb20 in cortical progenitors, and to a lesser degree in differentiating neurons, leads to an increase in the number of layer IV neurons at the expense of layer II/III neurons. Astrogliogenesis is also affected in the mutants with an increase in the number of a specific subset of astrocytes expressing GFAP. Astrogliogenesis is more severely disrupted by a ZBTB20 protein containing dominant mutations linked to Primrose syndrome, suggesting that ZBTB20 acts in concert with other ZBTB proteins that were also affected by the dominant-negative protein to instruct astrogliogenesis. Overall, our data suggest that ZBTB20 acts both in progenitors and in postmitotic cells to regulate cell fate specification in the mammalian neocortex.

Double In Utero Electroporation to Target Temporally and Spatially Separated Cell Populations.
In utero electroporation is an in vivo DNA transfer technique extensively used to study the molecular and cellular mechanisms underlying mammalian corticogenesis. This procedure takes advantage of the brain ventricles to allow the introduction of DNA of interest and uses a pair of electrodes to direct the entrance of the genetic material into the cells lining the ventricle, the neural stem cells. This method allows researchers to label the desired cells and/or manipulate the expression of genes of interest in those cells. It has multiple applications, including assays targeting neuronal migration, lineage tracing, and axonal pathfinding. An important feature of this method is its temporal and regional control, allowing circumvention of potential problems related with embryonic lethality or the lack of specific CRE driver mice. Another relevant aspect of this technique is that it helps to considerably reduce the economic and temporal limitations that involve the generation of new mouse lines,

which become particularly important in the study of interactions between cell types that originate in distant areas of the brain at different developmental ages. Here we describe a double electroporation strategy that enables targeting of cell populations that are spatially and temporally separated. With this approach we can label different subtypes of cells in different locations with selected fluorescent proteins to visualize them, and/or we can manipulate genes of interest expressed by these different cells at the appropriate times. This strategy enhances the potential of in utero electroporation and provides a powerful tool to study the behavior of temporally and spatially separated cell populations that migrate to establish close contacts, as well as long-range interactions through axonal projections, reducing temporal and economic costs.

Stick around: Cell-Cell Adhesion Molecules during Neocortical Development.
The neocortex is an exquisitely organized structure achieved through complex cellular processes from the generation of neural cells to their integration into cortical circuits after complex migration processes. During this long journey, neural cells need to establish and release adhesive interactions through cell surface receptors known as cell adhesion molecules (CAMs). Several types of CAMs have been described regulating different aspects of neurodevelopment. Whereas some of them mediate interactions with the extracellular matrix, others allow contact with additional cells. In this review, we will focus on the role of two important families of cell-cell adhesion molecules (C-CAMs), classical cadherins and nectins, as well as in their effectors, in the control of fundamental processes related with corticogenesis, with special attention in the cooperative actions among the two families of C-CAMs.

AIMS: Modulation of adult hippocampal neurogenesis (AHN) has been shown to influence the maintenance of drug-context associations. We aimed to study whether the enhancement of AHN by using a water maze spatial learning task (WM), solely or under conditions of neurogenesis stimulation (forced treadmill exercise), could facilitate extinction and prevent primed reinstatement of cocaine-context associations. METHODS: Adult male C57BL/6J mice (*N*=37) were trained in the Conditioned Place Preference (CPP) paradigm with ascending doses of cocaine (2, 4, 8, 16 mg/kg/d) and subsequently received bromodeoxyuridine (BrdU) injections to label newborn neurons. Then, experimental groups were submitted to 12 days of scheduled exercise and/or 8 days of spatial training in the WM. Sedentary and/or untrained groups stayed undisturbed in their home cages. When BrdU+ cells reached maturation (~6 weeks-old), all mice were tested for CPP memory retrieval. Finally, animals were submitted to forced CPP extinction and tested for CPP extinction and cocaine-primed reinstatement. RESULTS: Animals submitted either to the scheduled exercise protocol, training in the WM or both strategies combined, required fewer sessions to extinct cocaine-CPP associations than control animals. Furthermore, animals submitted to both environmental strategies showed a reduced reinstatement when compared to sedentary animals. These effects are partially related to the functional integration of the newborn neurons in the hippocampus. CONCLUSIONS: Both environmental strategies, alone and combined, can reduce the long-term persistence of cocaine-context associations, being AHN associated with these beneficial effects. MORPHOLOGICAL EVIDENCE OF NEURONAL REGULATION OF NEUROGENESIS IN THE RAT ROSTRAL MIGRATORY STREAM

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Adam Raček, Kamila Fabianová, Marcela Martončíková, Alexandra Popovičová, Eniko Račeková
Biomedical Research Center, SAS, Institute Of Neurobiology, Košice, Slovak Republic

Regulatory mechanisms of postnatal neurogenesis in the subventricular zone (SVZ) and the rostral migratory stream (RMS) are still not fully understood. Recent evidence suggests that neurogenesis in the SVZ/RMS could be regulated by neurons located directly in these regions. Till now, in the RMS two cell populations showing morphological characteristic of mature neurons have been identified: nitric oxide (NO) producing neurons and neurons expressing secretagogin (SCGN). The aim of our work was to obtain new morphological data about these populations of neurons in the RMS and to map their possible projections. Based on immunofluorescence labeling , we analyzed the distribution and the number of NO+ and SCGN+ cells in the RMS, as well as the relationship between these cells. To reveal projections of NO+ and SCGN+ neurons, a retrograde fluorescent tracer Fluoro-Gold (F-G) was *stereotactically injected* into the striatum. Microscopic observation confirmed the presence of NO+ and SCGN+ neurons with a different distribution pattern along the RMS. The number of SCGN+ neurons was significantly higher in all parts of the RMS, when compared to the number of NO+ neurons. We did not confirm the colocalization of NO+/SCGN+ cells, suggesting that these are two distinct neuronal populations. Confocal microscope analysis revealed the presence of F-G, administered into the striatum, in cells of different parts of the RMS. F-G-labelled cells in RMS were identified as nitrergic neurons, indicating the existence of a neuronal circuit in which NO producing neurons are involved. SECRETED FACTORS MODULATING DAMAGE-INDUCED PROLIFERATION IN THE ADULT FLY BRAIN AFTER TRAUMATIC INJURY

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Anabel Simões, Marta Neto, Carolina Alves, Christa Rhiner
Champalimaud Foundation, Stem Cells And Regeneration, Lisbon, Portugal

Brain injury can stimulate the activation of dormant adult neural stem cells in mammals and fruit flies and promote reactive neurogenesis. Nevertheless, the signals governing injury-dependent neural stem cell regulation are still poorly understood. Which are the molecular cues that recruit quiescent stem cells to repair? Here, we studied transcriptional fingerprints of injured versus intact fly brains, which revealed injury-dependent upregulation of stress, immune and tissue repair responses. We then activated RNAi against upregulated genes in adult flies prior to brain injury (stab lesion) and assessed the effect on injury-induced proliferation. This in vivo RNAi screening led to the identification of several secreted molecules, which modulated the regenerative response including a secreted lipocalin-like transporter (LCL-T), able to bind and promote the distribution of lipid- modified factors in the extracellular space. Our results show that LCL-T is not required for normal development, but its upregulation in glia is important for the mobilization of localized Wg/Wnt ligands from damage-responsive neurons to distant neural progenitors. We find that Wg pathway activity is required in disseminated neural progenitor cells for their proliferation. Moreover, we studied upstream control of LCL-T induction and found that these transporters are induced in a Hypoxia-induced factor 1 alpha (HIF1α)-dependent manner downstream of brain lesions. Interestingly, we find that mouse LCL-T is also upregulated in glia in the injured mouse brain suggesting a conserved function of the HIF1α/LCL-T/Wg module in brain restorative processes.

A Cold-Blooded View on Adult Neurogenesis.
During brain development, highly complex and interconnected neural circuits are established. This intricate wiring needs to be robust to faithfully perform adult brain function throughout life, but at the same time offer room for plasticity to integrate new information. In the mammalian brain, adult-born neurons are produced in restricted niches harboring neural stem cells. In the fruit fly , low-level adult neurogenesis arising from a dispersed population of neural progenitors has recently been detected in the optic lobes. Strikingly, these normally quiescent neural stem cells proliferate upon brain injury and produce new neurons for brain regeneration. Here, we review adult neurogenesis in crustaceans and insects and highlight that neurogenesis in the visual system is prominent in arthropods, but its role and underlying mechanisms are unclear. Moreover, we discuss how the study of damage-responsive progenitor cells in may help to understand robust regenerative neurogenesis and open new avenues to enhance brain repair after injury or stroke in humans.

Inhibitory Injury Signaling Represses Axon Regeneration After Dorsal Root Injury.
Following injury to peripheral axons, besides increased cyclic adenosine monophosphate (cAMP), the positive injury signals extracellular-signal-regulated kinase (ERK), c-Jun N-terminal kinase (JNK), and signal transducer and activator of transcription 3 (STAT-3) are locally activated and retrogradely transported to the cell body, where they induce a pro-regenerative program. Here, to further understand the importance of injury signaling for successful axon regeneration, we used dorsal root ganglia (DRG) neurons that have a central branch without regenerative capacity and a peripheral branch that regrows after lesion. Although injury to the DRG central branch (dorsal root injury (DRI)) activated ERK, JNK, and STAT-3 and increased cAMP levels, it did not elicit gain of intrinsic growth capacity nor the ability to overcome myelin inhibition, as occurred after peripheral branch injury (sciatic nerve injury (SNI)). Besides, gain of growth capacity after SNI was independent of ERK and cAMP. Antibody microarrays of dynein-immunoprecipitated axoplasm from rats with either DRI or SNI revealed a broad differential activation and transport of signals after each injury type and further supported that ERK, JNK, STAT-3, and cAMP signaling pathways are minor contributors to the differential intrinsic axon growth capacity of both injury models. Increased levels of inhibitory injury signals including GSK3β and ROCKII were identified after DRI, not only in

axons but also in DRG cell bodies. In summary, our work shows that activation and transport of positive injury signals are not sufficient to promote increased axon growth capacity and that differential modulation of inhibitory molecules may contribute to limited regenerative response.

CNS axons globally increase axonal transport after peripheral conditioning.
Despite the inability of CNS axons to regenerate, an increased regenerative capacity can be elicited following conditioning lesion to the peripheral branch of dorsal root ganglia neurons (DRGs). By in vivo radiolabeling of rat DRGs, coupled to mass spectrometry and kinesin immunoprecipitation of spinal cord extracts, we determined that the anterograde transport of cytoskeleton components, metabolic enzymes and axonal regeneration enhancers, was increased in the central branch of DRGs following a peripheral conditioning lesion. Axonal transport of mitochondria was also increased in the central branch of Thy1-MitoCFP mice following a peripheral injury. This effect was generalized and included augmented transport of lysosomes and synaptophysin- and APP-carrying vesicles. Changes in axonal transport were only elicited by a peripheral lesion and not by spinal cord injury. In mice, elevated levels of motors and of polyglutamylated and tyrosinated tubulin were present following a peripheral lesion and can explain the increase in axonal transport induced by conditioning. In summary, our work shows that a peripheral injury induces a global increase in axonal transport that is not restricted to the peripheral branch, and that, by extending to the central branch, allows a rapid and sustained support of regenerating central axons.

Effects of methylglyoxal and pyridoxamine in rat brain mitochondria bioenergetics and oxidative status.
Advanced glycation end products (AGEs) and methylglyoxal (MG), an important intermediate in AGEs synthesis, are thought to contribute to protein aging and to the pathogenesis of age-and diabetes-associated complications. This study was intended to investigate brain mitochondria bioenergetics and oxidative status of rats previously exposed to chronic treatment with MG and/or with pyridoxamine (PM), a glycation inhibitor. Brain mitochondrial fractions were obtained and several parameters were analyzed: respiratory chain [states 3 and 4 of respiration, respiratory control ratio (RCR), and ADP/O index] and phosphorylation system [transmembrane potential (ΔΨm), ADP-induced depolarization, repolarization lag phase, and ATP levels]; hydrogen peroxide (H_2O_2) production levels, mitochondrial aconitase activity, and malondialdehyde levels as well as non-enzymatic antioxidant defenses (vitamin E and glutathione levels) and enzymatic antioxidant defenses (glutathione disulfide reductase (GR), glutathione peroxidase (GPx), and manganese superoxide dismutase (MnSOD) activities). MG treatment induced a statistical significant decrease in RCR, aconitase and GR activities, and an increase in H_2O_2 production levels. The administration of PM did not counteract MG-induced effects and caused a significant decrease in ΔΨm. In mitochondria from control animals, PM caused an adaptive mechanism characterized by a decrease in aconitase and GR activities as well as an increase in both α-tocopherol levels and GPx and MnSOD activities. Altogether our results show that high levels of MG promote brain mitochondrial impairment and PM is not able to reverse MG-induced effects.

Role of inflammatory cytokines in peripheral nerve injury.
Inflammatory events occurring in the distal part of an injured peripheral nerve have, nowadays, a great resonance. Investigating the timing of action of the several cytokines in the important stages of Wallerian degeneration helps to understand the regenerative process and design pharmacologic intervention that promotes and expedites recovery. The complex and synergistic action of inflammatory cytokines finally promotes axonal regeneration. Cytokines can be divided into pro- and anti-inflammatory cytokines that upregulate and downregulate, respectively, the production of inflammatory mediators. While pro-inflammatory cytokines are expressed in the first phase of Wallerian degeneration and promote the recruitment of macrophages, anti-inflammatory cytokines are expressed after this recruitment and downregulate the production of all cytokines, thus determining the end of the process. In this review, we describe the major inflammatory cytokines involved in Wallerian degeneration and the early phases of nerve regeneration. In particular, we focus on interleukin-1, interleukin-2, interleukin-6, tumor necrosis factor-β, interleukin-10 and transforming growth factor-β.

Odor–reward association during appetitive learning is a fundamental process that requires multiple forms of plasticity. In the adult olfactory bulb, the continual production of newborn granular cells (GCs) contributes to both structural and functional plasticity of the system. Our recent findings unveil the unexpected role of adult-born neurons, but not neonatal-born neurons, in boosting odor-reward association. How could we interpret this functional difference? Several studies have highlighted distinct functional properties between neonatal-born and adult-born interneurons. In addition to these already identified cell-autonomous discrepancies between distinct GC subpopulations, the possibility of a dedicated connectivity remains to be explored. To tackle this question, we take advantage of a rabies-based mono-synaptic tracing technique to visualize brain-wide inputs to GCs. Our result demonstrated that adult-born GC show higher convergence (connectivity ratios) of these top-down inputs than neonatal ones during adulthood. Interestingly, some differences in the distribution of pre-synaptic partners were observed in olfactory cortex between GC subtypes. Adult and neonatal-born neurons are also differently targeted by top-down GABAergic and cholinergic input. Of note, neonatal-born GCs show a delayed wiring between 2-4 months, which was shortened by odor experience, while adult-born neurons connections remain unchanged. Overall, our data suggest that neurons generated postnatally maintain their singularity during adulthood according to their date of birth. Adult-born GCs integrate top-down fibers in a high convergent mode but invariant to the context of learning. In contrast, their neonatal counterparts integrate less divergent top-down brain inputs, yet the maturation rate of these inputs is amendable by olfactory experience.

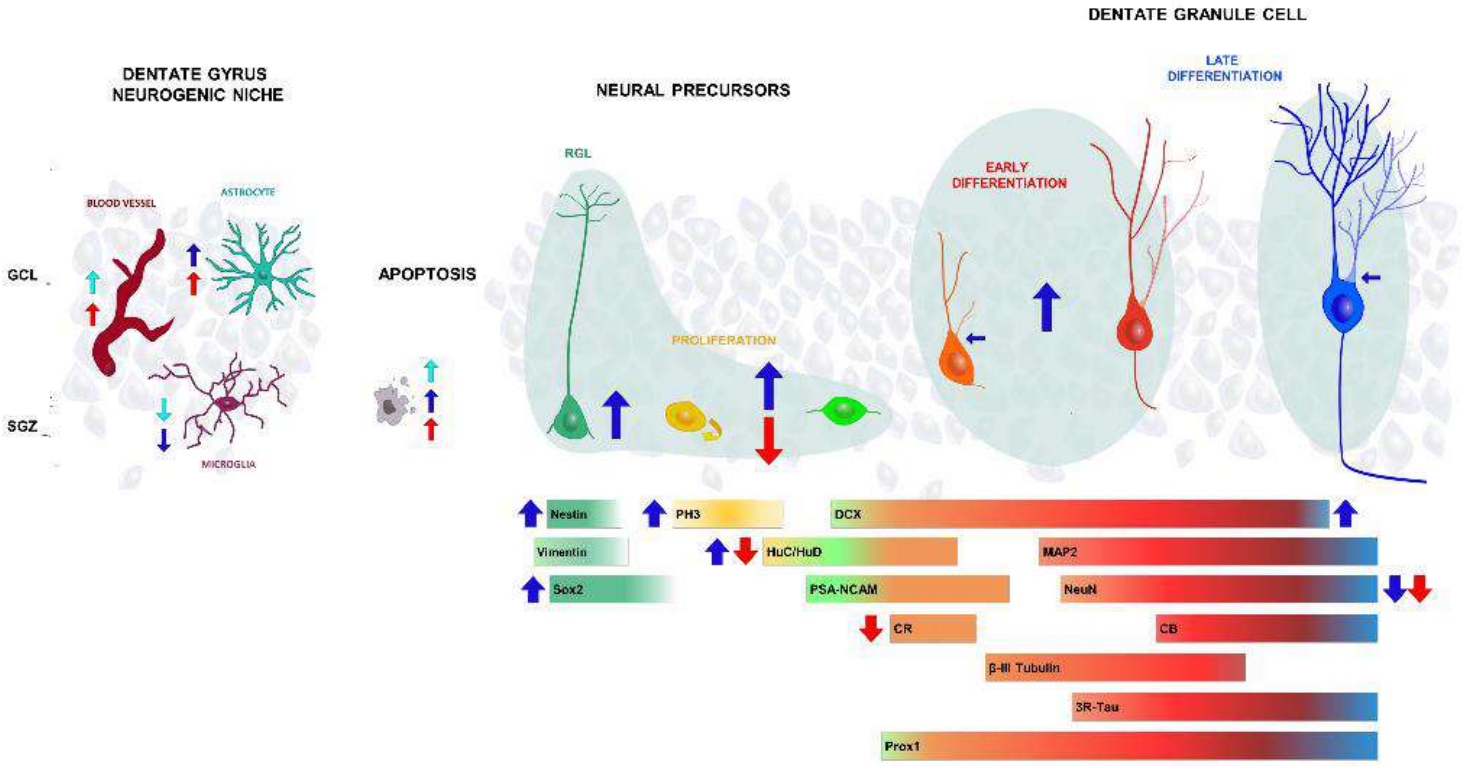
Aims: The hippocampus hosts a unique phenomenon of lifetime plasticity, named adult hippocampal neurogenesis (AHN), which includes the generation of new neurons in the dentate gyrus (DG). This process encompasses the division of neural stem cells (NSCs), which give rise to newly generated dentate granule cells (DGCs). AHN is orchestrated by the DG neurogenic niche, a specialized structure composed of astrocytes, microglia, and vasculature. Since the hippocampus is targeted by neurodegenerative diseases, we wondered whether altered AHN underlies hippocampal malfunctioning in these conditions.



Methods: We studied post-mortem human samples obtained from 15 neurologically healthy control subjects and patients with two α-synucleinopathies (Parkinson's disease (PD) (n=3) and dementia with Lewy bodies (LD) (n=6)), and Frontotemporal dementia (FTD) (n=6) to address the integrity of AHN. By using samples subjected to state-of-art tissue preservation and histological methodologies, we reconstructed the stages encompassed by human AHN in control and

patients. **Results:** Our results indicate that both α-synucleinopathies alter the homeostasis of the DG neurogenic niche, compromising the maturation of DGCs. Moreover, these conditions exhibited increased densities of NSCs and triggered morphological abnormalities in Doublecortin $(DCX)^+$ immature DGCs. Additionally, FTD caused milder alterations in AHN and the homeostasis of the DG neurogenic niche. FTD showed an imbalanced NSC/proliferative cells ratio. Furthermore, immature DGCs showed moderately impaired differentiation. **Conclusions:** Neurodegenerative diseases perturb the homeostasis of the human DG neurogenic niche and impair AHN. Moreover, each of the diseases studied is characterized by a specific AHN signature which might be a relevant mechanism underlying hippocampal malfunctioning.

Impact of neurodegenerative diseases on human adult hippocampal neurogenesis.
Disrupted hippocampal performance underlies psychiatric comorbidities and cognitive impairments in patients with neurodegenerative disorders. To understand the contribution of adult hippocampal neurogenesis (AHN) to amyotrophic lateral sclerosis, Huntington's disease, Parkinson's disease, dementia with Lewy bodies, and frontotemporal dementia, we studied postmortem human samples. We found that adult-born dentate granule cells showed abnormal morphological development and changes in the expression of differentiation markers. The ratio of quiescent to proliferating hippocampal neural stem cells shifted, and the homeostasis of the neurogenic niche was altered. Aging and neurodegenerative diseases reduced the phagocytic capacity of microglia, triggered astrogliosis, and altered the microvasculature of the dentate gyrus. Thus, enhanced vulnerability of AHN to neurodegeneration might underlie hippocampal dysfunction during physiological and pathological aging in humans.

Evidences for Adult Hippocampal Neurogenesis in Humans.
The rodent hippocampus generates new neurons throughout life. This process, named adult hippocampal neurogenesis (AHN), is a striking form of neural plasticity that occurs in the brains of numerous mammalian species. Direct evidence of adult neurogenesis in humans has remained elusive, although the occurrence of this phenomenon in the human dentate gyrus has been demonstrated in seminal studies and recent research that have applied distinct approaches to birthdate newly generated neurons and to validate markers of adult-born neurons. Our data point to the persistence of AHN until the 10th decade of human life, as well as to marked impairments in this process in patients with Alzheimer's disease. Moreover, our work demonstrates that the methods used to process and analyze postmortem human brain samples can limit the detection of various markers of AHN to the point of making them undetectable. In this Dual Perspectives article, we highlight the critical methodological aspects that should be strictly controlled in human studies and the robust evidence that supports the occurrence of AHN in humans. We also put forward reasons that may account for current discrepancies on this topic. Finally, the unresolved questions and future challenges awaiting the field are highlighted.

Unraveling human adult hippocampal neurogenesis.
Adult neurogenesis occurs in a few selected regions of the mammalian brain. One such region is the hippocampus, the so-called gateway to memory, where adult hippocampal neurogenesis (AHN) occurs. Here, we provide a comprehensive description of the methods used in our laboratory to unambiguously detect a population of immature neurons in the human hippocampus until the 10th decade of life. The criteria used to refine and develop the current protocol include obtaining post-mortem human samples of remarkable quality and under tightly controlled conditions for immunohistochemistry (IHC) studies, optimizing tissue processing and histological procedures, establishing criteria to reliably validate antibody signal and performing unbiased stereological cell counts. Moreover, we provide a detailed description of the parameters that, in our view, should be reported in human AHN studies. The opposing results obtained by introducing slight variations in the methodological conditions should be considered by future studies that seek to increase our knowledge of this fascinating process. By applying simple and inexpensive tissue pre-treatments, this protocol, which can be completed in 7 days, might be applicable to a variety of IHC studies performed on other tissues of human (or animal) origin.

An integration-free iPSC line, ICCSICi007-A, derived from a female Alzheimer's disease patient with the APOE-ε4/ε4 alleles. The epsilon4 (ε4) allele of the APOE gene, which encodes the apolipoprotein E4 (ApoE4), is the strongest genetic risk factor known for late-onset Alzheimer´s disease (LOAD). Here, we present the characterization of an iPSC line generated from

dermal fibroblasts of a female AD patient using Sendai viral vectors encoding the transcription factors OCT4, SOX2, KLF4 and c-MYC. The iPSCs maintained the original genotype, a normal karyotype, were free from Sendai viral vectors and reprogramming factors, presented a normal morphology, expressed endogenous pluripotency markers, and could be differentiated into ectodermal, mesodermal and endodermal cells, confirming its pluripotency.

Generation of an integration-free iPSC line, ICCSICi006-A, derived from a male Alzheimer's disease patient carrying the PSEN1-G206D mutation.
The familial form of Alzheimer's disease (FAD), which is caused by mutations in PRESENILIN 1 (PSEN1) and amyloid precursor protein (APP) genes, represents less than 5% of all AD cases and has an early-onset. We report the generation and characterization of an iPSC line derived from a FAD patient carrying the PSEN1-G206D mutation. The iPSC line maintained the original genotype, a normal karyotype, was free from Sendai viral vectors and reprogramming factors (OCT4, SOX2, KLF4 and c-MYC), presented a typical morphology, expressed endogenous pluripotency markers, and could be differentiated into ectodermal, mesodermal and endodermal cells, confirming its pluripotency.

A collection of four integration-free iPSC lines derived from diagnosed sporadic Alzheimer's disease patients with different APOE alleles.
Genetic polymorphism of apolipoprotein E (APOE) confers differential susceptibility to late-onset Alzheimer's disease (LOAD). The ε3 allele of APOE, the most common isoform, does not represent a risk factor for LOAD. In contrast, the ε4 allele is the strongest genetic risk factor for this disease. Here, we present the characterization of four iPSC lines generated from dermal fibroblasts of diagnosed sporadic AD patients using Sendai viral vectors encoding OCT4, SOX2, KLF4 and c-MYC. The iPSCs expressed endogenous pluripotency markers, could be differentiated into the three germ layers, maintained the original genotypes, and were free from Sendai vectors and reprogramming factors.

Activity-Dependent Reconnection of Adult-Born Dentate Granule Cells in a Mouse Model of Frontotemporal Dementia.
Frontotemporal dementia (FTD) is characterized by neuronal loss in the frontal and temporal lobes of the brain. Here, we provide the first evidence of striking morphological alterations in dentate granule cells (DGCs) of FTD patients and in a mouse model of the disease, Tau mice. Taking advantage of the fact that the hippocampal dentate gyrus (DG) gives rise to newborn DGCs throughout the lifetime in rodents, we used RGB retroviruses to study the temporary course of these alterations in newborn DGCs of female Tau mice. In addition, retroviruses that encode either PSD95:GFP or Syn:GFP revealed striking alterations in the afferent and efferent connectivity of newborn Tau DGCs, and monosynaptic retrograde rabies virus tracing showed that these cells are disconnected from distal brain regions and local sources of excitatory innervation. However, the same cells exhibited a predominance of local inhibitory innervation. Accordingly, the expression of presynaptic and postsynaptic markers of inhibitory synapses was markedly increased in the DG of Tau mice and FTD patients. Moreover, an increased number of neuropeptide Y-positive interneurons in the DG correlated with a reduced number of activated egr-1 DGCs in Tau mice. Finally, we tested the therapeutic potential of environmental enrichment and chemoactivation to reverse these alterations in mice. Both strategies reversed the morphological alterations of newborn DGCs and partially restored their connectivity in a mouse model of the disease. Moreover, our data point to remarkable morphological similarities between the DGCs of Tau mice and FTD patients. We show, for the first time to our knowledge, that the population of dentate granule cells is disconnected from other regions of the brain in the neurodegenerative disease frontotemporal dementia (FTD). These alterations were observed in FTD patients and in a mouse model of this disease. Moreover, we tested the therapeutic potential of two strategies, environmental enrichment and chemoactivation, to stimulate the activity of these neurons in mice. We found that some of the alterations were reversed by these therapeutic interventions.

The Social Component of Environmental Enrichment Is a Pro-neurogenic Stimulus in Adult c57BL6 Female Mice.
In rodents, the hippocampal dentate gyrus gives rise to newly generated dentate granule cells (DGCs) throughout life. This process, named adult hippocampal neurogenesis (AHN), converges in the functional integration of mature DGCs into the trisynaptic hippocampal circuit. Environmental enrichment (EE) is one of the most potent positive regulators of AHN. This paradigm includes the combination of three major stimulatory components, namely increased physical activity, constant

cognitive stimulation, and higher social interaction. In this regard, the pro-neurogenic effects of physical activity and cognitive stimulation have been widely addressed in adult rodents. However, the pro-neurogenic potential of the social aspect of EE has been less explored to date. Here we tackled this question by specifically focusing on the effects of a prolonged period of social enrichment (SE) in adult female C57BL6 mice. To this end, 7-week-old mice were housed in groups of 12 per cage for 8 weeks. These mice were compared with others housed under control housing (2-3 mice per cage) or EE (12 mice per cage plus running wheels and toys) conditions during the same period. We analyzed the number and morphology of Doublecortin-expressing (DCX) cells. Moreover, using RGB retroviruses that allowed the labeling of three populations of newborn DGCs of different ages in the same mouse, we performed morphometric, immunohistochemical, and behavioral determinations. Both SE and EE increased the number and maturation of DCX cells, and caused an increase in dendritic maturation in certain populations of newborn DGCs. Moreover, both manipulations increased exploratory behavior in the Social Interaction test. Unexpectedly, our data revealed the potent neurogenesis-stimulating potential of SE in the absence of any further cognitive stimulation or increase in physical activity. Given that an increase in physical activity is strongly discouraged under certain circumstances, our findings may be relevant in the context of enhancing AHN via physical activity-independent mechanisms.

Adult hippocampal neurogenesis is abundant in neurologically healthy subjects and drops sharply in patients with Alzheimer's disease.

The hippocampus is one of the most affected areas in Alzheimer's disease (AD). Moreover, this structure hosts one of the most unique phenomena of the adult mammalian brain, namely, the addition of new neurons throughout life. This process, called adult hippocampal neurogenesis (AHN), confers an unparalleled degree of plasticity to the entire hippocampal circuitry. Nonetheless, direct evidence of AHN in humans has remained elusive. Thus, determining whether new neurons are continuously incorporated into the human dentate gyrus (DG) during physiological and pathological aging is a crucial question with outstanding therapeutic potential. By combining human brain samples obtained under tightly controlled conditions and state-of-the-art tissue processing methods, we identified thousands of immature neurons in the DG of neurologically healthy human subjects up to the ninth decade of life. These neurons exhibited variable degrees of maturation along differentiation stages of AHN. In sharp contrast, the number and maturation of these neurons progressively declined as AD advanced. These results demonstrate the persistence of AHN during both physiological and pathological aging in humans and provide evidence for impaired neurogenesis as a potentially relevant mechanism underlying memory deficits in AD that might be amenable to novel therapeutic strategies.

Neural stem cells (NSCs) are multipotent cells situated in neurogenic niches of brain that keep the ability to self-renew and/or differentiate into specialised cell types such as neurons and glia throughout the lifetime. The transition of NSCs to their mature phenotypes require complex reconfiguration of gene expressional profiles that occur at multiple cell-fate decision checkpoints. Transcriptional regulator C-terminal binding protein 1 (CtBP1) was recently implicated in mammalian neurodevelopment. Specifically, a patient cohort was described with a de novo missense mutation in CtBP1 with developmental delay, intellectual disability, ataxia and hypotonia. However, the putative function of CtBP1 in the context of neurodevelopment is underexplored as well as mechanism, by which the mutation causes the observed phenotypic manifestations. Herein, we studied functions of CtBP1 in adult neurogenesis, which is a process recapitulating main features of brain neurodevelopment, using constitutive mouse model. First, we mapped the expression of CtBP1 in adult neurogenic lineage and characterized adult hippocampal neurogenesis in a CtBP1 knockout mouse model immunohistochemically using specific differentiation stage markers. Next, using BrdU pulse chase experiments, we assessed proliferation capacity of NSCs and differentiation of newly generated neuronal precursors in absence of CtBP1. Finally, we also isolated NSCs from the neurogenic niche of adult CtBP1 KO and WT mice and studied their proliferation and differentiation in vitro using RT-PCR profiling. Collectively, our results will reveal the role of CtBP1 in the regulation of adult neural stem cell proliferation and their neuronal cell-fate determination and differentiation.

NEUROGENIC AND OLIGODENDROGENIC PROGENITORS DERIVED FROM THE SUBEPENDYMAL ZONE OF POSTNATAL MICE EXHIBIT DIFFERENTIAL PROPERTIES IN CULTURES WITH POLYMORPHIC MICROENVIRONMENTS

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Maria Anesti, Ilias Kazanis
University of Patras, Laboratory Of Developmental Biology, Department Of Biology, Patras, Greece

Aims
Two major stem cell pools, exhibiting distinct spatial preferences, exist in the postnatal mammalian brain: multipotent Neural Stem Cells (NSCs) and the more lineage-restricted oligodendrocyte progenitor cells. The former are located only within specialized microenvironments (niches), while the latter are broadly dispersed in the brain parenchyma. Here, we investigate if the neurogenic versus oligodendrogenic properties of NSCs are differentially affected by aspects of their microenvironment.
Methods
We employed a polymorphic NSC culture assay in which cells were cultured as neurospheres and subsequently were plated on PDL-coated coverslips to create different microenvironments, that we classified either as “niche-like” 3D areas, or as “parenchyma-like” 2D areas. Cells were differentiated and the acquisition of a neurogenic or oligodendrogenic cell fate was identified.
Results
Neurogenesis was much more dependent on the cytoarchitecture, observed at significantly higher levels in “parenchyma-like” areas, more often at the periphery of the “niche-like” structures and being proportional to cell density, while oligodendrogenesis was independent of the cytoarchitecture. In the presence of laminin (a major niche extracellular component) cell cultures became more homogeneously two-dimensional, but neurogenesis was switched to a more “niche-like” behavior, while oligodendrogenesis was not affected. Notably, the inhibition of β1-integrin further enhanced cell fate diversion, almost eliminating neurogenesis but increasing oligodendrogenesis. Finally, microneurotrophin BNN-20 was the only factor that increased both cell fates and specifically in 2D areas.
Conclusions
Our novel method of analysis revealed higher microenvironment restrictions for neurogenesis versus oligodendrogenesis and can be used as a tool for assessing possible therapeutic molecules targeting NSCs.

Effect of rutin on anxiety-like behavior and activity of acetylcholinesterase isoforms in specific brain regions of pentylenetetrazol-treated mice.
The aim of the present study was to investigate the effect of rutin administration (100 mg/kg/day) to pentylenetetrazol (PTZ)-treated Balb-c mice (60 mg/kg/day), with respect to anxiety-like behavior using both open-field and elevated plus-maze (EPM) tests, and acetylcholinesterase (AChE) activity in salt-soluble (SS) fraction and detergent-soluble (DS) fraction of the cerebral cortex, hippocampus, striatum, midbrain, and diencephalon. Our results demonstrated that the administration of PTZ in 3 doses and the induction of seizures increased significantly anxiety behavior of mice and reduced significantly DS-AChE activity in all brain regions examined, while the reduction in the SS fraction was brain region-specific. Rutin administration to normal mice did not affect their behavior, while it induced a brain region-specific reduction in SS-AChE and a significant decrease in DS-AChE in all brain regions. We demonstrated for the first time that pretreatment of PTZ-mice with rutin (PTZ + Rutin group) prevented the manifestation of anxiety and induced interestingly a further significant reduction on the SS- and DS-AChE activities only in the cerebral cortex and striatum, in comparison with PTZ group. Our results show that rutin exhibits an important anxiolytic effect and an anticholinesterase activity in specific brain areas in the seizure model of PTZ.

Characterization of substantia nigra neurogenesis in homeostasis and dopaminergic degeneration: beneficial effects of the

microneurotrophin BNN-20.
Loss of dopaminergic neurons in the substantia nigra pars compacta (SNpc) underlines much of the pathology of Parkinson's disease (PD), but the existence of an endogenous neurogenic system that could be targeted as a therapeutic strategy has been controversial. BNN-20 is a synthetic, BDNF-mimicking, microneurotrophin that we previously showed to exhibit a pleiotropic neuroprotective effect on the dopaminergic neurons of the SNpc in the "weaver" mouse model of PD. Here, we assessed its potential effects on neurogenesis.

Newborn cells arising from the subventricular zone of the lateral ventricles (SVZ) of the rodent brain migrate for long distances along the rostral migratory (RMS) to the olfactory bulb (OB). During the postnatal period specifically arranged blood vessels serve as a scaffold along which neuronal precursors migrate in the RMS and OB. Between the RMS of the rat and mice several morphological and developmental differences were found and previous studies have also indicated differences in the vascular scaffold pattern between these species. However, a detailed morphological analysis of these differences has not yet been performed. Thus the aim of our study was to compare specific arrangement of blood vessels creating vascular scaffold in the RMS between adult mice and rats. The pattern of blood vessel arrangement in the RMS of mice and rats was analyzed qualitatively and quantitatively on immunohistochemically processed brain sections. We did not find significant interspecies differences in migration-promoting vascular scaffold in the RMS. For most of the pathway, blood vessels were aligned parallel to the RMS outline in both species. Contrary to this, blood vessels were turned under a distinct angle, creating a spiral shaped configuration in the caudal part of the RMS in rats as well as in mice. Similarity of the pattern of the vascular scaffold in adult mice and rats indicates that vascular scaffold guiding neuroblast migration in the RMS is the original mechanism with similar properties in different species. Several clinical cases have reported that urinary tract infections (UTI) cause cognitive deficits mainly in elderly patients increasing the chances of developing neuropsychiatric disorders. No studies have explored the mechanism of action and the effect of urinary tract infections on neurogenesis and brain plasticity. In this project, adult male Sprague-Dawley rats received transurethral instillation of LPS to their bladders to mimic UTI-associated inflammation. Here, we aim to investigate the effect of peripheral inflammation in the urothelium on adult hippocampal neurogenesis. Control groups were instilled with sterile saline. Bromodeoxyuridine (BrdU) analog was injected 24 hours before the sacrifice in order to assess hippocampal neural stem cells (NSCs) proliferation. Behavioral tests including, open field, Y-maze, and Novel Object Recognition, were used to assess anxiety-like behaviors, exploration, cognitive ability and working memory respectively. Preliminary results showed that rats that received LPS were more sensitive to thermal and mechanical pain. LPS injected rats also showed decreased cognitive abilities and decreased exploratory behavior after induction of the inflammation. This allows us to speculate that inflammation of the urinary tract potentially affects neurogenesis and subsequently cognitive behavior.

Background: Current therapeutic approaches to achieve neuronal renewal in damaged adult brains are focused on promoting endogenous neurogenesis to replace the lost neurons. We have previously demonstrated that 12-deoxyphorbols, as ER272, activate the proliferation of adult neural progenitor cells *in vitro* and *in vivo*, with the advantage that they lack tumorigenic activity. Intranasal administration of ER272 to healthy 2 months old CD1 mice, induced neurogenesis within the subventricular zone and the dentate gyrus (DG) of the hippocampus, facilitating the generation of new neurons. **Aims:** To analyze the effect of ER272 compound on neurogenesis and cognitive performance in the senescence-accelerated prone (SAMP8) 6 months old mouse, an accelerated-aging model. **Methods:** Four-month old SAMP8 mice were treated for two months with daily intranasal administrations of ER272. After assessing cognitive performance, brain tissues were analyzed by immunostaining to evaluate neurogenesis. The molecular mechanisms involved in the effect were tested in vitro in Hek293 cells and western blot was used to asses signaling pathways. **Results:** In vitro assays revealed that ER272 promotes the release of transforming growth factor alpha in a classical PKC dependent manner. Intranasal administration of ER272 during 2 months improved cognitive performance of aged mice. Moreover, the compound incremented the number of newly generated neuroblasts and neurons within the DG of the hippocampus not activating radial glial like cells but reducing astrocyte differentiation. The EGFR signaling pathway was involved. **Conclusions:** These results indicate that intranasal administration of the TGFa-releasing compound ER272 promotes neuronal replacement in the aged hippocampus improving cognitive performance.

Refinement of Active and Passive Membrane Properties of Layer V Pyramidal Neurons in Rat Primary Motor Cortex During Postnatal Development.
Achieving the distinctive complex behaviors of adult mammals requires the development of a great variety of specialized neural circuits. Although the development of these circuits begins during the embryonic stage, they remain immature at birth, requiring a postnatal maturation process to achieve these complex tasks. Understanding how the neuronal membrane properties and circuits change during development is the first step to understand their transition into efficient ones. Thus, using whole cell patch clamp recordings, we have studied the changes in the electrophysiological properties of layer V pyramidal neurons of the rat primary motor cortex during postnatal development. Among all the parameters studied, only the voltage threshold was established at birth and, although some of the changes occurred mainly during the second postnatal week, other properties such as membrane potential, capacitance, duration of the post-hyperpolarization phase or the maximum firing rate were not defined until the beginning of adulthood. Those modifications lead to a decrease in neuronal excitability and to an increase in the working range in young adult neurons, allowing more sensitive and accurate responses. This maturation process, that involves an increase in neuronal size and changes in ionic conductances, seems to be influenced by the neuronal type and by the task that neurons perform as inferred from the comparison with other pyramidal and motor neuron populations.

Effects of classical PKC activation on hippocampal neurogenesis and cognitive performance: mechanism of action.

Hippocampal neurogenesis has widely been linked to memory and learning performance. New neurons generated from neural stem cells (NSC) within the dentate gyrus of the hippocampus (DG) integrate in hippocampal circuitry participating in memory tasks. Several neurological and neuropsychiatric disorders show cognitive impairment together with a reduction in DG neurogenesis. Growth factors secreted within the DG promote neurogenesis. Protein kinases of the protein kinase C (PKC) family facilitate the release of several of these growth factors, highlighting the role of PKC isozymes as key target molecules for the development of drugs that induce hippocampal neurogenesis. PKC activating diterpenes have been shown to facilitate NSC proliferation in neurogenic niches when injected intracerebroventricularly. We show in here that long-term administration of diterpene ER272 promotes neurogenesis in the subventricular zone and in the DG of mice, affecting neuroblasts differentiation and neuronal maturation. A concomitant improvement in learning and spatial memory tasks performance can be observed. Insights into the mechanism of action reveal that this compound facilitates classical PKCα activation and promotes transforming growth factor alpha (TGFα) and, to a lesser extent, neuregulin release. Our results highlight the role of this molecule in the development of pharmacological drugs to treat neurological and neuropsychiatric disorders associated with memory loss and a deficient neurogenesis.

Phorbol Diesters and 12-Deoxy-16-hydroxyphorbol 13,16-Diesters Induce TGFα Release and Adult Mouse Neurogenesis.
A small library of phorbol 12,13-diesters bearing low lipophilicity ester chains was prepared as potential neurogenic agents in the adult brain. They were also used in a targeted UHPLC-HRMS screening of the latex of . Two new 12-deoxy-16-hydroxyphorbol 13,16-diesters were isolated, and their structures were deduced using two-dimensional NMR spectroscopy and NOE experiments. The ability of natural and synthetic compounds to stimulate transforming growth factor alpha (TFGα) release, to increase neural progenitor cell proliferation, and to stimulate neurogenesis was evaluated. All compounds that facilitated TGFα release promoted neural progenitor cell proliferation. The presence of two acyloxy moieties on the tigliane skeleton led to higher levels of activity, which decreased when a free hydroxyl group was at C-12. Remarkably, the compound bearing isobutyryloxy groups was the most potent on the TGFα assay and at inducing neural progenitor cell proliferation , also leading to enhanced neurogenesis when administered intranasally to mice.

Targeting Protein Kinase C in Glioblastoma Treatment.
Glioblastoma (GBM) is the most frequent and aggressive primary brain tumor and is associated with a poor prognosis. Despite the use of combined treatment approaches, recurrence is almost inevitable and survival longer than 14 or 15 months after diagnosis is low. It is therefore necessary to identify new therapeutic targets to fight GBM progression and recurrence. Some publications have pointed out the role of glioma stem cells (GSCs) as the origin of GBM. These cells, with characteristics of neural stem cells (NSC) present in physiological neurogenic niches, have been proposed as being responsible for the high resistance of GBM to current treatments such as temozolomide (TMZ). The protein Kinase C (PKC) family members play an essential role in transducing signals related with cell cycle entrance, differentiation and apoptosis in NSC and participate in distinct signaling cascades that determine NSC and GSC dynamics. Thus, PKC could be a suitable druggable target to treat recurrent GBM. Clinical trials have tested the efficacy of PKCβ inhibitors, and preclinical studies have focused on other PKC isozymes. Here, we discuss the idea that other PKC isozymes may also be involved in GBM progression and that the development of a new generation of effective drugs should consider the balance between the activation of different PKC subtypes.

Evolution of Experimental Models in the Study of Glioblastoma: Toward Finding Efficient Treatments.
Glioblastoma (GBM) is the most common form of brain tumor characterized by its resistance to conventional therapies, including temozolomide, the most widely used chemotherapeutic agent in the treatment of GBM. Within the tumor, the presence of glioma stem cells (GSC) seems to be the reason for drug resistance. The discovery of GSC has boosted the search for new experimental models to study GBM, which allow the development of new GBM treatments targeting these cells. In here, we describe different strategies currently in use to study GBM. Initial GBM investigations were focused in the development of xenograft assays. Thereafter, techniques advanced to dissociate tumor cells into single-cell suspensions, which generate aggregates referred to as neurospheres, thus facilitating their selective expansion. Concomitantly, the finding of genes involved in the initiation and progression of GBM tumors, led to the generation of mice models for the GBM. The latest advances have been the use of GBM organoids or 3D-bioprinted mini-brains. 3D bio-printing mimics tissue

cytoarchitecture by combining different types of cells interacting with each other and with extracellular matrix components. These models faithfully replicate human diseases in which the effect of new drugs can easily be tested. Based on recent data from human glioblastoma, this review critically evaluates the different experimental models used in the study of GB, including cell cultures, mouse models, brain organoids, and 3D bioprinting focusing in the advantages and disadvantages of each approach to understand the mechanisms involved in the progression and treatment response of this devastating disease.

Age-Dependent Vulnerability to Oxidative Stress of Postnatal Rat Pyramidal Motor Cortex Neurons.
Oxidative stress is one of the main proposed mechanisms involved in neuronal degeneration. To evaluate the consequences of oxidative stress on motor cortex pyramidal neurons during postnatal development, rats were classified into three groups: Newborn (P2-P7); infantile (P11-P15); and young adult (P20-P40). Oxidative stress was induced by 10 µM of cumene hydroperoxide (CH) application. In newborn rats, using the whole cell patch-clamp technique in brain slices, no significant modifications in membrane excitability were found. In infantile rats, the input resistance increased and rheobase decreased due to the blockage of GABAergic tonic conductance. Lipid peroxidation induced by CH resulted in a noticeable increase in protein-bound 4-hidroxynonenal in homogenates in only infantile and young adult rat slices. Interestingly, homogenates of newborn rat brain slices showed the highest capacity to respond to oxidative stress by dramatically increasing their glutathione and free thiol content. This increase correlated with a time-dependent increase in the glutathione reductase activity, suggesting a greater buffering capacity of newborn rats to resist oxidative stress. Furthermore, pre-treatment of the slices with glutathione monoethyl ester acted as a neuroprotector in pyramidal neurons of infantile rats. We conclude that during maturation, the vulnerability to oxidative stress in rat motor neurons increases with age.

A novel PKC activating molecule promotes neuroblast differentiation and delivery of newborn neurons in brain injuries.
Neural stem cells are activated within neurogenic niches in response to brain injuries. This results in the production of neuroblasts, which unsuccessfully attempt to migrate toward the damaged tissue. Injuries constitute a gliogenic/non-neurogenic niche generated by the presence of anti-neurogenic signals, which impair neuronal differentiation and migration. Kinases of the protein kinase C (PKC) family mediate the release of growth factors that participate in different steps of the neurogenic process, particularly, novel PKC isozymes facilitate the release of the neurogenic growth factor neuregulin. We have demonstrated herein that a plant derived diterpene, (EOF2; CAS number 2230806-06-9), with the capacity to activate PKC facilitates the release of neuregulin 1, and promotes neuroblasts differentiation and survival in cultures of subventricular zone (SVZ) isolated cells in a novel PKC dependent manner. Local infusion of this compound in mechanical cortical injuries induces neuroblast enrichment within the perilesional area, and noninvasive intranasal administration of EOF2 promotes migration of neuroblasts from the SVZ towards the injury, allowing their survival and differentiation into mature neurons, being some of them cholinergic and GABAergic. Our results elucidate the mechanism of EOF2 promoting neurogenesis in injuries and highlight the role of novel PKC isozymes as targets in brain injury regeneration.

Vitamin D deficiency as a potential risk factor for accelerated aging, impaired hippocampal neurogenesis and cognitive decline: a role for Wnt/β-catenin signaling.
Vitamin D is an essential fat-soluble vitamin that participates in several homeostatic functions in mammalian organisms. Lower levels of vitamin D are produced in the older population, vitamin D deficiency being an accelerating factor for the progression of the aging process. In this review, we focus on the effect that vitamin D exerts in the aged brain paying special attention to the neurogenic process. Neurogenesis occurs in the adult brain in neurogenic regions, such as the dentate gyrus of the hippocampus (DG). This region generates new neurons that participate in cognitive tasks. The neurogenic rate in the DG is reduced in the aged brain because of a reduction in the number of neural stem cells (NSC). Homeostatic mechanisms controlled by the Wnt signaling pathway protect this pool of NSC from being depleted. We discuss in here the crosstalk between Wnt signaling and vitamin D, and hypothesize that hypovitaminosis might cause failure in the control of the neurogenic homeostatic mechanisms in the old brain leading to cognitive impairment. Understanding the relationship between vitamin D, neurogenesis and cognitive performance in the aged brain may facilitate prevention of cognitive decline and it can open a door into new therapeutic fields by perspectives in the elderly.

Protein Kinase C: Targets to Regenerate Brain Injuries?
Acute or chronic injury to the central nervous system (CNS), causes neuronal death and irreversible cognitive deficits or

sensory-motor alteration. Despite the capacity of the adult CNS to generate new neurons from neural stem cells (NSC), neuronal replacement following an injury is a restricted process, which does not naturally result in functional regeneration. Therefore, potentiating endogenous neurogenesis is one of the strategies that are currently being under study to regenerate damaged brain tissue. The insignificant neurogenesis that occurs in CNS injuries is a consequence of the gliogenic/non-neurogenic environment that inflammatory signaling molecules create within the injured area. The modification of the extracellular signals to generate a neurogenic environment would facilitate neuronal replacement. However, in order to generate this environment, it is necessary to unearth which molecules promote or impair neurogenesis to introduce the first and/or eliminate the latter. Specific isozymes of the protein kinase C (PKC) family differentially contribute to generate a gliogenic or neurogenic environment in injuries by regulating the ADAM17 mediated release of growth factor receptor ligands. Recent reports describe several non-tumorigenic diterpenes isolated from plants of the genus, which specifically modulate the activity of PKC isozymes promoting neurogenesis. Diterpenes with 12-deoxyphorbol or lathyrane skeleton, increase NPC proliferation in neurogenic niches in the adult mouse brain in a PKCβ dependent manner exerting their effects on transit amplifying cells, whereas PKC inhibition in injuries promotes neurogenesis. Thus, compounds that balance PKC activity in injuries might be of use in the development of new drugs and therapeutic strategies to regenerate brain injuries.

AIMS: Physical exercise and cognitive training hippocampal dependent tasks are known to enhance adult hippocampal neurogenesis (AHN). Here we aimed to evaluate the effect of either a moderate-intensity exercise protocol, a working memory task and the combination of both treatments on mice AHN. METHODS: Adult male C57BL6/J mice (*N*=34) were submitted to a scheduled treadmill exercise protocol for 12 days (EX-groups) or remained at home cage (SED-groups). 24 hours later, animals either were perfused or trained in a spatial learning task in the Water Maze (WM groups) for 8 days while control groups remained at home cage (CAGE groups). Bromodeoxyuridine (BrdU) was injected at the beginning of every experimental procedure to label hippocampal cells that proliferated during the initial exercise sessions. RESULTS: Mice submitted to scheduled exercise showed an increased number of $BrdU^+$ and $PCNA^+$ dentate granule cells (DGCs) in the short but not in the long-term when compared to sedentary groups. Conversely, training in the WM solely reduced the amount of $BrdU^+$ and $PCNA^+$ DGCs compared to CAGE group. However, animals submitted to scheduled exercise and WM training showed increased proliferation/survival of DGCs in the long-term compared to all other groups. CONCLUSIONS: Our data suggests that the combination of moderate-intensity exercise with spatial training has a powerful neurogenic effect in the DG, being a valuable non-pharmacological strategy for the treatment of neurodegenerative diseases associated with impaired AHN. In the brain, neural stem and progenitor cells divide into restricted regions and their progenies migrate along complex trajectories to reach distant areas of the brain. Until now, the 3D organization of neurogenic zones and pathways of cell migration has remained undisclosed. In this study, we developed the new pipeline for 3D visualization and analysis of cell division and migration in the whole brain, based on whole-mount labeling dividing cells with 5-ethynyl-2'-deoxyuridine (EdU). Using this pipeline, we observed uneven distribution of EdU+ cells in the adult subventricular zone (SVZ) and found regions with high cell density forming three stripes, which merge into a rostral migration stream (RMS). Using an interval pulse labeling paradigm, we observed the displacement of the density of labeled cells from SVZ towards the olfactory bulb (OB). Three stripes in the V-SVZ were not visible clearly 2h after EdU injection and they appeared in 24 h. In 120 h after labeling, almost all EdU+ cells were located in OB. Thus, three stripes in SVZ correspond to three migration branches that have not been previously described. We also discovered two distinct segments of RMS with different proliferative potential - the anterior segment consisted of migrating but not dividing cells. Next, we visualized and analyzed patterns of dividing cells in the perinatal brain and found dynamics of cell migration differ from adults. Finally, we compared brain development of wt vs. autism model mice (16p11.2 df/+) and didn’t reveal a difference in 3D patterns and dynamics of proliferation in brain neurogenic zones.

INTERMITTENT HYPOXIA PROMOTES POST-STROKE RECOVERY IN RODENT STRIATUM THROUGH NEUROGENESIS

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Syed Roshan[1], Mahesh Kandasamy[2], Swaminathan Jayachandran[3], Anusuyadevi Muthuswamy[1]
[1]Bharathidasan University, Biochemistry, Tiruchirapalli, India, [2]Bharathidasan University, Animal Science, Tiruchirapalli, India, [3]Bharathidasan University, Bioinformatics, Tiruchirapalli, India

Aim: To investigate intermittent hypoxia (IH) therapy as a non-invasive method to stimulate neurogenesis in the striatal infarct area, and promote functional recovery in experimental focal cerebral ischemia in rats
Methods: Focal cerebral ischemia was induced in Wistar rats using the Middle Cerebral Artery Occlusion (MCAo) model. A week later, animals were exposed to intermittent hypoxia (12%O2, 4hr/day) for a period of 14 days. Post treatment analysis of functional recovery, and cellular regeneration were assessed using behavioral analysis batteries like Rotarod, Barnes maze, Narrow beam walking test, and immunofluorescence analysis of DCX and Vimentin positive cells respectively.
Results: IH treated MCAo group showed significant improvement in narrow beam walking test and Barnes maze test compared to the untreated MCAo group. Immunofluorescence analysis revealed a better increment in the number of DCX positive neuroblasts and in the striatal infarct region in the IH treated group. While morphology of vimentin positive cells appears round in shape in the contralateral side, elongated vimentin positive cells were evident in the ipsilateral hemisphere.
Conclusion: These outcomes suggest that exposure of MCAo stroke affected rats to intermittent hypoxia results in increase of newborn neurons in the infarct region, and thus suggesting an alternative non-invasive method of increasing neuroregeneration in the infarct area after stroke.

Possible Existence of the Hypothalamic-Pituitary-Hippocampal (HPH) Axis: A Reciprocal Relationship Between Hippocampal Specific Neuroestradiol Synthesis and Neuroblastosis in Ageing Brains with Special Reference to Menopause and Neurocognitive Disorders.
The hippocampus-derived neuroestradiol plays a major role in neuroplasticity, independent of circulating estradiol that originates from gonads. The response of hypothalamus-pituitary regions towards the synthesis of neuroestradiol in the hippocampus is an emerging scientific concept in cognitive neuroscience. Hippocampal plasticity has been proposed to be regulated via neuroblasts, a major cellular determinant of functional neurogenesis in the adult brain. Defects in differentiation, integration and survival of neuroblasts in the hippocampus appear to be an underlying cause of neurocognitive disorders. Gonadotropin receptors and steroidogenic enzymes have been found to be expressed in neuroblasts in the hippocampus of the brain. However, the reciprocal relationship between hippocampal-specific neuroestradiol synthesis along neuroblastosis and response of pituitary based feedback regulation towards regulation of estradiol level in the hippocampus have not completely been ascertained. Therefore, this conceptual article revisits (1) the cellular basis of neuroestradiol synthesis (2) a potential relationship between neuroestradiol synthesis and neuroblastosis in the hippocampus (3) the possible involvement of aberrant neuroestradiol production with mitochondrial dysfunctions and dyslipidemia in menopause and adult-onset neurodegenerative disorders and (4) provides a hypothesis for the possible existence of the hypothalamic-pituitary-hippocampal (HPH) axis in the adult brain. Eventually, understanding the regulation of hippocampal neurogenesis by abnormal levels of neuroestradiol concentration in association with the feedback regulation of HPH axis might provide additional cues to establish a neuroregenerative therapeutic management for mood swings, depression and cognitive decline in menopause and neurocognitive disorders.

Genetic reprogramming of somatic cells into neuroblasts through a co-induction of the doublecortin gene along the Yamanaka factors: A promising approach to model neuroregenerative disorders.

Neural stem cell (NSC) mediated adult neurogenesis represents the regenerative plasticity of the brain. The functionality of the neurogenic process appears to be operated by neuroblasts, the multipotent immature neuronal population of the adult brain. While neuroblasts have been realized to play a major role in synaptic remodeling and immunogenicity, neurodegenerative disorders have been characterized by failure in the terminal differentiation, maturation, integration and survival of newborn neuroblasts. Advancement in understanding the impaired neuroregenerative process along the neuropathological conditions has currently been limited by lack of an appropriate experimental model of neuroblasts. The genetic reprogramming of somatic cells into pluripotent state offers a potential strategy for the experimental modeling of brain disorders. Thus, the induced pluripotent stem cell (iPSC) based direct reprogramming of somatic cells into neuroblasts would represent a potential tool to understand the regenerative biology of the adult brain. Therefore, this concise article discusses the significance of iPSCs, the functional roles of neuroblasts in the adult brain and provides a research hypothesis for the direct reprogramming of somatic cells into neuroblasts through the co-induction of a potential proneurogenic marker, the doublecortin (DCX) gene along with the Yamanaka factors. The proposed cellular model of adult neurogenesis may provide us with further insights into neuropathogenesis of many neurodegenerative disorders and will provide a potential experimental platform for diagnostic, drug discovery and regenerative therapeutic strategies.

The Regulation of Reactive Neuroblastosis, Neuroplasticity, and Nutraceuticals for Effective Management of Autism Spectrum Disorder.

Autism spectrum disorder (ASD) encompasses a cluster of neurodevelopmental and genetic disorders that has been characterized mainly by social withdrawal, repetitive behavior, restricted interests, and deficits in language processing mainly in children. ASD has been known to severely impair behavioral patterns and cognitive functions including learning and memory due to defects in neuroplasticity. The biology of the ASD appears to be highly complex and heterogeneous, and thus, finding a therapeutic target for autism remains obscure. There has been no complete prevention or disease-modifying cure for this disorder. Recently, individuals with autism have been characterized by reactive neurogenesis, obstructions in axonal growth, heterotopia, resulting from dysplasia of neuroblasts in different brain regions. Therefore, it can be assumed that the aforementioned neuropathological correlates seen in the autistic individuals might originate from the defects mainly in the regulation of neuroblasts in the developing as well as adult brain. Nutrient deficiencies during early brain development and intake of certain allergic foods have been proposed as main reasons for the development of ASD. However, the integrated understanding of neurodevelopment and functional aspects of neuroplasticity working through neurogenesis in ASD is highly limited. Moreover, neurogenesis at the level of neuroblasts can be regulated by nutrition. Hence, defects in neuroblastosis underlying the severity of autism potentially could be rectified by appropriate implementation of nutraceuticals.

Intramuscular Injection of BOTOX® Boosts Learning and Memory in Adult Mice in Association with Enriched Circulation of Platelets and Enhanced Density of Pyramidal Neurons in the Hippocampus.

BOTOX® is a therapeutic form of botulinum neurotoxin. It acts by blocking the release of acetylcholine (ACh) from the synaptic vesicles at the neuromuscular junctions, thereby inhibiting the muscle contraction. Notably, many neurological diseases have been characterized by movement disorders in association with abnormal levels of ACh. Thus, blockade of aberrant release of ACh appears to be a potential therapeutic strategy to mitigate many neurological deficits. BOTOX® has widely been used to manage a number of clinical complications like neuromuscular disorders, migraine and neuropathic pain. While the beneficial effects of BOTOX® against movement disorders have extensively been studied, its possible role in the outcome of cognitive function remains to be determined. Therefore, we investigated the effect of BOTOX® on learning and memory in experimental adult mice using behavioural paradigms such as open field task, Morris water maze and novel object recognition test in correlation with haematological parameters and histological assessments of the brain. Results revealed that a mild dose of BOTOX® treatment via an intramuscular route in adult animals improves learning and memory in association with increased number of circulating platelets and enhanced structural plasticity in the hippocampus. In the future, this minimally invasive treatment could be implemented to ameliorate different forms of dementia resulting from abnormal ageing and various neurocognitive disorders including Alzheimer's disease (AD).

Nicolaus Copernicus University, Department Of Animal Physiology And Neurobiology, Toruń, Poland

Recently, an extremely low frequency electromagnetic field (ELF-EMF) has been proposed for the modulation of hippocampal functions, including synaptic plasticity and neurogenesis. However, ELF-EMF-induced notable long-term deficits in learning ability have been also noticed. **We hypothesized that the ability of ELF-EMF to support hippocampal plasticity depends on its intensity (magnetic flux density).** The aim of the research was to evaluate the effect of **50 Hz ELF-EMF of low (1 mT) and high (7 mT) intensity on expression of BDNF and related factors involved in brain plasticity.** Male adult (>3 months) rats (*Wistar* strain) were exposed 3 times to 50 Hz ELF-EMF of 1 or 7 mT intensity (each exposure lasted one week, 1h/day). After each exposure part of animals was sacrificed and hippocampi were collected. RT-qPCR was performed to measure expression of BDNF and related genes. We have shown that the low intensity ELF-EMF activates the BDNF–TrkB signalling pathway and modulate the expression of synaptic protein markers SYN1, GAP43 and PSD95. In contrast higher intensity of ELF-EMF inhibited the BDNF-related signalling pathways. Our research proved the beneficial effect of ELF-EMF of 1 mT on hippocampal plasticity. As there is a link between failure in some steps of adult neurogenesis (cell proliferation, migration, differentiation, and survival) and age-related cognitive decline, as well as neurodegenerative and neuropsychiatric disorders, the knowledge on properties of ELF-EMF improving brain plasticity is important in the development of new therapeutic treatments. Research supported by a grant from the National Science Centre, Poland, no. 2017/25/B/NZ7/00638.

INVESTIGATION OF EPENDYMAL CELLS IN THE MOUSE AND HUMAN SUBEPENDYMAL ZONE: IN VIVO ASSESSMENT AND IN VITRO CULTURES

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Michaela Kourla[1], Ilias Kazanis[1,2]
[1]University of Patras, Department Of Biology, Patras, Greece, [2]University of Cambridge, Wellcome Trust – Mrc Cambridge Stem Cell Institute, Cambridge, United Kingdom

Aims The brain's stem cell niche located at the Subependymal Zone (SEZ) hosts neurogenesis throughout life in rodents, but in humans this capacity becomes exhausted after the first 18 months. By "Milking" the rat SEZ we can isolate neural stem cells (NSCs) from live animals. This involves the controlled compromise of the ependymal layer, by injecting neuraminidase that is followed by NSCs flowing from into the cerebrospinal fluid whereof they can be collected. Here, we investigate the infant human SEZ in order to assess the transferability of "Milking" and we also explore the effects of neuraminidase on cultured mouse ependymal cells. **Methods** Brain sections from neonatal and 18 month-old infants were immunostained for neuroblast and astroglial markers. In addition, ependymal cells were isolated from adult mice and were kept in short-term cultures either alone or co-cultured with NSCs. **Results** The neonatal SEZ includes a range of ependymal architectures, which become less heterogeneous with age. Surprisingly, extensive areas of ependymal denudation, accompanied by astrogliosis and leaking of neuroblasts in the cerebrospinal fluid were detected. Several mouse ependymal subtypes were identified in cultures based on their size and β-catenin expression. Neuarminidase led to disorganized ependymal clusters, morphological changes and to induction of proliferation as did growth to NSC medium. **Conclusions** Similarities between the infant human and the rat SEZ suggest that "Milking" can be transferred to the clinic, while the presence of naturally-occurring ependymal loss opens a remarkable new question, as does the in vitro induction of proliferation in mouse ependymal cells.

Isolation of neural stem and oligodendrocyte progenitor cells from the brain of live rats.
Postnatal brain neural stem and progenitor cells (NSPCs) cluster in anatomically inaccessible stem cell niches, such as the subependymal zone (SEZ). Here, we describe a method for the isolation of NSPCs from live animals, which we term "milking." The intracerebroventricular injection of a release cocktail, containing neuraminidase, integrin-β1-blocking antibody, and fibroblast growth factor 2, induces the controlled flow of NSPCs in the cerebrospinal fluid, where they are collected via liquid biopsies. Isolated cells retain key in vivo self-renewal properties and their cell-type profile reflects the cell composition of their source area, while the function of the niche is sustained even 8 months post-milking. By changing the target area more caudally, we also isolate oligodendrocyte progenitor cells (OPCs) from the corpus callosum. This novel approach for sampling NSPCs and OPCs paves the way for performing longitudinal studies in experimental animals, for more in vivo relevant cell culture assays, and for future clinical neuro-regenerative applications.

THE WILD AND THE TAMED; A COMPARISON OF THE ACTIVITY OF POSTNATAL BRAIN NEURAL STEM AND PROGENITOR CELLS BETWEEN LAB AND WILD RODENTS.

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Theodosia Androutsopoulou[1,2], Athanasia Rapti[1,2], Maria Anesti[1], George Mitsainas[2], Ilias Kazanis[1]
[1]University of Patras, Laboratory Of Developmental Biology, Department Of Biology, Patras, Greece, [2]University of Patras, Laboratory Of Animal Biology, Department Of Biology, Patras, Greece

Aims Postnatal brain neural stem and progenitor cells (NSPCs) cluster within stem cell niches contributing to odour recognition, learning, memory and myelination, with their activity being modified by exercise, stress and environmental enrichment. Here, we investigate the hypothesis that lab-mouse NSPCs might remain in a “tamed”, hypoactive, status, due to their maintenance in very controlled conditions. **Methods** We use lab and wild *Mus musculus* and *Microtus thomasi* animals, the latter being a fossorial species. We analyze brain samples, by immunohistochemical staining for markers specific for cell proliferation (PCNA, Ki67) and neural progenitor identity (nestin, Sox2, Dcx and Olig2), focusing on the Subependymal Zone and the dentate gyrus stem cell niches, as well as on the corpus callosum. Furthermore, we culture NSPCs from the same animals and we assess similar markers immediately after isolation and after two or three passages. **Results** Our data reveal increased density and mitotic activity of NSPCs in the Subependymal Zone of wild species, with no changes in the hippocampus and the corpus callosum. We have also confirmed the ability to culture NSPCs from wild animals and we describe differences both in terms of morphology and behavior. **Conclusions** Our data indicate that the activity of pools of postnatal brain NSPCs are affected by external “life-style” stimuli. Whether such differences are hard-wired in NSPCs or are continuously maintained remains open, but can be addressed by this type of analysis. The above are important in terms of assessing the limitations of using lab animals in experimental analyses.

PLATELETS ACT AS REGULATORS OF POSTNATAL NEURAL STEM CELLS OF THE SUBEPENDYMAL ZONE AND OF THE NICHE MICROENVIRONMENT

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Christina Dimitriou[1,2], Konstantinos Papadimitriou[1], Konstantinos Roussis[1], Cedric Ghevaert[3], Robin Franklin[2], Ilias Kazanis[1,2]
[1]University of Patras, Laboratory Of Developmental Biology, Department Of Biology, Rio, Greece, [2]University of Cambridge, Wellcome Trust – Mrc Cambridge Stem Cell Institute, Cambridge, United Kingdom, [3]University of Cambridge, Wellcome-mrc Cambridge Stem Cell Institute, Cambridge, United Kingdom

Aims Postnatal Neural Stem Cells (pNSCs) reside in stem cell niches, such as the Subependymal Zone (SEZ) of the lateral ventricles' walls. Previous work revealed specific platelet (PLT) aggregation within the niche's vasculature after focal corpus callosum (CC) demyelination. Moreover, we have shown that PLTs interact directly with pNSCs, using a co-culture system that allows the assessment of direct cell-to-cell interactions. Here, we investigate the functional role of PLTs *in vivo.* **Methods** We assessed the presence of PLTs within the SEZ in a range of other models of degeneration impacting the niche (stroke, neuraminidase-induced ependyma disruption). We also performed CC demyelination in thrombocytopenic (Nbeal2$^{-/-}$,Crlf3$^{-/-}$) and thrombophilic (JAK2V6$^{fl/+}$) mice and analysed extensively the impact on cellular and non-cellular components of the SEZ and CC. We also performed co-cultures using Nbeal2$^{-/-}$-derived PLTs, characterized by non-functional α-granules. The investigation was complemented by transplantations of labelled PLTs in the SEZ and Striatum. **Results** We confirmed the specificity of PLTs' presence in the activated niche's vasculature and our analysis revealed an abnormal response of the SEZ vasculature in mice with altered numbers of circulating PLTs. Thrombocytopenic mice also showed deficient oligodendrogenic activation following the lesion, without changes in neurogenesis. Activated PLTs were observed inside blood vessels and in the brain parenchyma post-transplantation. Nbeal2$^{-/-}$-derived PLTs failed to affect proliferation and differentiation potential of pNSCs. **Conclusions** Overall, PLTs emerge as functional regulators of both pNSCs and their niche, with their role partially dependent on a-granules. ***Acknowledgements*** *The research work was supported by the HFRI and the GSRT.*

Isolation of neural stem and oligodendrocyte progenitor cells from the brain of live rats.
Postnatal brain neural stem and progenitor cells (NSPCs) cluster in anatomically inaccessible stem cell niches, such as the subependymal zone (SEZ). Here, we describe a method for the isolation of NSPCs from live animals, which we term "milking." The intracerebroventricular injection of a release cocktail, containing neuraminidase, integrin-β1-blocking antibody, and fibroblast growth factor 2, induces the controlled flow of NSPCs in the cerebrospinal fluid, where they are collected via liquid biopsies. Isolated cells retain key in vivo self-renewal properties and their cell-type profile reflects the cell composition of their source area, while the function of the niche is sustained even 8 months post-milking. By changing the target area more caudally, we also isolate oligodendrocyte progenitor cells (OPCs) from the corpus callosum. This novel approach for sampling NSPCs and OPCs paves the way for performing longitudinal studies in experimental animals, for more in vivo relevant cell culture assays, and for future clinical neuro-regenerative applications.

Subependymal Zone-Derived Oligodendroblasts Respond to Focal Demyelination but Fail to Generate Myelin in Young and Aged Mice.
Two populations of oligodendrogenic progenitors co-exist within the corpus callosum (CC) of the adult mouse. Local, parenchymal oligodendrocyte progenitor cells (pOPCs) and progenitors generated in the subependymal zone (SEZ) cytogenic niche. pOPCs are committed perinatally and retain their numbers through self-renewing divisions, while SEZ-derived cells are relatively "young," being constantly born from neural stem cells. We compared the behavior of these populations, labeling SEZ-derived cells using hGFAP:Cre mice, within the homeostatic and regenerating CC of the young-adult and aging brain. We found that SEZ-derived oligodendroglial progenitors have limited self-renewing potential and are therefore not bona fide OPCs but rather "oligodendroblasts" more similar to the neuroblasts of the neurogenic output of the SEZ. In the aged CC their mitotic activity is much reduced, although they still act as a "fast-response element" to focal demyelination. In contrast to pOPCs, they fail to generate mature myelinating oligodendrocytes at all ages studied.

Neural stem cells (NSCs) reside in specialized niches in the adult mammalian brain. The largest site of adult neurogenesis is the ventricular-subventricular stem cell niche, which extends along the brain lateral ventricles. V-SVZ NSCs give rise to different subtypes of olfactory bulb (OB) interneurons as well as some glia throughout life. It is just emerging that adult NSCs are not a uniform population. Instead they comprise a mosaic of cells with unique molecular identities and differentiation fates, depending on their spatial location in the niche. Moreover, NSCs can be found in both quiescent and actively proliferating states *in vivo*. The external signals regulating the balance between stem cell activation and dormancy, as well as the factors controlling regionally distinct NSCs, are still largely unknown. Here, we show that pregnancy activates specific stem cell subpopulations residing in spatially distinct domains of the V-SVZ, with different temporal dynamics. The recruitment of 'pregnancy-related' NSCs is transient, and results in a temporally-controlled generation of different subtypes of OB interneurons. Each wave of newborn neurons becomes fully functional at key physiological periods of motherhood, such as birth or perinatal care. The majority of these pregnancy-associated neurons are short-lived and are culled by weaning. Spatial transcriptomics revealed molecular correlates of OB remodeling during early motherhood, and identified new subtypes of interneurons, which dynamically change with pregnancy. Taken together, our results suggest that 'on-demand' neurogenesis occurs during pregnancy, contributing to OB plasticity and preparing the female brain for motherhood.

Pathological anxiety is an understudied co-morbidity to most psychiatric diseases. Here, we found that serum from spontaneously anxious mice or stressed mice reduced the proliferation of adult hippocampal neural stem/progenitor cells (aNPC) in vitro, in parallel to a reduction of adult neurogenesis in the hippocampus in vivo. Similarly, the serum of human patients reduced aNPC proliferation in vitro, proportionally to their anxiety scores. We identified that lysophosphatidic acid (LPA16:0) was both necessary and sufficient for the effect of serum on aNPC. The effect of LPA16:0 was mediated by the LPA1 receptor, which bore single nucleotide polymorphism variants associated with anxiety. Finally, LPA16:0 treatment decreased aNPC proliferation in the dentate gyrus of the hippocampus and increased stress sensitivity in mice. Together, these results show that blood-circulating LPA16:0 inhibit adult hippocampal neurogenesis in the context of stress and anxiety and may represent a therapeutic target for anxiety-related disorders.

The glucocorticoid receptor in the nucleus accumbens plays a crucial role in social rank attainment in rodents.
Social hierarchy in social species is usually established through competitive encounters with conspecifics. It determines the access to limited resources and, thus, leads to reduced fights among individuals within a group. Despite the known importance of social rank for health and well-being, the knowledge about the processes underlying rank attainment remains limited. Previous studies have highlighted the nucleus accumbens (NAc) as a key brain region in the attainment of social hierarchies in rodents. In addition, glucocorticoids and the glucocorticoid receptor (GR) have been implicated in the establishment of social hierarchies and social aversion. However, whether GR in the NAc is involved in social dominance is not yet known. To address this question, we first established that expression levels of GR in the NAc of high anxious, submissive-prone rats are lower than that of their low anxious, dominant-prone counterparts. Furthermore, virally-induced downregulation of GR expression in the NAc in rats led to an improvement of social dominance rank. We found a similar result in a cell-specific mouse model lacking GR in dopaminoceptive neurons (i.e., neurons containing dopamine receptors). Indeed, when cohabitating in dyads of mixed genotypes, mice deficient for GR in dopaminoceptive neurons had a higher probability to become dominant than wild-type mice. Overall, our results highlight GR in the NAc and in dopaminoceptive neurons as an important regulator of social rank attainment.

Metabolic signature in nucleus accumbens for anti-depressant-like effects of acetyl-L-carnitine.
Emerging evidence suggests that hierarchical status provides vulnerability to develop stress-induced depression. Energy metabolic changes in the nucleus accumbens (NAc) were recently related to hierarchical status and vulnerability to develop depression-like behavior. Acetyl-L-carnitine (LAC), a mitochondria-boosting supplement, has shown promising antidepressant-like effects opening therapeutic opportunities for restoring energy balance in depressed patients. We investigated the metabolic impact in the NAc of antidepressant LAC treatment in chronically-stressed mice using H-magnetic resonance spectroscopy (H-MRS). High rank, but not low rank, mice, as assessed with the tube test, showed behavioral vulnerability to stress, supporting a higher susceptibility of high social rank mice to develop depressive-like behaviors. High rank mice also showed reduced levels of several energy-related metabolites in the NAc that were counteracted by LAC

treatment. Therefore, we reveal a metabolic signature in the NAc for antidepressant-like effects of LAC in vulnerable mice characterized by restoration of stress-induced neuroenergetics alterations and lipid function.

Food for Mood: Relevance of Nutritional Omega-3 Fatty Acids for Depression and Anxiety.
The central nervous system (CNS) has the highest concentration of lipids in the organism after adipose tissue. Among these lipids, the brain is particularly enriched with polyunsaturated fatty acids (PUFAs) represented by the omega-6 (ω6) and omega-3 (ω3) series. These PUFAs include arachidonic acid (AA) and docosahexaenoic acid (DHA), respectively. PUFAs have received substantial attention as being relevant to many brain diseases, including anxiety and depression. This review addresses an important question in the area of nutritional neuroscience regarding the importance of ω3 PUFAs in the prevention and/or treatment of neuropsychiatric diseases, mainly depression and anxiety. In particular, it focuses on clinical and experimental data linking dietary intake of ω3 PUFAs and depression or anxiety. In particular, we will discuss recent experimental data highlighting how ω3 PUFAs can modulate neurobiological processes involved in the pathophysiology of anxiety and depression. Potential mechanisms involved in the neuroprotective and corrective activity of ω3 PUFAs in the brain are discussed, in particular the sensing activity of free fatty acid receptors and the activity of the PUFAs-derived endocannabinoid system and the hypothalamic-pituitary-adrenal axis.

Stress-Induced Depression: Is Social Rank a Predictive Risk Factor?
An intriguing question in the field of stress is what makes an individual more likely to be susceptible or resilient to stress-induced depression. Predisposition to stress susceptibility is believed to be influenced by genetic factors and early adversity. However, beyond genetics and life experiences, recent evidence has highlighted social rank as a key determinant of susceptibility to stress, underscoring dominant individuals as the vulnerable ones. This evidence is in conflict with epidemiological, clinical, and animal work pointing at a link between social subordination and depression. Here, we review and analyze rodent protocols addressing the relevance of social rank to predict vulnerability to chronic social stress. We also discuss whether a specific social status (i.e., dominance or subordination) is the appropriate predictor of vulnerability to develop stress-induced depression or rather, the loss of social rank and resources.

Hierarchical Status Predicts Behavioral Vulnerability and Nucleus Accumbens Metabolic Profile Following Chronic Social Defeat Stress.
Extensive data highlight the existence of major differences in individuals' susceptibility to stress [1-4]. While genetic factors [5, 6] and exposure to early life stress [7, 8] are key components for such neurobehavioral diversity, intriguing observations revealed individual differences in response to stress in inbred mice [9-12]. This raised the possibility that other factors might be critical in stress vulnerability. A key challenge in the field is to identify non-invasively risk factors for vulnerability to stress. Here, we investigated whether behavioral factors, emerging from preexisting dominance hierarchies, could predict vulnerability to chronic stress [9, 13-16]. We applied a chronic social defeat stress (CSDS) model of depression in C57BL/6J mice to investigate the predictive power of hierarchical status to pinpoint which individuals will exhibit susceptibility to CSDS. Given that the high social status of dominant mice would be the one particularly challenged by CSDS, we predicted and found that dominant individuals were the ones showing a strong susceptibility profile as indicated by strong social avoidance following CSDS, while subordinate mice were not affected. Data from H-NMR spectroscopy revealed that the metabolic profile in the nucleus accumbens (NAc) relates to social status and vulnerability to stress. Under basal conditions, subordinates show lower levels of energy-related metabolites compared to dominants. In subordinates, but not dominants, levels of these metabolites were increased after exposure to CSDS. To the best of our knowledge, this is the first study that identifies non-invasively the origin of behavioral risk factors predictive of stress-induced depression-like behaviors associated with metabolic changes.

Amplification of mGlu-Endocannabinoid Signaling Rescues Behavioral and Synaptic Deficits in a Mouse Model of Adolescent and Adult Dietary Polyunsaturated Fatty Acid Imbalance.
Energy-dense, yet nutritionally poor food is a high-risk factor for mental health disorders. This is of particular concern during adolescence, a period often associated with increased consumption of low nutritional content food and higher prevalence of mental health disorders. Indeed, there is an urgent need to understand the mechanisms linking unhealthy diet and mental disorders. Deficiency in n-3 polyunsaturated fatty acids (PUFAs) is a hallmark of poor nutrition and mood disorders. Here, we developed a mouse model of n-3 PUFA deficiency lasting from adolescence into adulthood. Starting nutritional deficits in

dietary n-3 PUFAs during adolescence decreased n-3 PUFAs in both medial prefrontal cortex (mPFC) and nucleus accumbens, increased anxiety-like behavior, and decreased cognitive function in adulthood. Importantly, we discovered that endocannabinoid/mGlu-mediated LTD in the mPFC and accumbens was abolished in adult n-3-deficient mice. Additionally, mPFC NMDAR-dependent LTP was also lacking in the n-3-deficient group. Pharmacological enhancement of the mGlu/eCB signaling complex, by positive allosteric modulation of mGlu or inhibition of endocannabinoid 2-arachidonylglycerol degradation, fully restored synaptic plasticity and normalized emotional and cognitive behaviors in malnourished adult mice. Our data support a model where nutrition is a key environmental factor influencing the working synaptic range into adulthood, long after the end of the perinatal period. These findings have important implications for the identification of nutritional risk factors for disease and design of new treatments for the behavioral deficits associated with nutritional n-3 PUFA deficiency. In a mouse model mimicking n-3 PUFA dietary deficiency during adolescence and adulthood, we found strong increases in anxiety and anhedonia which lead to decreases in specific cognitive functions in adulthood. We found that endocannabinoid/mGlu-mediated LTD and NMDAR-dependent LTP were lacking in adult n-3-deficient mice. Acute positive allosteric modulation of mGlu or inhibition of endocannabinoid degradation normalized behaviors and synaptic functions in n-3 PUFA-deficient adult mice. These findings have important implications for the identification of nutritional risk for disease and the design of new treatments for the behavioral deficits associated with nutritional n-3 PUFAs' imbalance.

Endocannabinoid-Mediated Plasticity in Nucleus Accumbens Controls Vulnerability to Anxiety after Social Defeat Stress.
Chronic social defeat stress (CSDS) is a clinically relevant model of mood disorders. The relationship between the CSDS model and a physiologically pertinent paradigm of synaptic plasticity is not known. Here, we found that cluster analysis of the emotional behavior states of mice exposed to CSDS allowed their segregation into anxious and non-anxious groups. Endocannabinoid-mediated spike-timing dependent plasticity (STDP) in the nucleus accumbens was attenuated in non-anxious mice and abolished in anxious mice. Anxiety-like behavior in stressed animals was specifically correlated with their ability to produce STDP. Pharmacological enhancement of 2-arachidonoyl glycerol (2-AG) signaling in the nucleus accumbens normalized the anxious phenotype and STDP in anxious mice. These data reveal that endocannabinoid modulation of synaptic efficacy in response to a naturalistic activity pattern is both a molecular correlate of behavioral adaptability and a crucial factor in the adaptive response to chronic stress.

Nutritional Omega-3 Deficiency Alters Glucocorticoid Receptor-Signaling Pathway and Neuronal Morphology in Regionally Distinct Brain Structures Associated with Emotional Deficits.
Extensive evidence suggests that long term dietary n-3 polyunsaturated fatty acids (PUFAs) deficiency results in altered emotional behaviour. We have recently demonstrated that n-3 PUFAs deficiency induces emotional alterations through abnormal corticosterone secretion which leads to altered dendritic arborisation in the prefrontal cortex (PFC). Here we show that hypothalamic-pituitary-adrenal (HPA) axis feedback inhibition was not compromised in n-3 deficient mice. Rather, glucocorticoid receptor (GR) signaling pathway was inactivated in the PFC but not in the hippocampus of n-3 deficient mice. Consequently, only dendritic arborisation in PFC was affected by dietary n-3 PUFAs deficiency. In addition, occlusion experiment with GR blockade altered GR signaling in the PFC of control mice, with no further alterations in n-3 deficient mice. In conclusion, n-3 PUFAs deficiency compromised PFC, leading to dendritic atrophy, but did not change hippocampal GR function and dendritic arborisation. We argue that this GR sensitivity contributes to n-3 PUFAs deficiency-related emotional behaviour deficits.

Dietary n-3 PUFAs Deficiency Increases Vulnerability to Inflammation-Induced Spatial Memory Impairment.
Dietary n-3 polyunsaturated fatty acids (PUFAs) are critical components of inflammatory response and memory impairment. However, the mechanisms underlying the sensitizing effects of low n-3 PUFAs in the brain for the development of memory impairment following inflammation are still poorly understood. In this study, we examined how a 2-month n-3 PUFAs deficiency from pre-puberty to adulthood could increase vulnerability to the effect of inflammatory event on spatial memory in mice. Mice were given diets balanced or deficient in n-3 PUFAs for a 2-month period starting at post-natal day 21, followed by a peripheral administration of lipopolysaccharide (LPS), a bacterial endotoxin, at adulthood. We first showed that spatial memory performance was altered after LPS challenge only in n-3 PUFA-deficient mice that displayed lower n-3/n-6 PUFA ratio in the hippocampus. Importantly, long-term depression (LTD), but not long-term potentiation (LTP) was impaired in the hippocampus of LPS-treated n-3 PUFA-deficient mice. Proinflammatory cytokine levels were increased in the plasma of both n-3 PUFA-deficient and n-3 PUFA-balanced mice. However, only n-3 PUFA-balanced mice showed an increase in cytokine

expression in the hippocampus in response to LPS. In addition, n-3 PUFA-deficient mice displayed higher glucocorticoid levels in response to LPS as compared with n-3 PUFA-balanced mice. These results indicate a role for n-3 PUFA imbalance in the sensitization of the hippocampal synaptic plasticity to inflammatory stimuli, which is likely to contribute to spatial memory impairment.

EFFECT OF A PEPTIDE SECRETED BY ASTROCYTES ON HIPPOCAMPAL ADULT NEUROGENESIS

POSTER SESSION 07 - SECTION: ADULT NEUROGENESIS

Charline Carron, Frédéric Cassé, Kevin Richetin, Thomas Larrieu, Nicolas Toni
Lausanne University Hospital, Department Of Psychiatry, Center For Psychiatric Neurosciences, Prilly, Switzerland

Adult hippocampal neurogenesis is regulated by the neurogenic niche, which provides a structural and molecular environment enabling adult neurogenesis. In the niche, astrocytes play a predominant role, by participating to the regulation of multiple steps of adult neurogenesis, from adult neural stem cell (aNSCs) proliferation and differentiation to the functional integration of new neurons. In this study, we used a combination of *in vitro* approaches, biochemistry and mass spectrometry to identify a peptide released by astrocytes that regulate adult neurogenesis. The secreted peptide, named peptide P9, is derived from the phosphoprotein enriched in astrocyte protein (PEA15) which is a cytoplasmic protein involved in the regulation of proliferation and apoptosis. Using live-cell imaging, we found that P9 increased the proliferation and reduced cell death of aNSCs. *In vivo*, P9 increased cell proliferation in the dentate gyrus, resulting in increased net hippocampal neurogenesis. We next used immunoprecipitation and transcriptomics to define the molecular pathways involved in the effects of P9 on cell proliferation. These results indicate that astrocytes release peptides that regulate hippocampal neurogenesis in the adult brain. Since astrocytes are regulated by neuronal activity, this mechanism may contribute to an on-demand addition of new neurons in the hippocampus. Furthermore, understanding the mechanism of action of the astrocyte-secreted peptide P9 on adult neurogenesis in the hippocampus could be an interesting therapeutic strategy to stimulate adult neurogenesis in pathological conditions.

Introduction. Alzheimer's disease (AD) remains the leading neurodegenerative disorder needed to study and intervene timely. The brain intrinsic defense mechanisms towards chronic injury are not yet fully understood. Here we revealed the response of the main neurogenic niche - ubventricular zone (SVZ) - in case of amyloid exposure, associated structural and synaptic activity changes. *Methods.* Flow cytometry of Nestin, Vimentin, Nestin/Vimentin, NeuN, GFAP, NeuN/GFAP, NSE, BrdU, Wnt, BrdU/Wnt, VEGF positive cells was performed in the subventricular zone (SVZ) of rats' brain on the 90th day from intracerebroventricular (i.c.v.) injection of Aβ (1-42) fraction. The relative structural changes in the same areas and synaptic activity disruption in the entorhinal cortex-hippocampus circuit were provided as well. *Results.* Flow analyses revealed a reduction of Nestin, Vimentin, and Nestin/Vimentin positive cells in neurogenic niche. These changes were accompanied by an increased number of BrdU positive cells in the subventricular zone. The latest changes were strongly correlated with the fluctuations of VEGF positive cells, which pinpoint the fact that neurogenesis often appear parallel to changes in angiogenesis. The morphological changes were characterized by significant neural loss alongside with characteristic shift of entorhinal cortex-hippocampus circuit activity. *Conclusion.* We conclude, that although beta-amyloid 1-42 induces stem cell proliferation and triggers neurogenesis in SVZ, the process is incomplete and leads to "neuronal stem cell immaturity" phenomenon.

The Involvement of Insulin-Like Growth Factor 1 and Nerve Growth Factor in Alzheimer's Disease-Like Pathology and Survival Role of the Mix of Embryonic Proteoglycans: Electrophysiological Fingerprint, Structural Changes and Regulatory Effects on Neurotrophins.
Alzheimer's disease (AD)-associated neurodegeneration is triggered by different fragments of amyloid beta (Aβ). Among them, Aβ (25-35) fragment plays a critical role in the development of neurodegeneration-it reduces synaptic integrity by disruption of excitatory/inhibitory ratio across networks and alters the growth factors synthesis. Thus, in this study, we aimed to identify the involvement of neurotrophic factors-the insulin-like growth factor 1 (IGF-1) and nerve growth factor (NGF)-of AD-like neurodegeneration induced by Aβ (25-35). Taking into account our previous findings on the neuroprotective effects of the mix of proteoglycans of embryonic genesis (PEG), it was suggested to test its regulatory effect on IGF-1 and NGF levels. To evaluate the progress of neurodegeneration, in vivo electrophysiological investigation of synaptic activity disruption of the entorhinal cortexhippocampus circuit at AD was performed and the potential recovery effects of PEG with relative structural changes were provided. To reveal the direct effects of PEG on brain functional activity, the electrophysiological pattern of the single cells from nucleus supraopticus, sensomotor cortex and hippocampus after acute injection of PEG was examined. Our results demonstrated that after injection of Aβ (25-35), the level of NGF decreased in cerebral cortex and hypothalamus, and, in contrast, increased in hippocampus, prompting its multidirectional role in case of brain damage. The concentration of IGF-1 significantly increased in all investigated brain structures. The administration of PEG balanced the growth factor levels accompanied by substantial restoration of neural tissue architecture and synaptic activity. Acute injection of PEG activated the hypothalamic nucleus supraopticus and hippocampal neurons. IGF-1 and NGF levels were found to be elevated in animals receiving PEG in an absence of amyloid exposure. We suggest that IGF-1 and NGF play a critical role in the development of AD. At the same time, it becomes clear that the neuroprotective effects of PEG are likely mediated via the regulation of neurotrophins.

Background: In response to a cortical injury, neural stem cells of the subventricular zone (SVZ) in the mouse adult brain, are activated producing neuroblasts that alter their migration pattern attempting to migrate toward the injury. However, neuronal replacement post-injury is limited. **Aims:** To understand the signaling events that are involve in the proliferation, differentiation and migration of neuroblasts from the SVZ in response to a cortical injury. **Methods:** We have performed mechanical cortical injuries in adult mice and have studied the expression and concentration of neuregulin and TGFa as well as their receptors. We have also studied neurogenesis mediated by compounds that stimulate TGFa and neuregulin1 release. **Results:** In response to the injury, the concentration of TGFa increases in the cerebrospinal fluid (CSF). The expression of TGFa, neuregulin 1 and their receptors is altered in the SVZ and in the perilesional area. Treatment of injured mice with a compound that stimulates TGFa release (ER272), increased level of TGFa in the CSF, and the number of neuroblasts within the SVZ but these cells did not migrate toward the injury. The administration of a compound that stimulated neuregulin 1 release (EOF2) increased the concentration of neuregulin in the CSF and facilitated neuroblast migration toward the injury resulting in neuroblast enrichment of the perilesional area. The pro-migratory effect of EOF2 was potentiated when mice were treated with ER272 before performing the injury. **Conclusions:** These results indicate that modulating TGFa and neuregulin1 release may promote neuronal replacement in brain injuries.

Droplet-based single-cell RNA sequencing provides a powerful tool to evaluate the transcriptomic landscape and heterogeneity of thousands of cells in parallel. However, complex study designs or the unavailability of in-house instruments require the temporal disconnection between sample preparation and library construction, raising the need for efficient sample preservation methods which are compatible with downstream applications. Here, we evaluated the suitability of cryopreservation and methanol fixation for preserving single cell suspensions of the murine dentate gyrus. To evaluate the performance of both methods, we first evaluated the recovery after thawing and rehydration of the papain-dissociated cell suspensions. Due to the low recovery rates after cryopreservation, further evaluation steps were focused on methanol fixation. Its efficacy was determined via flow cytometry of Sytox-stained samples. RNA quality was assessed on an Agilent bioanalyzer. To test whether and how methanol fixation affects transcriptome profiling, we performed a SORTseq experiment on fresh and methanol-fixed cell suspensions. Methanol fixation resulted in higher recovery rates than cryopreservation. It had an efficacy of 100% and no effects on RNA integrity. Transcriptome analysis revealed that methanol fixation results in a slight drop in read and gene counts, suggesting RNA leakage. However, it did not interfere with clustering and cell-type composition. Moreover, it resulted in more high-quality cells and reduced signs of mitochondrial stress compared to fresh samples. Together, these data suggest that methanol fixation is suitable for storing neural cells for subsequent single-cell RNA profiling, helping to overcome challenges arising with complex workflows and to improve the experimental flexibility.

Aims
The meninges represent a protective tissue of the central nervous system providing a nutritive and supportive support to the brain. Recent data from our lab and others revealed that in this compartment, a large panel of resident immune cells are found, the most abundant being macrophages. Yet, whether meningeal macrophages (MM) could act in neurogenesis processes remains poorly understood. Meninges deeply penetrate the parenchyma between the major brain substructures, including hemispheres and the hippocampus. In this line, we investigated whether MM could influence developmental neurogenesis and/or adult neurogenesis. Methods We used multiple chemical and genetic innovative models of meningeal macrophage depletion in i) neonatal mice and ii) adult mice upon voluntary exercise to evaluate by immunohistochemistry the impact of macrophage depletion on developmental and activity-induced adult neurogenesis. Results
Preliminary results showed that MM depletion at early time point decreased neurogenesis in the hippocampus of neonatal mice. Concerning adult neurogenesis, we confirmed the positive effect of exercise on neurogenesis, which was abolished by the depletion of MM. To better understand the underlying mechanisms, we achieved single-cell RNA sequencing of MM and are now exploring the impact of specific meningeal macrophage deletion of neurogenic factors. Conclusions
Ultimately, this work owes the potential to shed new light on the role of immune cells in neurogenesis and open up new perspectives to modulate/target neurogenesis.

DYNAMIC INTERPLAY BETWEEN CAV2 CHANNELS AND THE PRESYNAPTIC CYTOMATRIX IN MECHANISMS OF NEUROTRANSMISSION

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Michela Borghi[1], Enes Yagiz Akdas[2], Artur Bikbaev[1], Anna Fejtova[2], Martin Heine[1]

The structural organization of the presynaptic terminal is of utmost importance for the release of neurotransmitter-containing synaptic vesicles (SV). This process is essential for neuronal communication, that represents the major determinant of high cognitive functions such as memory and behavior. In the presynaptic active zone (AZ), voltage-gated calcium channels' (VGCC) proximity to docked SV is fundamental for fast neurotransmitter release. Scaffold proteins RIM, RBP2 and Bassoon were shown to mediate tethering of Cav2.1 and Cav2.2 channels close to synaptic vesicles (~20 nm). Indeed, scaffolding proteins present peculiar binding domains that can be specific for individual channel subtypes. Interestingly, deletion of these binding domains results in decreased channel abundance and impaired vesicle release. However, the mechanisms by which individual VGCC subtypes enter and/or escape AZs are still elusive. Particularly, VGCC synaptic localization could be mediated by direct interaction with scaffolding proteins or through a general trapping in a phase-separated compartment. Here, we deliver cell-penetrating peptides that mimic known binding sites between VGCC and scaffold proteins to cultured hippocampal neurons, acutely disturbing the affinity landscape of VGCC/scaffold interactions. Our functional glutamate imaging results indicated time-dependent alterations in synaptic transmission following incubation with interfering peptides, that translated in local rearrangement of VGCC observed through single-particle tracking. Additionally, confocal imaging confirmed VGCC's differential distribution in AZs following acute interference with scaffold interactions. Thus, the ability of the presynapse to quickly rearrange its channel composition lays the foundation for further investigations on how this property is exploited in terms of synaptic remodeling following plasticity events.

Setting the synaptic efficacy and short-term plasticity based on the postsynaptic target cell type is one of the most intriguing synaptic mechanisms that enhance the computational power of the cortical network. Here, using whole-cell patch-clamp paired recordings, we show that adult mouse hippocampal CA1 pyramidal cell (PC) connections on fast spiking interneurons (FSIN) have 15-fold larger unitary EPSC amplitudes than those made by PCs on oriens lacunosum-moleculare (O-LM) interneurons. Freeze-fracture replica immunolabeling showed similar nano-topologies and coupling distances between Ca^{2+} channels (Cav2.1) and synaptic vesicle release sites (Munc13-1 clusters) in both synapses, and showed only 20% higher density of Cav2.1-type Ca^{2+} channels in the active zones targeting FSINs. Consistent with this, 2-photon [Ca^{2+}] imaging showed 40% larger AP-evoked [Ca^{2+}] transient peak amplitudes in FSIN-targeting boutons. Increasing the Ca^{2+} influx at PC – O-LM synapses by 40% with the K^+ channel blocker 4-AP caused only 2.6-fold increase in uEPSC amplitudes. However, application of a phorbol ester analog (PDBU) resulted in a larger augmentation of uEPSC amplitudes at PC – O-LM synapses (5-fold) than at PC – FSIN synapses (1.8-fold), suggesting incomplete docking or priming of vesicles at PC – O-LM synapses. Serial section electron microscopy (EM) and EM tomography ruled out low release site occupancy, as there was no difference in the density of docked vesicles between the two types of synapses. Our results demonstrate that ill-primed docked vesicles limit the output of PC – O-LM synapses.

Reliable delivery of presynaptic material, including active zone and synaptic vesicle proteins from neuronal somata to synaptic terminals, is prerequisite for successful synaptogenesis and neurotransmission. However, molecular mechanisms controlling the somatic assembly of presynaptic precursors remain insufficiently understood. We show here that in mutants of the small GTPase Rab2 both active zone and synaptic vesicle proteins accumulated in the neuronal cell body at the *trans*-Golgi and were, consequently, depleted at synaptic terminals, provoking neurotransmission deficits. Ectopic presynaptic material accumulations consisted of heterogeneous vesicles and short tubules of 40x60 nm and segregated in subfractions either positive for active zone proteins or synaptic vesicle proteins and LAMP1, a lysosomal membrane protein. Genetically, Rab2 behaved epistatically over Arl8, a lysosomal adaptor controlling the axonal export of precursors. Collectively, we here identified a Golgi-associated assembly sequence for presynaptic precursor vesicle biogenesis controlled by Rab2-dependent protein export and sorting at the *trans*-

Golgi.

A KV3.3 VOLTAGE-GATED POTASSIUM CHANNEL MUTATION INDUCES PRESYNAPTIC HYPEREXCITABILITY AND RAISES THE NUMBER OF DOCKED VESICLES AT HIPPOCAMPAL EXCITATORY SYNAPSES

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Josh Whittingham[1], Todor Gerdjikov[1], Ian Forsythe[1], Will Norton[2]

Postsynaptic hyperexcitability is well characterised, but increased action potential firing will also influence presynaptic function and neurotransmitter release. Synaptic vesicles play a role in the rate of neurotransmitter release and are known to be modulated by voltage gated potassium channels. Spinocerebellar ataxia type 13 (SCA13) is a mutation of the Kv3.3 voltage-gated potassium channel subunit which has a role in presynaptic AP repolarization and causes epilepsy in a CRISPR/CAS9 gene edited mouse model of this human disease. The mechanism could be interruption of ion conduction but direct influence on transmitter release has been postulated. In this investigation, ultrastructure changes in presynaptic terminals of hippocampal neurons from the SCA13 mouse were imaged using electron microscope imaging of osmium-thiocarbohydrazide stained tissue. The number of vesicles bound to the active zone of excitatory synaptic terminals in the CA1 was increased relative to wildtype CBA mice, whilst in inhibitory synaptic terminals the active zone size increases. Similar results were observed in tissue from a Kv3.3 knockout mouse. We conclude that changes in presynaptic Kv3.3 channels can influence the ultrastructure of the hippocampal synapses. This remains to be shown whether it is a direct effect of the impaired ion channel on excitability, a secondary influence on excitability, or whether the Kv3.3 subunit directly changes transmitter release from the terminal.

In neurons, alpha2delta subunits of voltage-gated calcium channels (VGCC) regulate synaptic functions independently from their channel specific role. The human genes encoding for alpha2delta isoforms have been linked to a variety of neurological disorders. Particularly alpha2dela-3 (CACNA2D3) has been strongly associated with autism spectrum disorders. Thus, we hypothesize that alpha2delta-3 knockout mice may serve as a potential model for studying neurodevelopmental disorders. We further suggest that defects in specific synapses or synaptic connections might explain an autism-like phenotype. To test this, we performed initial behavioural tests, which illustrated a mild anxiogenic phenotype together with increased active coping in alpha2delta-3 knockout mice compared to littermate controls. Structural brain analysis in serial Nissl-stained sections revealed no gross morphological changes of knockout brains but showed a slightly reduced brain volume. The suggested synaptic importance of alpha2delta-3 was underpinned by analysing presynaptic calcium signals, which were reduced in knock out synapses after stimulation with 1 action potential (AP), 3 APs, and 10 APs. Additional biochemical analysis of whole brain and synaptosomal lysates demonstrated a significant reduction of striatal NMDAR2B expression in alpha2delta-3 knockout brains. Therefore, we next analysed the intrinsic excitability of striatal neurons in slice electrophysiology, revealing a hypo-excitability of medium spiny neurons. Taking together, alpha2delta-3 deficiency results in a mild reduction of brain volume, causes changes of synaptic protein expression, and interferes with proper presynaptic function. Consistent with previous observations in neurodevelopmental disorders and putative autism mouse models, alpha2delta-3 knockout mice display striatal hypo-excitability, a mild anxiogenic phenotype, and increased active coping.

OPTIMISATION OF PROTOCOLS TO STUDY SYNAPTIC INTEGRITY DURING DROSOPHILA AGEING

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Ethlyn Lloyd-Morris, George Chennell, Deepak Srivastava, Alessio Vagnoni
King's College London, Department Of Basic And Clinical Neuroscience, Institute Of Psychiatry, Psychology And Neuroscience, London, United Kingdom

Background: Cell adhesion molecules neurexin and neuroligin are critical for synapse formation and maintenance. The intracellular trafficking of neurexin and neuroligin towards the synapse is important for synaptic integrity, and decreased trafficking of these proteins may cause synaptic dysfunction. Decreased intracellular cargo transport is a feature of ageing, and so the synaptic dysfunction observed in ageing and Alzheimer's disease may be caused by age-related changes in the trafficking and localisation of synaptic proteins, however no study has confirmed this link. Aims: We aim to assess whether there are changes in the intracellular trafficking of synaptic proteins, which could contribute to synaptic dysfunction during ageing. This poster outlines the first steps towards optimisation of two measures of synaptic integrity in the adult fly. Methods: We test the optical clearing protocol published by Pende et al. (2018, PMID: 30413688) using *Drosophila* expressing CD8::GFP pan-neuronally. Secondly, we optimise live-imaging protocols to capture the transport of fluorescently-tagged synaptic proteins (neurexin, neuroligin and amyloid precursor protein (APP)) along the fly wing's sensory neuron axons *in situ*. Results: Neuronal structures are visible following tissue clearing of adult flies. APP trafficking is prevalent under two pan-neuronal drivers, nsyb-Gal4 and APPL-Gal4. Tracking of neurexin and neuroligin trafficking requires the generation of genetic double insertions to increase the abundance of these fluorescently-tagged proteins. Conclusions: Combining tissue clearing and live imaging protocols to study the transport of synaptic proteins in adult *Drosophila* will enable us to better characterise the mechanisms of synaptic maintenance during ageing.

The release of neurotransmitters relies on the fusion of synaptic vesicles with the presynaptic membrane. This fusion only occurs at a restricted area of the presynaptic membrane called active zone. Our group identified a partner of the active zone scaffolding protein Bassoon called Mover. Mover KO mice display an increase in facilitation in hippocampal mossy fiber terminals, but normal facilitation at Schaffer collateral synapses, indicating that Mover has synapse-specific roles. At the calyx of Held lack of Mover reduces the release probability of a subset of primed synaptic vesicles, further highlighting how specific the role of Mover can be. We found that Mover is primarily associated with excitatory synapses in immature neuronal cultures but shifts to being predominantly found at inhibitory synapses in advanced cultures stages. These results support the view that Mover has a specific role depending on the type of synapse and on the type of docked synaptic vesicle at an individual release site. To determine how Mover is arranged within the presynaptic architecture we used super-resolution microscopy of presynaptic terminals in cultured neurons. We found that unlike the synaptic vesicle protein synaptophysin, Mover STED signals appear as discrete puncta. Using dual-color Minflux microscopy <10 nm resolution we found that Mover is less widely distributed at active zones than synaptophysin. Together, these data suggest that Mover is a presynaptic protein heterogeneously expressed among synapses of the brain and in cultured neurons and may act to dampen transmitter release during repeated activity to prevent runaway excitation.

Zinc and Copper Effects on Stability of Tubulin and Actin Networks in Dendrites and Spines of Hippocampal Neurons.
Zinc and copper ions can modulate the activity of glutamate receptors. However, labile zinc and copper ions likely represent only the tip of the iceberg and other neuronal functions are suspected for these metals in their bound state. We performed synchrotron X-ray fluorescence imaging with 30 nm resolution to image total biometals in dendrites and spines from hippocampal neurons. We found that zinc is distributed all along the dendrites while copper is mainly pinpointed within the spines. In spines, zinc content is higher within the spine head while copper is higher within the spine neck. Such specific distributions suggested metal interactions with cytoskeleton proteins. Zinc supplementation induced the increase of β-tubulin content in dendrites. Copper supplementation impaired the β-tubulin and F-actin networks. Copper chelation resulted in the decrease of F-actin content in dendrites, drastically reducing the number of F-actin protrusions. These results indicate that zinc is involved in microtubule stability whereas copper is essential for actin-dependent stability of dendritic spines, although copper excess can impair the dendritic cytoskeleton.

Manganese levels in infant formula and young child nutritional beverages in the United States and France: Comparison to breast milk and regulations.
Exposure to high levels of manganese (Mn) in children has recently been associated with adverse neurodevelopmental effects. Current infant formula regulations for Mn content were set between 1981 (United States), 2006 (European Union, France), and 2007 (Codex Alimentarius) prior to the publication of much of the growing body of research on the developmental neurotoxicity of Mn. In this study, we sought to measure the concentrations of Mn in some infant formulas and young child nutritional beverages available on the United States (US) and French markets using ion beam analysis by particle induced X-ray emission (PIXE) spectrometry and then compare the analytical results to concentrations reported in the literature for breast milk and applicable infant formula regulations and guidelines. We were particularly interested in measuring Mn concentrations in product types for which there is very little data from previous surveys, especially soy-based, rice-based, goat-milk based, chocolate-flavored, and nutritional beverages for young children that are not regulated as infant

or follow-on formulas (e.g. "toddler formulas" and "toddler powders"). We purchased 44 infant formulas and young child nutritional beverage products in the US and France with varying protein sources (cow-milk, goat-milk, soy, rice) labelled for birth to 3 years. We selected these samples using maximum variation sampling to explore market extremes to facilitate comparisons to regulatory limits. Since this sampling method is non-probabilistic, other inferences cannot be made beyond this set of samples to the overall markets. We used ion beam analysis to measure the concentrations of Mn in each product. The range of measured Mn concentrations in the products is 160-2,800 µg/L, substantially higher than the 3-6 µg/L mean Mn concentration reported in human breast milk. All products satisfied national and Codex Alimentarius Commission (CAC) international standards for minimum Mn content in infant formulas; however, 7/25 of the products purchased in the US exceeded the CAC Guidance Upper Level of 100 µg Mn/kcal for infant formula.

Correlating STED and synchrotron XRF nano-imaging unveils cosegregation of metals and cytoskeleton proteins in dendrites.
Zinc and copper are involved in neuronal differentiation and synaptic plasticity but the molecular mechanisms behind these processes are still elusive due in part to the difficulty of imaging trace metals together with proteins at the synaptic level. We correlate stimulated-emission-depletion microscopy of proteins and synchrotron X-ray fluorescence imaging of trace metals, both performed with 40 nm spatial resolution, on primary rat hippocampal neurons. We reveal the co-localization at the nanoscale of zinc and tubulin in dendrites with a molecular ratio of about one zinc atom per tubulin-αβ dimer. We observe the co-segregation of copper and F-actin within the nano-architecture of dendritic protrusions. In addition, zinc chelation causes a decrease in the expression of cytoskeleton proteins in dendrites and spines. Overall, these results indicate new functions for zinc and copper in the modulation of the cytoskeleton morphology in dendrites, a mechanism associated to neuronal plasticity and memory formation.

Cytoplasmic aggregation of uranium in human dopaminergic cells after continuous exposure to soluble uranyl at non-cytotoxic concentrations.
Uranium exposure can lead to neurobehavioral alterations in particular of the monoaminergic system, even at non-cytotoxic concentrations. However, the mechanisms of uranium neurotoxicity after non-cytotoxic exposure are still poorly understood. In particular, imaging uranium in neurons at low intracellular concentration is still very challenging. We investigated uranium intracellular localization by means of synchrotron X-ray fluorescence imaging with high spatial resolution (< 300 nm) and high analytical sensitivity (< 1 µg.g per 300 nm pixel). Neuron-like SH-SY5Y human cells differentiated into a dopaminergic phenotype were continuously exposed, for seven days, to a non-cytotoxic concentration (10 µM) of soluble natural uranyl. Cytoplasmic submicron uranium aggregates were observed accounting on average for 62 % of the intracellular uranium content. In some aggregates, uranium and iron were co-localized suggesting common metabolic pathways between uranium and iron storage. Uranium aggregates contained no calcium or phosphorous indicating that detoxification mechanisms in neuron-like cells are different from those described in bone or kidney cells. Uranium intracellular distribution was compared to fluorescently labeled organelles (lysosomes, early and late endosomes) and to fetuin-A, a high affinity uranium-binding protein. A strict correlation could not be evidenced between uranium and the labeled organelles, or with vesicles containing fetuin-A. Our results indicate a new mechanism of uranium cytoplasmic aggregation after non-cytotoxic uranyl exposure that could be involved in neuronal defense through uranium sequestration into less reactive species. The remaining soluble fraction of uranium would be responsible for protein binding and for the resulting neurotoxic effects.

Imaging the structural organization of chemical elements in growth cones of developing hippocampal neurons.
During neurodevelopment, neurons form growth cones, F-actin rich extensions located at the distal end of the neurites. Growth cones allow dendrites and axons to build synaptic connections through a process of neurite guidance whose mechanisms have not been fully elucidated. Calcium is an important element in this process by inducing F-actin reorganization. We hypothesized that other biologically active elements might be involved in the growth cone-mediated neurite guidance mechanisms. We performed super resolution and confocal microscopy of F-actin, followed by synchrotron X-ray fluorescence microscopy of phosphorous, sulfur, chlorine, potassium, calcium, iron and zinc on growth cones from primary rat hippocampal neurons. We identified two main patterns of element organization. First, active growth cones presenting an asymmetric distribution of Ca co-localized with the cytoskeleton protein F-actin. In active growth cones, we found that the distributions of P, S, Cl, K, and Zn are correlated with Ca. This correlation is lost in the second pattern, quiescent growth cones, exhibiting a spread elemental distribution. These results suggest that Ca is not the only element required in the F-actin rich active regions of growth cones. In addition, highly concentrated Fe spots of submicrometer size

were observed in calcium-rich areas of active growth cones. These results reveal the need for biological active elements in growth cones during neural development and may help explain why early life deficiencies of elements, such as Fe or Zn, induce learning and memory deficits in children.

The roles of auxiliary $\alpha_2\delta$ subunits of voltage-gated calcium channels in modulating membrane expression and calcium current properties are widely recognized. In addition, recent literature suggests an important role of $\alpha_2\delta$ proteins in synapse formation and differentiation. Therefore, it is not surprising that $\alpha_2\delta$ genes have been linked to neurological and neuropsychiatric disorders. Here we aimed to investigate human mutations in $\alpha_2\delta$ proteins by addressing their synaptic functions, besides their role as channel subunit, to shed light on the underlying pathophysiological mechanisms. We characterized two mutations, the autism-associated mutation p.Arg351Thr in $\alpha_2\delta$-1 (CACNA2D1) and the epilepsy-related mutation p.Arg596Pro in $\alpha_2\delta$-2 (CACNA2D2) , cloned into mouse cDNA, by employing primary hippocampal neurons as homologous expression system. To this end we quantified plasma membrane trafficking and analyzed potential consequences on synaptic composition. To determine potential effects on the biophysical channel properties, we performed electrophysiological recordings after heterologous expression of either Cav2.1 or Cav1.3 together with the mutated $\alpha_2\delta$ and auxiliary β subunits. Live-cell labelling of cultured hippocampal neurons transfected with 2HA-tagged $\alpha_2\delta$ subunits revealed a strong reduction in membrane and synaptic targeting of both mutants. However, only neurons transfected with $\alpha_2\delta$-2_p.Arg596Pro showed a significantly reduced mismatched localization of postsynaptic $GABA_AR$s opposite glutamatergic nerve terminals, a previously identified synaptogenic function of $\alpha_2\delta$-1 and $\alpha_2\delta$-2 splices lacking exon 23. Similarly, preliminary electrophysiological analysis indicated that current density of Cav2.1 was not compromised by $\alpha_2\delta$-1_p.Arg351Thr, contrary to co-expression $\alpha_2\delta$-2_p.Arg596Pro , which resulted in a strongly reduced current density.

TO DIE OR NOT TO DIE – DOES BASSOON PLAY A ROLE IN CONE PHOTORECEPTOR SURVIVAL?

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Miriam Ryl[1], Kaspar Gierke[1], Enes Yagiz Akdas[2], Anna Fejtova[2], Julia Von Wittgenstein[1], Johann Helmut Brandstätter[1]
[1]Friedrich-Alexander-Universität Erlangen-Nürnberg, Animal Physiology, Department Of Biology, Erlangen, Germany, [2]Universitätsklinikum Erlangen, Psychiatrische Und Psychotherapeutische Klinik, Erlangen, Germany

The presynaptic protein Bassoon (BSN) is an important component of the active zone of chemical synapses, where it contributes to synapse assembly and function. Recent studies show an additional function of BSN as an inhibitor of presynaptic autophagy and proteasomal degradation in brain neurons. In the retina of two BSN-deficient mouse lines, *Bsn*$^{\Delta Ex4/5}$ and *Bsn*^{gt}, we found degeneration of cone photoreceptors and neurite outgrowth. This raises the question, whether BSN is important for the survival of these highly active sensory neurons by controlling homeostasis pathways. However, a third BSN-deficient mouse line (*Bsn*^{ko}) did not show a retinal phenotype. Since proteasomal degradation was impaired in the retinae of both *Bsn*^{gt} and *Bsn*^{ko} mice, disruption of protein degradation alone is not sufficient for cone photoreceptor degeneration. We hypothesize that an additional trigger is required. The trigger for cone photoreceptor degeneration could be the presence of a residual BSN fragment as it is found in the *Bsn*$^{\Delta Ex4/5}$ mouse line. This hypothesis is supported by the finding that crossbreeding of *Bsn*^{ko} mice with *Bsn*^{gt} mice induced a retinal phenotype in *Bsn*^{ko} mice. In our study we want to find out whether *Bsn*^{gt} mice express a residual BSN fragment, and whether its presence disrupts homeostasis processes and leads to cone photoreceptor cell death. So far, our data suggest that in addition to its synaptic function, BSN plays a role in processes of cellular homeostasis and survival of cone photoreceptors in the retina.

Genetic disruption of bassoon in two mutant mouse lines causes divergent retinal phenotypes.
Bassoon (BSN) is a presynaptic cytomatrix protein ubiquitously present at chemical synapses of the central nervous system, where it regulates synaptic vesicle replenishment and organizes voltage-gated Ca channels. In sensory photoreceptor synapses, BSN additionally plays a decisive role in anchoring the synaptic ribbon, a presynaptic organelle and functional extension of the active zone, to the presynaptic membrane. In this study, we functionally and structurally analyzed two mutant mouse lines with a genetic disruption of Bsn-Bsn and Bsn -using electrophysiology and high-resolution microscopy. In both Bsn mutant mouse lines, full-length BSN was abolished, and photoreceptor synaptic function was similarly impaired, yet synapse structure was more severely affected in Bsn than in Bsn photoreceptors. The synaptic defects in Bsn retina coincide with remodeling of the outer retina-rod bipolar and horizontal cell sprouting, formation of ectopic ribbon synaptic sites-and death of cone photoreceptors, processes that did not occur in Bsn retina. An analysis of Bsn hybrid mice revealed that the divergent retinal phenotypes of Bsn and Bsn mice can be attributed to the expression of the Bsn allele, which triggers cone photoreceptor death and neurite sprouting in the outer retina. These findings shed new light on the existing Bsn mutant mouse models and might help to understand mechanisms that drive photoreceptor death.

Odorant Binding Proteins of the Desert Locust (Orthoptera, Acrididae): Topographic Expression Patterns in the Antennae.
Odorant binding proteins (OBPs) enriched in the sensillum lymph are instrumental in facilitating the transfer of odorous molecules to the responsive receptors. In Orthopteran locust species, an in-depth understanding of this important soluble protein family is still elusive. In a previous study, we have demonstrated that the repertoire of locust OBPs can be divided into four major clades (I-IV) on the phylogenetic scale and for representatives of subfamily I-A and II-A a distinct sensilla-specific expression pattern was determined. In this study, by focusing on a representative locust species, the desert locust , we have explored the antennal topographic expression for representative OBPs of other subfamilies. First, subtypes of subfamily III-A and III-B were exclusively found in sensilla chaetica. Then, a similar expression pattern in this sensillum type was observed for subfamily I-B subtypes, but with a distinct OBP that was expressed in sensilla coeloconica additionally. Moreover, the atypical OBP subtype from subfamily IV-A was expressed in a subpopulation of sensilla coeloconica. Last, the plus-C type-B

OBP subtype from subfamily IV-B seems to be associated with all four antennal sensillum types. These results profile diversified sensilla-specific expression patterns of the desert locust OBPs from different subfamilies and complex co-localization phenotypes of distinct OBP subtypes in defined sensilla, which provide informative clues concerning their possible functional mode as well as a potential interplay among OBP partners within a sensillum.

ENDOSOMAL PHOSPHATIDYLINOSITOL 3-PHOSPHATE LEVELS CONTROL PRESYNAPTIC VESICLE CYCLING AND NEUROTRANSMISSION

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Guan-Ting Liu, Gaga Kochlamazashvili, Dmytro Puchkov, Volker Haucke, Tolga Soykan
Leibniz Institut für Molekulare Pharmakologie (FMP), Molecular Pharmacology And Cell Biology, Berlin, Germany

Neural circuit function requires mechanisms for the control of neurotransmitter release and the activity of neuronal networks including modulation by synaptic contacts, synaptic plasticity, and homeostatic scaling. The molecular mechanisms by which neurons intrinsically monitor and feedback control presynaptic neurotransmitter release and synaptic vesicle (SV) recycling to restrict neuronal network activity are poorly understood. Here we investigated the reciprocal interplay between neuronal endosomes, organelles of central importance for the function of synapses, and synaptic activity. We show that elevated neuronal activity represses the synthesis of the endosomal lipid phosphatidylinositol 3-phosphate [PI(3)P] by the lipid kinase VPS34. Neuronal activity in turn is regulated by endosomal PI(3)P, the depletion of which reduces neurotransmission as a consequence of perturbed SV endocytosis. We find that this mechanism involves Calpain 2-mediated hyperactivation of Cyclin-dependent kinase 5 (Cdk5) downstream of receptor- and activity-dependent calcium influx. Our results unravel an unexpected function for PI(3)P-containing neuronal endosomes in the control of presynaptic vesicle cycling and neurotransmission that may explain the involvement of the PI(3)P-producing VPS34 kinase in neurological disease and neurodegeneration.

THE IMPACT OF ALTERNATIVE SPLICING OF P/Q-TYPE CALCIUM CHANNELS ON SYNAPTIC PROPERTIES AND SHORT-TERM PLASTICITY

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Ana Carolina Palmeira Do Amaral[1], Jennifer Heck[2], Artur Bikbaev[1], Abderazzaq El Khallouqi[1], Anna Bodzeta[1], Melanie Mark[3], Stefan Herlitze[4], Martin Heine[1]
[1]Johannes Gutenberg University Mainz, Institute For Developmental Biology And Neurobiology, Mainz, Germany, [2]European Molecular Biology Laboratory (EMBL), Genome Biology Unit, Heidelberg, Germany, [3]Ruhr-University Bochum, Behavioral Neurobiology, Bochum, Germany, [4]Ruhr University Bochum, Department Of Zoology And Neurobiology, Bochum, Germany

Alternative splicing (AS) is crucial for expanding proteomic diversity. Here, we focus on presynaptic voltage-gated P/Q-type calcium channels ($Ca_V2.1$) that are essential for triggering transmitter release in central synapses. Their relative position to readily releasable synaptic vesicles and their regulatory role in pre-synaptic release probability are critically influenced by AS within the channel's C-terminus at exon 37 and 47. Previous investigations, focusing on the importance of these exons separately, indicated a strong relevance for short-term plasticity. Here, we ask to which extent the AS of exon 37 and 47 influence each other to tune information processing within the presynaptic compartment. To dissect how the interplay between exon 37 and 47 influences synaptic physiology, we generated four Halo-tagged channel variants, $Ca_V2.1$ [37a/+47], [37a/Δ47], [37b/+47], and [37b/Δ47]. We will examine calcium influx and glutamate release of synapses dominated by each splice variant using functional imaging in mouse hippocampal neurons. Preliminary data suggest differences in calcium influx. Moreover, the local channel dynamic organization will be investigated for each splice variant by single-molecule tracking photoactivated localization microscopy. To evaluate whether different C-terminal configurations interfere with the presynaptic localization of endogenous $Ca_V2.1$ channels, we are using a $Ca_V2.1$::YFP knock-in mouse line. Using localization microscopy, we will evaluate the density and localization of YFP-tagged versus Halo-tagged channels within individual synapses and whether different splice variants have different affinities to scaffold proteins. Concluding, our goal is to clarify the impact of exons 37 and 47 AS at the C-terminus of $Ca_V2.1$ channels on synaptic properties.

More than a pore: How voltage-gated calcium channels act on different levels of neuronal communication regulation.
Voltage-gated calcium channels (VGCCs) represent key regulators of the calcium influx through the plasma membrane of excitable cells, like neurons. Activated by the depolarization of the membrane, the opening of VGCCs induces very transient and local changes in the intracellular calcium concentration, known as calcium nanodomains, that in turn trigger calcium-dependent signaling cascades and the release of chemical neurotransmitters. Based on their central importance as concierges of excitation-secretion coupling and therefore neuronal communication, VGCCs have been studied in multiple aspects of neuronal function and malfunction. However, studies on molecular interaction partners and recent progress in omics technologies have extended the actual concept of these molecules. With this review, we want to illustrate some new perspectives of VGCCs reaching beyond their function as calcium-permeable pores in the plasma membrane. Therefore, we will discuss the relevance of VGCCs as voltage sensors in functional complexes with ryanodine receptors, channel-independent actions of auxiliary VGCC subunits, and provide an insight into how VGCCs even directly participate in gene regulation. Furthermore, we will illustrate how structural changes in the intracellular C-terminus of VGCCs generated by alternative splicing events might not only affect the biophysical channel characteristics but rather determine their molecular environment and downstream signaling pathways.

Design, Synthesis and Characterization of a New Series of Fluorescent Metabotropic Glutamate Receptor Type 5 Negative Allosteric Modulators.
In recent years, new drug discovery approaches based on novel pharmacological concepts have emerged. Allosteric modulators, for example, target receptors at sites other than the orthosteric binding sites and can modulate agonist-mediated activation. Interestingly, allosteric regulation may allow a fine-tuned regulation of unbalanced neurotransmitter' systems, thus

providing safe and effective treatments for a number of central nervous system diseases. The metabotropic glutamate type 5 receptor (mGluR) has been shown to possess a druggable allosteric binding domain. Accordingly, novel allosteric ligands are being explored in order to finely regulate glutamate neurotransmission, especially in the brain. However, before testing the activity of these new ligands in the clinic or even in animal disease models, it is common to characterize their ability to bind mGluRs in vitro. Here, we have developed a new series of fluorescent ligands that, when used in a new NanoBRET-based binding assay, will facilitate screening for novel mGluR allosteric modulators.

THE EFFECTS OF ALPHA-SYNUCLEIN ON THE PHASE SEPARATION AT SYNAPSES

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Roberto Sansevrino, Christian Hoffmann, Gwendolin Schneider, Han Wang, Dragomir Milovanovic
Deutsches Zentrum für Neurodegenerative Erkrankungen e.V. (DZNE), Molecular Neuroscience, Berlin, Germany

Neuronal communication depends on the tightly regulated spatial and temporal release of messenger molecules known as neurotransmitters. Neurotransmitters are packed into synaptic vesicles (SVs). Hundreds of SVs form biomolecular condensates through the interaction with synapsins. Other disordered proteins at the presynapse include synucleins, most notably alpha-synuclein. The precise role of alpha-synuclein in synaptic physiology remains elusive, albeit its role has been implicated in all steps of the SV cycle. To determine the effect of alpha-synuclein on the synapsin phase, we employ the reconstitution approaches using purified SVs from rat brains and the heterologous cell system to generate synapsin condensates. We demonstrate that synapsin condensates recruit alpha-synuclein, and while enriched into these synapsin condensates, alpha-synuclein still maintains its high mobility. The presence of SVs enhances the rate of synapsin/ alpha-synuclein condensation, suggesting that SVs catalyze the formation of synapsin condensates. At physiological conditions, alpha-synuclein alone cannot trigger the phase separation of SVs. Excess of alpha-synuclein attenuates the kinetics of synapsin/SV condensate formation, indicating that the molar ratio between synapsin and alpha-synuclein is important in assembling the functional condensates of SVs. Alpha-Synuclein can be depleted from synapsin condensates by synphilin 1, another intrinsically disordered, scaffold protein at the presynapse implicated in Parkinson’s Disease. Interestingly, synphilin 1 forms fluid condensates by itself, and alpha-synuclein shows the ability to wet synphilin condensates in a salt-dependent manner. Understanding the molecular mechanism of alpha-synuclein interactions at the nerve terminals is crucial for clarifying the pathogenesis of synucleinopathies, where alpha-synuclein, synaptic proteins, and lipid organelles all accumulate as insoluble intracellular inclusions.

COMPUTATIONAL MODELLING FRAMEWORK TO STUDY CA2+ ACTIVATION OF SYNAPTIC VESICLE FUSION BY DIFFERENT SYNAPTOTAGMIN ISOFORMS

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Christopher Norman[1], Shyam Krishnakumar[2,3], Yulia Timofeeva[3,4], Kirill Volynski[2,3]
[1]The University of Warwick, Mathematics For Real-world Systems Centre For Doctoral Training, Coventry, United Kingdom, [2]Yale University School of Medicine, Department Of Cell Biology, New Haven, United States of America, [3]University College London, Institute Of Neurology, London, United Kingdom, [4]Department of Computer Science, University Of Warwick, Coventry, United Kingdom

Controlled release of neurotransmitters stored in synaptic vesicles (SVs) is central to information processing in the brain. This process relies on fast (sub-millisecond) coupling of SV fusion to the triggering signal, action potential (AP)-evoked presynaptic Ca^{2+} influx. During the last three decades the key proteins that mediate SV exocytosis have been identified. Yet, the molecular mechanisms that allow synchronisation of SV fusion to APs remain in the centre of debate. SV fusion is catalysed by synaptic SNARE proteins, VAMP2 on the vesicles (v-SNAREs) and syntaxin/SNAP25 on the pre-synaptic membrane (t-SNAREs). The current prevailing view is that the SNARE assembly process is arrested in a 'half-zippered' state to prevent continuous release of neurotransmitters and to allow for rapid and synchronous SV fusion following the Ca^{2+} influx. The key players that 'clamp' vesicle release and synchronise the late SV fusion steps are complexin proteins and isoforms of the presynaptic Ca^{2+} release sensor synaptotagmin (Syt). Here we describe a computational modelling framework that allows for simulation of release controlled by the Syt1 and Syt7 isoforms under different molecular configurations and stimulation patterns. The discrete state Markov model structure is based on recent structural data describing the interaction of Syt isoforms with the SNARE complex and complexin. State transition parameters are constrained by the known Ca^{2+} and membrane binding affinities of Syt1 and Syt7. Our stochastic simulations demonstrate that this relatively simple model can successfully capture the kinetics and Ca^{2+} dependency of synchronous and asynchronous neurotransmitter release in central synapses.

Slow-decaying presynaptic calcium dynamics gate long-lasting asynchronous release at the hippocampal mossy fiber to CA3 pyramidal cell synapse.
Action potentials trigger two modes of neurotransmitter release, with a fast synchronous component and a temporally delayed asynchronous release. Asynchronous release contributes to information transfer at synapses, including at the hippocampal mossy fiber (MF) to CA3 pyramidal cell synapse where it controls the timing of postsynaptic CA3 pyramidal neuron firing. Here, we identified and characterized the main determinants of asynchronous release at the MF-CA3 synapse. We found that asynchronous release at MF-CA3 synapses can last on the order of seconds following repetitive MF stimulation. Elevating the stimulation frequency or the external Ca concentration increased the rate of asynchronous release, thus, arguing that presynaptic Ca dynamics is the major determinant of asynchronous release rate. Direct MF bouton Ca imaging revealed slow Ca decay kinetics of action potential (AP) burst-evoked Ca transients. Finally, we observed that asynchronous release was preferentially mediated by Ca influx through P/Q-type voltage-gated Ca channels, while the contribution of N-type VGCCs was limited. Overall, our results uncover the determinants of long-lasting asynchronous release from MF terminals and suggest that asynchronous release could influence CA3 pyramidal cell firing up to seconds following termination of granule cell bursting.

Introduction: Synaptic pathology is associated with over 130 brain diseases and there is a pressing need to evaluate synaptic pathology in living individuals. PET tracers targeting the presynaptic protein SV2A (Synaptic Vesicle protein 2A) can be used to quantify synapse damage or loss using brain imaging in a clinical setting. Although SV2A has been posited as a marker of all synapses, synaptome mapping studies show excitatory synapses are highly diverse (Zhu et al, *Neuron* 2018 doi.org/10.1016/j.neuron.2018.07.007). **Aims and Methodology:** To determine if SV2A was expressed in all adult mouse brain synapses we used immunostaining techniques to label synapses in brain tissue sections with antibodies to SV2A together with a battery of genetic and immunolabelled presynaptic and postsynaptic markers and then imaged individual synapses using confocal microscopy. **Results:** We focussed on cortex, hippocampus, thalamus and striatum which we confirmed were labelled with the SV2A PET tracer [^{18}F]MNI1126 *(R*-enantiomer) in living mice. Our results of presynaptic terminals labelled with SV2A showed a wide range of sizes, density and intensity. SV2A was expressed in subpopulations of excitatory and inhibitory synapses and the size of these populations varied between brain regions. **Conclusion:** Characterising the subpopulations of SV2A-positive synapses in different brain diseases will be important for interpreting imaging data obtained with SV2A PET tracers.

DEVELOPMENTAL RECONFIGURATION OF NANODOMAIN COUPLING BETWEEN CALCIUM CHANNELS AND RELEASE SENSORS AT A GABAERGIC CENTRAL SYNAPSE

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Jingjing Chen[1], Walter Kaufmann[2], Ryuichi Shigemoto[3], Peter Jonas[1]
[1]Institute of Science and Technology Austria, Cellular Neuroscience, Klosterneuburg, Austria, [2]Institute of Science and Technology Austria, Electron Microscopy Facility, Klosterneuburg, Austria, [3]Institute of Science and Technology Austria, Molecular Neuroscience, Klosterneuburg, Austria

GABAergic synapses show tight ("nanodomain") coupling between presynaptic Ca^{2+} channels and release sensors and undergo substantial changes during development. However, the exact coupling topography and stoichiometry remains unknown. To address this question, we analyzed the coupling configuration at the basket cell-to-Purkinje cell synapse in mouse cerebellum at different developmental stages, combining paired recording, intracellular pipette perfusion, transmission electron microscopy (TEM), and freeze-fracture replica immunolabeling (FRIL). To functionally probe the coupling configuration, we examined the shape of the presynaptic action potential (AP) by direct presynaptic recording. Presynaptic APs showed substantial shortening during development, suggesting reduced efficacy of Ca^{2+} channel activation. Furthermore, we probed the coupling distance between Ca^{2+} channels and release sensors by intracellular application of the Ca^{2+} chelator EGTA via patch pipette perfusion. The sensitivity of transmitter release to 10 mM EGTA decreased (IPSC-EGTA / IPSC-control: 47.6% at ~P7, 86.2% at ~P14, and 89.7% at ~P21; n = 15 pairs total; p = 0.013), indicating tightening of coupling during synaptic maturation. Structural analysis by TEM and FRIL demonstrated a change in the coupling stoichiometry. During development, the number of clusters per active zone (AZ) in basket cell terminals increased 1.59-fold, whereas the number of Ca^{2+} channels per cluster was unchanged. In contrast, the number of docked vesicles per AZ increased more strongly, 2.75-fold during synaptic maturation. Nanodomain coupling with decreasing efficacy of Ca^{2+} channel activation and increasing vesicle-to-Ca^{2+} channel cluster stoichiometric ratio during development may ensure fast and sustained transmitter release during *in vivo*-like repetitive activity at cerebellar GABAergic synapses.

EVIDENCE FOR LOCAL FATTY ACID METABOLISM IN PRESYNAPTIC BOUTONS

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Anne-Sophie Hafner, Sara Said
Donders Centre for Neuroscience, Department Of Molecular Neurobiology, Radboud University, Nijmegen, Netherlands

The brain is the fattiest organ in our body, roughly 60% of its dry mass. Nonetheless, lipids (fatty acids, phospholipids, cholesterols) are seldom overlooked in Neuroscience. Strikingly, individuals consuming a diet rich in saturated fatty acids are twice as likely to exhibit a form of dementia, an age-related condition characterized by deteriorating cognitive abilities. The biological mechanisms underlying this increased risk are unknown. The blood brain barrier is permeable to fatty acids known in other organs (e.g. pancreas) to incorporate into membrane bilayers and change the fusion properties of intracellular vesicles. In neurons, synaptic vesicles fuse with the presynaptic membrane to pass on information. **Could fatty acid metabolism regulate synaptic vesicle fusion?** Recently, I published the transcriptome of forebrain excitatory presynaptic boutons. Surprisingly, the mRNA coding for the enzyme FASN (fatty acid synthetase) -the central enzyme in the biosynthesis of fatty acids- appeared to be highly abundant in these subcellular compartments. Importantly, **FASN is a rate-limiting enzyme. Thus, increasing FASN copy number at boutons through local translation of FASN mRNA, will result in an increased production of fatty acids, namely palmitic acids**. Using biochemistry, immunocytochemistry and in situ hybridization assays on synaptosomes prepared from adult mouse brains, we validated the presence of FASN mRNA and protein at both excitatory and inhibitory presynapses. Our preliminary data subject that the presence of FASN is tightly linked to the presence of mitochondria inside a bouton. This work opens a new door toward a better undertanding of the role of lipid metabolism in synaptic function.

DISSECTING THE FUNCTIONAL CONSEQUENCES OF CAPS DELETION ON SEROTONIN RELEASE FROM MOUSE ENTEROCHROMAFFIN CELLS.

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Sudeeksha Tyagi[1], Ahmed Shaaban[1], Sabine Beuermann[2,3], Frederike Maaß[2,4], Benjamin Cooper[2,3], Cordelia Imig[1]
[1]University of Copenhagen, Department Of Neuroscience, Copenhagen N, Denmark, [2]Max Planck Institute of Experimental Medicine, Department Of Molecular Neurobiology, Göttingen, Germany, [3]Max Planck Institute for Multidisciplinary Sciences, Department Of Molecular Neurobiology, Göttingen, Germany, [4]Max Planck Institute for Multidisciplinary Sciences, Department Of Nanobiophotonics, Göttingen, Germany

Enterochromaffin cells of the intestinal epithelium are the predominant producers of serotonin (5-HT) in the body with an estimated 95% of total 5-HT residing in the gut. Enterochromaffin cells are chemo- and mechanosensitive and respond to nutrients, metabolites, and physical force. An increasing number of studies have uncovered the functions of 5-HT in the periphery, which range from regulation of gut motility to its role in homeostatic metabolism. Although there is a growing understanding of the different mechanisms orchestrating these functions, the cellular mechanisms and molecular machinery responsible for the transduction of stimuli to 5-HT secretion is largely unknown. To gain a better understanding of the 5-HT release machinery in the gut, we investigated the roles of Calcium-dependent activator protein for secretion (CAPS) 1 and 2 in enterochromaffin cells. CAPS proteins are important components of the neuronal presynaptic release machinery with established roles in neuronal transmitter release, short-term plasticity, and importantly, in the priming of secretory granules in neuroendocrine cells and neurons. To this end, we established the expression of CAPS1 in mouse and human enterochromaffin cells using immunocytochemistry and biochemical assays, and generated CAPS1 knock-out organoids derived from adult mouse intestinal epithelial stem cells. The functional consequences of CAPS1 loss were measured using single-cell carbon fiber amperometry to detect 5-HT release from individual fusing granules. We present here an experimental workflow to study on the single cell level the role of individual molecular components of the presynaptic vesicle fusion machinery in the regulation of 5-HT secretion in the gut.

The ionotropic glutamate delta receptor GluD1, encoded by the GRID1 gene on chromosome 10, is involved in synapse formation, function, and plasticity. GluD1 does not bind glutamate, but instead cerebellin and D-serine, which allow the formation of trans-synaptic bridges, and trigger metabotropic signaling. Though widely expressed in the nervous system, pathogenic mutations of GluD1 have not been characterized in humans so far. We report homozygous missense GRID1 mutations in siblings from two consanguineous families presenting with intellectual disability and spastic paraplegia, without or with glaucoma, a threefold phenotypic association whose genetic bases had not been elucidated previously. Molecular modeling indicated that one mutation alters cooperativity between cerebellin and D-serine binding GluD1 domains, whereas the other mutation alters D-serine binding. Expression, trafficking, physical interaction with metabotropic glutamate receptor mGlu1, and cerebellin binding of GluD1 mutants were not conspicuously altered. Conversely, we found that GluD1 mutants hampered signaling of metabotropic glutamate receptor mGlu1/5 via the ERK pathway in primary cortical cell culture. Moreover, both mutants impaired dendrite morphology and excitatory synapse density in neurons of primary hippocampal culture. These results show that the clinical phenotypes are distinct entities segregating in the families as an autosomal recessive trait, and caused by pathophysiological effects of GluD1 mutants involving metabotropic glutamate receptor signaling and neuronal connectivity. Our findings unravel the importance of the GluD1 receptor signaling in sensory, cognitive and motor functions of the human nervous system.

MDGA1 AND MDGA2 DIFFERENTIALLY INTERACT WITH NEUROLIGIN-2 TO FUNCTIONALLY REGULATE INHIBITORY SYNAPSES

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Tommaso Zeppillo[1,2], Heba Ali[2], Sally Wenger[2], Francisco J. Lopez-Murcia[2], Michael Schmeisser[1], Nils Brose[2], Holger Taschenberger[2], Dilja Krueger-Burg[1,2,3]
[1]Universitätsmedizin der Johannes-Gutenberg Universität Mainz, Institute For Microscopic Anatomy And Neurobiology, Mainz, Germany, [2]Max Planck Institute of Multidisciplinary sciences, Department Of Molecular Neurobiology, Göttingen, Germany, [3]University Medical Center of the Georg-August-University Göttingen, Department Of Psychiatry And Psychotherapy, Göttingen, Germany

Alterations in synaptic inhibition are noted causes of many psychiatric disorders, and accordingly, understanding the molecular components regulating their formations is crucial for new treatments. Two of these components are the postsynaptic protein Neuroligin-2 (Nlgn2), which plays a key role in the formation of inhibitory synapses by binding the presynaptic proteins of the Neurexin (NRX) family, and the MAM-domain-GPI-anchored proteins 1 and 2 (MDGA1-MDGA2), which recently aroused interest due to their ability to bind Nlgn2 at the same binding site as the NRXN family members. Here, we generated MDGA1 x Nlgn2 double KO (dKO) and MDGA2-het x Nlgn2 KO mice, to investigate the consequences of the Nlgn2-MDGA interaction for the structure and function of inhibitory synapses in the adult hippocampal area CA1 and amygdala. We show that MDGA1 is differentially expressed across CA1 layers, with a nearly absent expression in the stratum pyramidale, and that absence of MDGA1 and MDGA2 alters gephyrin, VIAAT, and $GABA_A$Rs γ2-subunit expression in a layer specific manner. Moreover, several phenotypes characteristic of the Nlgn2 KO mice, i.e., the increase in extrasynaptically located gephyrin aggregates, the impairment of GABAergic transmission, and the increased anxiety-related behavior, are partially normalized in MDGA1 x Nlgn2 dKO but not in MDGA2-het x Nlgn2 KO mice. In conclusion, our study shows that MDGA1 and MDGA2 functionally interact with Nlgn2 to allow for the correct assembly of inhibitory synapses. Moreover, our data place MDGA1 rather than MDGA2 as a new target for anxiolytic treatments.

Leucine-Rich Repeat Transmembrane (LRRTM) proteins are adhesion molecules enabling neurons to connect and communicate at **synapses**. Mutations in the genes encoding LRRTMs, their synaptic partners, neurexins and their functional competitors, neuroligins, are associated with psychiatric and neurological disorders. However, the molecular regulation of LRRTMs and how they structure and modulate synapse strength remain elusive. **LRRTM2**, the most synaptogenic member of the family, is exclusively localised and enriched at excitatory synapses, where it exhibits low **membrane dynamics**. Interestingly, LRRTM2 is involved in synaptic transmission and plasticity and regulates the surface levels of **AMPARs**, the main glutamatergic receptors responsible for fast neurotransmission in the brain. In this project, we investigated the molecular mechanisms underlying LRRTM2 **stabilisation** and **trafficking** at excitatory synapses, as well as the **interplay between LRRTM2 and AMPARs**. We developed a structure-function approach in a novel transgenic mouse model where LRRTM2 is conditionally knocked-out during synapse formation. We demonstrated that the C-terminal domain of LRRTM2 controls its compartmentalisation in dendrites as well as its enrichment and compaction at synapses. Surprisingly, LRRTM2 **synaptic confinement** was found to be independent of its PDZ-like binding domain and was instead regulated by the recently identified YxxC intracellular sequence, also critical for LRRTM2 trafficking and **exocytosis**. We then showed that the recently identified neurexin-binding site in LRRTM2 (E348) is involved in membrane stabilisation of synaptic AMPARs. These results demonstrate that the intracellular region of LRRTM2 controls its **synaptic clustering**, membrane dynamics and confinement, while extracellular binding interfaces are involved in stabilising AMPARs at the synapse.

The Activity Regulated-Cytoskeleton associated-protein Arc is pivotal to mediate plastic responses in neuronal cells. In vitro studies suggest its ability to form large and small order oligomers which are potentially involved in interneuronal trafficking. Despite its important function, no direct observation of Arc oligomers in cells has been presented due to the small size, and lack of appropriate labelling strategies. Here, we take advantage of STED microscopy to study Arc nanoscale organization in cellular environment especially at the synapses. Arc oligomers role in the regulation of AMPA receptor surface levels, together with their close association to the plasma membrane, were addressed via chemical mutagenesis and molecular dynamic simulation studies. Furthermore, for the first time, Arc-Arc molecular interaction and its liquid-liquid phase separation properties were uncovered in cellular system. Together, our observations support the model by which Arc oligomerization at the post-synaptic endocytic zone, favors AMPA receptors endocytosis inducing plasma membrane curvature.

Aim: Protein turnover is required for synapse maintenance and activity-dependent remodelling. The lifetime of synaptic proteins may be brain region- and synapse-specific, but due to technical limitations endogenous protein turnover in individual synapses had not been examined to date. We quantified the lifetime of postsynaptic scaffolding protein PSD95 in individual excitatory synapses across the mouse brain and lifespan. **Methods:** Transgenic mice carrying a HaloTag domain fused to endogenous PSD95 were intravenously injected with a fluorescent ligand that irreversibly binds the HaloTag domain, labelling PSD95 containing synapses with a fluorescent date-stamp. Fluorescent protein levels were visualized in brain sections using confocal microscopy, with loss of fluorescence over time used for estimating PSD95 protein degradation. **Results:** PSD95 protein lifetime differed more than 6-fold between brain regions in adult mice, from ~1-2 days in olfactory bulb and thalamic nuclei to ~10-12 days in the superficial layers of the cortex. Protein lifetime increased with age, from development to adulthood and into ageing. Synapse subtypes, as defined by molecular and morphological features, revealed distinct PSD95 protein lifetimes. Short protein lifetime (SPL) synapses were enriched in developing animals and in regions controlling innate behaviours. Long protein lifetime (LPL) synapses accumulated during development, were enriched in the cortex and CA1 and were preferentially preserved in old age. **Conclusion:** Synapses with diverse protein lifetimes show distinct spatial distributions across the brain and are differentially affected during development and ageing. Brain-wide maps of synaptic protein lifetime will form a valuable resource for future research into molecular and synapse biology.

ANALYSIS OF SYNAPTIC NANOARCHITECTURE USING FRET AT THE LEVEL OF SINGLE PROTEIN COMPLEXES AND AT THE WHOLE MOUSE BRAIN SCALE

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Takeshi Kaizuka[1], Katie Morris[2], Ricky Qiu[1], Edita Bulovaite[1], Gabor Varga[1], Noboru Komiyama[1], Mathew Horrocks[2], Seth Grant[1]
[1]University of Edinburgh, Centre For Clinical Brain Sciences, Edinburgh, United Kingdom, [2]University of Edinburgh, School Of Chemistry, Edinburgh, United Kingdom

Proteins within the postsynaptic terminal of excitatory synapses play an essential role in synaptic physiology and behaviour. Individual proteins are physically organised into multiprotein complexes and supercomplexes. Recent studies using super-resolution microscopy reveal that postsynaptic proteins are not uniformly distributed but form nanoclusters where the proteins are densely distributed. However, these studies are limited to a spatial resolution of 20-50nm. To study the postsynaptic nanoarchitecture at a resolution of 1-10nm, we have used Förster Resonance Energy Transfer (FRET) on brain tissue and brain extracts from mice containing genetic tags on the C-terminus of PSD95, an abundant postsynaptic scaffold protein that controls synaptic plasticity and learning. Individual protein complexes containing PSD95 were examined using both single-molecule confocal and total internal reflection fluorescence (TIRF) microscopy and found to contain dimers of PSD95 that lacked FRET, indicating their C-terminal labels are separated by >10nm. In intact synapses in the brain, however, we were able to detect FRET between PSD95 molecules carrying a PSD95-HaloTag labelled with mixtures of HaloTag flurophore-labelled ligands or mice carrying PSD95-HaloTag and PSD95-CLIP tags. Synaptic PSD95 FRET intensity and efficiency was quantified from individual synapses imaged across whole sagittal sections of mouse brain and showed variation between brain regions. These findings indicate that PSD95 multiprotein complexes are closely packed in synapses and that this packing differs between synapses in areas of the brain.

ENDOCYTOSIS AND POLARITY MAINTENANCE AT THE AXON INITIAL SEGMENT

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Vivek Belapurkar[1], Kelsie Eichel[2], Kang Shen[2], David Perrais[1]
[1]University of Bordeaux, CNRS, UMR5297, Interdisciplinary Institute For Neuroscience, Bordeaux, France, [2]Howard Hughes Medical Institute, Department Of Biology, Stanford University, Stanford, United States of America

Neurons are highly polarized cells with sorting of proteins between dendrites and axon. A key component for this sorting is the axon initial segment (AIS), a specialized structure at the proximal end of the axon concentrating protein complexes of actin, βIV-spectrin, ankyrinG and anchored transmembrane proteins such as sodium channels. At least two mechanisms maintaining polarity and which occur in the AIS have been identified. First, the AIS forms a diffusion barrier on the membrane, preventing intermixing of somatic and dendritic constituents. Second, intracellular vesicles are sorted for transport, distinguishing dendritic from axonal vesicles. In this work, we tested the possibility that endocytosis of dendritic cargo at the AIS constitutes another mechanism which maintains neuronal polarity. We used rat hippocampal neurons transfected at 7 DIV with the transferrin receptor, a dendritic receptor, tagged with Superecliptic pHluorin (TfR-SEP). The AIS was identified by co-transfection with NavII-III-mScarlet or by live antibody labelling of neurofascin. We measured with the pulsed pH assay (Sposini et al. Nature Protocols 2020) the rate of endocytosis in the soma, proximal dendrites and AIS of neurons at 9-10 DIV. We found that endocytic events occurred at similar rates in all compartments, arguing for an active role of endocytosis in maintaining the dendritic membrane proteins in their normal compartment. Using *C elegans* neurons, we showed that selective inhibition of endocytosis of dendritic proteins at the AIS leads to defective axon-dendrite polarity. We thus propose that endocytosis at the AIS is an important, evolutionary conserved mechanism to maintain neuronal polarity.

NERVE GUIDANCE IN CANCER: A NEW ROLE FOR NETRIN-1

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Hiba Haidar[1], Benjamin Gibert[2], Patrick Mehlen[2], Fanny Mann[1]
[1]Aix Marseille Univ,, Cnrs, Ibdm, Marseille, France, [2]Apoptosis, Cancer and Development Laboratory, Centre De Recherche En Cancérologie De Lyon, Inserm U1052-cnrs Umr5286, Lyon, France

Aims: Nerve-tumor interactions have received increased attention recently because of their effect on tumorigenesis. We have demonstrated that sympathetic axons remodel and branch during early development of pancreatic ductal adenocarcinoma (PDAC), but the underlying molecular mechanisms are still unknown. Netrin-1 is a secreted protein involved in axon guidance during embryonic development and known to be reexpressed in cancers. Here we investigated the role of Netrin-1 in PDAC tumor-induced neuronal plasticity. **Methods:** Expression of Netrin-1 and its receptors was analyzed in transgenic mouse model of PDAC (KIC mice) and in a model of metaplastic lesions (precursor lesions of PDAC) induced by chronic inflammation. The function of Netrin-1 on axonal remodeling was studied using a humanized Netrin-1 blocking antibody (NET-H-mab) and by conditional genetic deletion of netrin-1. Sympathetic axonal density was measured on tissue sections or whole cleared organs. **Results:** During pancreatic inflammation, Netrin-1 was detected in proinflammatory macrophages and pancreatic metaplastic cells, while the Netrin-1 receptor DCC was reexpressed on sympathetic axons. Blockage of Netrin-1 by NET-H-mab administration resulted in a decrease of sympathetic axonal density around metaplastic lesions. To identify the source of Netrin-1 responsible for this effect, we generated transgenic mouse models with conditional knockdown of netrin-1 in macrophages or in pancreatic cells. Preliminary results revealed no significant change of sympathetic axonal density when netrin-1 was depleted from macrophages. **Conclusion:** Our results suggest that Netrin-1 expression in metaplastic pancreatic lesions triggers sympathetic axonal plasticity, possibly through the axonal receptor DCC.

TAU – A MASTER REGULATOR OF RECYCLING SYNAPTIC VESICLE CLUSTERING AT THE PRESYNAPSE

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Shanley Sanders[1], Ramón Martínez-Mármol[1], Merja Joensuu[1], Mahdie Mollazade[1], Tristan Wallis[1], Rachel Gormal[1], Jesse Wark[2], Ashley Waardenberg[3], Christopher Small[1], Mark Graham[2], Frederic Meunier[1]
[1]University of Queensland, Clem Jones Centre For Ageing Dementia Research (cjcadr), Queensland Brain Institute (qbi), St Lucia, Australia, [2]University of Sydney, Synapse Proteomics, Children's Medical Research Institute, Westmead, Australia, [3]James Cook University, Australian Institute Of Tropical Health & Medicine, Smithfield, Australia

Background: Synaptic vesicles (SVs) underpin neuronal communication through fusion and the release of neurotransmitters at the synaptic cleft. SVs form homogenous clusters adjacent to their active zone and are characterised into functional pools differentiated by their release properties. The molecular mechanisms that link the organisation of SVs into pools and their clustering remain unknown. Recently, liquid-liquid phase separation (LLPS) has been suggested to control the organisation of SVs into clusters. The microtubule-binding protein Tau is a highly phosphorylated and intrinsically disordered protein found to form LLPS *in vitro* and bind SVs. **Aim:** To assess the ability of Tau to form nano-biomolecular condensates at the pre-synapse and investigate its role in the organisation of SVs. **Methods:** Activity-dependent phosphoproteome analysis of hippocampal neurons. Subdiffractional tracking of internalised molecules, single-particle tracking photo-activated localisation microscopy and nanoscale spatiotemporal index clustering of trajectory segments. **Results:** Pharmacological modulation of synaptic protein phosphorylation significantly impacted the mobility of recycling SVs. Tau knockout (KO) increased the mobility of recycling vesicles, making this pool insensitive to pharmacological phosphorylation. Re-expression of Tau in the Tau KO background restored the mobility of recycling vesicles to control levels. Using rescued expression of Tau-mEos2 in Tau KO background and TALEN-based gene-edited mice expressing endogenous Tau-mEos2, we demonstrate that Tau forms transient nano-biomolecular condensates, that are highly sensitive to stimulation, level of expression and to 1,6-hexanediol, an aliphatic alcohol capable of dissolving biomolecular condensates. **Conclusion:** Tau regulates the nanoscale organisation of the recycling pool of SVs by forming nano-biomolecular condensates sensitive to synaptic activity.

SYNAPTIC INTERLEUKIN-4 RECEPTOR SIGNALING MODULATES NEURONAL NETWORK ACTIVITY

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Christina Francisca Vogelaar[1], Nicholas Hanuscheck[1], Carine Thalman[1], Micaela Domingues[1], Samantha Schmaul[1], Manuela Ecker[1], Johannes Vogt[2], Frauke Zipp[1]
[1]University Medical Center of the Johannes Gutenberg University Mainz, Department Of Neurology, Section Neuroimmunology, Mainz, Germany, [2]University of Cologne, Faculty of Medicine and University Hospital Cologne, Department Of Molecular And Translational Neurosciences, Cologne, Germany

There is emerging evidence that immune responses not only play a part in the central nervous system (CNS) in disease, but may also be relevant for healthy conditions. We have previously shown neuro-protective and –regenerative effects of interleukin-4 (IL-4) in neuroinflammation and identified a direct neuronal signaling pathway via IRS1-PI3K-PKC, leading to axonal repair (Vogelaar et al., STM, 2018). Based on this signaling pathway, we now hypothesized a homeostatic role in synaptic function. We discovered a major role for the IL-4/IL-4Rα signaling pathway in synaptic processes. IL-4Rα is expressed presynaptically and locally available IL-4 regulates synaptic transmission (Hanuscheck et al, JEM, 2022). IL-4Rα-deficient neurons displayed reduced synaptic vesicle pools, altered postsynaptic currents and a higher excitatory drive in cortical networks. IL-4 treatment of wild type neurons led to increased inhibitory postsynaptic currents, mediated via PKCγ signaling. In fact, deficiency of IL-4Rα resulted in increased network activity in vivo, accompanied by altered exploration and anxiety-related learning behavior. We conclude that neuronal IL-4Rα and its presynaptic prevalence appears relevant for maintaining homeostasis of CNS synaptic function. Vogelaar CF*, Mandal S*, Lerch S*, et al. Fast direct neuronal signaling via the IL-4 receptor as therapeutic target in neuroinflammation. **Sci Translational Medicine,** 10, doi: eaao2304 (2018)

INTERLEUKIN-4 RECEPTOR SIGNALING MODULATES NEURONAL TRANSCRIPTOME

POSTER SESSION 07 - SECTION: SYNAPTIC ARCHITECTURE

Samantha Schmaul, Nicholas Hanuscheck, Micaela Domingues, Muthuraman Muthuraman, Christina Francisca Vogelaar, Frauke Zipp
University Medical Center of the Johannes Gutenberg University Mainz, Department Of Neurology, Section Neuroimmunology, Mainz, Germany

Interleukin-4 (IL-4) is a pleiotrophic cytokine that acts not only peripherally on immune cells, but also directly on neurons. We recently identified a neuronal IL-4 receptor alpha (IL-4Rα) signaling pathway and showed direct effects of locally applied IL-4 on axonal regeneration in experimental autoimmune encephalomyelitis, the mouse model for multiple sclerosis, without affecting the immune system (Vogelaar et al, STM, 2018). Using different techniques, we demonstrated cortical and hippocampal expression of IL-4Rα by neurons. Transcriptome analysis of mouse and human neurons revealed differential regulation of synaptic processes and vesicle signaling, as well as IL-4/IL-4Rα-dependent regulation of molecules involved in excitatory and inhibitory transmission (Hanuscheck et al, JEM, 2022). To distinguish whether these effects may be receptor subtype specific we have characterized the subtype expression regulation in different brain regions and cell types. We conclude that IL-4/IL-4Rα signaling in mouse neurons is largely influencing genes involved in synaptic transmission, placing IL-4 at a central position for brain homeostasis. Background: Intact mitochondrial function is required for synaptic ATP maintenance and Ca^{2+} buffering capacity, being important in synaptic structural maintenance. However, molecular targets linking synaptic neuronal activity and mitochondria remain scarce. Postsynaptic SAPAP3 scaffolding protein is involved in synaptic structure maintenance and its defects have been linked to several human pathologies. **Aims:**To uncover SAPAP3 as a possible mitochondrial regulator, establishing a link between synaptic and mitochondrial function. **Methods:**SAPAP3 interactome was assessed by mass spectrometry using rat synaptoneurosomes. Protein proximity ligation assay (PLA) was used to define SAPAP3 physical interaction with mitochondrial interactor (Mic60). Silencing (sh) SAPAP3 plasmids were used to study SAPAP3 involvement on mitochondrial function and dynamics inST*Hdh*$^{Q7/Q7}$cells and WT striatal primary neurons. Also, we studied isolated mitochondria from SAPAP3 knock-out (KO) mouse brains. **Results:**Data show that SAPAP3 molecular interactors are mainly mitochondrial, being Mic60 the one with the highest affinity. SAPAP3/Mic60 physical interaction was confirmed by PLA. Moreover, SAPAP3 preferentially co-localized with mitochondria in striatal cells. Following silencing, SAPAP3 mitochondrial levels were reduced in striatal neurons and ST*Hdh*$^{Q7/Q7}$ cells, accompained by decreased interaction with Mic60. In these cells, mitochondrial morphology was impaired, followed by decreased mitochondrial neurite trafficking. Disrupting SAPAP3 triggered mitochondrial dysfunction through diminished membrane potential, augmented reactive oxygen species (ROS) levels, altered mitochondrial Ca^{2+} buffering capacity, and reduced activity of mitochondrial respiratory complexes in SAPAP3-KO mouse cortex and striatum. **Conclusions:** ur study reveals a novel role for SAPAP3 in regulating mitochondrial function and dynamics that goes beyond its prototypical role as a synaptic scaffolding protein.

CKII MEDIATED AXONL PLASTICITY VIA MITOCHONDRIA NCLX CA2+ HANDLING

POSTER SESSION 07 - SECTION: MITOCHONDRIA

Tomer Katoshevski[1], Lior Bar[2], Eliav Tikochinsky[2], Bernard Attali[2], Israel Sekler[1]
[1]Ben Gurion University, Department Of Physiology And Cell Biology, Beer Sheva, Israel, [2]Tel-Aviv University, Department Of Physiology & Pharmacology, Tel Aviv, Israel

Mitochondrial Ca^{2+} -$[Ca^{2+}]$m signaling has several key roles in cell function, such as regulating ATP production and cell apoptosis. Ca^{2+} flows into the mitochondria through the mitochondrial Ca^{2+} uniporter and is extruded through much slower Na^{+}/Ca^{2+} exchanger, NCLX, a rate limiting step in mitochondrial Ca^{2+} transport. Mass spectral analysis of NCLX revealed the presence of a Casein Kinase 2 (CKII) phosphorylation site, on the regulatory loop on Ser271 residue. Previous studies showed that the axon initial segment (AIS) plasticity is dependent on CKII activity. The AIS, the spike generation region of the axon, can exhibit plasticity over time, a vital proses for a dynamic neuronal network. One method of triggering AIS plasticity is via direct blocking of axonal M-type K^{+} channels, which induces a distal relocation of Na^{+} and M-channels on the AIS. We hypothesized that this AIS plasticity is directly linked to $[Ca^{2+}]$m handling by NCLX. First, we tested whether CKII inhibitor TBCA affect NCLX activity, and found that its application downregulated NCLX dependent $[Ca^{2+}]$m efflux. Furthermore, we showed that phosphomimetic mutant S271A and S271D, a constitutively active or inhibited NCLX mutants, respectively and independently of TBCA, had a similar effect on NCLX activity. Finally, we found that CKII dependent AIS distal plasticity, is blocked in NCLX KO hippocampal neurons. Thus, our results indicate that CKII is a crucial regulator of NCLX and thereby controls AIS plasticity.

INVESTIGATING THE ROLE OF CALCIUM IN REGULATION OF MITOCHONDRIAL DYNAMICS IN MYELINATING OLIGODENDROCYTES.

POSTER SESSION 07 - SECTION: MITOCHONDRIA

Dagny Gammelsaeter[1], Sverre Grødem[2], Jawed Azimi[1], Ada Greve[2], Marianne Fyhn[2], Magnar Bjørås[3,4], Johanne Rinholm[1,3]
[1]Institute for basic medical sciences, Faculty of Medicine, University of Oslo, Department Of Molecular Medicine, Oslo, Norway, [2]University of Oslo, Department Of Biosciences, Oslo, Norway, [3]Division of laboratory medicine,Oslo University Hospital (Rikshospitalet), Department Of Microbiology, Oslo, Norway, [4]Norwegian University of Science and Technology, Institute Of Clinical And Molecular Medicine, Trondheim, Norway

Myelin is a lipid-rich membrane that wraps around axons and facilitates rapid action potential propagation. Myelin loss is seen in many brain diseases including MS, stroke, diabetes and early stages of dementia. In the brain myelin is synthesized and maintained by oligodendrocytes. This is an energy demanding process, requiring an increase in ATP and carbon substrates obtained through a surge of mitochondrial activity. We know very little about the dynamics of oligodendrocyte mitochondria and it is unclear how mitochondria are recruited to active myelination sites. A better understanding of how the energy producing mitochondria are controlled during myelination, could lead to new therapies for myelin loss in the future. The objective of this project is to investigate the role of calcium as a regulator of mitochondrial dynamics in myelinating oligodendrocytes. We use a combination of viral transduction and live confocal imaging of mitochondria and calcium transients in myelinating oligodendrocytes in organotypic mouse brain slices.

The high demand of neurons for energy and calcium buffering capacity highlights the importance of properly functioning mitochondria in the nervous system. Strikingly, dysfunction and abnormal morphology of mitochondria are observed in several neurodegenerative diseases. The mitochondrial isoform of the actin nucleator SPIRE1 (mitoSPIRE1) was shown to have a regulatory function in both mitochondrial division and motility. Although mitoSPIRE1 is expressed in the mouse brain, its role in the nervous system is still unknown. In our current study, we investigate, in which distinct regions and cell types of the brain mitoSPIRE1 is expressed and which functions mitoSPIRE1 fulfills in the mouse brain. To this end, we examine the brains as well as primary neurons and astrocytes isolated from mitoSPIRE1 knockout mice, in which mitoSPIRE1 is specifically knocked out while the vesicular SPIRE1 isoforms are still present. Currently, we quantitatively measure mitoSPIRE1 gene expression in primary neurons and astrocytes isolated from cortex, hippocampus and cerebellum. Furthermore, we examine the effects of a mitoSPIRE1 knockout on the mitochondrial morphology and dynamics, focusing on mitochondrial length and motility. Here, mitochondrial parameters are determined by fluorescence microscopy and analyzed in a semi-automated way using the Imaris software. Moreover, we investigate whether a loss of mitoSPIRE1 facilitates neurodegenerative changes in the mouse brain by histological analysis. We hypothesize that mitoSPIRE1 is expressed in neurons and astrocytes and that it is involved in the regulation of mitochondrial morphology and dynamics in both cell types, thus possibly playing a role in the homeostasis of the nervous system.

Neuronal mitochondria are central to not only maintaining cellular bioenergetics, calcium dynamics and modulation of ROS signalling, but are also critical for specialized functions including synaptic plasticity and neurotransmission. While mitochondria are postulated to have a fundamental role in the functioning of neurons, it's only recently that factors that influence mitochondria in neurons and the central nervous system are being investigated. Here, we identify a critical role of neurotransmitter Norepinephrine in modulating mitochondria in rodent hippocampal cells. Norepinephrine increases mitochondrial biogenesis, enhances the expression of regulators of mitochondrial biogenesis, regulates ATP synthesis and influences mitochondrial function. Increasing Norepinephrine content at the synapse via treatment with selective norepinephrine reuptake inhibitors, also evoked robust increases in mitochondrial biogenesis and ATP content. These effects of Norepinephrine appear to be mediated by the β adrenergic receptor subtypes and involve a critical role of the master modulator of mitochondrial biogenesis PGC1a. These findings identify a novel and exciting role for Norepinephrine in impacting mitochondrial turnover and biogenesis in the hippocampus.

Thyroid hormone regulation of adult hippocampal neurogenesis: Putative molecular and cellular mechanisms.
Adult hippocampal neurogenesis is sensitive to perturbations in thyroid hormone signaling, with evidence supporting a key role for thyroid hormone and thyroid hormone receptors (TRs) in the regulation of postmitotic progenitor survival and neuronal differentiation. In this book chapter we summarize the current understanding of the effects of thyroid hormone signaling on adult hippocampal progenitor development, and also critically address the role of TRs in regulation of distinct aspects of stage-specific hippocampal progenitor progression. We highlight actions of thyroid hormone on thyroid hormone responsive target genes, and the implications for hippocampal progenitor regulation. Given the influence of thyroid hormone on both mitochondrial and lipid metabolism, we discuss a putative role for regulation of metabolism in the effects of thyroid hormone on adult hippocampal neurogenesis. Finally, we highlight specific ideas that require detailed experimental investigation, and the need for future studies to obtain a deeper mechanistic insight into the influence of thyroid hormone and TRs in the developmental progression of adult hippocampal progenitors.

Chronic hM4Di-DREADD-Mediated Chemogenetic Inhibition of Forebrain Excitatory Neurons in Postnatal or Juvenile Life Does Not Alter Adult Mood-Related Behavior.
G-protein-coupled receptors (GPCRs) coupled to G signaling, in particular downstream of monoaminergic neurotransmission, are posited to play a key role during developmental epochs (postnatal and juvenile) in shaping the emergence of adult anxiodepressive behaviors and sensorimotor gating. To address the role of G signaling in these developmental windows, we used a CaMKIIα-tTA::TRE hM4Di bigenic mouse line to express the hM4Di-DREADD (designer receptor exclusively activated by designer drugs) in forebrain excitatory neurons and enhanced G signaling via chronic administration of the DREADD agonist, clozapine--oxide (CNO) in the postnatal window (postnatal days 2-14) or the juvenile window (postnatal days 28-40). We confirmed that the expression of the HA-tagged hM4Di-DREADD was restricted to CaMKIIα-positive neurons in the forebrain, and that the administration of CNO in postnatal or juvenile windows evoked inhibition in forebrain circuits of the hippocampus and cortex, as indicated by a decline in expression of the neuronal activity marker c-Fos. hM4Di-DREADD-mediated inhibition of CaMKIIα-positive forebrain excitatory neurons in postnatal or juvenile life did not impact the weight profile of mouse pups, and also did not influence the normal ontogeny of sensory reflexes. Further, postnatal or juvenile hM4Di-DREADD-mediated inhibition of CaMKIIα-positive forebrain excitatory neurons did not alter anxiety- or despair-like

behaviors in adulthood and did not impact sensorimotor gating. Collectively, these results indicate that chemogenetic induction of G signaling in CaMKIIα-positive forebrain excitatory neurons in postnatal and juvenile temporal windows does not appear to impinge on the programming of anxiodepressive behaviors in adulthood.

GPCR signaling: role in mediating the effects of early adversity in psychiatric disorders.
Early adversity is a key risk factor for the development of several psychiatric disorders, including anxiety and depression. During early life, neurocircuits that regulate emotionality undergo substantial structural remodeling and functional maturation, and are thus particularly susceptible to modification by environmental experience. Preclinical evidence indicates that early stress enhances adult anxio-depressive behaviors. A commonality noted across diverse early stress models is life-long alterations in neuroendocrine stress responses and monoaminergic neurotransmission in key limbic circuits. Dysregulation of G protein-coupled receptor (GPCR) signaling is noted across multiple early stress models and is hypothesized to be an important player in the programming of aberrant emotionality. This raises the possibility that disruption of GPCR signaling in key limbic regions during critical temporal windows could establish a substrate for enhanced risk of adult psychopathology. Here, we review literature, predominantly from preclinical models, which supports the building hypothesis that a disruption of GPCR signaling could play a central role in programming persistent molecular, cellular, functional, and behavioral changes as a consequence of early adversity.

Chronic postnatal chemogenetic activation of forebrain excitatory neurons evokes persistent changes in mood behavior.
Early adversity is a risk factor for the development of adult psychopathology. Common across multiple rodent models of early adversity is increased signaling via forebrain Gq-coupled neurotransmitter receptors. We addressed whether enhanced Gq-mediated signaling in forebrain excitatory neurons during postnatal life can evoke persistent mood-related behavioral changes. Excitatory hM3Dq DREADD-mediated chemogenetic activation of forebrain excitatory neurons during postnatal life (P2-14), but not in juvenile or adult windows, increased anxiety-, despair-, and schizophrenia-like behavior in adulthood. This was accompanied by an enhanced metabolic rate of cortical and hippocampal glutamatergic and GABAergic neurons. Furthermore, we observed reduced activity and plasticity-associated marker expression, and perturbed excitatory/inhibitory currents in the hippocampus. These results indicate that Gq-signaling-mediated activation of forebrain excitatory neurons during the critical postnatal window is sufficient to program altered mood-related behavior, as well as functional changes in forebrain glutamate and GABA systems, recapitulating aspects of the consequences of early adversity.

ROLE OF INTRAMEMBRANE SPASTIC PARAPLEGIA PROTEINS IN ORGANIZATION OF AXONAL ER AND ER-MITOCHONDRIA CONTACTS IN DROSOPHILA

POSTER SESSION 07 - SECTION: MITOCHONDRIA

Zeynep Ozturk, Holly Robertson, Joe Stone, Shuler Xu, Cahir O'Kane
University of Cambridge, Genetics, Cambridge, United Kingdom

The HSPs are a group of rare, clinically and genetically heterogeneous, inherited neurodegenerative and neurodevelopmental diseases characterised by spasticity and lower limb weaknesses. More than 80 causative genes are known, and some of them imply the importance of endoplasmic reticulum (ER) -**a neuron within a neuron**- function and morphogenesis in HSPs. These HSP proteins are Spastin (SPG4), Atlastin (SPG3A), Receptor Expression Enhancing Protein 1 (REEP1/SPG31) and Reticulon (SPG12). In Drosophila, removing these families leads to fewer ER tubules in axons of wider diameter, although there is no widespread absence of tubules. Therefore, other proteins must be involved in shaping the tubular ER network in Drosophila axons. Another HSP protein with predicted hairpin domains is C19orf12; this is, therefore, another candidate protein for contributing to shaping the axon ER network. Mutations in this gene are found in patients with autosomal recessive HSP and NBIA. C19orf12 protein colocalises with mitochondria and ER and with ER-mitochondria contacts.To investigate possible roles of C19orf12 in ER and mitochondria structure and function, we have generated loss-of-function mutants of the widely expressed Drosophila ortholog of C19orf12, CG3740, using P element excision and CRISPR/cas9. These mutants are homozygous viable, as are quadruple mutants lacking CG3740 and all the widely expressed reticulon and REEP proteins, suggesting that these 4 proteins together are not sufficient for tubular ER formation. Testing of ER and mitochondria morphology in these mutants we have also generated flies carrying a split-GFP reporter for ER-mitochondrial sites.

Axonal Endoplasmic Reticulum Dynamics and Its Roles in Neurodegeneration.
The physical continuity of axons over long cellular distances poses challenges for their maintenance. One organelle that faces this challenge is endoplasmic reticulum (ER); unlike other intracellular organelles, this forms a physically continuous network throughout the cell, with a single membrane and a single lumen. In axons, ER is mainly smooth, forming a tubular network with occasional sheets or cisternae and low amounts of rough ER. It has many potential roles: lipid biosynthesis, glucose homeostasis, a Ca store, protein export, and contacting and regulating other organelles. This tubular network structure is determined by ER-shaping proteins, mutations in some of which are causative for neurodegenerative disorders such as hereditary spastic paraplegia (HSP). While axonal ER shares many features with the tubular ER network in other contexts, these features must be adapted to the long and narrow dimensions of axons. ER appears to be physically continuous throughout axons, over distances that are enormous on a subcellular scale. It is therefore a potential channel for long-distance or regional communication within neurons, independent of action potentials or physical transport of cargos, but involving its physiological roles such as Ca or organelle homeostasis. Despite its apparent stability, axonal ER is highly dynamic, showing features like anterograde and retrograde transport, potentially reflecting continuous fusion and breakage of the network. Here we discuss the transport processes that must contribute to this dynamic behavior of ER. We also discuss the model that these processes underpin a homeostatic process that ensures both enough ER to maintain continuity of the network and repair breaks in it, but not too much ER that might disrupt local cellular physiology. Finally, we discuss how failure of ER organization in axons could lead to axon degenerative diseases, and how a requirement for ER continuity could make distal axons most susceptible to degeneration in conditions that disrupt ER continuity.

ABSTRACT Mitophagy neutralises defective mitochondria *via* lysosomal elimination and has major relevance for neurodegenerative disease. Increased mitophagy coincides with metabolic reprogramming, yet it remains unknown whether mitophagy is a cause or consequence of such state changes. The signalling pathways that integrate with mitophagy to sustain cell and tissue integrity also remain a mystery. We performed temporal metabolomics on mammalian cells treated with deferiprone, a therapeutic iron chelator that stimulates PINK1-Parkin independent mitophagy. Iron depletion profoundly rewired the metabolome, hallmarked by remodelling of lipid metabolism within minutes of treatment. DGAT1-dependent lipid droplet (LD) biosynthesis occurred several hours upstream of mitochondrial clearance, with LDs bordering mitochondria upon iron chelation. We demonstrate that DGAT1 inhibition restricts mitophagy *in vitro*, with impaired lysosomal homeostasis and cell viability. Importantly, genetic depletion of DGAT1 *in vivo* significantly impaired neuronal mitophagy and locomotor function in *Drosophila*. Our data defines iron depletion as a potent signal that rapidly reshapes metabolism and establishes an unexpected synergy between lipid homeostasis and mitophagy that safeguards neural integrity.

Mitochondria are dynamics organelles that continuously move, fuse and divide. In neurons, depending on their sub-cellular localization, mitochondria shape varies and this diversity of shapes reflects the heterogeneity of the demand mitochondria need to face. *In vitro*, mitochondria motility impacts its intracellular distribution and its ability to be present at sites of high ATP consumption and Ca^{2+} buffering needs such as synapses. **However, whether *in vivo* mitochondria motility is required in memory has not been addressed yet.** Here we used the Drosophila model to address this question. Indeed, Drosophila can feature elaborate associative memory processes and actors of mitochondria dynamics as well as the molecular pathways supporting memory are largely conserved from flies to mammals. Thus, we have recently shown that, in the drosophila's major memory center, long-term memory (LTM) formation requires an acute upregulation of mitochondria metabolism. Here by genetically targeting mitochondria motility main actors in the fly's major memory center, we establish that motile mitochondria are required specifically for LTM. Then using STED microscopy to image mitochondria in the fly's memory center, we show that upon LTM formation, mitochondria dynamics is regulated. Eventually, using *in vivo* imaging we evidenced that when mitochondria motility is impaired, upregulation of mitochondria metabolism required for LTM formation is abolished. Our study shows that **mitochondria motility is a key process *in vivo* to full-fill increased neuronal metabolic demand upon LTM formation.** Further investigation would help to decipher how defect in mitochondrial transport and altered distribution are implicated in major neurological disorders.

Brain cells are one of the most energy-demanding cell types in the body. Differences in metabolic profile and electron transport chain (ETC) structure of astrocytes and neurons have functional implications during conditions with varying oxygen supply (brain activity, hypoxia etc.) We assessed the redox state of the ETC of mitochondria with simultaneous analysis of blood oxygenation level in awake C57Bl/6 mice with Raman microspectroscopy. The mice expressed green fluorescent protein in astrocytes following AAV injection in the somatosensory cortex (S1). Raman spectra recorded from astrocytes and GFP-non fluorescent cells (predominantly neurons) were used to quantify reduced C and B-type cytochromes. Raman spectra recorded from blood vessels were used to quantify oxyhaemoglobin in the blood. The relative amount of reduced cytochromes reversibly increased in astrocytes but not in neurons in response to animal activity: running on the trade-mill, grooming. Simultaneously the amount of oxyhaemoglobin also increased. Thus, astrocytic mitochondria respond to local brain activity by ETC overloading with electrons, which may result in the production of reactive oxygen species. The work is supported by the Russian Science Foundation (grant 20-14-00241).

Co-administration of Anti microRNA-124 and -137 Oligonucleotides Prevents Hippocampal Neural Stem Cell Loss Upon Non-convulsive Seizures.
Convulsive seizures promote adult hippocampal neurogenesis (AHN) through a transient activation of neural stem/progenitor cells (NSPCs) in the subgranular zone (SGZ) of the dentate gyrus (DG). However, in a significant population of epilepsy patients, non-convulsive seizures (ncSZ) are observed. The response of NSPCs to non-convulsive seizure induction has not been characterized before. We here studied first the short-term effects of controlled seizure induction on NSPCs fate and identity. We induced seizures of controlled intensity by intrahippocampally injecting increasing doses of the chemoconvulsant kainic acid (KA) and analyzed their effect on subdural EEG recordings, hippocampal structure, NSPC proliferation and the number and location of immature neurons shortly after seizure onset. After establishing a KA dose that elicits ncSZ, we then analyzed the effects of ncSZ on NSPC proliferation and NSC identity in the hippocampus. ncSZ specifically triggered neuroblast proliferation, but did not induce proliferation of NSPCs in the SGZ, 3 days post seizure onset. However, ncSZ induced significant changes in NSPC composition in the hippocampus, including the generation of reactive NSCs. Interestingly, intrahippocampal injection of a combination of two anti microRNA oligonucleotides targeting microRNA-124 and -137 normalized neuroblast proliferation and prevented NSC loss in the DG upon ncSZ. Our results show for the first time that ncSZ induce significant changes in neuroblast proliferation and NSC composition. Simultaneous antagonism of both microRNA-124 and -137 rescued seizure-induced alterations in NSPC, supporting their coordinated action in the regulation of NSC fate and proliferation and their potential for future seizure therapies.

Objectives: The aim of this study is to explore the impact of the abnormal accumulation of alpha-synuclein (aSyn) on mitochondrial quality control mechanisms in neurons, with a focus on mitophagy. **Methods:** We used a model of primary mouse cortical neurons (E16) in which aSyn aggregation is promoted by fibrils of normal human aSyn (f91) preformed *in vitro*. Experiments were performed in both wild type type neurons and neurons deficient for Parkin, to explore specifically the PINK1/Parkin-dependent mitophagy pathway. Mitophagy was investigated in live neurons with the fluorescent MitoRosella reporter, monitoring the presence of mitochondria within lysosomes. The reporter was expressed by means of lentiviral vector-mediated gene delivery. **Results:** At two weeks of treatment with f91, 30% of the neuronal cell bodies and many neuronal processes contained deposits of phosphorylated aSyn (P-aSyn). There was a 40%-70% overlap between P-aSyn immunoreactive deposits and TOM20-positive mitochondria. Exposure to f91 resulted in a 60-100% increase in the Mito-Rosella fluorescent signal associated with lysosomes, in both wild type and Parkin-deficient neurons. By contrast, exposure of neurons to the mitochondrial complex III inhibitor antimycin A (100 nM, 3h) enhanced mitophagy by 150% in wild-type neurons only. Intriguingly, in neurons exposed to f91 there was no correlation between the increase in mitophagy and the presence of P-aSyn deposits in the soma. **Conclusions:** Synucleinopathy mediated by f91 stimulates the autophagy of mitochondria in a PINK1/Parkin-independent manner. Further studies are required to evaluate possible effects of aSyn accumulation on non-elective bulk autophagy and lysosomal function.

Aim: In this presentation, I will address how the different domains of Mitofusin work together during mitochondrial docking and fusion, as well as the role of lipids in mitochondrial fusion. Methods and details: Mitochondria are double-membrane bound organelles that constantly fuse and divide within cells. Mitofusins 1 and 2 are two mammalian proteins involved in the fusion of outer mitochondrial membranes. Mitofusins are composed of an N-terminal GTPase domain, a first heptad repeat domain (HR1), a transmembrane region, and a second heptad repeat domain (HR2). Studies from our lab and others suggest that the GTPase domain could form a long-distance homotypic membrane-bridging complex bringing membranes in closer proximity through a GTP-dependent conformational change, while the HR2 domain may stabilize short-distance membrane docking. The HR1 domain was found to induce fusion via its amphipathic helix which can perturb the lipid bilayer structure. The lipid composition of mitochondrial membranes can also impact mitochondrial fusion. However, the exact mode of action of lipids in mitochondrial fusion is not fully understood. The role of the HR domains was studied *in vitro* using their reconstitution into liposomes. The docking capacity of HR2 was tested by multi-angle dynamic light scattering, while fusion was monitored by a fluorescence resonance energy transfer-based lipid mixing assay. Results and conclusion: Our results show an increased kinetics and extent of fusion when HR1 and HR2 are anchored together in the same liposome, compared to the effect of HR1 or HR2 alone, suggesting that these two fragments work in synergy.

Calcium (Ca2+) in nerve terminals controls the strength of neurotransmission and much effort in the past decades has been focused on understanding the molecular underpinnings controlling presynaptic Ca2+ levels during neuronal activity. During firing, non-acidic organelles, such as mitochondria or the endoplasmic reticulum, buffer presynaptic Ca2+ in a process that modulates synaptic vesicle exocytosis. However, other organelles in the presynapse, such as lysosomes or synaptic vesicles (SV) themselves, contain very high levels of Ca2+ in their lumen and present ion channels, transporters and pumps to uptake or release Ca2+ on demand. This steep gradient of Ca2+ concentration in these organelles has been proposed to be involved in controlling presynaptic function, either by modulating presynaptic Ca2+ dynamics or by controlling the function of these organelles directly. However, due to the lack of suitable optical tools to quantify Ca2+ in acidic environments, the functional role of intraluminal Ca2+ in presynaptic acidic organelles remains poorly understood. To tackle this problematic, we developed two novel genetically encoded optical tools to measure Ca2+ at high micromolar levels in these acidic organelles. Using this technology, we will be able to directly approach two long-standing questions in the field: 1) Can synaptic vesicles act as sink or sources of Ca2+ during firing to modulate SV exocytosis? 2) Can lysosomal Ca2+ modulate synaptic transmission? Solving these questions will increase our basic understanding of the fundamental mechanisms regulating neurotransmission, providing a framework for the future studies of Ca2+ in acidic organelles and its role in synaptic physiology.

Increasing evidence from rodent and human studies supports the contribution of brain mitochondria and bioenergetics to anxiety-related disorders and depression. We previously demonstrated that, in rats, acute pharmacological manipulation of mitochondrial complexes in the nucleus accumbens (NAc) alters the outcome of social competition between conspecifics and promotes passive coping behavior in the forced swim test. Here, we investigated the ionic mechanisms whereby acute mitochondrial manipulation impinges on NAc excitability. In patch-clamp recordings from mouse slices, we found that exposure to the mitochondrial complex I inhibitor rotenone (100 nM) decreased the intrinsic excitability of NAc medium spiny neurons (MSNs), without affecting cholinergic interneurons. The effect of rotenone was reduced when augmenting the intracellular concentration of ATP, suggesting an ATP-sensitive mechanism. Fluorescent in situ hybridization revealed that MSNs express ATP-dependent K^+ (K-ATP) channels containing the Kir6.2 subunit. Notably, K-ATP channel blockade by Glibenclamide (0.02 mM) boosted MSN firing and abolished the cellular effects of rotenone. In the forced swim test, local infusion of Glibenclamide reverted the effects of rotenone by normalizing the floating time to levels measured in vehicle-infused mice. These results indicate that K-ATP channels act as fast ionic sensors translating mitochondrial activity into MSN responsiveness, suggesting a novel target to rescue the behavioral consequences of NAc mitochondrial dysfunction in anxiety-related disorders and depression.

Recent studies show that exosomes are remarkably stable in body fluids proving their utility as a cargo of biomarkers. However, it is still unknown which proteins are secreted as exosomes in diverse neurodevelopmental diseases. This study investigated the proteome in exosomes isolated from the cortex and primary neuron/astrocyte of *Fmr1* KO mice. We established isolation methods to collect highly purified exosomes by combining gradient ultracentrifugation with tangential flow filtration or size-exclusion chromatography. Exosomes' relevant characteristics, including size, density, morphology, and composition, are confirmed by transmission electron microscopy, nanoparticle tracking analysis, and western blot. Matching results from Exocarta DB and LC-MS/MS data showed that diverse mitochondrial components related to OXPHOS and mitochondrial translocators decreased in FXS mouse models compared with wild-type mouse models. Interestingly, mitochondrial components such as ATP5A and ATPB for ATP synthases, and VDAC1 for a mitochondrial membrane protein, were reduced in exosomes from cortices, neurons, and astrocytes of *Fmr1* KO mice. When mitochondrial functions were analyzed by mitochondrial membrane potential (MMP), MMP was found to be high in neurons versus low in astrocytes from *Fmr1* KO mice. When expression of mitochondrial components was examined in neurons and astrocytes, they were decreased in both total lysate and the mitochondrial fraction of astrocytes. In contrast, they were not altered in the Fmr1 KO mouse neurons. Our results suggest that mitochondrial dysfunctions in cortical neurons and astrocytes can be monitored by depletion of the components in EVs, but the mitochondrial-exosome trafficking is differentially regulated in neuron *vs.* astrocyte for the pathogenesis associated with FXS.

The investigation of the sex-dependent differences in healthy brain aging remains to be of considerable interest to neurobiology and medicine. **The aim** was to study the behavioral, functional, and morphological changes observed in male and female C3H mice in healthy aging. **Methods.** In C3H mice, grouped by age (young: 4-8 months; old: 20-24 months) and sex (male and female), we tested the motor and exploratory activity, long-term and short-term memory. The functional activity of the brain mitochondria was assessed using High-Resolution Respirometry. We analyzed the morphology and distribution of neurons, microglial cells and astrocytes using immunohistochemistry, ultrastructural features using transmission electron microscopy, and the role of neuroinflammation using Western Blotting and RT-PCR. **Results.** Healthy aging significantly reduced locomotor activity and the number of basic behavioral acts in males, but not in females. Decreased learning ability was sex-independent, spatial memory mostly declined in females. In old mice, the overall trend of decreased ATP-dependent respiration was observed, whereas oxidative phosphorylation was significantly altered in females. The coupling between oxidation and phosphorylation was initially higher in young females, but, in comparison to males, the age-dependent changes were more prominent. The results were confirmed by morphological studies of the brain cell mitochondria. **Conclusion.** The study outlined several sex-dependent differences in morphological and functional changes in the brain cell mitochondria associated with brain aging. The study was supported by the Russian Foundation for Basic Research (Project No. 22-15-20043).

Introduction: Alterations in mitochondrial structure, morphology, and dynamics have been identified as a contributor to the pathophysiology of many neurological disorders characterized by progressive loss of function and death of neurons, as for example in Alzheimer's disease (AD) and Amyotrophic Lateral Sclerosis (ALS). Considering the complexity of neurodegenerative diseases and the mitochondrial diversity across different cell types of the CNS, bulk mitochondria investigations may camouflage important cell type specific mitochondrial changes. **Aims:** To find mitochondrial signatures in the CNS of AD and ALS animal models, as well as to investigate cell type specific mitochondrial diversity linked to disease progression in different tissues. **Methods:** In order to achieve this, we have been working with the APP NL-G-F and SOD1 G93A mice, which are AD and ALS animal models respectively, to investigate structural and functional mitochondrial diversity from neurons and astrocytes. Both disease animal models are crossed with the MitoTag mouse, allowing cell type specific mitochondria isolation due to its *cre*-dependent GFP protein expression at the outer mitochondrial membrane (OMM). **Results:** Expression pattern of GFP-OMM validated the GFP expression mostly in the cell type of interest. Moreover, our mitochondrial isolation protocol results in functional mitochondria, as demonstrated by analysis of the oxygen consumption rate (OCR), and enough mitochondrial yield for downstream analysis. **Conclusions:** This approach allows the isolation of functional mitochondria from different cell type and tissue in the CNS, and the subsequent application of omics analysis in cell type specific mitochondria isolated from mouse models of neurodegenerative diseases.

Inflammation in the central nervous system (CNS) can impair the function of neuronal mitochondria and contributes to axon degeneration in the common neuroinflammatory disease multiple sclerosis (MS). Here we combine cell type-specific mitochondrial proteomics with in vivo biosensor imaging to dissect how inflammation alters the molecular composition and functional capacity of neuronal mitochondria. We show that neuroinflammatory lesions in the mouse spinal cord cause widespread and persisting axonal ATP deficiency, which precedes mitochondrial oxidation and calcium overload. This axonal energy deficiency is associated with impaired electron transport chain function, but also an upstream dysbalance of tricarboxylic acid (TCA) cycle enzymes. Among these, isocitrate dehydrogenase 3 (Idh3), a rate-limiting enzyme of the TCA cycle, is depleted in neuronal mitochondria in experimental models and in MS lesions. Notably, viral overexpression of an Idh3 subunit ameliorates the axonal energy deficits in neuroinflammatory lesions, suggesting that TCA cycle dysfunction in MS may be amendable to therapy.
