inflammatory effect of DZX in the central nervous system, an injury was induced in the hypoglossal and facial nuclei and in the oculomotor nucleus by unilateral axonal transection and unilateral target deprivation (enucleation), respectively. On the fourth day after surgery, microglial analysis was performed on tissue in which microglia were DAB-labeled and motoneurons were labeled with immunofluorescence. DZX treatment was given either prophylactically, starting 7 days prior to the injury and continuing until the animals were sacrificed, or postoperatively only, with daily intraperitoneal injections (1.25 mg/kg; in 10 mg/ml dimethyl sulfoxide in distilled water). Prophylactically + postoperatively applied DZX completely eliminated the microglial reaction in each motor nuclei. If DZX was applied only postoperatively, some microglial activation could be detected, but its magnitude was still significantly smaller than the non-DZX-treated controls. The effect of DZX could also be demonstrated through an extended period, as tested in the hypoglossal nucleus on day 7 after the operation. Neuronal counts, determined at day 4 after the operation in the hypoglossal nucleus, demonstrated no loss of motor neurons, however, an increased Feret's diameter of mitochondria could be measured, suggesting increased oxidative stress in the injured cells. The increase of mitochondrial Feret's diameter could also be prevented with DZX treatment.

Passive Transfer of Sera from ALS Patients with Identified Mutations Evokes an Increased Synaptic Vesicle Number and Elevation of Calcium Levels in Motor Axon Terminals, Similar to Sera from Sporadic Patients.
Previously, we demonstrated increased calcium levels and synaptic vesicle densities in the motor axon terminals (MATs) of sporadic amyotrophic lateral sclerosis (ALS) patients. Such alterations could be conferred to mice with an intraperitoneal injection of sera from these patients or with purified immunoglobulin G. Later, we confirmed the presence of similar alterations in the superoxide dismutase 1 G93A transgenic mouse strain model of familial ALS. These consistent observations suggested that calcium plays a central role in the pathomechanism of ALS. This may be further reinforced by completing a similar analytical study of the MATs of ALS patients with identified mutations. However, due to the low yield of muscle biopsy samples containing MATs, and the low incidence of ALS patients with the identified mutations, these examinations are not technically feasible. Alternatively, a passive transfer of sera from ALS patients with known mutations was used, and the MATs of the inoculated mice were tested for alterations in their calcium homeostasis and synaptic activity. Patients with 11 different ALS-related mutations participated in the study. Intraperitoneal injection of sera from these patients on two consecutive days resulted in elevated intracellular calcium levels and increased vesicle densities in the MATs of mice, which is comparable to the effect of the passive transfer from sporadic patients. Our results support the idea that the pathomechanism underlying the identical manifestation of the disease with or without identified mutations is based on a common final pathway, in which increasing calcium levels play a central role.

EFFECTS OF EARLY-ONSET ALS PATHOLOGY ON NEURAL NETWORK DYNAMICS

POSTER SESSION 03 - SECTION: AMYOTROPHIC LATERAL SCLEROSIS

Anna Mikalsen Kollstrøm[1], Ioanna Sandvig[1], Axel Sandvig[1,2,3]
[1]Norwegian University of Science and Technology (NTNU), Department Of Neuromedicine And Movement Science, Faculty Of Medicine And Health Sciences, Trondheim, Norway, [2]Umeå University Hospital, Department Of Clinical Science, Division Of Neuroscience, Umeå, Sweden, [3]Umeå University Hospital, Department Of Community Medicine And Rehabilitation, Division Of Rehabilitation Medicine, Umeå, Sweden

Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease causing gradual paralysis of voluntary muscles due to the progressive degeneration of upper and lower motor neurons. There is no cure and patients usually die 3-5 years after the onset of symptoms. A crucial aspect for developing effective treatment is early intervention, but this remains a challenge due to the lack of biomarkers. Evolving pathological processes in ALS can cause changes in the dynamical interplay between structural and functional connectivity, and we hypothesize that such changes emerge before the manifestation of symptoms. We aim to identify how ALS affects the underlying structural organization and the accompanying functional connectivity of *in vitro* neural networks. We study neural networks using human induced pluripotent stem cell (hiPSC)-derived motor neurons from ALS patients and healthy donors on micro-electrode arrays (MEAs) and high-density CMOS MEAs. We apply graph theoretical and topological methods to infer differences between healthy and ALS conditions. We hypothesize that subtle changes in the underlying network structure are accompanied by abnormal network activity which may compromise the global network efficiency. Such changes could be a result of intrinsic cellular responses attempting to preserve normal function in an increasingly impaired network, effectively masking overt signs of pathology at early stages. A better understanding of early-onset network configurations could contribute to the improvement of diagnostic tools, as well as the identification of critical phases for therapeutic intervention.

ALTERATIONS IN WWOX PROTEIN AND GENE LEAD TO MITOCHONDRIAL DYSFUNCTION IN AMYOTROPHIC LATERAL SCLEROSIS

POSTER SESSION 03 - SECTION: AMYOTROPHIC LATERAL SCLEROSIS

Tiziana Petrozziello[1], Spencer Kim[1], Alexandra Mills[1], Sali Farhan[2], Jennie Roy[3], Nicholas Lorocco[3], Austin Birmingham[3], Khashayar Vakili[4], James Berry[1], James Walker[3], Ricardo Mouro-Pinto[3], Ghazaleh Sadri-Vakili[1]
[1]Massachusetts General Hospital, Neurology, Boston, United States of America, [2]Massachusetts General Hospital, Medicine, Boston, United States of America, [3]Massachusetts General Hospital, Center For Genomic Medicine, Boston, United States of America, [4]Boston Children's Hospital, Surgery, Boston, United States of America

Aims. To date, there are only two modestly beneficial treatments for amyotrophic lateral sclerosis (ALS), highlighting the importance of unraveling the mechanisms leading to motor neuron loss. One potential pathway is mediated by the WW domain-containing oxidoreductase (WWOX), a protein involved in neurodegeneration. ***Methods.*** Western blots were used to assess the levels of WWOX, and proteins involved in the mitochondrial electron transport chain in ALS and control post-mortem motor cortex (mCTX). Project MinE was analyzed to identify genetic variants in *WWOX*. Cell viability, ATP, and reactive oxygen species (ROS) were measured in SH-SY5Y cells following WWOX knock down using small interfering RNA (siWWOX) or treatment with wild-type and mutant recombinant WWOX proteins. siWWOX was used in a fly model and alterations in behavior were assessed. ***Results.*** WWOX levels were decreased in ALS mCTX and correlated with disease duration, suggesting a role for WWOX loss in ALS. Accordingly, siWWOX increased ROS levels in SH-SY5Y cells indicating a link between loss of WWOX and increases in oxidative stress. Similarly, siWWOX decreased sleep in a fly model, further supporting a pathogenic role. Additionally, we identified several rare and ALS specific variants in WWOX. Among these variants, the 261E stop codon mutation decreased cell viability and ATP levels, and increased ROS *in vitro*, consistent with decreases in the mitochondrial ATP synthase of complex V and the cytochrome c oxidase of complex IV in ALS mCTX. ***Conclusions.*** Together, our findings suggest that loss of WWOX or mutations in the gene exacerbate mitochondrial dysfunction in ALS.

BENEFICIAL AND SEXUALLY DIMORPHIC RESPONSE TO COMBINED HDAC INHIBITOR VALPROATE AND AMPK/SIRT1 PATHWAY ACTIVATOR RESVERATROL IN THE TREATMENT OF ALS MICE

POSTER SESSION 03 - SECTION: AMYOTROPHIC LATERAL SCLEROSIS

Oluwamolakun Bankole[1], Ilaria Scambi[1], Edoardo Parrella[2], Matilde Muccilli[1], Roberta Bonafede[1], Ermanna Turano[1], Marina Pizzi[2], Raffaella Mariotti[1]

Introduction: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disorder. Epigenetic modulation in the acetylation state of NF-kB RelA and histone 3 (H3) protein, involved in the development of neurodegeneration, is a drugable target for the class-I histone deacetylases (HDAC) inhibitors, valproate, and the AMP-activated kinase (AMPK)-sirtuin 1 pathway activator, resveratrol. Aim: In this study, we demonstrated that the combination of valproate and resveratrol can restore the acetylation state of RelA in the SOD1(G93A) murine model of ALS. We also investigated the sexually dimorphic development of the disease, as well as the sex-sensibility to the treatment administered. Method: Animals where subjected to behavioural tests to examine motor function. They were sacrificed at the end stage, and immunohistochemistry and molecular analysis were carried out on the spinal cord of the mice. Results: The combined drugs, which rescued RelA and the histone 3 acetylation state, reduced the motor deficit and the disease pathology associated with motor neuron loss and microglial reactivity, Brain-Derived Neurotrophic Factor (BDNF) and B-cell lymphoma-extra large (Bcl-xL) level decline. Specifically, the treatment administered at 50 days of life, postponed the time of onset in the male by 22 days, but not significantly in females. Nevertheless, in females, the drugs significantly reduced symptom severity of the later phase of the disease and prolonged the mice's survival. Only minor beneficial effects were produced in the latter stage in males. Conclusion: Overall, this study shows a beneficial and sexually dimorphic response to valproate and resveratrol treatment in ALS mice.

Dopamine binds calmodulin during autoregulation of dopaminergic D2 receptor signaling through CaMKIIα-calmodulin complex.
The role of dopaminergic D2 receptor (D2R) autoregulation in dopamine (DA) neurotransmission cannot be overemphasized in cause and progression of disorders associated with complex behaviors. Although previous studies have shown that D2R is structurally and physiologically linked with calcium/calmodulin-dependent kinase II (CaMKIIα), however, the role of calmodulin in the CaMKIIα complex in D2R regulation remains elusive. In this study, using structural biology modeling softwares (iGEMDOCK and CueMol), we have shown the interaction between D2R, CaMKIIα, calmodulin, and DA under varying conditions. The outcomes of this study suggest that CaMKIIα causes a change in DA binding affinity to the D2R receptive site while the detached DA binds to calmodulin to stop the activity of D2R in the D2R-dopaminergic D1 receptor (D1R) heteromer. Ultimately, we concluded that D2R autoregulates to stop its heteromeric combination with D1R. D2R interacts with D1R to facilitate calcium movement that activates calmodulin, then CaMKIIα. The CaMKIIα-calmodulin complex changes the affinity of DA-D2R causing DA to break free and bind with calmodulin.

Kolaviron was protective against sodium azide (NaN3) induced oxidative stress in the prefrontal cortex.
Kolaviron is a phytochemical isolated from Garcina kola (G. kola); a common oral masticatory agent in Nigeria (West Africa). It is a bioflavonoid used--as an antiviral, anti-inflammatory and antioxidant--in relieving the symptoms of several diseases and infections. In this study we have evaluated the neuroprotective and regenerative effect of kolaviron in neurons of the prefrontal cortex (Pfc) before or after exposure to sodium azide (NaN3) induced oxidative stress. Separate groups of animals were treated as follows; kolaviron (200 mg/Kg) for 21 days; kolaviron (200 mg/Kg for 21 days) followed by NaN3 treatment (20 mg/Kg for 5 days); NaN3 treatment (20 mg/Kg for 5 days) followed by kolaviron (200 mg/Kg for 21 days); 1 ml of corn-oil (21 days-vehicle); NaN3 treatment (20 mg/Kg for 5 days). Exploratory activity associated with Pfc function was assessed in the open field test (OFT) following which the microscopic anatomy of the prefrontal cortex was examined in histology

(Haematoxylin and Eosin) and antigen retrieval Immunohistochemistry to show astroglia activation (GFAP), neuronal metabolism (NSE), cytoskeleton (NF) and cell cycle dysregulation (p53). Subsequently, we quantified the level of Glucose-6-phosphate dehydrogenase (G6PDH) and lactate dehydrogenase (LDH) in the brain tissue homogenate as a measure of stress-related glucose metabolism. Kolaviron (Kv) and Kolaviron/NaN3 treatment caused no prominent change in astroglia density and size while NaN3 and NaN3/Kv induced astroglia activation and scar formation (astrogliosis) in the Pfc when compared with the control. Similarly, Kolaviron and Kv/NaN3 did not alter NSE expression (glucose metabolism) while NaN3 and NaN3/Kv treatment increased cortical NSE expression; thus indicating stress related metabolism. Further studies on enzymes of glucose metabolism (G6PDH and LDH) showed that NaN3 increased LDH while kolaviron reduced LDH in the brain tissue homogenate ($P < 0.001$). In addition kolaviron treatment before ($P < 0.001$) or after ($P < 0.05$) NaN3 treatment also reduced LDH expression; thus supporting its role in suppression of oxidative stress. Interestingly, NF deposition increased in the Pfc after kolaviron treatment while Kv/NaN3 showed no significant change in NF when compared with the control. In furtherance, NaN3 and NaN3/Kv caused a decrease in NF deposition (degeneration). Ultimately, the protective effect of KV administered prior to NaN3 treatment was confirmed through p53 expression; which was similar to the control. However, NaN3 and NaN3/Kv caused an increase in p53 expression in the Pfc neurons (cell cycle dysregulation). We conclude that kolaviron is not neurotoxic when used at 200 mg/Kg BW. Furthermore, 200 mg/Kg of kolaviron administered prior to NaN3 treatment (Kv/NaN3) was neuroprotective when compared with Kolaviron administered after NaN3 treatment (NaN3/Kv). Some of the observed effects of kolaviron administered before NaN3 treatment includes reduction of astroglia activation, absence of astroglia scars, antioxidation (reduced NSE and LDH), prevention of neurofilament loss and cell cycle regulation.

Neural and behavioural changes in male periadolescent mice after prolonged nicotine-MDMA treatment.
The interaction between MDMA and Nicotine affects multiple brain centres and neurotransmitter systems (serotonin, dopamine and glutamate) involved in motor coordination and cognition. In this study, we have elucidated the effect of prolonged (10 days) MDMA, Nicotine and a combined Nicotine-MDMA treatment on motor-cognitive neural functions. In addition, we have shown the correlation between the observed behavioural change and neural structural changes induced by these treatments in BALB/c mice. We observed that MDMA (2 mg/Kg body weight; subcutaneous) induced a decline in motor function, while Nicotine (2 mg/Kg body weight; subcutaneous) improved motor function in male periadolescent mice. In combined treatment, Nicotine reduced the motor function decline observed in MDMA treatment, thus no significant change in motor function for the combined treatment versus the control. Nicotine or MDMA treatment reduced memory function and altered hippocampal structure. Similarly, a combined Nicotine-MDMA treatment reduced memory function when compared with the control. Ultimately, the metabolic and structural changes in these neural systems were seen to vary for the various forms of treatment. It is noteworthy to mention that a combined treatment increased the rate of lipid peroxidation in brain tissue.

Beneficial and Sexually Dimorphic Response to Combined HDAC Inhibitor Valproate and AMPK/SIRT1 Pathway Activator Resveratrol in the Treatment of ALS Mice.
Amyotrophic lateral sclerosis (ALS) is a fatal adult-onset neurodegenerative disorder. There is no cure and current treatments fail to slow the progression of the disease. Epigenetic modulation in the acetylation state of NF-kB RelA and the histone 3 (H3) protein, involved in the development of neurodegeneration, is a drugable target for the class-I histone deacetylases (HDAC) inhibitors, entinostat or valproate, and the AMP-activated kinase (AMPK)-sirtuin 1 pathway activator, resveratrol. In this study, we demonstrated that the combination of valproate and resveratrol can restore the normal acetylation state of RelA in the SOD1(G93A) murine model of ALS, in order to obtain the neuroprotective form of NF-kB. We also investigated the sexually dimorphic development of the disease, as well as the sex-sensibility to the treatment administered. We showed that the combined drugs, which rescued AMPK activation, RelA and the histone 3 acetylation state, reduced the motor deficit and the disease pathology associated with motor neuron loss and microglial reactivity, Brain-Derived Neurotrophic Factor (BDNF) and B-cell lymphoma-extra large (Bcl-xL) level decline. Specifically, vehicle-administered males showed earlier onset and slower progression of the disease when compared to females. The treatment, administered at 50 days of life, postponed the time of onset in the male by 22 days, but not in a significant way in females. Nevertheless, in females, the drugs significantly reduced symptom severity of the later phase of the disease and prolonged the mice's survival. Only minor beneficial effects were produced in the latter stage in males. Overall, this study shows a beneficial and sexually dimorphic response to valproate and resveratrol treatment in ALS mice.

SLEEP AND OREXINERGIC PATHWAY ALTERATIONS IN MICE MODELS OF AMYOTROPHIC LATERAL SCLEROSIS

POSTER SESSION 03 - SECTION: AMYOTROPHIC LATERAL SCLEROSIS

Simon Guillot[1], Luc Dupuis[1], Matei Bolborea[1,2]
[1]Inserm UMR-S 1118, Department Of Neurology, Strasbourg, France, [2]University of Warwick, School Of Life Science, Coventry, United Kingdom

Amyotrophic lateral sclerosis (ALS) is a progressive motor neuron disease inexorably leading to an early death. Sleep disturbances have been described and appear at a later stage of the disease. Those disturbances can be triggered by muscle cramps, spasticity, or restless legs syndrome, all leading to increased wakefulness. However, sleep changes were rarely studied in the context of ALS. We used two murine models of ALS, Superoxide Dismutase 1 G86R ($Sod1^{G86R}$) and Fused in Sarcoma ($Fus^{\Delta NLS}$), which both represent 25% of the familial cases of ALS, to underpin the structural and cellular mechanism involved. A recent pathological study in ALS patients observed decreased neurons immunoreactive for orexin, a neuropeptide highly involved in sleep regulation. In both $Sod1^{G86R}$ and $Fus^{\Delta NLS}$ mice, there was no change in the number of Orexin-positive neurons in the lateral hypothalamus. However, electroencephalograms showed an increase in wakefulness and a decrease in rapid eye movement (REM) episodes in both mouse models before the onset of major motor troubles, while Suvorexant® - a dual Orexin receptor antagonist - was able to increase the REM episodes and decrease the wakefulness in both $Sod1^{G86R}$ and $Fus^{\Delta NLS}$ mice. Thus, our results show that two mouse models of ALS models display an impaired sleep pattern, that is, at least partially, dependent upon orexinergic neurons. This study is a starting point for a better comprehension of sleep defects observed in ALS patients and the potential benefit from pharmacological manipulation.

Mutations in the *Fused in Sarcoma (FUS)* gene, encoding for a ubiquitous and multifunctional DNA/RNA-binding protein, cause severe forms of amyotrophic lateral sclerosis (ALS), particularly when the nuclear localisation signal (NLS) of FUS is truncated. This truncation leads to the cytoplasmic mislocalisation of the protein, which is also observed in ALS and frontotemporal dementia (FTD) patients devoid of mutations. Our laboratory generated a mouse model displaying a constitutive and ubiquitous NLS deletion, and effectively induced the cytoplasmic delocalisation of FUS. This led to a cortical hyperactivity associated with molecular and ultrastructural alterations of GABAergic synapses, ALS-like motor impairments and FTD-like behavioural dysfunctions. The aim of my PhD is then to understand the contribution of inhibitory neurons in *FUS*-ALS and *FUS*-FTD. To conduct my project, we developed two new mouse models using a Cre-Lox recombination technology and mice in which the Cre recombinase expression is restricted to vesicular GABA transporter-positive neurons. By crossing these mice with mice in which *Fus* can be truncated upon recombination, we mutated *Fus* solely in inhibitory neurons. In parallel, by using mice displaying a constitutive NLS deletion which can be rescued to the wild type situation upon recombination, we truncated *Fus* in every cell type except inhibitory neurons. With histological studies we validated the recombination efficiency and are investigating the potential effects on neurons degeneration and pathological hallmarks appearance. These models are now being characterised for behavioural outcomes to determine if *Fus* truncation in inhibitory neurons is sufficient and/or necessary to induce ALS and FTD-like symptoms.

Amyotrophic lateral sclerosis (ALS) is a fatal disorder characterized by a progressive inability to execute movement. Although the disease is characterized by the loss of spinal motor neurons (MNs), novel evidence from our laboratory has pointed towards the implication of interneurons (INs) in the progression of the disease. Specifically, V1 spinal inhibitory INs (positive for Engrailed 1 – En1) lose their connections to MNs at early pre-symptomatic stages, which might lead to a MN hyperexcitability and cell death. The present study aimed to investigate whether forced overexpression of the presynaptic protein Extended Synagtotagmin 1 (ESYT1) in INs could stabilize MN-IN connectivity and ameliorate associated behavioral deficits. ESYT1, which is downregulated in spinal neurons early in disease, has been shown to enhance neurotransmission and modulate membrane trafficking. Here, intraspinal lumbar injections of the *cre*-dependent AAV8-hSyn-DIO-hESYT1-W3SL viral construct were performed in SOD1^{G93A} mice crossed with En1^{cre} mice. Four genotypes were investigated: SOD1, SOD1;En1^{cre}, En1^{cre} and wild-type. Locomotor behavior assessment between P49 and P112 showed that viral injections attenuated the deficits in SOD1;En1^{cre} compared to SOD1 animals, in parameters such as speed, peak acceleration, step frequency, and stride length. MN quantification showed that SOD1;En1^{cre} exhibited a significantly higher number of MN compared to SOD1 littermates and wildtype mice. Together, our results suggest that interneurons can be a potential therapeutic target to delay the development of ALS motor symptoms and point to a relevant role of ESYT1 in promoting MN survival.

NMR-based Metabolomics and Fatty Acid Profiles to Unravel Biomarkers in Preclinical Animal Models of Compulsive Behavior.
Compulsivity is a key manifestation of inhibitory control deficit and a cardinal symptom of psychopathological conditions such as obsessive-compulsive and attention-deficit hyperactivity disorders, in which metabolic alterations have raised attention as putative biomarkers for early identification. The present study assessed the metabolic profile in a preclinical model of a compulsive phenotype of rats. We used the schedule-induced polydipsia (SIP) method to classify male Wistar rats into high drinkers (HDs) or low drinkers (LDs) according to their compulsive drinking rate developed by exposure to a fixed-time 60 s (FT-60) schedule of reinforcement with water available during 20 sessions. Before and after SIP, blood samples were collected for subsequent serum analysis by nuclear magnetic resonance spectroscopy coupled to multivariate analysis. Although no differences existed in the pre-SIP set, the compulsive drinking behavior induced remarkable metabolic alterations: HD rats selected by SIP exhibited a hyperlipidemic, hypoglycemic, and hyperglutaminergic profile compared with their low-compulsive counterparts. Interestingly, these alterations were not attributable to the mere exposure to reward pellets because a control experiment did not show differences between HDs and LDs after 20 sessions of pellet consumption without intermittent reinforcement. Our results shed light toward the implication of dietary and metabolic factors underpinning the vulnerability to compulsive behaviors.

The Role of Social Stress in the Development of Inhibitory Control Deficit: A Systematic Review in Preclinical Models.
Inhibitory control deficit and impulsivity and compulsivity behaviours are present in different psychopathological disorders such as addiction, obsessive-compulsive disorders and schizophrenia, among others. Social relationships in humans and animals are governed by social organization rules, which modulate inhibitory control and coping strategies against stress. Social stress is associated with compulsive alcohol and drug use, pointing towards a determining factor in an increased

vulnerability to inhibitory control deficit. The goal of the present review is to assess the implication of social stress and dominance on the vulnerability to develop impulsive and/or compulsive spectrum disorders, with the aid of the information provided by animal models. A systematic search strategy was carried out on the PubMed and Web of Science databases, and the most relevant information was structured in the text and tables. A total of 34 studies were recruited in the qualitative synthesis. The results show the role of social stress and dominance in increased drug and alcohol use, aggressive and impulsive behaviour. Moreover, the revised studies support the role of Dopaminergic (DA) activity and the alterations in the dopaminergic D1/D2 receptors as key factors in the development of inhibitory control deficit by social stress.

Increased Compulsivity in Adulthood after Early Adolescence Immune Activation: Preclinical Evidence.
Immune activation during early developmental stages has been proposed as a contributing factor in the pathogenesis of neuropsychiatric conditions such as obsessive-compulsive disorder, attention-deficit/hyperactivity disorder, and autism in both human and animal studies. However, its relationship with the vulnerability to inhibitory control deficit, which is a shared feature among those conditions, remains unclear. The present work studied whether postnatal immune activation during early adolescence, combined with exposure to early-life adverse events, could lead to adult vulnerability to impulsive and/or compulsive behaviors. Male Wistar rats were exposed to lipopolysaccharide (LPS) in early adolescence at postnatal day 26 (PND26). During peripuberal period, half of the animals were exposed to a mild stress protocol. In adulthood, behavioral assessment was performed with the aid of the sustained attentional 5-choice serial reaction time (5-CSRT) task, schedule-induced polydipsia (SIP), and open-field locomotor activity and novelty reactivity. Rats exposed to LPS showed more compulsive responses than their control counterparts on 5-CSRT task, although no differences were observed in SIP or locomotor responses. Our study contributes to the knowledge of the relationship between immune activation and inhibitory control deficit. Future studies should aim to disentangle how, and to what extent, immune activation impacts behavior, and to understand the role of early life mild stress.

Increased vulnerability to impulsive behavior after streptococcal antigen exposure and antibiotic treatment in rats.
The inflammation induced by Group A Streptococcus (GAS) infection has been viewed as a vulnerability factor in mental disorders characterized by inhibitory control deficits, such as attention-deficit/hyperactivity disorder or obsessive-compulsive disorder. Antibiotic treatment reduces GAS symptoms; however, its effects on impulsivity have not been fully assessed.

Increased amygdala and decreased hippocampus volume after schedule-induced polydipsia in high drinker compulsive rats.
Fronto-limbic structures and serotonin 2A receptors (5-HT) have been implicated in the pathophysiology and treatment of compulsive spectrum disorders. Schedule-Induced Polydipsia (SIP), characterized by the development of excessive drinking under intermittent food reinforcement schedules, is a valid preclinical model for studying the compulsive phenotype. In the present study, we explored the individual differences and effect of SIP in brain volume and 5-HT receptor binding in fronto-limbic structures in rats selected according to their compulsive drinking behavior. Rats were divided into high (HD) and low drinkers (LD) by SIP (20 sessions); later, we analyzed the brains of HD and LD selected rats, in two different conditions: non-re-exposure (NRE) or re-exposure to SIP (RE), with four groups: LD-NRE, LD-RE, HD-NRE and HD-RE. Histological analyses were carried out for volumetric (stereology) and receptor binding (autoradiography) in the prelimbic and infralimbic cortex, dorsal hippocampus and basolateral amygdala. After SIP re-exposure, HD-RE showed an increased basolateral amygdala and a reduced hippocampus volume compared to HD-NRE rats, and also compared to LD-RE rats. No differences were found between HD and LD in NRE condition. Moreover, HD rats exhibit a lower 5-HT receptor binding in the basolateral amygdala, independently of SIP re-exposure, compared to LD rats. However, LD-RE showed a decreased 5-HT receptor binding in basolateral amygdala compared to LD-NRE. No differences were found in the remaining structures. These findings suggest that SIP might be differentially impacting HD and LD brains, pointing towards a possible explanation of how the latent vulnerability to compulsivity is triggered.

Neuropsychiatric consequences of childhood group A streptococcal infection: A systematic review of preclinical models.
In recent years, clinical studies have shown strong epidemiological evidence of an increased risk of developing neuropsychiatric disorders after childhood exposure to streptococcal infection, including the Pediatric Autoimmune Neuropsychiatric Disorders Associated with Streptococcal infection (PANDAS). New preclinical studies on group A streptococcus (GAS) exposure investigate how to disentangle the influences of immune activation to induce long-term

neurobehavioral effects associated with neuropsychiatric disorders such as obsessive-compulsive disorder, schizophrenia or autism. The present systematic review collects neurobehavioral evidence regarding the use of GAS exposure in animal models to study the vulnerability to different neuropsychiatric disorders, improving our understanding of its possible causes and consequences, and compares its contribution with other preclinical models of immune activation in a variety of paradigms. Specifically, we reviewed the effects of postnatal GAS exposure, in comparison with post- and prenatal exposure to Lipopolysaccharide (LPS) and Polyinosinic:polycytidylic acid (Poly I:C), on the long-term effects concerning psychomotor, cognition and socioemotional outcomes in rodents. GAS exposure in animal models has revealed different behavioral alterations such as reduced locomotion and motor coordination, a deficit in sensorimotor gating, learning, working memory, altered social behavior, and increased anxiety and stereotyped behavior. Most of the results found are in accordance with other immune activation models -LPS and Poly I:C-, with some discrepancies. The systematic review of the literature supports the preclinical model of GAS exposure as a valid model for studying the neurobehavioral consequences of streptococcal infections. Future studies on streptococcal infection could contribute increasing our knowledge on preventive actions or treatments for neuropsychiatric disorders.

Increased Fear Memory and Glutamatergic Modulation in Compulsive Drinker Rats Selected by Schedule-Induced Polydipsia.
Compulsive behavior is observed in several neuropsychiatric disorders such as obsessive-compulsive disorder (OCD), anxiety, depression, phobia, and schizophrenia. Thus, compulsivity has been proposed as a transdiagnostic symptom with a highly variable pharmacological treatment. Recent evidence shows that glutamate pharmacotherapy may be of benefit in impaired inhibitory control. The purpose of the present study was: first, to test the comorbidity between compulsivity and other neuropsychiatric symptoms on different preclinical behavioral models; second, to assess the therapeutic potential of different glutamate modulators in a preclinical model of compulsivity. Long Evans rats were selected as either high (HD) or low (LD) drinkers corresponding with their water intake in schedule-induced polydipsia (SIP). We assessed compulsivity in LD and HD rats by marble burying test (MBT), depression by forced swimming test (FST), anxiety by elevated plus maze (EPM) and fear behavior by fear conditioning (FC) test. After that, we measured the effects of acute administration (i.p.) of glutamatergic drugs: N-Acetylcysteine (NAC; 25, 50, 100 and 200 mg/kg), memantine (3.1 and 6.2 mg/kg) and lamotrigine (15 and 30 mg/kg) on compulsive drinking on SIP. The results obtained showed a relation between high compulsive drinking on SIP and a higher number of marbles partially buried in MBT, as well as a higher percentage of freezing on the retrieval day of FC test. We did not detect any significant differences between LD and HD rats in FST, nor in EPM. The psychopharmacological study of glutamatergic drugs revealed that memantine and lamotrigine, at all doses tested, decreased compulsive water consumption in HD rats compared to LD rats on SIP. NAC did not produce any significant effect on SIP. These results indicate that the symptom clusters of different forms of compulsivity and phobia might be found in the compulsive phenotype of HD rats selected by SIP. The effects of memantine and lamotrigine in HD rats point towards a dysregulation in the glutamatergic signaling as a possible underlying mechanism in the vulnerability to compulsive behavior on SIP. Further studies on SIP, could help to elucidate the therapeutic role of glutamatergic drugs as a pharmacological strategy on compulsive spectrum disorders.

Excessive habit formation in schedule-induced polydipsia: Microstructural analysis of licking among rat strains and involvement of the orbitofrontal cortex.
Schedule-induced polydipsia (SIP) is an animal model of compulsive drinking that selects for individual differences and varies across rat strains. The aim of this study was to investigate excessive habit formation by analyzing the SIP licking microstructure among rat strains, and to compare the brain areas activated by SIP in different populations. Wistar, Long Evans and Roman High- and Low-Avoidance rat strains were compared using a cluster analysis of 2 main variables, that is, frequency of licking (percentage of interpellet intervals with drinking episodes) and intensity of licking (mean number of licks per interpellet interval), and were found to exhibit high intensity and frequent licking (compulsive drinkers, CD), low intensity but frequent licking (habitual drinkers, HD), and low intensity and low-frequency licking (low drinkers, LD). The Wistar strain showed a higher frequency and intensity of licking, and had the largest group of CD rats when compared with the other strains. Regarding the acquisition of SIP, CD rats showed a higher intensity of licking when compared with the HD and LD rats. Moreover, c-Fos quantification revealed that rats in the CD group showed hyperactivity in the lateral orbitofrontal cortex and basolateral amygdala when compared with the LD group. Analyzing the SIP microstructure could be a valuable tool for understanding the role of excessive habit formation in the development of compulsive drinking and its underpinning neurobiological mechanisms.

Reduced cortical serotonin 5-HT receptor binding and glutamate activity in high compulsive drinker rats.
Serotonin receptors and glutamate signaling have been implicated in the pathophysiology and treatment of compulsive spectrum disorders. Schedule-Induced Polydipsia (SIP), characterized by excessive drinking under intermittent food reinforcement schedules, is a valid model for studying the compulsive phenotype in rats. We explored the expression, function, and neurochemistry of 5-HT receptors in the frontal cortex (FC) of rats with individual differences to compulsivity. Rats were selected for high (HD) versus low (LD) drinking on SIP. First, we measured 5-HT, 5-HT, and mGlu receptors and serotonin transporter binding in different brain regions. Second, we assessed the effect of microinfusion into the medial prefrontal cortex (mPFC) of the 5-HT receptor agonist DOI, the mGlu agonist LY379268, and the combination of DOI with the 5-HT receptor antagonist M100907 and the 5-HT receptor antagonist SB242084. Finally, we measured the serotonin and glutamate efflux in mPFC in basal condition and after DOI local application. The compulsive HD rats showed a specific reduction of 5-HT receptor binding in FC compared to LD rats. The highest dose of DOI reduced compulsive drinking in HD rats on SIP, whereas LY379268 did not induce any significant effect. The 5-HT receptor antagonist M100907 reversed the DOI induced reduction on compulsive drinking in HD rats while blocking the 5-HT receptor did not affect SIP. Compulsive HD rats showed increased serotonin and decreased glutamate efflux in basal conditions that were modified by the DOI application. These findings indicate that reduced 5-HT receptor binding and glutamate neurochemical mechanisms may underlie compulsive behavior vulnerability.

Do psychoactive drugs have a therapeutic role in compulsivity? Studies on schedule-induced polydipsia.
Clinical studies have shown that some psychoactive recreational drugs have therapeutic applications in anxiety, depression, and schizophrenia. However, to date, there are few studies on the therapeutic potential efficacy of recreational drugs in compulsive neuropsychiatric disorders.

MOTOR AND COGNITIVE BEHAVIORAL ALTERATIONS IN A NOVEL RAT MODEL OF TDP-43 OVEREXPRESSION

POSTER SESSION 03 - SECTION: AMYOTROPHIC LATERAL SCLEROSIS

Barış Can Çakır[1], Elif Polat Corumlu[2], Irem Armagan[3], Handan Kapkac[4], Muhittin Arslanyolu[4], Emel Ulupinar[5]
[1]Eskisehir Osmangazi University, Faculty Of Medicine, Eskişehir, Turkey, [2]Eskisehir Osmangazi University, Health Sciences Institute, Interdisciplinary Neuroscience Department, Eskisehir, Turkey, [3]Hacettepe University, Faculty Of Medicine, Ankara, Turkey, [4]Eskisehir Technical University, Department Of Biology, Eskisehir, Turkey, [5]Eskisehir Osmangazi University, Department Of Anatomy, Eskisehir, Turkey

Aims: Overexpression of TarDNA-binding protein-43(TDP-43) has recently been identified as one of the reasons of proteinopathy seen in various neurodegenerative diseases. In this study, we aimed to investigate behavioral alterations of rats following TDP-43 transduction via viral vectors. **Methods:** Sprague-Dawley male rats(n=8) were injected with Adeno-Associative Virus serotype 9 ($1.5X10^{12}$ gc/ml) containing the native TDP-43 with GFP under CMV promoter(AAV9-pCMV-TDP43-GFP). Control groups(n=6/each group) were received IV injections of either saline (SF) or vectors encoding only GFP (AAV9-pCMV-GFP) at postnatal day 30. After 15 days, motor skills of animals were assessed using the horizontal ladder rung walking test(HLRWT), attention and retention abilities via the novel object recognition (NOR) test, and spatial learning, memory performances via the 8-arm radial maze test(RA). **Results**: In HLRWT, motor performances of control animals were better and foot fault scores were significantly ($p<0.01$) lower than those of the experimental group. NOR test evaluated three different cognitive indexes; discrimination, recognition, and preference. Control groups received higher scores ($p<0.05$) in all of them. The time elapsed until all food rewards were consumed and the time spent in the center area of RA were significantly ($p< 0.05$) lower in the control groups. **Conclusion:** AAV9-based TDP-43 overexpression rat model induced motor, retention, and attention deficits, perhaps due to the natural neurotropism of viral capsid. This relatively low-cost and rapidly induced animal model might be used to investigate TDP-43 mediated disease mechanisms whose spectrum spans both FTLD and ALS (Supported by TUBITAK-Grant#1919B012004851). **Keywords**: AAV, TDP-43, CMV, motor behavior

PERIPHERAL INFLAMMATORY CHANGES AROUND MOTOR AXON TERMINALS IN THE TDP-43 MOUSE MODEL OF AMYOTROPHIC LATERAL SCLEROSIS

POSTER SESSION 03 - SECTION: AMYOTROPHIC LATERAL SCLEROSIS

Roland Patai[1], Bernát Nógrádi[1,2], Kinga Molnár[1], Rebeka Kristóf[3], Thomas Gillingwater[4], Helena Chaytow[4], Antal Nógrádi[3], László Siklós[1]
[1]Biological Research Centre, Szeged, Institute Of Biophysics, Szeged, Hungary, [2]University of Szeged, Department Of Neurology, Szeged, Hungary, [3]University of Szeged, Albert Szent-Györgyi Medical School, Department Of Anatomy, Histology And Embryology, Szeged, Hungary, [4]University of Edinburgh, Euan Macdonald Centre For Motor Neurone Disease Research, Edinburgh, United Kingdom

Mutations in TDP-43 are only present in 2-3% of ALS patients, but TDP-43 pathology is described in 95% of the cases, suggesting a prominent role in the pathogenesis. TDP-43 mislocalization induces a pro-inflammatory response around the spinal motoneurons, but similar alterations might also present around neuromuscular junctions (NMJs). We aimed to characterize the inflammatory changes around NMJs and their role in the propagation of TDP-43 pathology. Transgenic mice with neuron-specific TDP-43 pathology and age-matched hTDP-43 -/- control animals were used at postnatal day 20, representing a late-stage pathology. The tibialis anterior (TA) and gastrocnemius (GC) muscles were used for immunostaining and quantification of CD45+ leukocytes, CD3+ T-cells, and CD68+ macrophages. Cell counting was carried out both in the innervation zone (IZ) and outside of the innervation zone (OIZ). In both muscles, the number of CD45+ and CD3+ cells was elevated, but the elevation was more pronounced in the IZ. Furthermore, these changes were more prominent in the GC, than in the TA muscle. The CD68+ cell count was only elevated in the IZ. Protein microarray revealed increased pro-inflammatory factors in both muscles. Our results showed extensive immunoreaction in the muscle samples of hTDP-43 +/+ animals. Interestingly, the higher leukocyte density and chemotactic activity in the GC muscle was inversely proportional to the rate of NMJ degeneration, since denervation is known to be more prominent in the TA, than in the GC muscle. Such elevated immunoactivity around the degenerating NMJs, suggests NMJ-specific processes.

Calcium in the pathomechanism of amyotrophic lateral sclerosis - Taking center stage?
Amyotrophic lateral sclerosis is an incurable, relentlessly progressive disease primarily affecting motor neurons. The cause of the disease, except for the mutations identified in a small fraction of patients, is unknown. The major mechanisms contributing to the degeneration of motor neurons have already been disclosed and characterized, including excitotoxicity, oxidative stress, mitochondrial dysfunction, and immune/inflammatory processes. During the progression of the disease these toxic processes are not discrete, but each facilitates the deleterious effect of the other. However, due to their common reciprocal calcium dependence, calcium ions may act as a common denominator and through a positive feedback loop may combine the individual pathological processes into a unified escalating mechanism of neuronal destruction. This mini-review provides an overview of the mutual calcium dependence of the major toxic mechanisms associated with amyotrophic lateral sclerosis.

[Calcium ion is a common denominator in the pathophysiological processes of amyotrophic lateral sclerosis].
Amyotrophic lateral sclerosis (ALS), the most frequent motor neuron disease is characterized by progressive muscle weakness caused by the degeneration of the motor neurons in the spinal cord and motor cortex. However, according to the recent observations, ALS is a rather complex syndrome which frequently involves symptoms of cognitive impairment. Therefore, ALS cases can be interpreted in a clinico-pathological spectrum spanning from the classical ALS involving only the motor system to the fronto-temporal dementia. The progression of the disease, however, manifested in the degeneration of the upper and lower motor neurons, is based on the same complex pathobiology. The main elements of the pathomechanism, such as oxidative stress, excitotoxicity, immune/inflammatory processes and mitochondrial dysfunction are well described already, which operate in orchestrated way and amplify the deleterious effect of each other. It is assumed that calcium ions act as a catalyst in this interaction, hence each of the individual mechanisms has strong, positive and reciprocal

calcium dependence thus may combine the individual pathological processes into a unified escalating mechanism of neuronal destruction. This review provides an overview of the role of calcium in connecting and amplifying the major mechanisms which lead to degeneration of the motor neurons in ALS.

Response of the neurovascular unit to brain metastatic breast cancer cells.
Therapeutic resistance of cerebral secondary tumours largely depends on unique aspects linked to the neurovascular unit, especially cerebral endothelial cells and astrocytes. By using advanced microscopy techniques, here we explored novel mechanisms related to the neurovascular unit during extravasation and proliferation of triple negative breast cancer cells in the brain. Metastatic mammary carcinoma cells arrested and elongated within one hour in cerebral microvessels, but their number decreased by almost 80% in the first two days. Interestingly, malignant cells induced vasoconstriction and development of intraluminal endothelial plugs, which isolated invading cells from the circulation. During diapedesis - which usually took place on day four and five after inoculation of the tumour cells - continuity of cerebral endothelial tight junctions remained intact, indicating migration of cancer cells through the transcellular pathway. In addition, metastatic cells induced formation of multiluminal vessels and claudin-5-positive endothelial blebs. However, even severe endothelial blebbing could be reversed and the vessel morphology was restored shortly after the tumour cells completed transendothelial migration. Similar to neuro-inflammatory leukocytes, tumour cells migrated not only through the endothelial layer, but through the glia limitans perivascularis as well. Nevertheless, along with the growth of metastatic lesions by co-option of pre-existing capillaries, astrocytes and astrocyte end-feet were gradually expelled from the vessels to the border of the tumour. Taken together, we identified previously unknown mechanisms involved in the reaction of brain resident cells to invading breast cancer cells. Our results contribute to a better understanding of the complex cross-talk between tumour cells and host cells in the brain, which is essential for the identification of new therapeutic targets in this devastating disease.

Passive Transfer of Blood Sera from ALS Patients with Identified Mutations Results in Elevated Motoneuronal Calcium Level and Loss of Motor Neurons in the Spinal Cord of Mice.
Previously, we demonstrated the degeneration of axon terminals in mice after repeated injections of blood sera from amyotrophic lateral sclerosis (ALS) patients with identified mutations. However, whether a similar treatment affects the cell body of motor neurons (MNs) remained unresolved. Sera from healthy individuals or ALS patients with a mutation in different ALS-related genes were intraperitoneally injected into ten-week-old male Balb/c mice (= 3/serum) for two days. Afterward, the perikaryal calcium level was measured using electron microscopy. Furthermore, the optical disector method was used to evaluate the number of lumbar MNs. The cytoplasmic calcium level of the lumbar MNs of the ALS-serum-treated mice, compared to untreated and healthy-serum-treated controls, was significantly elevated. While injections of the healthy serum did not reduce the number of MNs compared to the untreated control group, ALS sera induced a remarkable loss of MNs. Similarly to the distant motor axon terminals, the injection of blood sera of ALS patients has a rapid degenerative effect on MNs. Analogously, the magnitude of the evoked changes was specific to the type of mutation; furthermore, the degeneration was most pronounced in the group treated with sera from ALS patients with a mutation in the gene.

Diazoxide blocks or reduces microgliosis when applied prior or subsequent to motor neuron injury in mice.
Diazoxide (DZX), an anti-hypertonic and anti-hypoglycemic drug, was shown to have anti-inflammatory effects in several injured cell types outside the central nervous system. In the brain, the neuroprotective potential of DZX is well described, however, its anticipated anti-inflammatory effect after acute injury has not been systematically analyzed. To disclose the anti-inflammatory effect of DZX in the central nervous system, an injury was induced in the hypoglossal and facial nuclei and in the oculomotor nucleus by unilateral axonal transection and unilateral target deprivation (enucleation), respectively. On the fourth day after surgery, microglial analysis was performed on tissue in which microglia were DAB-labeled and motoneurons were labeled with immunofluorescence. DZX treatment was given either prophylactically, starting 7 days prior to the injury and continuing until the animals were sacrificed, or postoperatively only, with daily intraperitoneal injections (1.25 mg/kg; in 10 mg/ml dimethyl sulfoxide in distilled water). Prophylactically + postoperatively applied DZX completely eliminated the microglial reaction in each motor nuclei. If DZX was applied only postoperatively, some microglial activation could be detected, but its magnitude was still significantly smaller than the non-DZX-treated controls. The effect of DZX could also be demonstrated through an extended period, as tested in the hypoglossal nucleus on day 7 after the operation. Neuronal counts, determined at day 4 after the operation in the hypoglossal nucleus, demonstrated no loss of motor neurons, however,

an increased Feret's diameter of mitochondria could be measured, suggesting increased oxidative stress in the injured cells. The increase of mitochondrial Feret's diameter could also be prevented with DZX treatment.

Experimental Motor Neuron Disease Induced in Mice with Long-Term Repeated Intraperitoneal Injections of Serum from ALS Patients.
In an earlier study, signs of commencing degeneration of spinal motor neurons were induced in mice with short-term intraperitoneal injections of immunoglobulin G (IgG) taken from patients with amyotrophic lateral sclerosis (ALS). Since in that study, neither weakness nor loss of motor neurons was noted, to test whether the ALS IgG in this paradigm has the potential to evoke relentless degeneration of motor neurons, treatment with repeated injections over a longer period was carried out. Mice were systematically injected intraperitoneally with serum taken from ALS patients over a 75-day period. At selected time points, the isometric force of the limbs, number of spinal motor neurons and their intracellular calcium levels were determined. Furthermore, markers of glial activation and the motoneuronal uptake of human IgG were monitored. During this period, gliosis and progressive motoneuronal degeneration developed, which led to gradual loss of spinal motor neurons, more than 40% at day 21, along with decreasing muscle strength in the limbs. The inclusion-like accumulation of IgG appeared in the perikarya with the increase of intracellular calcium in the cell bodies and motor nerve terminals. Our results demonstrate that ALS serum can transfer motor neuron disease to mice.

Upregulation of Nucleotide-Binding Oligomerization Domain-, LRR- and Pyrin Domain-Containing Protein 3 in Motoneurons Following Peripheral Nerve Injury in Mice.
Neuronal injuries are accompanied by release and accumulation of damage-associated molecules, which in turn may contribute to activation of the immune system. Since a wide range of danger signals (including endogenous ones) are detected by the nucleotide-binding oligomerization domain-, LRR- and pyrin domain-containing protein 3 (NLRP3) pattern recognition receptor, we hypothesized that NLRP3 may become activated in response to motor neuron injury. Here we show that peripheral injury of the oculomotor and the hypoglossal nerves results in upregulation of NLRP3 in corresponding motor nuclei in the brainstem of mice. Although basal expression of NLRP3 was observed in microglia, astroglia and neurons as well, its upregulation and co-localization with apoptosis-associated speck-like protein containing a caspase activation and recruitment domain, suggesting inflammasome activation, was only detected in neurons. Consequently, increased production of active pro-inflammatory cytokines interleukin-1β and interleukin-18 were detected after hypoglossal nerve axotomy. Injury-sensitive hypoglossal neurons responded with a more pronounced NLRP3 upregulation than injury-resistant motor neurons of the oculomotor nucleus. We further demonstrated that the mitochondrial protector diazoxide was able to reduce NLRP3 upregulation in a post-operative treatment paradigm. Our results indicate that NLRP3 is activated in motoneurons following acute nerve injury. Blockade of NLRP3 activation might contribute to the previously observed anti-inflammatory and neuroprotective effects of diazoxide.

Passive Transfer of Sera from ALS Patients with Identified Mutations Evokes an Increased Synaptic Vesicle Number and Elevation of Calcium Levels in Motor Axon Terminals, Similar to Sera from Sporadic Patients.
Previously, we demonstrated increased calcium levels and synaptic vesicle densities in the motor axon terminals (MATs) of sporadic amyotrophic lateral sclerosis (ALS) patients. Such alterations could be conferred to mice with an intraperitoneal injection of sera from these patients or with purified immunoglobulin G. Later, we confirmed the presence of similar alterations in the superoxide dismutase 1 G93A transgenic mouse strain model of familial ALS. These consistent observations suggested that calcium plays a central role in the pathomechanism of ALS. This may be further reinforced by completing a similar analytical study of the MATs of ALS patients with identified mutations. However, due to the low yield of muscle biopsy samples containing MATs, and the low incidence of ALS patients with the identified mutations, these examinations are not technically feasible. Alternatively, a passive transfer of sera from ALS patients with known mutations was used, and the MATs of the inoculated mice were tested for alterations in their calcium homeostasis and synaptic activity. Patients with 11 different ALS-related mutations participated in the study. Intraperitoneal injection of sera from these patients on two consecutive days resulted in elevated intracellular calcium levels and increased vesicle densities in the MATs of mice, which is comparable to the effect of the passive transfer from sporadic patients. Our results support the idea that the pathomechanism underlying the identical manifestation of the disease with or without identified mutations is based on a common final pathway, in which increasing calcium levels play a central role.

Presymptomatically applied AMPA receptor antagonist prevents calcium increase in vulnerable type of motor axon terminals of mice modeling amyotrophic lateral sclerosis.
Increased intracellular calcium (Ca), which might be the consequence of an excess influx through Ca-permeable α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors, plays a crucial role in degeneration of motor neurons. Previously we demonstrated that the presymptomatic application of AMPA receptor antagonist, talampanel, could reduce Ca elevation in spinal motor neurons of mice carrying the G93A mutation of superoxide dismutase 1 (SOD1), modeling amyotrophic lateral sclerosis (ALS). It remained to be examined whether the remote, functionally semi-autonomous motor axon terminals could be rescued from the Ca overload, or if the terminals, where the degeneration possibly starts, already experience intractable changes at early time points. Thus using electron microscopic techniques, we measured the Ca level of motor axon terminals in the interosseus muscle of the SOD1 mutant animals, which are prototypes of vulnerable nerve endings in ALS. In line with the results obtained in the perikarya, talampanel treatment could reduce Ca increase evoked by the presence of mutant SOD1 in the axon terminals if the treatment was started presymptomatically but not at an early symptomatic stage. We also tested the Ca level in the cell bodies and axon terminals of the oculomotor neurons, which are resistant to the disease. Neither Ca increase, nor talampanel effect could be demonstrated at either time point. This is consistent with the observations that oculomotor neurons contain increased level of Ca buffer, which could reduce excess Ca load, and they also express glutamate receptor subunit type 2, which renders AMPA receptors impermeable to Ca.

Axotomy Leads to Reduced Calcium Increase and Earlier Termination of CCL2 Release in Spinal Motoneurons with Upregulated Parvalbumin Followed by Decreased Neighboring Microglial Activation.
Motoneurons with naturally elevated calcium binding protein content, such as parvalbumin, are more resistant against injury. Furthermore, increase of intracellular calcium, which plays a pivotal role in injury of neurons, could be moderated by elevating their calcium binding proteins.

Microglia has helpful and detrimental actions in amyotrophic lateral sclerosis (ALS). The development of humanized mouse models with human microglia might be a promising tool to better understand the role of microglia in ALS and overcoming the limitations of the current ALS mouse models. **Aims:** We aimed to characterize *in vitro* human induced pluripotent stem cell (iPSC)-derived ALS microglia and, in an *in vivo* context, assess its cytotoxic effects to motoneurons (MN), as well as, to evaluate the differentiation of human iPSC-ALS microglial precursors in the mouse spinal cord. **Methods:** Human SOD^{I114T} iPSC were derived to microglia-like cells and their phenotype was confirmed by flow cytometry and immunofluorescence. We then, stimulated microglia with lipopolysaccharide and analysed cytokine expression by qPCR. Conditioned medium from ALS microglia was injected in the lumbar mouse spinal cord and MN counting was performed to assess its cytotoxicity. Finally, human SOD^{I114T} iPSC-derived microglial precursors were transplanted in the lumbar mouse spinal cord and studied their integration and differentiation. **Results:** *In vitro* human SOD^{I114T} iPSC-derived microglia-like cells expressed the main microglial markers (CD45^{low}, CD11b, Iba1, P2RY12), exhibited a ramified morphology and responded to a proinflammatory stimulus. Additionally, human SOD1^{I114T} iPSC-derived microglia released neurotoxic factors that induced MN degeneration in the mouse spinal cord. Transplantation of human SOD1^{I114T} iPSC-derived microglial precursors integrated and differentiated into microglia in the mouse spinal cord. **Conclusions:** This work recapitulates the preliminary data to further optimize a chimeric mouse with human ALS microglia.

Interleukin-4 and interleukin-13 induce different metabolic profiles in microglia and macrophages that relate with divergent outcomes after spinal cord injury.
Microglia and macrophages adopt a pro-inflammatory phenotype after spinal cord injury (SCI), what is thought to contribute to secondary tissue degeneration. We previously reported that this is due, in part, to the low levels of anti-inflammatory cytokines, such as IL-4. Since IL-13 and IL-4 share receptors and both cytokines drive microglia and macrophages towards an anti-inflammatory phenotype , here we studied whether administration of IL-13 and IL-4 after SCI leads to beneficial effects. We injected mice with recombinant IL-13 or IL-4 at 48 h after SCI and assessed their effects on microglia and macrophage phenotype and functional outcomes. We also performed RNA sequencing analysis of macrophages and microglia sorted from the injured spinal cords of mice treated with IL-13 or IL-4 and evaluated the metabolic state of these cells by using Seahorse technology. We observed that IL-13 induced the expression of anti-inflammatory markers in microglia and macrophages after SCI but, in contrast to IL-4, it failed to mediate functional recovery. We found that these two cytokines induced different gene signatures in microglia and macrophages after SCI and that IL-4, in contrast to IL-13, shifted microglia and macrophage metabolism from glycolytic to oxidative phosphorylation. These findings were further confirmed by measuring the metabolic profile of these cells. Importantly, we also revealed that macrophages stimulated with IL-4 or IL-13 are not deleterious to neurons, but they become cytotoxic when oxidative metabolism is blocked. This suggests that the metabolic shift, from glycolysis to oxidative phosphorylation, is required to minimize the cytotoxic responses of microglia and macrophages. These results reveal that the metabolic fitness of microglia and macrophages after SCI contributes to secondary damage and that strategies aimed at boosting oxidative phosphorylation might be a novel approach to minimize the deleterious actions of microglia and macrophages in neurotrauma.

Inhibition of the NLRP3 inflammasome by OLT1177 induces functional protection and myelin preservation after spinal cord injury.

Spinal cord injury (SCI) leads to irreversible functional deficits due to the disruption of axons and the death of neurons and glial cells. The inflammatory response that occurs in the injured spinal cord results in tissue degeneration; thus, targeting inflammation after acute SCI is expected to ameliorate histopathological evidence indicative of damage and, consequently, reduce functional disabilities. Interleukin 1 beta (IL-1β) and interleukin 18 (IL-18) are pro-inflammatory cytokines members of the IL-1 family that initiate and propagate inflammation. Here, we report that protein levels of IL-1β and IL-18 were increased in spinal cord parenchyma after SCI, but with different expression profiles. Whereas levels of IL-1β were rapidly increased reaching peak levels at 12 h after the injury, levels of IL-18 did not increase until 7 days after the injury. Since activation of the NLRP3 inflammasome is required for the processing and release of IL-1β and IL-18, we intraperitoneally administered OLT1177, a selective inhibitor of the NLRP3 inflammasome, to reduce the contribution of these cytokines to SCI. At a dose of 200 mg/kg, OLT1177 protected against neurological deficits and histological evidence of damage. OLT1177 also reduced the levels of IL-1β in the spinal cord after contusion injury and diminished the accumulation of neutrophils and macrophages at later time points. These data suggest that targeting the NLRP3 inflammasome with OLT1177 could be a novel therapeutic strategy to arrest neuroinflammation and reduce functional impairments after acute SCI in humans.

Amyotrophic lateral sclerosis (ALS) is a devastating neurodegenerative disease characterised by the death of upper and lower motoneurons (MNs). The mechanisms underlying MN degeneration in ALS are not fully known, but it might be a combination of multiple pathogenic mechanisms that culminate in a larger network disruption. Current studies are mostly focused on treating a single pathogenic pathway involved, leading to lack of effective cure for ALS. Therefore, it is pursued to find novel and combinational therapeutic strategies. In this project, we evaluate whether the simultaneous activation of two complementary targets, the voltage-gated potassium channels 7.2/3 (Kv7.2/3) and the mitochondrial translocator protein (TSPO), by the novel synthetized GRTX chemical compound could be effective for neuroprotection and gliosis reduction in MN degenerative models. GRTX effectively preserved spinal cord neurons and modulated glial reactivity in spinal cord organotypic cultures under exposure to astrocyte conditioned medium (ACM) derived from $SOD1^{G93A}$ mice astrocytes and $SOD1^{D90A}$ primary human astrocytes derived from SOD1 patients. Similar results are shown when cultures are exposed to ACM derived from $TDP43^{A90V}$ astrocytes differentiated from human induced pluripotent stem cells. *In vivo* toxicological studies indicated the safety profile of GRTX and its capacity to cross the blood-brain barrier. Daily oral administration of GRTX compound in $SOD1^{G93A}$ mice improved motor function determined by electrophysiologic, rotarod and treadmill tests. Histological studies proved that GRTX preserves motoneuron degeneration, modulates glial reactivity and maintains neuromuscular junction innervation. All these data suggest GRTX is a good candidate to be explored for the treatment of ALS.

AIMS In amyotrophic lateral sclerosis (ALS), glial cells contribute to disease progression and motoneuron damage. Although ALS etiology has not been entirely elucidated, the role of glutamate-mediated excitotoxicity and the involvement of metabotropic glutamate receptor type-5 (mGluR5) is widely accepted. We aimed to investigate the impact of in-vivo partial deletion of mGluR5 in $SOD1^{G93A}$ mice ($SOD1^{G93A}mGluR5^{+/-}$) on microglia inflammatory, bioenergetic, and oxidative characteristics and sex influence. METHODS Spinal cord microglia was acutely isolated from 30-and 120-days-old WT, $SOD1^{G93A}$, $WTmGluR5^{+/-}$ and $SOD1^{G93A}mGluR5^{+/-}$ mice by CD11b-linked magnetic MicroBeads. Microglia expression of pro-(CD40, CD86, MHCII, iNOS) and anti-inflammatory (CD16-32, CD206, CD163, Arg1) markers was detected by flow cytometry. Oxygen consumption, ATP synthesis, aerobic/anaerobic glucose metabolism, glutathione reductase and peroxidase, catalase and malondialdehyde were also studied. RESULTS 120-days-old microglia displayed a significantly different inflammatory pattern with respect to 30-days-old ones, showing increased MHCII, CD16-32, ARG1 and CD86. The two WT phenotypes showed high expression of CD206, CD163, and iNOS, while the $SOD1^{G93A}$ phenotypes were characterized by a higher expression of CD40. Deletion of mGluR5 did not affect the inflammatory WT or $SOD1^{G93A}$ patterns. Bioenergetic studies highlighted increased oxygen consumption and decreased ATP synthesis, accompanied by increased anaerobic glycolysis in $SOD1^{G93A}$ mice. Also, antioxidant responses and lipid peroxidation augmented in $SOD1^{G93A}$ mice. All the above changes were restored in $SOD1^{G93A}mGluR5^{+/-}$mice. Finally, sex always induced no significant differences. CONCLUSIONS Pre- and late-symptomatic microglia exhibited a different inflammatory pattern. Deleting mGluR5 in $SOD1^{G93A}$ micerestored the energetic metabolism/red-ox failure while not affecting the inflammatory status.

Nearly 30 Years of Animal Models to Study Amyotrophic Lateral Sclerosis: A Historical Overview and Future Perspectives. Amyotrophic lateral sclerosis (ALS) is a fatal, multigenic, multifactorial, and non-cell autonomous neurodegenerative disease characterized by upper and lower motor neuron loss. Several genetic mutations lead to ALS development and many emerging gene mutations have been discovered in recent years. Over the decades since 1990, several animal models have been generated to study ALS pathology including both vertebrates and invertebrates such as yeast, worms, flies, zebrafish, mice, rats, guinea pigs, dogs, and non-human primates. Although these models show different peculiarities, they are all useful and complementary to dissect the pathological mechanisms at the basis of motor neuron degeneration and ALS progression, thus contributing to the development of new promising therapeutics. In this review, we describe the up to date and available ALS genetic animal models, classified by the different genetic mutations and divided per species, pointing out their features in modeling, the onset and progression of the pathology, as well as their specific pathological hallmarks. Moreover, we highlight similarities, differences, advantages, and limitations, aimed at helping the researcher to select the most appropriate experimental animal model, when designing a preclinical ALS study.

Blocking glutamate mGlu receptors with the negative allosteric modulator CTEP improves disease course in SOD1 mouse model of amyotrophic lateral sclerosis.

The pathogenesis of amyotrophic lateral sclerosis (ALS) is not fully clarified, although excessive glutamate (Glu) transmission and the downstream cytotoxic cascades are major mechanisms for motor neuron death. Two metabotropic glutamate receptors (mGlu and mGlu) are overexpressed in ALS and regulate cellular disease processes. Expression and function of mGlu receptors are altered at early symptomatic stages in the SOD1 mouse model of ALS and knockdown of mGlu5 receptors in SOD1 mice improved disease progression.

Enhanced Function and Overexpression of Metabotropic Glutamate Receptors 1 and 5 in the Spinal Cord of the SOD1 Mouse Model of Amyotrophic Lateral Sclerosis during Disease Progression.
Glutamate (Glu)-mediated excitotoxicity is a major cause of amyotrophic lateral sclerosis (ALS) and our previous work highlighted that abnormal Glu release may represent a leading mechanism for excessive synaptic Glu. We demonstrated that group I metabotropic Glu receptors (mGluR1, mGluR5) produced abnormal Glu release in SOD1 mouse spinal cord at a late disease stage (120 days). Here, we studied this phenomenon in pre-symptomatic (30 and 60 days) and early-symptomatic (90 days) SOD1 mice. The mGluR1/5 agonist ()-3,5-Dihydroxyphenylglycine (3,5-DHPG) concentration dependently stimulated the release of [H]d-Aspartate ([H]d-Asp), which was comparable in 30- and 60-day-old wild type mice and SOD1 mice. At variance, [H]d-Asp release was significantly augmented in 90-day-old SOD1 mice and both mGluR1 and mGluR5 were involved. The 3,5-DHPG-induced [H]d-Asp release was exocytotic, being of vesicular origin and mediated by intra-terminal Ca release. mGluR1 and mGluR5 expression was increased in Glu spinal cord axon terminals of 90-day-old SOD1 mice, but not in the whole axon terminal population. Interestingly, mGluR1 and mGluR5 were significantly augmented in total spinal cord tissue already at 60 days. Thus, function and expression of group I mGluRs are enhanced in the early-symptomatic SOD1 mouse spinal cord, possibly participating in excessive Glu transmission and supporting their implication in ALS. Please define all abbreviations the first time they appear in the abstract, the main text, and the first figure or table caption.

Presynaptic GLP-1 receptors enhance the depolarization-evoked release of glutamate and GABA in the mouse cortex and hippocampus.
Glucagon-like peptide-1 receptors (GLP-1Rs) have been shown to mediate cognitive-enhancing and neuroprotective effects in the central nervous system. However, little is known about their physiological roles on central neurotransmission, especially at the presynaptic level. Using purified synaptosomal preparations and immunofluorescence techniques, here we show for the first time that GLP-1Rs are localized on mouse cortical and hippocampal synaptic boutons, in particular on glutamatergic and GABAergic nerve terminals. Their activation by the selective agonist exendin-4 (1-100 nM) was able to increase the release of either [H]d-aspartate or [H]GABA. These effects were abolished by 10 nM of the selective GLP1-R antagonist exendin-3 (9-39) and were prevented by the selective adenylyl cyclase inhibitor 2',5'-dideoxyadenosine (10 µM), indicating the involvement of classic GLP-1Rs coupled to G protein stimulating cAMP synthesis. Our data demonstrate the existence and activity of presynaptic receptors for GLP-1 that could represent additional mechanisms by which this neurohormone exerts its effects in the CNS. © 2017 BioFactors, 44(2):148-157, 2018.

Memory-enhancing effects of GEBR-32a, a new PDE4D inhibitor holding promise for the treatment of Alzheimer's disease.
Memory loss characterizes several neurodegenerative disorders, including Alzheimer's disease (AD). Inhibition of type 4 phosphodiesterase (PDE4) and elevation of cyclic adenosine monophosphate (cAMP) has emerged as a promising therapeutic approach to treat cognitive deficits. However, PDE4 exists in several isoforms and pan inhibitors cannot be used in humans due to severe emesis. Here, we present GEBR-32a, a new PDE4D full inhibitor that has been characterized both in vitro and in vivo using biochemical, electrophysiological and behavioural analyses. GEBR-32a efficiently enhances cAMP in neuronal cultures and hippocampal slices. In vivo pharmacokinetic analysis shows that GEBR-32a is rapidly distributed within the central nervous system with a very favourable brain/blood ratio. Specific behavioural tests (object location and Y-maze continuous alternation tasks) demonstrate that this PDE4D inhibitor is able to enhance memory in AD transgenic mice and concomitantly rescues their hippocampal long-term potentiation deficit. Of great relevance, our preliminary toxicological analysis indicates that GEBR-32a is not cytotoxic and genotoxic, and does not seem to possess emetic-like side effects. In conclusion, GEBR-32a could represent a very promising cognitive-enhancing drug with a great potential for the treatment of Alzheimer's disease.

ALS is the most common motor neuron disease in humans, whereby upper and lower motor neurons degenerate, eventually resulting in death. A major hypothesis underlying the mechanistic origin of neurodegeneration in ALS postulates that cortical hyperexcitability facilitates cell death. Previous research has identified the G_4C_2 hexanucleotide repeat expansion in the *C9orf72* gene as the most common genetic cause of ALS; however, little is known about the contribution of the *C9orf72* gene to neuronal excitability in the primary motor cortex. Thus, using a *C9orf72* knockout loss-of-function (C9-KO LOF) mouse model, we assessed the intrinsic firing excitability of corticomotor neurons using whole-cell patch-clamp recordings made from acute brain slices. We have found that after disease onset, the action potential firing frequency is significantly higher in the C9-KO LOF mice compared to wildtype mice, highlighting cortical excitability at this timepoint. Moreover, we have found a significant reduction in spontaneous and miniature excitatory postsynaptic current frequency, as well as a significant increase in miniature excitatory postsynaptic current amplitude in the C9-KO LOF mice compared to wildtype mice, suggesting impaired basal excitatory network function. Further investigation into the local inhibitory circuitry will reveal essential information about the neurophysiological mechanisms underlying neurodegeneration in *C9orf72* ALS patients, which could contribute to the development of future therapeutic strategies.

Mapping Stakeholder Perspectives on Engagement in Concussion Research to Theory.
Involving stakeholders has been acknowledged as a way to improve quality and relevance in health research. The mechanisms that support effective research engagement with stakeholders have not been studied in the area of concussion. Concussion is a large public health concern worldwide with billions of dollars spent on health care services and research with improvements in care and service delivery not moving forward as quickly as desired. Enabling effective stakeholder engagement could improve concussion research and care.

Background. Increased levels of a peptide derived from Gpnmb in the cerebrospinal fluid (CSF) were recently associated with a poor prognosis in patients affected by Amyotrophic Lateral Sclerosis (ALS). On the other hand, other studies highlighted that upregulation of Gpnmb could play a neuroprotective and immunomodulatory role. **Aims.** In this study we engaged an in-depth characterization of Gpnmb alterations in SOD1.G93A transgenic (TG) rat model of ALS and in patients, to clarify the value of Gpnmb as prognostic biomarker and to identify a precise time-window, during the disease process, suitable for successful therapeutic intervention. **Methods.** We applied in-situ hybridization (ISH) and immunohistochemistry (IHC) in the central and peripheral nervous system, coupled to the assessment of Gpnmb ectodomain ($Gpnmb^{E}$) in the CSF and blood of TG rats. In parallel, $Gpnmb^{E}$ was assessed in a small cohort of ALS patients. **Results and discussion.** Gpnmb is mainly expressed in MNs in healthy conditions. However, in TG animals there is an early decrease of Gpnmb mRNA and protein levels in MNs and upregulation in reactive microglia after symptom onset. ISH and IHC highlighted a critical role for glial cells in the synthesis and release of $Gpnmb^{E}$. In parallel, we spotted a significant increase of $Gpnmb^{E}$ in the CSF and blood of TG rats, as well as in ALS patients, when the pathology is more severe. We are currently running a preclinical proof of concept study to verify the therapeutic potential of early administration of recombinant Gpnmb while monitoring $Gpnmb^{E}$ as biomarker of target engagement.

Background. Neuroinflammation is recognized as a pathological hallmark and potential therapeutic target for many neurodegenerative diseases including Amyotrophic Lateral Sclerosis (ALS). However, neuroinflammatory responses are heterogeneous and reflect not only the extent of neuronal demise but also variable engagement glial cells in the attempt to cope with the neuronal damage. Thus, new pharmacological tools targeting specific cell subpopulations are warranted. We hypothesized that TSPO ligands, already widely used in the clinic to track neuroinflammation through PET, could be exploited to achieve selective cell targeting via a novel theranostic platform based on MRI/PET traceable nanoparticles (NPs). **Aims.** In this work we aimed at: i) obtaining an in-depth analysis of TSPO distribution and correlation with disease stage in ALS animal models; ii) validating TSPO-targeted nanoparticles as potential novel cell-specific pharmacological tool. **Methods.** We performed in-situ hybridization (ISH) and immunohistochemistry (IHC) experiments to investigate the expression and distribution of TSPO in the CNS of transgenic SOD1(G93A) rat model of ALS, which recapitulates the heterogeneous disease manifestations observed in patients. In parallel, we developed and validated novel polymeric NPs functionalized with TSPO-ligands. **Results, conclusions.** We confirmed by ISH/IHC a clearcut upregulation of TSPO in microglia cells in the CNS areas most severely affected by the disease. Functionalization of NPs with two TSPO-selective PET tracers (PBR-28, PK11195) determined a TSPO-dependent NPs internalization in microglia cells both in vitro and in vivo. Based on these results, we launched a proof-of-concept preclinical study (in progress) to test the therapeutic potential of NPs targeting the NF-kB proinflammatory pathway.

Heterogeneity of Neuroinflammatory Responses in Amyotrophic Lateral Sclerosis: A Challenge or an Opportunity?
Amyotrophic Lateral Sclerosis (ALS) is a complex pathology: (i) the neurodegeneration is chronic and progressive; it starts focally in specific central nervous system (CNS) areas and spreads to different districts; (ii) multiple cell types further than motor neurons (i.e., glial/immune system cells) are actively involved in the disease; (iii) both neurosupportive and neurotoxic neuroinflammatory responses were identified. Microglia cells (a key player of neuroinflammation in the CNS) attracted great interest as potential target cell population that could be modulated to counteract disease progression, at least in preclinical ALS models. However, the heterogeneous/multifaceted microglia cell responses occurring in different CNS districts during the disease represent a hurdle for clinical translation of single-drug therapies. To address this issue, over the past ten years, several studies attempted to dissect the complexity of microglia responses in ALS. In this review, we shall summarize these results highlighting how the heterogeneous signature displayed by ALS microglia reflects not only the extent of neuronal demise in different regions of the CNS, but also variable engagement in the attempts to cope with the neuronal damage. We shall discuss novel avenues opened by the advent of single-cell and spatial transcriptomics technologies, underlining the potential for discovery of novel therapeutic targets, as well as more specific diagnostic/prognostic not-invasive markers of neuroinflammation.

MODELLING ALS WITH GENOME ENGINEERED HUMANISED DROSOPHILA

POSTER SESSION 03 - SECTION: AMYOTROPHIC LATERAL SCLEROSIS

Emma Kallstig, Evelyne Ruchti, Marine Van Campenhoudt, Bernard Schneider, Brian Mccabe
EPFL Swiss Federal Institute of Technology, Bmi, Lausanne, Switzerland

Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disorder which induces motor system degeneration causing paralysis and death within 3-5 years of diagnosis. While the underlying cause of the majority of ALS cases is unknown, over 25 different genes have been linked to inherited familial forms of the disease (fALS). Among these is Fused in Sarcoma (FUS) which is mutated in 5% of fALS cases. FUS is an RNA and DNA binding nuclear protein that regulates gene expression and mRNA splicing. In fALS patients mutations in the *FUS* gene can cause disruption of FUS nuclear localization and induce cytoplasmic aggregation. We have used novel CRISPR/Cas9 based genome engineering technology to replace the *Drosophila* FUS ortholog Caz with wildtype or ALS-associated mutant human FUS, creating strains where human FUS is expressed in the correct pattern and level for the host animal. We will present data on the motor system and other phenotypes of these models which contrasts with existing overexpression and misexpression FUS models. We envision these new high fidelity humanised strains will enable interrogation of the molecular mechanisms of ALS in a genetically tractable animal model.

MOLECULAR EFFECTS OF B-RAF AND 14-3-3 ζ/δ ON EMBRYONIC SPINAL CORD CELLS IN A SEVERE MODEL FOR SPINAL MUSCULAR ATROPHY (SMA)

POSTER SESSION 03 - SECTION: AMYOTROPHIC LATERAL SCLEROSIS

Antonia Joseph[1,2,3], Hensel[3,4], Peter Claus[1,3]
[1]SMATHERIA gGmbH, Prof. Claus, Hannover, Germany, [2]University of Veterinary Medicine Hannover, Department Of Pharmacology, Toxicology And Pharmacy, Hannover, Germany, [3]University of Veterinary Medicine Hannover, Center For Systems Neuroscience, Hannover, Germany, [4]University of Ottawa, Ottawa Hospital Research Institute, Ottawa, Canada

Aims: Spinal Muscular Atrophy (SMA) is an autosomal-recessive neurodegenerative disease. Mutations of the Survival of Motoneuron 1 (*SMN1*) gene cause SMA. Low levels of the SMN protein cause death of motoneurons in the spinal cord and brain stem resulting in muscular atrophy. Approved therapies focus on enhancing SMN levels. However, not all dysregulated pathways in SMA are restored by those treatments. ERK1/2, a member of the MAPK-signaling cascade, and AKT are both hyper-phosphorylated in SMA. Furthermore B-RAF, an upstream factor of ERK, and 14-3-3 ζ/δ, an upstream regulator of B-Raf, are both downregulated. B-Raf functions as a central hub between altered AKT and 14-3-3 ζ/δ signaling clusters (Hensel et al. 2021; PNAS). In this study, we aimed to evaluate the effects of upregulation of both factors on pathway regulation. Methods: Embryonic spinal cord cells of a severe mouse model of SMA were transfected with an Adeno-associated virus-vector comprising either the cDNA of B-Raf or 14-3-3 ζ/δ. Protein levels were evaluated by Western blot analyses. Results: A significant upregulation of phosphorylated ERK was observed in control cells, but not in SMA cells. No influence on B-Raf or 14-3-3 ζ/δ was observed in control and SMA cells after transduction. Conclusion: We conclude from those experiments that ERK phosphorylation is not only regulated by B-Raf, but instead by additional mechanisms. Therefore, additional strategies on top of B-Raf restauration have to be taken into consideration to achieve a more pronounced rescue of the SMA phenotype.

University of Turin, Department Of Neuroscience, Neuroscience Institute Cavalieri Ottolenghi, Turin, Italy

Spinal Muscular Atrophy (SMA) is a paediatric neuromuscular disease caused by survival motor neuron (*SMN*) 1 gene mutation, leading to degeneration of lower alpha motor neurons, muscular atrophy and premature death. Despite the genetic causes of SMA are known, many aspects of its pathogenesis are still poorly understood. In the last years, mitochondrial dysfunction is emerging as a key factor in several diseases, including SMA. Here, we deepened the role of mitochondrial morpho-functional dysfunctions in SMA both at central and peripheral level in lumbar spinal cord and mouse embryonic fibroblasts (MEFs) from delta7 SMA mouse model, and in human fibroblasts derived from patients. TEM analysis highlighted dramatic ultrastructural mitochondrial alterations in SMA compared to healthy controls. Mitochondrial Network Analysis in MEFs underlined an increased mitochondrial network fragmentation and the presence of giant and swollen organelles in SMA. Then, by 2-DE and MALDI-TOF mass spectrometry on pure mitochondria isolated from the spinal cord, we identified m-Aco as differentially expressed between SMA and controls. Co-immunoprecipitation and enzymatic tests revealed Aconitase ubiquitination and loss of function both in murine and human fibroblasts. Overall, these observations suggest mitochondria as possible new targets for SMA treatment: indeed the maintenance of mitochondria integrity and mitochondrial turnover could potentially become one major site of pharmacological intervention, in the effort of identifying innovative SMN-independent therapies.

STORE-OPERATED CA2+ ENTRY IS ALTERED IN SPASTIN-LINKED HEREDITARY SPASTIC PARAPLEGIA

POSTER SESSION 03 - SECTION: AMYOTROPHIC LATERAL SCLEROSIS

Tania Rizo[1], Lisa Gebhardt[2], Julia Riedlberger[1], Jürgen Winkler[3], Michael Fischer[4], Barbara Niemeyer[5], Beate Winner[1]
[1]Universitätsklinikum Erlangen, Department Of Stem Cell Biology, Erlangen, Germany, [2]Friedrich-Alexander-Universität Erlangen-Nürnberg, Institute Of Physiology And Pathophysiology, Erlangen, Germany, [3]Friedrich-Alexander-Universität Erlangen-Nürnberg, Department Of Molecular Neurology, Erlangen, Germany, [4]Medical University of Vienna, Center Of Physiology And Pharmacology, Vienna, Austria, [5]University of Saarland, Molecular Biophysics, Homburg/Saar, Germany

Pathogenic variants in SPAST, the gene coding for spastin are the single most common cause of Hereditary spastic paraplegia (HSP), a progressive motor neuron disorder which mainly affects the axons of corticospinal motor neurons in a “dying-back” manner. Spastin is a microtubule-severing protein that in addition contributes to the ER-morphogenesis. How spastin dysregulation leads to axonal degeneration is still unclear. Increasing evidence shows that the endoplasmic reticulum (ER) and its interplay with the microtubule network is crucial for effective store-operated calcium entry (SOCE), a cellular process which is triggered by ER-Ca2+ store depletion, and requires reshaping of ER and of the ER-resident protein STIM1. Here, we link the dysregulation of spastin, to alterations in the ER structure and dynamic transport of STIM1, and show that Ca2+ regulation via SOCE is compromised in neurons derived from the induced pluripotent stem cells (iPSCs) of patients with pathogenic mutations in SPAST. Genome editing using CRISPR/Cas9 technology to correct the pathogenic variants in spastin, successfully restored spastin expression levels, Ca2+ regulation, and axonal integrity. Our results show that spastin is a key component in the regulation of Ca2+ homeostasis via SOCE and implicates SOCE dysregulation as a pathogenic mechanism in spastin-linked motor neuron disease

Modeling Cell-Cell Interactions in Parkinson's Disease Using Human Stem Cell-Based Models.
Parkinson's disease (PD) is the most frequently occurring movement disorder, with an increasing incidence due to an aging population. For many years, the post-mortem brain was regarded as the gold standard for the analysis of the human pathology of this disease. However, modern stem cell technologies, including the analysis of patient-specific neurons and glial cells, have opened up new avenues for dissecting the pathologic mechanisms of PD. Most data on morphological changes, such as cell death or changes in neurite complexity, or functional deficits were acquired in 2D and few in 3D models. This review will examine the prerequisites for human disease modeling in PD, covering the generation of midbrain neurons, 3D organoid midbrain models, the selection of controls including genetically engineered lines, and the study of cell-cell interactions. We will present major disease phenotypes in human models of PD, focusing on those phenotypes that have been detected in genetic and sporadic PD models. An additional point covered in this review will be the use of induced pluripotent stem cell (iPSC)-derived technologies to model cell-cell interactions in PD.

Mechanistic basis of an epistatic interaction reducing age at onset in hereditary spastic paraplegia.
Many genetic neurological disorders exhibit variable expression within affected families, often exemplified by variations in disease age at onset. Epistatic effects (i.e. effects of modifier genes on the disease gene) may underlie this variation, but the mechanistic basis for such epistatic interactions is rarely understood. Here we report a novel epistatic interaction between SPAST and the contiguous gene DPY30, which modifies age at onset in hereditary spastic paraplegia, a genetic axonopathy. We found that patients with hereditary spastic paraplegia caused by genomic deletions of SPAST that extended into DPY30 had a significantly younger age at onset. We show that, like spastin, the protein encoded by SPAST, the DPY30 protein controls endosomal tubule fission, traffic of mannose 6-phosphate receptors from endosomes to the Golgi, and lysosomal ultrastructural morphology. We propose that additive effects on this pathway explain the reduced age at onset of hereditary spastic paraplegia in patients who are haploinsufficient for both genes.

Defects in ER-endosome contacts impact lysosome function in hereditary spastic paraplegia.
Contacts between endosomes and the endoplasmic reticulum (ER) promote endosomal tubule fission, but the mechanisms involved and consequences of tubule fission failure are incompletely understood. We found that interaction between the microtubule-severing enzyme spastin and the ESCRT protein IST1 at ER-endosome contacts drives endosomal tubule fission. Failure of fission caused defective sorting of mannose 6-phosphate receptor, with consequently disrupted lysosomal enzyme trafficking and abnormal lysosomal morphology, including in mouse primary neurons and human stem cell-derived neurons. Consistent with a role for ER-mediated endosomal tubule fission in lysosome function, similar lysosomal abnormalities were seen in cellular models lacking the WASH complex component strumpellin or the ER morphogen REEP1. Mutations in , , or cause hereditary spastic paraplegia (HSP), a disease characterized by axonal degeneration. Our results implicate failure of the ER-endosome contact process in axonopathy and suggest that coupling of ER-mediated endosomal tubule fission to lysosome function links different classes of HSP proteins, previously considered functionally distinct, into a unifying pathway for axonal degeneration.

NLRP3 inflammasome is expressed by astrocytes in the SOD1 mouse model of ALS and in human sporadic ALS patients.
Amyotrophic lateral sclerosis (ALS) is characterized by the degeneration of motoneurons in the cerebral cortex, brainstem and spinal cord. Neuroinflammation plays an important role in the pathogenesis of ALS and involves the activation of microglia and astrocytes. Intracellular inflammasome complexes are part of the innate immunity as they sense and execute host inflammatory responses. The best characterized component is the NLRP3 inflammasome comprised of the NLR protein NLRP3, the adaptor ASC and pro-caspase 1. The NLRP3 inflammasome is critical for the activation of caspase 1 and the processing and release of IL1β and IL18. In this study, we investigated the expression, activation and co-localization of the NLRP3 inflammasome in the spinal cord of male SOD1(G93A) mice carrying a mutant human superoxide dismutase 1 (SOD1) variant and regarded as an animal model for ALS as well as in post-mortem tissue of ALS patients. NLRP3 and its molecular components as well as IL1β were already detectable in SOD1 mice at a pre-symptomatic stage after 9 weeks and further increased in 14 week old animals. Spinal cord astrocytes were identified as the major cell type expressing NLRP3 components. In human ALS tissue, we also found increased NLRP3, ASC, IL18 and active caspase 1 levels compared to control patients. Our findings suggest that astroglial NLRP3 inflammasome complexes are critically involved in neuroinflammation in ALS.

Amyotrophic lateral sclerosis (ALS) is the most prevalent motor neuron disease characterized by the progressive degeneration of motor functions and other non-motor symptoms, including cognitive deficits. Interestingly, it has been described a positive correlation between body mass index and delayed symptoms in ALS patients suggesting that high levels of leptin of obese patients could be underlying the increased survival rate. Thus, the aim of this study was to evaluate, in a murine model of ALS, the effect of a chronic high fat diet (HFD) intake, capable to increase leptin levels, on hippocampal synaptic transmission and plasticity and neuroinflammation markers in the hippocampus and motor cortex. Transgenic TDP43^{A315T} (Tg) and wildtype five-week old male mice were fed *ad libitum* with HFD and standard rodent chow for 8 weeks. Long-Term Potentiation (LTP) and basal synaptic transmission (BST) were measured using extracellular field potential recordings in hippocampal slices. The changes in microglia and astrocytes of hippocampus (CA1, CA2, CA3 and dentate gyrus) and motor cortex (M1 and M2) were examined by inmmunofluorescence. Our results showed that hippocampal BST and LTP were impaired in Tg regardless of the diet. Related to immunofluorescence assay, we found an increase of inflammation markers (microgliosis and astrocytosis) for most of the areas studied in Tg mice, both in the hippocampus and in the motor cortex. These effects are not modulated by HFD intake, indicating that this diet, at least in our conditions, is not enough to revert ALS effects in both areas.

Aims: Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disease, affecting mainly motor function, as well as, in some cases, cognitive function. The relevance of astrocytes in excitotoxicity and neurodegeneration has recently been recognized. Thus, we aimed to study the astrocytic contribution for synaptic activity and plasticity in the hippocampus and motor cortex of SOD1^{G93A} and wild-type (wt) mice. **Methods:** Astrocytic metabolism was selectively reduced using fluorocitrate (FC), and synaptic plasticity and transmission was assessed by eliciting long-term potentiation (LTP) protocols and recording input/output curves, respectively, in the CA1 area of hippocampal slices and layer II of primary motor cortex slices. **Results:** In the presence of FC, hippocampal synaptic responses were significantly lower in pre-symptomatic (4-6w) SOD1^{G93A} mice, when compared with wt mice. In the symptomatic phase (14-18w), SOD1^{G93A} mice exhibited higher post-tetanic potentiation and LTP magnitudes when compared with wt mice. However, astrocytic inhibition impaired significantly LTP, as well as synaptic responses, in both wt and SOD1^{G93A} mice. Regarding the motor cortex, pre-symptomatic SOD1^{G93A} mice showed an impairment in LTP magnitude and basal synaptic transmission. Interestingly, presence of FC led to an impairment of LTP only in wt mice, to similar levels that of SOD1^{G93A} mice, in both stages of disease. **Conclusions:** These findings suggest that, in the hippocampus, astrocytes are essential for the maintenance of LTP in healthy and ALS conditions. More importantly, in the motor cortex of SOD1^{G93A} mice, astrocytes seem to be impaired even before the onset of symptoms. Exosomes from NSC-34 Cells Transfected with hSOD1-G93A Are Enriched in miR-124 and Drive Alterations in Microglia Phenotype.
Amyotrophic lateral sclerosis (ALS) is a fatal adult-onset neurodegenerative disorder affecting motor neurons (MNs). Evidences indicate that ALS is a non-cell autonomous disease in which glial cells participate in both disease onset and progression. Exosomal transfer of mutant copper-zinc superoxide dismutase 1 (mSOD1) from cell-to-cell was suggested to contribute to disease dissemination. Data from our group and others showed that exosomes from activated cells contain inflammatory-related microRNAs (inflamma-miRNAs) that recapitulate the donor cell. While glia-derived exosomes and their effects in neurons have been addressed by several studies, only a few investigated the influence of motor neuron (MN)-derived exosomes in other cell function, the aim of the present study. We assessed a set of inflamma-miRs in NSC-34 MN-like cells transfected with mutant SOD1(G93A) and extended the study into their derived exosomes (mSOD1 exosomes). Then, the effects produced by mSOD1 exosomes in the activation and polarization of the recipient N9 microglial cells were investigated. Exosomes in coculture with N9 microglia and NSC-34 cells [either transfected with either wild-type (wt) human SOD1 or mutant SOD1(G93A)] showed to be transferred into N9 cells. Increased miR-124 expression was found in mSOD1 NSC-34 cells and in their derived exosomes. Incubation of mSOD1 exosomes with N9 cells determined a sustained 50% reduction in the cell phagocytic ability. It also caused a persistent NF-kB activation and an acute generation of NO, MMP-2, and MMP-9 activation, as well as upregulation of IL-1β, TNF-α, MHC-II, and iNOS gene expression, suggestive of induced M1 polarization. Marked elevation of IL-10, Arginase 1, TREM2, RAGE, and TLR4 mRNA levels, together with increased miR-124, miR-146a, and miR-155, at 24 h incubation, suggest the switch to mixed M1 and M2 subpopulations in the exosome-treated N9 microglial cells. Exosomes from mSOD1 NSC-34 MNs also enhanced the number of senescent-like positive N9 cells. Data suggest that miR-124 is translocated from the mSOD1 MNs to exosomes, which determine early and late phenotypic alterations in the recipient N9-microglial cells. In conclusion, modulation of the inflammatory-associated miR-124, in mSOD1 NSC-34 MNs, with potential benefits in the cargo of their exosomes may reveal a promising therapeutic strategy in halting microglia activation and associated effects in MN degeneration.

Neuronal Dynamics and miRNA Signaling Differ between SH-SY5Y and Mutant iPSC-Derived AD Models upon Modulation with miR-124 Mimic and Inhibitor.
Neuronal miRNA dysregulation may have a role in the pathophysiology of Alzheimer's disease (AD). miRNA(miR)-124 is largely abundant and a critical player in many neuronal functions. However, the lack of models reliably recapitulating AD pathophysiology hampers our understanding of miR-124's role in the disease. Using the classical human SH-SY5Y-neuroblastoma cells (SH-) and the mutant iPSC-derived neurons (iNEU-), we observed a sustained upregulation of miR-124/miR-125b/miR-21, but only miR-124 was consistently shuttled into their exosomes. The miR-124 mimic reduced gene expression in both AD models. While miR-124 mimic in SH- neurons led to neurite outgrowth, mitochondria activation and small Aβ oligomer reduction, in iNEU- cells it diminished Tau phosphorylation, whereas miR-124 inhibitor decreased dendritic spine density. In exosomes, cellular transfection with the mimic predominantly downregulated miR-125b/miR-21/miR-146a/miR-155. The miR-124 inhibitor upregulated miR-146a in the two experimental cell models, while it led to distinct miRNA signatures in cells and exosomes. In sum, though miR-124 function may be dependent on the neuronal AD model, data indicate that keeping miR-124 level strictly controlled is crucial for proper neuronal function. Moreover, the iNEU- cellular model stands out as a useful tool for AD mechanistic studies and perhaps for the development of personalized therapeutic strategies.

Phenotypic Effects of Wild-Type and Mutant SOD1 Expression in N9 Murine Microglia at Steady State, Inflammatory and Immunomodulatory Conditions.
Accumulation of mutated superoxide dismutase 1 (mSOD1) in amyotrophic lateral sclerosis (ALS) involves injury to motor neurons (MNs), activation of glial cells and immune unbalance. However, neuroinflammation, besides its detrimental effects, also plays beneficial roles in ALS pathophysiology. Therefore, the targeting of microglia to modulate the release of inflammatory neurotoxic mediators and their exosomal dissemination, while strengthening cell neuroprotective properties, has gained growing interest. We used the N9 microglia cell line to identify phenotype diversity upon the overexpression of wild-type (WT; hSOD1) and mutated G93A (hSOD1) protein. To investigate how each transduced cell respond to an inflammatory stimulus, N9 microglia were treated with lipopolysaccharide (LPS). Glycoursodeoxycholic acid (GUDCA) and dipeptidyl vinyl sulfone (VS), known to exert neuroprotective properties, were tested for their immunoregulatory properties. Reduced Fizz1, IL-10 and TLR4 mRNAs were observed in both transduced cells. However, in contrast with hSOD1-induced decreased of inflammatory markers, microglia transduced with hSOD1 showed upregulation of pro-inflammatory (TNF-α/IL-1β/HMGB1/S100B/iNOS) and membrane receptors (MFG-E8/RAGE). Importantly, their derived exosomes were enriched in HMGB1 and SOD1. When inflammatory-associated miRNAs were evaluated, increased miR-146a in cells with overexpressed hSOD1 was not recapitulated in their exosomes, whereas hSOD1 triggered elevated exosomal miR-155/miR-146a, but no changes in cells. LPS stimulus increased M1/M2 associated markers in the naïve microglia, including MFG-E8, miR-155 and miR-146a, whose expression was decreased in both hSOD1 and hSOD1 cells treated with LPS. Treatment with GUDCA or VS led to a decrease of TNF-α, IL-1β, HMGB1, S100B and miR-155 in hSOD1 microglia. Only GUDCA was able to increase cellular IL-10, RAGE and TLR4, together with miR-21, while decreased exosomal miR-155 cargo. Conversely, VS reduced MMP-2/MMP-9 activation, as well as upregulated MFG-E8 and miR-146a, while producing miR-21 shuttling into exosomes. The current study supports the powerful role of overexpressed hSOD1 in attenuating M1/M2 activation, and that of hSOD1 in switching microglia from the steady state into a reactive phenotype with low responsiveness to stimuli. This work further reveals GUDCA and VS as promising modulators of microglia immune response by eliciting common and compound-specific molecular mechanisms that may promote neuroregeneration.

Caffeine, the most consumed psychoactive substance worldwide, positively impacts the risk to develop Parkinson's disease and Alzheimer's disease. Compelling epidemiological evidence also support that regular caffeine consumption modulates synaptic plasticity and reduces cognitive decline in ageing, Alzheimer's disease and other neurological/neuropsychiatric conditions. Amyotrophic Lateral Sclerosis (ALS), a fatal and devastating neurodegenerative disease, is characterized by the loss of corticospinal neurons and motor neurons within the brainstem and spinal cord leading to death within 2-5 years following diagnosis. About 50% of ALS patients also develop non-motor symptoms encompassing cognitive and behavioral changes that appear before or after motor onset. While few studies addressed the impact of habitual caffeine on ALS risk, its impact on the progression of the cognitive disorders has been overlooked. To address this question we used the Pulse cohort, a prospective multi-centric and multi-modal French cohort following ALS patients from diagnosis up to end of life. Among the 463 patients included, 358 filled out a detail consumption caffeine survey. The link to ALS phenotype, ALSFRS scale, cognitive (ECAS) scores was then investigated. We observed a significative correlation between regular caffeine consumption and ECAS ($p<0.01$, $r=0.19$) within the 358 patients' population that was more pronounced within the population presenting with bulbar phenotype ($n=78$, $p<0.01$, $r=0.43$). In the later, we also observed a trend for a longer survival linked to the caffeine consumption ($p=0.08$). We demonstrate for the first time a positive impact of the regular caffeine consumption on cognitive function in ALS patients, predominantly on the bulbar form.

Amyotrophic lateral sclerosis (ALS) is a degenerative disorder affecting both upper and lower motor neurons, leading to skeletal muscle atrophy and weakness. Increased energy expenditure, lipid metabolism alterations and oxidative stress, related to mitochondrial dysfunction, play crucial roles in ALS onset and progression. The interplay between mitochondria and peroxisomes, mainly in controlling lipid and reactive oxygen species (ROS) metabolism, is receiving growing attention, as (dys)-functions in either of the two determine altered metabolism of the other. Importantly, peroxisomes are highly dynamic, responding to physiopathological changes, by altering their enzyme content, morphology, size and abundance. These features are modulated by peroxisome-proliferator activated receptors (PPARs), a class of ligand-activated transcription factors, and by their coactivator PGC1α, which also controls mitochondrial biogenesis. We addressed the role played by peroxisomes in ALS, by analyzing the expression of peroxisomal membrane protein of 70 kDa, acyl-CoA oxidase, acetyl-CoA acyltransferase and catalase, in the spinal cord and striated muscle of a transgenic mouse model overexpressing the human mutation SOD1-G93A. The expression of mitochondrial and cytosolic antioxidant enzymes were also studied. Immunoblotting analysis of peroxisomal proteins and antioxidant enzymes shows an increase concomitant with pathology progression, suggesting an enhancement in the number of peroxisomes and in fatty acyl β-oxidation. Consistent results were obtained by qRT-PCR analysis of the same markers. These data correlate with the increase of PGC1-α that, stimulating peroxisomal and mitochondrial biogenesis, elicits an antioxidant response to redox imbalance. Overall, we suggest an involvement of peroxisomes in ALS onset and progression, possibly coping with mitochondrial dysfunction.

ROLE OF THE CHRONIC STRESS ON THE TDP-43 SUBCELLULAR LOCALIZATION IN FIBROBLASTS OF THREE DIFFERENT ALS-RELATED TARDBP MUTATIONS

POSTER SESSION 03 - SECTION: AMYOTROPHIC LATERAL SCLEROSIS

Martina Pecoraro[1], Antonietta Notaro[1], Alice Conigliaro[1], Rossella Spataro[2], Francesca Conforti[3], Riccardo Alessandro[1], Vincenzo La Bella[1]
[1]University of Palermo, Department of Biomedicine, Neurosciences and Advanced Diagnostics, Palermo, Italy, [2]IRCCS Bonino Pulejo, Neurorehabilitation Unit, Palermo, Italy, [3]University of Calabria, Department of Pharmacy, Health and Nutritional Sciences, Rende, Italy

Aims. TAR-DNA-Binding-Protein 43 (TDP-43) forms cytoplasmic aggregates in ALS, thought to play a role in the pathogenesis of the disease. Here, we analyzed the subcellular localization of TDP-43 after chronic stress in fibroblasts of three patients, each affected by a specific TARDBP gene mutation.

Methods. Skin fibroblasts were purified from three ALS patients, each carrying a pathogenic TARDBP variant (G376D,familial; G294V, sporadic; A382T,sporadic). The G376D variant associated to a more aggressive phenotype. Control fibroblasts were from a sporadic ALS, without known mutations. Chronic stress was induced by arsenite for 30 hours. Immunofluorescence was performed at rescue, and 24,48,72 hours later. We used antibodies to TDP-43 and TIA-R (a marker for SG). The co-expression of TDP-43 and G3BP1 in each mutant fibroblast was analyzed with the confocal microscope Nikon A1.

Results. Chronic stress induced the formation of TIA-R-positive SGs that persisted up to 48h after rescue. In all three cell types, TDP-43 formed cytoplasmic inclusions, which co-localized with TIA-R. The TDP-43 inclusions disappeared at 48h after rescue. Note that TDP-43 was diffusely expressed in the cytoplasm of the mutant G376D fibroblasts, but not in the other mutant cells.

Conclusions. Chronic stress induced TDP-43 translocation to the cytoplasm of all mutant cells, where it forms transient aggregates. Therefore, these inclusions are probably not related to the persistent aggregates found in the disease. Furthermore, the diffuse cytoplasm mislocalization of the G376D TDP-43 protein after stress might represent a biological correlate of the more aggressive phenotype that characterizes this mutation.

HIDDEN TARGETS OF AUTISM SPECTRUM DISORDERS: DISSECTING THE PATHOPHYSIOLOGY OF WAC IN THE UBIQUITIN-PROTEASOME SYSTEM

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Lena A. Schwarz, Magdalena Ladron De Guevara, Satish Arcot Jayaram, Gaia Novarino
Institute of Science and Technology, Life Sciences, Klosterneuburg, Austria

Aims: In order to enable and maintain the physiological organization and functioning of the cerebral cortex, an internal balance of necessary elements, including protein synthesis and breakdown, are crucial. A prevailing hypothesis suggests that protein levels are altered upon mutations in the ubiquitin-proteasome system (UPS), leading to an accumulation of protein substrates and thus interfering with an usually balanced system. Unsurprisingly, our current understanding supports an involvement of ubiquitin-dependent degradation in the development of autism spectrum disorders (ASDs). Therefore, we aim to decipher effects and consequences of proteasome dysfunction by analyzing the molecular and behavioral changes of a mouse model haploinsufficient for the high risk ASD gene *Wac.* **Methods:** We first assessed *Wac* regional and temporal expression throughout mouse development and adulthood by western blot and qPCR analyses. Furthermore, we employed a broad array of histological, molecular and behavioral assays in *Wac*$^{+/-}$ mice. Specific attention is drawn onto neurogenesis, neuronal proliferation and migration, but also other processes mutually affected. **Results and Conclusion:** *Wac* haploinsufficient animals display hyperactivity, mild sociability defects and aberrant freezing behavior in the contextual fear conditioning task. In addition, *Wac* animals present slight brain abnormalities at juvenile and adult stages. To investigate effects of Wac loss on brain protein composition and its direct interaction partners, quantitative proteomic analyses are ongoing. The multidisciplinary combination of cellular, molecular und quantitative techniques aims to tackle the role of UPS function in brain development from multiple angles. Our findings indicate a pivotal role of *Wac* for normal brain development and function.

IMPAIRMENT OF OLFACTORY HABITUATION AND DISRUPTED AFFECTIVE DISCRIMINATION IN NEGR1 MOUSE MODEL FOR AUTISM

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Kwang Hwan Kim[1], Kyungchul Noh[2], Sung Joong Lee[2]
[1]Seoul National University, Brain And Cognitive Sciences, Seoul, Korea, Republic of, [2]Seoul National University, Neuroscience And Physiology, College Of Dentistry, Seoul, Korea, Republic of

Olfaction is the most prominent sensory input for affective recognition in animals. Although it is well-known that both olfactory and social dysfunctions are observed simultaneously in autism specturm disroder (ASD), little is known about the neural mechanism that explains both impairments are interrelated. Neuronal growth regulator 1 (Negr1) belongs to the the immunoglobulin superfamily of cell adhesion molecules, which has been reported as one of the autism candidate genes. Here we showed Negr1$^{-/-}$ mice impaired in discrminating between affective and control demonstrator mice (i.e., stressful or painful vs neutral), meaning that they did not approach or avoid the affective demonstrator in a preferential way. Besides, Negr1$^{-/-}$ mice, although, had intact olfactory sensitivity on motivational state, were not (dis)habituated to replaced or repetitive odors. Next, when newly generated olfactory neurons fail to integrate into the olfactory bulb, olfactory functions such as odor discrimination are dysregulated. Furthermore, we reported that hippocampal neurogenesis was reduced in Negr1$^{-/-}$ mouse in our previous work. So we measured the number of proliferative cells (Ki67^{+}) using immunohistochemstry along the rostral migratory stream (RMS) known as the migratory pathway for the olfactory neuronal precursor cells. We found the number of Ki67^{+} cells along the RMS of Negr1$^{-/-}$ mouse was decreased. These results suggested, in Negr1$^{-/-}$ autism model mouse, the capacity for neurogenesis along the RMS is limited, which in turn would diminish the integration of newly generated inhibitory neurons into the olfactory bulb. This fail of integration would lead to dysregulated olfactory response, followed by maladaptive affective recognition.

CHARACTERISING SMALL INTESTINE MOTILITY PATTERNS IN THE NEUROLIGIN-3R451C MOUSE MODEL OF AUTISM

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Tanya Abo-Shaban
RMIT University, School Of Health And Biomedical Sciences, Melbourne, Australia

Gastrointestinal (GI) motility is regulated by the intrinsic nervous system of the gut; the enteric nervous system (ENS). GI dysfunction is commonly reported in individuals with autism spectrum disorder (ASD; autism). We previously reported colonic dysfunction in mice expressing the autism-associated R451C mutation in neuroligin-3 ($NL3^{R451C}$ mice) and increased numbers of neuronal nitric oxide synthase (NOS)-expressing myenteric neurons in the jejunum of the small intestine, however whether small intestine motility is altered is unknown. Here we aimed to characterise small intestine function in $NL3^{R451C}$ mice. Mouse jejunum and ileum segments were cannulated and perfused with physiological saline in an organ bath. Neurally-mediated gut contractions were recorded in control, NOLA (Nω-Nitro-L-arginine; an inhibitor of Nitric Oxide Synthase (NOS)) and washout conditions for 1 hour each. We utilized customised MATLAB based software (“GutMap”) to convert video recordings to spatiotemporal heatmaps to analyse motility patterns. Propagating contractile clusters (PCCs) in the jejunum decreased in response to NOLA, suggesting PCCs are NOS-dependent. Compared to wild-type mice, the proximal, mid, and distal jejunal diameter of $NL3^{R451C}$ mice was constricted in control conditions. In NOLA and washout conditions, the diameter of the distal jejunum was also constricted compared to wild-type mice. High frequency (0.5-0.7 Hz) contractions were increased in $NL3^{R451C}$ jejunum in control and washout conditions. Ileal motility patterns were similar across genotypes and in response to NOLA. We show that small intestinal (jejunal) motility patterns are altered in $NL3^{R451C}$ mice suggesting that alterations in the ENS may contribute to GI dysfunction in autism.

Autism spectrum disorder (ASD) is characterized by deficits in social communication as well as increased stereotyped and repetitive behavior. Motor and gait impairments are amongst the earliest and most consistent signs of this neurodevelopmental disorder but remain excluded from the diagnosis criteria of the disease. Recently, omega-3 long chain polyunsaturated fatty acids (PUFA) have been shown to decrease motor symptoms in ASD patients and prevent behavioral deficits in maternal immune activation mouse models of ASD**.** Our main aim is to determine omega-3 long chain PUFA impact on both motor and social behaviors as well as cellular correlates in the valproic acid mouse model (VPA). Pregnant female mice (C57BL/6J) were injected i.p. either with valproic acid (450mg/kg) or saline solution at embryonic day E12.5. Both dams and offspring were subjected to omega-3 long chain PUFA supplemented diet or omega-3 precursor PUFA balanced diet from the first day of gestation to the end of the experiment. From P45 on, male and female offspring underwent social and motor behavioral tests before being sacrificed at P60 for further biological analysis. Stereological analysis of Purkinje cell number was performed, cerebellum and liver lipid composition were investigated, and feces from all animal groups were analyzed to determine microbiota and metabolic profiles. Our results indicate that a balanced diet with omega-3 PUFA precursor may be sufficient to alleviate ASD motor and social symptoms and that omega-3 long chain PUFA supplementation brings only limited benefits in these conditions.

METABOLIC DEFECTS IN 16P11.2-DEFICIENT PRIMARY MOUSE BRAIN ENDOTHELIAL CELLS

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Julie Ouellette[1], Shama Naz[2], David Patten[2], Baptiste Lacoste[3]
[1]University of Ottawa/ Ottawa Hospital Research Institute, Cellular And Molecular Medicine/ Neuroscience, Ottawa, Canada, [2]University of Ottawa Metabolomics Core Facility, Medicine, Ottawa, Canada, [3]University of Ottawa/ Ottawa Hospital Research Institute/ University of Ottawa Brain and Mind Research Institute, Cellular And Molecular Medicine/ Neuroscience, Ottawa, Canada

Brain development and function are highly reliant on adequate development and maintenance of vascular networks. As such, early impairments in vascular health can lead to neurodevelopmental defects. Despite a wealth of knowledge on neuronal mechanisms of autism spectrum disorders (ASD), very few studies have considered the role of the brain vasculature in ASD. ASD are neurodevelopmental conditions associated with genetic origins such as the common 16p11.2 deletion, which leads to a haploinsufficiency of ~30 genes. We recently revealed that the 16p11.2 deletion induced endothelial-dependent structural and functional vascular abnormalities in the mouse brain, establishing a novel link between vascular impairments and ASD. While we now know that the 16p11.2 deletion leads to endothelial dysfunction, the mechanisms leading to these dysfunctions remain unknown. To address this knowledge gap, we used metabolomics and assessed mitochondrial parameters to decipher core features of brain endothelial cells (ECs) isolated from 14-day-old 16p11.2-deficient and wild-type (WT) mice. We identified a lower concentration of metabolites in 16p11.2-deficient ECs compared to WT ECs. Notably, 16p11.2-deficient ECs displayed an energetic failure with a 50% reduction of high energy metabolites including ATP, CTP, GTP, and UTP, which are critical energy fuels required for the maintenance of cellular processes. Currently, we are attempting to rescue these phenotypes by targeting various pathways. This study will provide new insight into key players of ASD pathogenesis, an essential pre-requisite for the development of transformative therapeutic strategies.

Vascular contributions to 16p11.2 deletion autism syndrome modeled in mice.
While the neuronal underpinnings of autism spectrum disorder (ASD) are being unraveled, vascular contributions to ASD remain elusive. Here, we investigated postnatal cerebrovascular development in the 16p11.2 mouse model of 16p11.2 deletion ASD syndrome. We discover that 16p11.2 hemizygosity leads to male-specific, endothelium-dependent structural and functional neurovascular abnormalities. In 16p11.2 mice, endothelial dysfunction results in impaired cerebral angiogenesis at postnatal day 14, and in altered neurovascular coupling and cerebrovascular reactivity at postnatal day 50. Moreover, we show that there is defective angiogenesis in primary 16p11.2 mouse brain endothelial cells and in induced-pluripotent-stem-cell-derived endothelial cells from human carriers of the 16p11.2 deletion. Finally, we find that mice with an endothelium-specific 16p11.2 deletion (16p11.2) partially recapitulate some of the behavioral changes seen in 16p11.2 syndrome, specifically hyperactivity and impaired motor learning. By showing that developmental 16p11.2 haploinsufficiency from endothelial cells results in neurovascular and behavioral changes in adults, our results point to a potential role for endothelial impairment in ASD.

From Neurodevelopmental to Neurodegenerative Disorders: The Vascular Continuum.
Structural and functional integrity of the cerebral vasculature ensures proper brain development and function, as well as healthy aging. The inability of the brain to store energy makes it exceptionally dependent on an adequate supply of oxygen and nutrients from the blood stream for matching colossal demands of neural and glial cells. Key vascular features including a dense vasculature, a tightly controlled environment, and the regulation of cerebral blood flow (CBF) all take part in brain health throughout life. As such, healthy brain development and aging are both ensured by the anatomical and functional interaction between the vascular and nervous systems that are established during brain development and maintained

throughout the lifespan. During critical periods of brain development, vascular networks remodel until they can actively respond to increases in neural activity through neurovascular coupling, which makes the brain particularly vulnerable to neurovascular alterations. The brain vasculature has been strongly associated with the onset and/or progression of conditions associated with aging, and more recently with neurodevelopmental disorders. Our understanding of cerebrovascular contributions to neurological disorders is rapidly evolving, and increasing evidence shows that deficits in angiogenesis, CBF and the blood-brain barrier (BBB) are causally linked to cognitive impairment. Moreover, it is of utmost curiosity that although neurodevelopmental and neurodegenerative disorders express different clinical features at different stages of life, they share similar vascular abnormalities. In this review, we present an overview of vascular dysfunctions associated with neurodevelopmental (autism spectrum disorders, schizophrenia, Down Syndrome) and neurodegenerative (multiple sclerosis, Huntington's, Parkinson's, and Alzheimer's diseases) disorders, with a focus on impairments in angiogenesis, CBF and the BBB. Finally, we discuss the impact of early vascular impairments on the expression of neurodegenerative diseases.

Isolation and functional characterization of primary endothelial cells from mouse cerebral cortex.
Endothelial cells (ECs) lining blood vessels are implicated in organ development, function, and maintenance. We present a detailed protocol enabling isolation and characterization of primary mouse brain ECs, including quality controls and functional assays. These procedures promote survival of primary brain ECs for the assessment of endothelial health. Since alterations in brain ECs are involved in the onset and progression of neurological disorders, this protocol represents a valuable tool to better understand the roles of ECs in brain health. For complete details on the use and execution of this profile, please refer to Ouellette et al. (2020).

CHARACTERIZATION OF THE NITRERGIC SYSTEM IN THE VPA MURINE MODEL OF AUTISM

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Valeria Lorena Cabedo[1,2,3], Laura Pérez-Revuelta[1,2,3], Ester Pérez-Martín[1,2,3], Eduardo Weruaga[1,2,3], David Díaz[1,2,3], José Ramón Alonso[1,2,3]

Although progresses have been made in the knowledge of autism, there is still a long way to understand its cellular, neuroanatomical, and behavioural bases. One of the main neuronal alterations observed in autism is an imbalance between excitatory and inhibitory activity due to GABAergic system defects. It has also been shown that nitric oxide (NO) participates in the modulation of excitatory *versus* inhibitory neurotransmission by interacting with both glutamate and GABA. Until now, little is known about how the nitrergic system works in the autistic brain. In this study we investigated the nitrergic system in the valproic acid-induced rodent model of autism (VPA). We focused on olfactory bulb, since recent studies report the importance of sensorial dysregulations in this neurodevelopmental disorder, highlighting olfaction. We carried out histochemistry for nicotinamide adenine dinucleotide phosphate diaphorase (NADPH-d) and immunohistochemistry for the different isoforms of nitric oxide synthase (NOS) to analyse the expression of enzymes involved in NO production. Finally, we determined the NO levels through quantification of its metabolites using the Griess technique. Our preliminary results indicate a relevant decrease in both NADPH-d activity and neuronal NOS expression. This leads us to think that NO production could be significantly reduced in the VPA model. Examining the nitrergic system will shed light on the research field of autism spectrum disorders, as it is known that alterations in this system, as a regulator of neuronal excitability, could be participating in or aggravating the important excitatory/inhibitory imbalance observed. IMMUNE ACTIVATION DURING EARLY-LIFE DEVELOPMENT CHANGES THE PSYCHOSOCIAL BEHAVIOR OF ADULT MICE

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Karolina Protokowicz, Iwona Sirocka, Leszek Kaczmarek
Nencki Institute of Experimental Biology, Polish Academy of Sciences, Braincity, Laboratory Of Neurobiology, Warsaw, Poland

The development of the nervous system is a complex and fragile process. Any aberration may lead to abnormal brain functioning. Collectively, disorders that affect the nervous system development are called neurodevelopmental disorders (NDDs). NDDs characterized by altered psychosocial behavior, such as Autism spectrum disorder or schizophrenia are considered to have a multifactorial etiology. It is believed that besides genetic predispositions inflammatory reactions may be one of the causes. Aim The aim of this study was to evaluate changes in psychosocial behavior of adult mice treated with lipopolysaccharide (LPS) in early life. Methods LPS injections are commonly used to mimic bacterial infection in animal models. In terms of onset of exuberant synaptogenesis, postnatal day 7 (P7) in mice corresponds with the second trimester of pregnancy in humans. On P7, mice pups of both sexes were injected either with LPS or physiological saline. After 3 weeks, a wide range of behavioral tests evaluating activity, sociability, and learning abilities was conducted. Results Mice after LPS treatment were less anxious and were less active. The LPS-treated group spent more time together in the course of the social test. Interestingly, males avoided social stimulus from unknown animals, whilst females were more interested in social stimulus than a control group. Additionally, animals injected with LPS needed more time to learn new conditions. Conclusions In aggregate the presented results suggest, that immune activation during the critical stage of neurodevelopment induces alterations of behavior that resemble symptoms observed in human NDD patients.

LOW INTENSITY REPETITIVE MAGNETIC STIMULATION (LI RTMS) EFFECTS ON A MODEL OF PATHOLOGICAL CEREBELLAR DEVELOPMENT

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Svethna Ribeiro, Manon Boyer, Rachel Sherrard
Sorbonne Université, Umr8256-b2a,, Paris, France

The etiology of neurodevelopmental disorders (NDD) e.g. autism spectrum disorder (ASD) is still poorly understood because of their complexity, and wide range of symptoms. However, there is increasing interest in the contribution of the cerebellum to NDDs** because of its protracted period of development making it vulnerable to injury, and its extensive connections to the forebrain showing its involvement in motor, emotional and cognitive functions. To understand the contribution of the cerebellum to NDDs, we evaluate cerebellar development in a mouse haplodeficient for a transcription factor essential for normal cerebellar development, Retinoic acid Orphan related Receptor alpha (RORα+/-), and seek to improve its pathology at behavioral, cellular and molecular levels with LI rTMS (low intensity repetitive transcranial magnetic stimulation). We stimulated mouse pup's cerebellum between 2 and 14 postnatal days with either cTBS, iTBS (continuous or intermittent theta burst stimulation) or SHAM and assessed motor, social and cognitive development as well as cerebellar Purkinje cell (PC) morphology at different ages. We found developmental delay in RORα+/- pups compared to wild-type (WT) littermates, at both behavioral and PCs levels. We found that cTBS stimulation did not change development in either group but iTBS improves behavioral performances in RORα+/- mice compared to SHAM treated ones. These results indicate that the RORα-mediated cerebellar pathological development may contribute to the emergence of NDDs and could be a therapeutic target in young population with LI-rTMS. **Tsai PT et al, (2018) Cell Rep 25:357-367. doi:10.1016/j.celrep.2018.09.039.

SELECTIVE NKCC1 INHIBITORS FOR THE TREATMENT OF AUTISM, DOWN SYNDROME AND BRAIN DISORDERS WITH DEFECTIVE NKCC1/KCC2 RATIO

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Annalisa Savardi[1], Marco Borgogno[2], Marco De Vivo[3], Laura Cancedda[4]
[1]IAMA Therapeutics, Neuropharmacology, Genova, Italy, [2]IAMA Therapeutics, Discovery Chemistry, Genova, Italy, [3]Istituto Italiano di Tecnologia, Molecular Modeling And Drug Discovery Laboratory, Genova, Italy, [4]Istituto Italiano di Tecnologia, Brain Development And Disease Laboratory, Genova, Italy

Proper intracellular Cl concentration is fundamental for physiological brain development and function. Accordingly, the aberrant expression-ratio of Cl importer NKCC1 and exporter KCC2 is implicated in several brain conditions, including autism spectrum disorders (ASD) and Down syndrome (DS). Interestingly, NKCC1 inhibition rescues core symptoms of these brain conditions in rodent models and/or clinical trials. However, current NKCC1 inhibitors have diuretic effects inhibiting the kidney Cltransporter NKCC2. These effects create critical issues with health concerns, strongly jeopardizing them from becoming a viable therapy for long-term chronic treatment. Selective NKCC1 inhibitors would be devoid of diuretic effects, thus solving these problems. Here, we present the discovery of a new class of selective NKCC1 inhibitors (lead compound IAMA-6 and backup compound IAMA-92) obtained by an extensive drug discovery effort. IAMA-6 and IAMA-92 have a favourable drug-like profile. IAMA-6 was able to rescue social/repetitive behaviours in ASD mice. IAMA-6 and IAMA-92 were able to recover cognitive deficits in DS mice. Both compounds did not show any diuretic effect in animals. IAMA-6 neither showed any significant off-target *in vitro* nor induced histopathological alterations *in vivo*. Thus, IAMA-6 represents a solid lead compound ready for advanced preclinical studies toward its development into a clinically relevant drug for unprecedented sustainable therapeutics in ASD and DS. IAMA-92 further strengthens the potential of our class of compounds. Currently in the discovery phase, new classes of selective NKCC1 inhibitors will expand our pipeline of compounds to treat additional and diverse brain conditions characterized by defective NKCC1/KCC2 expression-ratio.

BEHAVIORAL CHANGES AND FUNCTIONAL, MORPHOLOGICAL ALTERATIONS IN THE RAT VALPROATE MODEL OF AUTISM

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Viktor Kelemen[1], Tímea Májer[1], Veronika Bódi[1], Zsuzsanna Faragó[1], Júlia Puskás[1], Sándor Borbély[2], Attila Szucs[3], Petra Varró[2], Ildikó Világi[3]

Autism is a neurodevelopmental disorder associated with loss of excitation-inhibition balance and increased risk of developing epilepsy. The valproate rat model is commonly used to study autism-like behaviors. In our study, pregnant Wistar rats received 500 mg/bwkg valproate i.p. on gestation day 12.5. Pups were tested for various motor functions and behaviors. Electrophysiological and immunohistochemical studies were performed in 6 weeks and 3 months. Entorhinal and prefrontal cortex slices were prepared for field potential measurements and parallel detection of intrinsic optical signals (IOS). Excitability changes were tested with spontaneous bursts evoked by magnesium-free solution and afterdischarges evoked by high-frequency stimulation. Intracellular functions were observed with whole-cell patch clamp method, using standard current clamp and dynamic clamp stimulation. Behavioral tests indicate that VPA-treatment delays the appearance of surface righting reflex, negative geotaxis and visual placing reflex significantly. In slices, the pattern of electrical activity and the extent of IOS changes depended on the stimulation method. Valproate treatment increased epileptiform activity, suggesting an increased tendency to epilepsy. Regarding patch clamp recordings, resting membrane potential, membrane resistance, rheobase, and spike amplitude altered according to VPA treatment, sex and age. Alterations in glutamate receptor density were also observed. After prenatal VPA exposure, developmental delay and disturbed social skills confirm the presence of autistic traits in treated animals. There are significant differences in cortical network excitability between sexes and age groups, which VPA treatment may enhance. The present study was supported by CELSA (grant no. 874735) and Gedeon Richter Plc. Centenarial Foundation.

Alterations of the Hippocampal Networks in Valproic Acid-Induced Rat Autism Model.
Autism Spectrum Disorder (ASD) is one of the most frequently diagnosed neurodevelopmental disorders, characterized among others by impairments in social interactions and repetitive behavior. According to one of the leading hypotheses about its origin, ASD is caused by the imbalance of excitatory and inhibitory circuit activity. ASD-related morphological and functional changes can be observed in several brain regions i.e., in the prefrontal cortex and the hippocampus. It is well-established that prenatal valproic-acid (VPA) exposure of rats on day 12.5 leads to neurodevelopmental alterations with autism-like clinical and behavioral symptoms. The aim of this study was to investigate potential changes in the excitability of neuronal networks and individual neurons of the hippocampus elicited by prenatal VPA treatment. As there are marked sex differences in ASD, offspring of both sexes were systematically tested, using two different age groups, to elucidate eventual differences in neurodevelopment after VPA treatment. Excitatory connections and long-term synaptic plasticity as well as intrinsic excitability of CA1 pyramidal cells were examined. Pregnant female Wistar rats received saline or 500 mg/kg VPA i. p. on gestation day 12.5. Brain slices of 6-week-old and 3-month-old offspring were investigated using extra- and intracellular electrophysiological techniques. Field potential- and whole-cell patch clamp recordings were carried out to measure network excitability and single cell activity in the CA1 region hippocampus. Enhanced excitability of hippocampal networks was detected in the 6-week-old VPA-treated male rats; however, this change could not be observed in 3-month-old males. Intrinsic excitability of single neurons, however, was increased in 3-month-old males. In 6-week-old treated females, the most prominent effect of VPA was an increase in voltage sag, to a similar degree to the neurons of the older age group. In 3-month-old females, a network excitability increase could be demonstrated, in a lesser degree than in younger males. It can be concluded, that VPA treatment had diverse effects on hippocampal excitability depending on the sex and the age of the animals. We found that certain alterations manifested in 6-week-old rats were compensated later, on the other hand, other

changes persisted until the age of 3 months.

INFLUENCE OF PERINATAL INFLAMMATION ON MENINGEAL IMMUNITY AND NEURODEVELOPMENT

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Narjess Haidar[1], Julie Rebejac[1], Valéry Matarazzo[2], Ugo Zayan[2], Pierre Gressens[3], Rejane Rua[1]
[1]Centre d'Immunologie de Marseille Luminy Parc Scientifique et technologique de Luminy, Amu Inserm Cnrs, Marseille, France, [2]Institut de Neurobiologie de la Méditerranée (INMED), Aix-marseille Université Inserm U1249, Marseille, France, [3]Hôpital Robert Debré, Inserm Umrs1141, Paris, France

Aims Early-life inflammation correlates with an increased risk of developing neurological disorders, including autism. Studies in rodents have shown that perinatal inflammation can lead to cytokine signaling in brains of neonates, abnormal neurodevelopment and social behavior. The meninges represent an immunologically active site, at the interface between the brain and the periphery. Hence, because the meninges can nurture the brain but also relay and amplify inflammation, we hypothesize that they could play a major role in inflammation-induced neurodevelopmental disorders. In particular, the meninges are inhabited by a dense population of immune sentinels which are absent from the brain parenchyma itself. Two meningeal macrophage (MM) populations have been identified: an MHC-II- MM population abundant in neonates, and a post-natal MHC-II+ MM population increasing over time. Methods We have investigated their response to peripheral inflammation, using single-cell transcriptomics and imaging approaches. Results Both populations of MM responded to compounds injected intravascularly such as viruses (LCMV), LPS and cytokines (IFNs, …) although in different manners. Neonatal MHC-II- macrophages decreased pathways linked with tissue growth and development while post-natal MHC-II+ macrophages up-regulated pathways linked with cytokine production. Using innovative transgenic mice models and pharmacological approaches, we are depleting MM and their cytokine signaling pathway to know if this influences 1/brain development (myelination, neurogenesis) and 2/behavior in neonates and in adult mice. Conclusions We hope that this work will provide a new link between peripheral inflammation and neurodevelopmental disorders, that could provide a rationale to target meningeal macrophages in the clinic.

EXPLORING PAIN AND NOCICEPTION IN A VALPROATE-INDUCED MOUSE MODEL OF AUTISM SPECTRUM DISORDER

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Lucien Ruelle-Le Glaunec, Rémy Schlichter, Jean-Louis Bossu
CNRS UPR3212, Institut Des Neurosciences Cellulaires Et Intégratives, Strasbourg, France

Autism Spectrum Disorders (ASD) are neurodevelopmental disorders in which abnormalities in sensory information processing have been described. Among sensory functions, nociception and its potential result, pain, are of a critical importance due to their crucial role for survival and the high prevalence of potentially painful comorbidities in ASD. However, there is no consensus among studies in humans and hypo-, hyper- as well as normal sensitivity to pain have been described. We decided to use an animal model of ASD to try to answer this question, allowing us to do standardize measures of pain sensitivity as well as study of the underlying cellular and molecular mechanisms. Using an environmental model of ASD taking advantage of teratogenic drug sodium valproate (VPA) in CD1 mice, we explored behavioral response to nociceptive and painful situations and tried to elucidate underlying molecular and cellular mechanisms using electrophysiology, calcium imaging and immunohistochemistry. Our model showed differences in non-nociceptive comfort temperature, nociceptive heat, as well as a reduced sensitivity to capsaicin- and formalin-induced pain models. These differences are mostly present in males and only appears at a post-puberty age. Our results showed reduced responses to nociceptive and potentially painful situations in VPA animals, affecting mostly adult males. Given the predominant phenotype on heat modality and capsaicin, these could potentially involve modifications in heat-related nociceptive tracts.

ASSESSMENT OF VASCULARIZATION AND NEUROGENESIS IN AN IPSC-DERIVED 16P11.2 DELETION ORGANOID MODEL

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Nicole Blakeley[1], Baptiste Lacoste[2]
[1]University of Ottawa, Cellular And Molecular Medicine/ Neuroscience, University Of Ottawa/ Ottawa Hospital Research Institute, Ottawa, Canada, [2]University of Ottawa/ Ottawa Hospital Research Institute/ University of Ottawa Brain and Mind Research Institute, Cellular And Molecular Medicine/ Neuroscience, Ottawa, Canada

This project aims at expanding upon previous Lacoste lab findings to better understand the effect of the 16p11.2 deletion (16pDel) specific to endothelial cells (EC) on angiogenesis and neural development by using Human-induced-Pluripotent-Stem-Cells and microfluidic plates, through the creation of vascularized cerebral organoids. HiPSCs with 16pDel and non-isogenic control lines were differentiated into human induced-ECs. HiECs underwent positive selection after which cell identity was confirmed using immunocytochemistry. A Matrigel-based network-formation assay is used to quantify network length and sprouting, comparing control and 16pDel lines. Angiogenic activity of 16pDel and control hiECs will be compared using Microfluidic 3-Lane OrganoPlate. Vascular tube formed in the perfusable channel, sprouts through a collagen channel towards angiogenic factors. Sprouts are quantified for length, diameter, and branching. The microfluidic Graft OrganoPlate will be used to embed a cerebral organoid in growing vascular networks using 16pDel or control hiECs. This is expected to create vascularized organoids which will then be characterized using immunohistochemistry and transcriptomics. Complexity of vascular incorporation into cerebral organoids will be investigated once optimal experimental conditions have been established. Neuronal, vascular and glial cell types identified in the control versus 16pDel organoids will be compared at select time points in order to detect neurodevelopmental delays resulting from defective vascularization as seen in 16pDel mice. Early timepoints will focus on the presence of precursor cells and later timepoints will focus on differences in neuronal layering. Overall, this will further the understanding of the altered function of ECs associated with the 16pDel and its neurodevelopmental consequences.

Aims
Autism Spectrum Disorder (ASD) is a heterogeneous neurodevelopmental condition characterized by deficits in social communication and interaction, and repetitive/stereotyped behaviors. In recent years, the role of microbiota-gut-brain axis (MBGA) in ASD pathogenesis received growing attention, appearing as an attractive therapeutic target. A key mediator in MBGA is butyrate, a short-chain fatty acid produced by bacterial fermentation of dietary fibers, involved in the regulation of gut permeability and immune system, found impaired in ASD. The present study evaluated the role of early-life sodium butyrate (NaB) supplementation in the modulation of ASD-like behavioral phenotype, neuroinflammatory response, and gut microbiota alterations in the maternal immune activation (MIA) mouse model. **Methods**
We modeled MIA by treating C57BL6/J female mice with a single dose of polyinosinic:polycytidylic acid (Poly I:C, 20 mg/kg, i.p.) at gestational day 12.5. After delivery, dams received NaB (200 mg/kg) administered in drinking water through the whole duration of lactation. In order to detect ASD-like behavioral deficits in offspring, we assessed their behavioral phenotype from early neonatal stage to adulthood. At the end of behavioral testing, we analyzed i) gut microbiota composition by 16S rRNA sequencing and ii) neuroinflammatory markers in prefrontal cortex, hippocampus and cerebellum by Real-Time PCR. **Results**
Early-life NaB supplementation attenuated some of the MIA-induced behavioral alterations (i.e. stereotyped behavior), and exerted modulatory effects on neuroinflammation and gut microbiota composition in MIA adult offspring. **Conclusions**
Our data support the development of therapeutic interventions targeting gut microbiota to modulate brain and behavioral changes in ASD.

Prenatal exposure to neurotoxic metals and micronutrients and neurodevelopmental outcomes in early school age children from Poland.
Exposure to environmental factors, such as neurotoxic metals and micronutrients, during critical periods of development can contribute to long-term consequences in offspring's health, including neurodevelopmental outcomes. The aim of this study was to evaluate the association between simultaneous prenatal exposure to metals [lead (Pb), cadmium (Cd), mercury (Hg)] and micronutrients [selenium (Se), zinc (Zn), copper (Cu)] and neurodevelopmental outcomes in school-age children from the Polish Mother and Child Cohort (REPRO_PL). Metals and micronutrients concentrations were measured in cord blood (Pb, Cd, Se, Zn, Cu) and in maternal hair (Hg) collected during the 3rd trimester of pregnancy. Behavioral and emotional problems, as well as children's cognitive and psychomotor development, were assessed in 436 school-age children using the Strengths and Difficulties Questionnaire (SDQ, filled in by the mothers) and the Polish adaptation of the Intelligence and Development Scales (IDS, administered by trained psychologists). Multivariate regression models were applied after imputation of missing values, using two approaches: (i) a joint analysis taking into account all metals and micronutrients simultaneously, and (ii) an ExWAS study (single-exposure model). In the SDQ, Hyperactivity/Inattention problems and Total difficulties were associated with higher Hg concentrations in maternal hair (0.18, 95% CI: 0.05; 0.3; and 0.14, 95% CI: 0.01; 0.3, respectively), whereas Emotional symptoms were inversely associated with Se and Zn levels in cord blood (-0.13, 95% CI: -0.3; 0.004; and -0.10, 95% CI: -0.2; 0.02, respectively). In the IDS, cord blood Pb levels were found to be negatively associated with Fluid and Crystallized IQ (-0.12, 95% CI: -0.3; 0.02; and -0.14, 95% CI: -0.3; 0.007, respectively) as well as

Mathematical skills (-0.15, 95% CI: -0.3; 0.01). The current research has been able to simultaneously assess the exposure to various interacting chemicals during the prenatal period. We demonstrate that prenatal co-exposures to Pb, Hg, Zn and Se have long-term influences on the neuropsychological outcome of school-age children.

Systemic depletion of histone macroH2A1.1 boosts hippocampal synaptic plasticity and social behavior in mice.
Gene expression and epigenetic processes in several brain regions regulate physiological processes such as cognitive functions and social behavior. MacroH2A1.1 is a ubiquitous variant of histone H2A that regulates cell stemness and differentiation in various organs. Whether macroH2A1.1 has a modulatory role in emotional behavior is unknown. Here, we employed macroH2A1.1 knock-out ( ) mice to perform a comprehensive battery of behavioral tests, and an assessment of hippocampal synaptic plasticity (long-term potentiation) accompanied by whole hippocampus RNA sequencing. MacroH2A1.1 mice exhibit a stunningly enhancement both of sociability and of active stress-coping behavior, reflected by the increased social behavior in social activity tests and higher mobility time in the forced swim test, respectively. They also display an increased hippocampal synaptic plasticity, accompanied by significant neurotransmission transcriptional networks changes. These results suggest that systemic depletion of histone macroH2A1.1 supports an epigenetic control necessary for hippocampal function and social behavior.

Sex-Dependent Effects of Developmental Lead Exposure in Wistar Rats: Evidence from Behavioral and Molecular Correlates.
Lead (Pb) exposure in early life affects brain development resulting in cognitive and behavioral deficits. Epidemiologic and experimental evidence of sex as an effect modifier of developmental Pb exposure is emerging. In the present study, we investigated Pb effects on behavior and mechanisms of neuroplasticity in the hippocampus and potential sex differences. To this aim, dams were exposed, from one month pre-mating to offspring weaning, to Pb via drinking water at 5 mg/kg body weight per day. In the offspring of both sexes, the longitudinal assessment of motor, emotional, and cognitive end points was performed. We also evaluated the expression and synaptic distribution of N-methyl-D-Aspartate receptor (NMDA) and α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptor subunits at post-natal day (pnd) 23 and 70 in the hippocampus. Neonatal motor patterns and explorative behavior in offspring were affected in both sexes. Pb effects in emotional response and memory retention were observed in adult females only, preceded by increased levels of GluN2A and GluA1 subunits at the post-synapse at pnd 23. These data suggest that Pb exposure during development affects glutamatergic receptors distribution at the post-synaptic spine in females. These effects may contribute to alterations in selected behavioral domains.

Pregnancy exposome and child psychomotor development in three European birth cohorts.
Characterization of the exposome, the totality of all environmental factors that one is exposed to from conception onwards, has been recommended to better evaluate the role of environmental influences on developmental programming and life-course vulnerability to major chronic diseases. In the framework of the Health and Environment-wide Associations based on Large population Surveys (HEALS) project we considered the pregnancy exposome exploiting two databases (PHIME and REPRO_PL) that include birth cohorts from three EU countries (Croatia, Slovenia and Poland). The databases contained information on several chemical exposures, socio-demographic, lifestyle and health related factors from conception to child birth, and neuropsychological scores assessed by the Bayley Scales of Infant and Toddler Development in the first two years of life. Our main goal was to assess consistency of environmental influences on neurodevelopment, if any, across European countries differing for geographical, socio-demographic characteristics and levels of chemical exposures to metals such as lead (Pb), mercury (Hg), cadmium (Cd) and trace elements, including micronutrients such as zinc (Zn) and selenium (Se). To this aim, we first selected variables common to the different databases, then applied univariate and multivariate regression analyses to identify factors linked to neurodevelopment, and finally performed meta-analysis to detect potential heterogeneity among cohorts and pooled estimates. Significant differences in exposure levels among the three sub-cohorts were observed as for Hg and Se; exposure levels under study were relatively low and within the range described in existing EU biomonitoring studies. The univariate analyses did not show any common pattern of association as only in the Polish cohort chemical exposure had an impact on neuropsychological outcome. In the meta-analysis, some consistent trends were evident, relative to the adverse influence of Pb on children's language and cognition and the positive influence of Se on language abilities. The effects of the neurotoxic metal Hg positively influenced the motor scores in the Polish cohorts, while it decreased the

motor scores in the Slovenia and Croatian sub-cohorts. The only socio-demographic factor consistently associated to the outcome among cohorts was child's sex, with females performing better than males on cognitive and language scores. These findings point to the need of harmonizing existing cohorts or creating prospective study designs that facilitate comparisons in the exposome over time, places and kind of environmental exposures.

Prenatal and early postnatal phthalate exposure and child neurodevelopment at age of 7 years - Polish Mother and Child Cohort.
Phthalates are among the most frequently investigated environmental chemicals influencing children's health and particularly their neuropsychological development. However, the reported effects of these compounds on child behavior, cognitive and psychomotor outcomes are not fully consistent. The aim of this study is to evaluate the associations between prenatal and early postnatal phthalate exposures and child neurodevelopment at age of 7 years. A total of 134 mother-child pairs from Polish Mother and Child Cohort (REPRO_PL) constitute the basis for current analysis. Eleven phthalate metabolites were measured in urine samples collected from mothers in the 3rd trimester of pregnancy and from children at the age of 2 years. Child neuropsychological development at early school age (7 years) was assessed by both the Strengths and Difficulties Questionnaire (SDQ) filled by mothers and the Polish adaptation of the Intelligence and Development Scales (IDS) performed by psychologists. Mono-ethyl phthalate (MEP) concentration during pregnancy was significantly associated with increased risk of peer relationship problems in SDQ (OR = 2.7, p = 0.03). The results of the IDS analyses focused on child's cognitive and psychomotor development are not fully conclusive. Negative associations were evident between some phthalates in early childhood period and fluid intelligence and cognition (MEP: β = -5.2; p = 0.006; β = -4.2; p = 0.006; mono-n-butyl phthalate (MnBP): β = -4.9; p = 0.03; β = -4.0; p = 0.03; respectively), while positive associations have been found in the prenatal period (mono-2-ethyl-5-oxo-hexyl phthalate (oxo-MEHP): β = 3.6; p = 0.03 for fluid intelligence; β = 2.9; p = 0.03 for cognition). Further studies are required in order to elucidate which are the most critical periods of phthalate exposure on children's neurodevelopmental outcomes.

Prenatal valproate in rodents as a tool to understand the neural underpinnings of social dysfunctions in autism spectrum disorder.
Impairments in social interaction and verbal and non verbal communication are among the main features of Autism Spectrum Disorder (ASD). The causes of ASD are still unknown but the research efforts of the last decade have identified a number of factors (rare gene mutations, gene variations and adverse environmental events) that, interacting in complex ways, affect early brain development. The clinical evidence that prenatal exposure to the antiepileptic drug valproate (VPA) is associated with increased risk of neurodevelopmental delay, cognitive deficits and autism in children, has drawn the attention of scientists on VPA as a tool to unravel the environment contribution to ASD risk in children. In agreement with the clinical evidence, rodents prenatally exposed to VPA display behavioral anomalies resembling ASD symptoms. The mechanisms by which administration of VPA in pregnancy increases the risk of autism are still far to be clear as are still undetermined the specific targets of VPA in the developing brain both in humans and rodents. However, the robustness of the behavioral alterations, mainly in the social domain, and the neural/molecular changes revealed so far support the VPA model as a reliable instrument to investigate the neural underpinnings of social impairment. Here we provide an update of preclinical studies on prenatal exposure to VPA in rodents with a focus on the social and communication deficits induced by VPA, discussing potential pitfalls and future directions in this research field and corroborating the potential of the VPA model to identify new pharmacological targets for ASD. This article is part of the Special Issue entitled 'The neuropharmacology of social behavior: from bench to bedside'.

Early Behavioral Alterations and Increased Expression of Endogenous Retroviruses Are Inherited Across Generations in Mice Prenatally Exposed to Valproic Acid.
Prenatal treatment with the antiepileptic drug valproic acid (VPA) is associated with a significant risk of somatic anomalies, neurodevelopmental delays, and 7-10× increase in the incidence of autism spectrum disorders (ASD) in children. Rodents exposed to VPA in pregnancy show birth defects, deficits in neurodevelopment, and cognitive/social anomalies resembling those of ASD children. Mechanisms of VPA neurobehavioral toxicity are still unclear but as VPA is a non-selective inhibitor of histone deacetylases, epigenetic modifications are likely involved. This study was aimed to evaluate the transgenerational impact of prenatal VPA exposure on mouse early behavioral development, studying F, F, and F generations after VPA

challenge on gestational day (GD) 10.5. We also analyzed in brain and in peripheral blood mononuclear cells the expression levels of different endogenous retrovirus (ERV) families, potential biomarkers of derailed brain development, since human ERVs have been implicated in the pathogenesis of neurodevelopmental disorders (NDDs) such as ASD. Somatic effects of VPA were evident only in F generation and more markedly in the female sex. Across F and F generations, VPA delayed righting reflex, increased motor activity, and reduced ultrasonic vocalizations. The behavioral changes in F are milder though in the same direction. VPA increased expression of most ERVs across the three generations in brain and blood. In utero VPA induced neurodevelopmental alterations more marked in the maternal lineage that persisted also in F, suggesting ERVs as possible downstream effectors of the VPA epigenetic alterations.

High expression of Endogenous Retroviruses from intrauterine life to adulthood in two mouse models of Autism Spectrum Disorders.
Retroelements, such as Human Endogenous Retroviruses (HERVs), have been implicated in many complex diseases, including neurological and neuropsychiatric disorders. Previously, we demonstrated a distinctive expression profile of specific HERV families in peripheral blood mononuclear cells from Autistic Spectrum Disorders (ASD) patients, suggesting their involvement in ASD. Here we used two distinct ASD mouse models: inbred BTBR T+tf/J mice and CD-1 outbred mice prenatally exposed to valproic acid. Whole embryos, blood and brain samples from the offspring were collected at different ages and the expression of several ERV families (ETnI, ETnII-α, ETnII-β, ETnII-γ, MusD and IAP), proinflammatory cytokines (IL-1β, IL-6 and TNF-α) and Toll-like receptors (TLR3 and TLR4) was assessed. In the two distinct mouse models analysed, the transcriptional activity of the ERV families was significant higher in comparison with corresponding controls, in whole embryos, blood and brain samples. Also the expression levels of the proinflammatory cytokines and TLRs were significantly higher than controls. Current results are in agreement with our previous findings in ASD children, supporting the hypothesis that ERVs may serve as biomarkers of atypical brain development. Moreover, the changes in ERVs and proinflammatory cytokines expression could be related with the autistic-like traits acquisition in the two mouse models.

Aberrant self-grooming as early marker of motor dysfunction in a rat model of Huntington's disease.
In the study of neurodegenerative diseases, rodent models provide experimentally accessible systems to study multiple pathogenetic aspects. The identification of early and robust behavioural changes is crucial to monitoring disease progression and testing potential therapeutic strategies in animals. Consistent experimental data support the translational value of rodent self-grooming as index of disturbed motor functions and perseverative behaviour patterns in different rodent models of brain disorders. Huntington's disease (HD) is a progressive neurodegenerative disorder, characterized by severe degeneration of basal ganglia, cognitive and psychiatric impairments and motor abnormalities. In the rat species, intrastriatal injection of the excitotoxin quinolinic acid (QA) mimics some of the neuroanatomical and behavioural changes found in HD, including the loss of GABAergic neurons and the appearance of motor and cognitive deficits. We show here that striatal damage induced by unilateral QA injection in dorsal striatum of rats triggers aberrant grooming behaviour as early as three weeks post-lesion in absence of other motor impairments: specifically, both quantitative (frequency and duration) and qualitative (the sequential pattern of movements) features of self-grooming behaviour were significantly altered in QA-lesioned rats placed in either the elevated plus-maze and the open-field. The consistent abnormalities in self-grooming recorded in two different experimental contexts support the use of this behavioural marker in rodent models of striatal damage such as HD, to assess the potential effects of drug and cell replacement therapy in the early stage of disease.

Early-Life Toxic Insults and Onset of Sporadic Neurodegenerative Diseases-an Overview of Experimental Studies.
The developmental origin of health and disease hypothesis states that adverse fetal and early childhood exposures can predispose to obesity, cardiovascular, and neurodegenerative diseases (NDDs) in adult life. Early exposure to environmental chemicals interferes with developmental programming and induces subclinical alterations that may hesitate in pathophysiology and behavioral deficits at a later life stage. The mechanisms by which perinatal insults lead to altered programming and to disease later in life are still undefined. The long latency between exposure and onset of disease, the difficulty of reconstructing early exposures, and the wealth of factors which the individual is exposed to during the life course make extremely difficult to prove the developmental origin of NDDs in clinical and epidemiological studies. An overview of animal studies assessing the long-term effects of perinatal exposure to different chemicals (heavy metals and pesticides) supports the link between exposure and hallmarks of neurodegeneration at the adult stage. Furthermore, models of maternal immune activation show that brain inflammation in early life may enhance adult vulnerability to environmental toxins, thus

supporting the multiple hit hypothesis for NDDs' etiology. The study of prospective animal cohorts may help to unraveling the complex pathophysiology of sporadic NDDs. In vivo models could be a powerful tool to clarify the mechanisms through which different kinds of insults predispose to cell loss in the adult age, to establish a cause-effect relationship between "omic" signatures and disease/dysfunction later in life, and to identify peripheral biomarkers of exposure, effects, and susceptibility, for translation to prospective epidemiological studies.

MITOCHONDRIAL MORPHOLOGICAL REMODELING IN RESPONSE TO MITOCHONDRIAL STRESS IN A NEURONAL CELL MODEL

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Erin Buchanan, Sophia Bam, Emma Frickel, Caitlyn Mahony, Mignon Van Der Watt, Colleen O'Ryan
University of Cape Town, Molecular And Cell Biology, Cape Town, South Africa

The significance of mitochondrial function in neuronal differentiation is well established and is important for neurodevelopmental disorders like Autism Spectrum Disorder (ASD). We identified differentially methylated genes, including a gene that results in propionate accumulation, associated with mitochondrial function in a South African ASD cohort. Sodium propionate (NaP) has been used to study ASD in rat models. **Aims:** (i) Induce mitochondrial dysfunction in SH-SY5Y cells using NaP treatment and (ii) Investigate the effects of NaP on mitochondrial biogenesis, dynamics and morphology. **Methods:** We set-up a mitochondrial stress model using NaP (1.5mM, 3mM, 5mM) to induce mitochondrial dysfunction in SH-SY5Y cells. PGC1α expression and mitochondrial copy number confirmed mitochondrial dysfunction using RT-qPCR. Microscopy (cryogenic electron and fluorescent) measured changes in mitochondrial dynamics and morphology. Bright-field microscopy and immunocytochemistry measured neurodifferentiation after NaP treatment. Significance was determined using one-way ANOVA ($p<0.05$). **Results:** NaP treatment at all concentrations altered mitochondrial biogenesis and dynamics in undifferentiated and differentiated SH-SY5Y cells. PGC1α expression and mitochondrial copy number (1.5mM and 3mM NaP) indicated changes in biogenesis. Changes in mitochondrial morphology were seen by differences between mitochondrial length, area and aspect ratio at different NaP concentrations. Higher NaP concentrations (5mM) inhibited neurodifferentation with decreases in neurite extensions being observed. **Conclusions:** These data are consistent with the link between mitochondrial dysfunction and fluctuations in biogenesis and dynamics. This study offers insight into how mitochondrial induced stress impacts neurogenesis, and thus may potentially play a role in ASD aetiology.

CAECAL DYSFUNCTION IN THE NEUROLIGIN-3 R451C MOUSE MODEL OF AUTISM

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Chalystha Yie Qin Lee[1], Gayathri Balasuriya[1], Ashley Franks[2], Elisa Hill-Yardin[1]

Individuals with autism often experience gastrointestinal symptoms alongside core behavioural traits which may indicate a role for the gut-brain axis and neuro-immune cross-talk. The gastrointestinal tract houses both the largest immune organ and the enteric nervous system (ENS), which regulates gut function. The mouse caecum corresponds to the human appendix and serves as a fermentation site and reservoir for commensal bacteria, and is thus an ideal region to study neuro-immune interactions. Here we assessed for changes in caecal function in mice expressing an autism-associated missense mutation encoding the post-synaptic protein neuroligin-3 ($NL3^{R451C}$ mice). These mice have reduced caecal weight, altered caecal ENS architecture, and changes in immune cell morphology in the lymphoid tissue, known as the caecal patch. To characterise neuro-immune interactions in autism, caecal motility was assessed using an *ex vivo* video imaging technique. Changes in caecal secretion of fluids and mucosal permeability were also investigated using an Ussing chamber, and immune cell morphology was studied using immunofluorescence for the dendritic cell marker, CD11c. NL3 mouse caecal motility showed a higher frequency and shorter duration of contractile patterns compared to wildtypes. Neurally-evoked secretion was decreased in NL3 mice, whereas mucosal permeability was unchanged. NL3 mice had less caecal content and more lymphoid patches, with no morphological difference observed in $CD11c^{+}$ dendritic cells. These findings indicate that the R451C nervous system mutation alters caecal structure, motility and secretion. These findings provide a foundation for future investigations into how caecal function contributes to health and neurodevelopmental disorders via the gut-brain axis.

An Overview of Survival Tactics in the Hostile Human Stomach Environment.
is well established as a causative agent for gastritis, peptic ulcer, and gastric cancer. Armed with various inimitable virulence factors, this Gram-negative bacterium is one of few microorganisms that is capable of circumventing the harsh environment of the stomach. The unique spiral structure, flagella, and outer membrane proteins accelerate movement within the viscous gastric mucosal layers while facilitating its attachment to the epithelial cells. Furthermore, secretion of urease from eases the acidic pH within the stomach, thus creating a niche for bacteria survival and replication. Upon gaining a foothold in the gastric epithelial lining, bacterial protein CagA is injected into host cells through a type IV secretion system (T4SS), which together with VacA, damage the gastric epithelial cells. does not only establishes colonization in the stomach, but also manipulates the host immune system to permit long-term persistence. Prolonged infection causes chronic inflammation that precedes gastric cancer. The current review provides a brief outlook on survival tactics, bacterial-host interaction and their importance in therapeutic intervention as well as vaccine development.

Podoplanin Drives Motility of Active Macrophage Regulating Filamin C During Infection.
Podoplanin (Pdpn) is a mucin-type transmembrane protein that has been implicated in multiple physiological settings including lymphangiogenesis, platelet aggregation, and cancer metastasis. Here, we reported an absence of Pdpn transcript expression in the resting mouse monocytic macrophages, RAW264.7 cells; intriguingly, a substantial upregulation of Pdpn was observed in activated macrophages following or lipopolysaccharide stimulation. Pdpn-knockout macrophages demonstrated intact phagocytic and intracellular bactericidal activities comparable to wild type but exhibited impaired migration due to attenuated filopodia formation. In contrast, an ectopic expression of Pdpn augmented filopodia protrusion in activated macrophages. NanoString analysis uncovered a close dependency of Filamin C gene on the presence of Pdpn, highlighting an involvement of Filamin C in modulation of actin polymerization activity, which controls cell filopodia formation and migration. In addition, interleukin-1β production was significantly declined in the absence of Pdpn, suggesting a role of

Pdpn in orchestrating inflammation during infection besides cellular migration. Together, our findings unravel the Pdpn network that modulates movement of active macrophages.

Ebselen prevents cigarette smoke-induced gastrointestinal dysfunction in mice.
Gastrointestinal (GI) dysfunction is a common comorbidity of chronic obstructive pulmonary disease (COPD) for which a major cause is cigarette smoking (CS). The underlying mechanisms and precise effects of CS on gut contractility, however, are not fully characterised. Therefore, the aim of the present study was to investigate whether CS impacts GI function and structure in a mouse model of CS-induced COPD. We also aimed to investigate GI function in the presence of ebselen, an antioxidant that has shown beneficial effects on lung inflammation resulting from CS exposure. Mice were exposed to CS for 2 or 6 months. GI structure was analysed by histology and immunofluorescence. After 2 months of CS exposure, ex vivo gut motility was analysed using video-imaging techniques to examine changes in colonic migrating motor complexes (CMMCs). CS decreased colon length in mice. Mice exposed to CS for 2 months had a higher frequency of CMMCs and a reduced resting colonic diameter but no change in enteric neuron numbers. Ten days cessation after 2 months CS reversed CMMC frequency changes but not the reduced colonic diameter phenotype. Ebselen treatment reversed the CS-induced reduction in colonic diameter. After 6 months CS, the number of myenteric nitric-oxide producing neurons was significantly reduced. This is the first evidence of colonic dysmotility in a mouse model of CS-induced COPD. Dysmotility after 2 months CS is not due to altered neuron numbers; however, prolonged CS-exposure significantly reduced enteric neuron numbers in mice. Further research is needed to assess potential therapeutic applications of ebselen in GI dysfunction in COPD.

Autism-associated synaptic mutations impact the gut-brain axis in mice.
Interactions between the gut microbiome and the brain affect mood and behaviour in health and disease. Using preclinical animal models, recent discoveries begin to explain how bacteria in the gut influence our mood as well as highlighting new findings relevant to autism. Autism-associated gene mutations known to alter synapse function in the CNS also affect inflammatory response and modify the enteric nervous system resulting in abnormal gastrointestinal motility and structure. Strikingly, these mutations additionally affect the gut microbiome in mice. This review describes the changes in gut physiology and microbiota in mouse models of autism with modified synapse function. The rationale for different regions of the gastrointestinal tract having variable susceptibility to dysfunction is also discussed. To dissect underlying biological mechanisms involving gut-brain axis dysfunction in preclinical models, a range of multidisciplinary approaches are required. This research will provide insights into the role of the gut-brain axis in health and neurodevelopmental disorders including autism.

Chronic Inflammatory Diseases at Secondary Sites Ensuing Urogenital or Pulmonary Infections.
and are members of the family of obligate intracellular bacteria. The former causes diseases predominantly at the mucosal epithelial layer of the urogenital or eye, leading to pelvic inflammatory diseases or blindness; while the latter is a major causative agent for pulmonary infection. On top of these well-described diseases at the respective primary infection sites, are notoriously known to migrate and cause pathologies at remote sites of a host. One such example is the sexually acquired reactive arthritis that often occurs at few weeks after genital infection. , on the other hand, has been implicated in an extensive list of chronic inflammatory diseases which include atherosclerosis, multiple sclerosis, Alzheimer's disease, asthma, and primary biliary cirrhosis. This review summarizes the infection associated diseases at the secondary sites of infection, and describes the potential mechanisms involved in the disease migration and pathogenesis.

Diversity of endocervical microbiota associated with genital Chlamydia trachomatis infection and infertility among women visiting obstetrics and gynecology clinics in Malaysia.
The cervical microbiota constitutes an important protective barrier against the invasion of pathogenic microorganisms. A disruption of microbiota within the cervical milieu has been suggested to be a driving factor of sexually transmitted infections. These include Chlamydia trachomatis which frequently causes serious reproductive sequelae such as infertility in women. In this study, we profiled the cervical microbial composition of a population of 70 reproductive-age Malaysian women; among which 40 (57.1%) were diagnosed with genital C. trachomatis infection, and 30 (42.8%) without C. trachomatis infection. Our findings showed a distinct compositional difference between the cervical microbiota of C. trachomatis-infected subjects and

subjects without C. trachomatis infection. Specifically, significant elevations of mostly strict and facultative anaerobes such as Streptococcus, Megasphaera, Prevotella, and Veillonella in the cervical microbiota of C. trachomatis-positive women were detected. The results from the current study highlights an interaction of C. trachomatis with the environmental microbiome in the endocervical region.

: Diseases in Primary Hosts and Zoonosis.
Bacteria of the family are a type of Gram-negative microorganism typified by their obligate intracellular lifestyle. The majority of the members in the family are known pathogenic organisms that primarily infect the host mucosal surfaces in both humans and animals. For instance, is a well-known etiological agent for ocular and genital sexually transmitted diseases, while has been implicated in community-acquired pneumonia in humans. Other chlamydial species such as , , , , , and are important pathogens that are associated with high morbidities in animals. Importantly, some of these animal pathogens have been recognized as zoonotic agents that pose a significant infectious threat to human health through cross-over transmission. The current review provides a succinct recapitulation of the characteristics as well as transmission for the previously established members of the family and a number of other recently described chlamydial organisms.

CPAF, HSP60 and MOMP antigens elicit pro-inflammatory cytokines production in the peripheral blood mononuclear cells from genital Chlamydia trachomatis-infected patients.
Persistent inflammation caused by Chlamydia trachomatis in the female genital compartment represents one of the major causes of pelvic inflammatory disease (PID), ectopic pregnancy and infertility in females. Here, we examined the pro-inflammatory cytokine response following stimulation with three different types of C. trachomatis antigens, viz. chlamydial protease-like factor (CPAF), heat shock protein 60 (HSP60) and major outer membrane protein (MOMP).

T-Cell Exhaustion in Chronic Infections: Reversing the State of Exhaustion and Reinvigorating Optimal Protective Immune Responses.
T-cell exhaustion is a phenomenon of dysfunction or physical elimination of antigen-specific T cells reported in human immunodeficiency virus (HIV), hepatitis B virus (HBV), and hepatitis C virus (HCV) infections as well as cancer. Exhaustion appears to be often restricted to CD8+ T cells responses in the literature, although CD4+ T cells have also been reported to be functionally exhausted in certain chronic infections. Although our understanding of the molecular mechanisms associated with the transcriptional regulation of T-cell exhaustion is advancing, it is imperative to also explore the central mechanisms that control the altered expression patterns. Targeting metabolic dysfunctions with mitochondrion-targeted antioxidants are also expected to improve the antiviral functions of exhausted virus-specific CD8+ T cells. In addition, it is crucial to consider the contributions of mitochondrial biogenesis on T-cell exhaustion and how mitochondrial metabolism of T cells could be targeted whilst treating chronic viral infections. Here, we review the current understanding of cardinal features of T-cell exhaustion in chronic infections, and have attempted to focus on recent discoveries, potential strategies to reverse exhaustion and reinvigorate optimal protective immune responses in the host.

Lung-infiltrating T helper 17 cells as the major source of interleukin-17A production during pulmonary Cryptococcus neoformans infection.
IL-17A has emerged as a key player in the pathologies of inflammation, autoimmune disease, and immunity to microbes since its discovery two decades ago. In this study, we aim to elucidate the activity of IL-17A in the protection against Cryptococcus neoformans, an opportunistic fungus that causes fatal meningoencephalitis among AIDS patients. For this purpose, we examined if C. neoformans infection triggers IL-17A secretion in vivo using wildtype C57BL/6 mice. In addition, an enhanced green fluorescence protein (EGFP) reporter and a knockout (KO) mouse models were used to track the source of IL-17A secretion and explore the protective function of IL-17A, respectively.

BLOCKING THE P2X7-NLRP3-IL-1β PATHWAY IN THE MATERNAL IMMUNE ACTIVATION MODEL PREVENTS AUTISM-LIKE PHENOTYPE IN MALE MOUSE OFFSPRING

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Autism spectrum disorder (ASD) is a complex neurodevelopmental condition caused by environmental and genetic factors. Mimicking a perinatal infection, treating pregnant mice with a double-stranded RNA (poly(I:C)) activates an antiviral immune response. Elevation of extracellular ATP activates P2X7 resulting in the formation of active NLRP3 and caspase-1, leading to the synthesis of IL-1β. Our aim was to identify downstream signaling pathways coupled to P2X7, converting maternal immune activation (MIA) to ASD-like features. To induce MIA dams were challenged with poly(I:C) injection on E12.5 and E17.5. A cohort of pregnant mice was pretreated with NLRP3 antagonist MCC950 or with neutralizing anti-mouse IL-1β antibody on E12. Behavioral experiments were performed on male offspring in the following order: social preference, self-grooming, marble-burying, and rotarod test followed by immunostained Purkinje cell counting and electron microscopic synaptosome integrity examination. Concentrations of inflammatory cytokines and chemokines were measured in fetal brain, and maternal plasma samples collected 0,1,6,24 or 48 hours following MIA induction. Maternal treatment with MCC950 and IL-1β antibodies counteracted the development of autistic behavioral and morphological characteristics in the offspring. We also explored time-dependent changes of a widespread cytokine and chemokine profile in maternal blood and fetal brain samples of poly(I:C)/saline-treated dams. MIA-induced increases in plasma RANTES, MCP-1, and fetal brain IL-1β, IL-2, IL-6, MCP-1 concentrations have been shown to be the effect of P2X7/NLRP3 regulation. Our results highlight that in addition to P2X7, NLRP3 and inflammatory cytokines may also be potential biomarkers and therapeutic targets of repetitive behavioral and social deficits observed in ASD.

JANUS KINASE AND MICROTUBULE-INTERACTING PROTEIN 1 (JAKMIP1), A NOVEL REGULATOR OF NUCLEAR RNA EXPORT IN NEURONS: COUPLING TRANSCRIPTION TO CYTOPLASMIC TRANSLATION THROUGH THE MICROTUBULE CYTOSKELETON

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Josan Gandawijaya[1], Natsuki Takamura[2], John Chilton[3], Helen Dawe[4], Asami Oguro-Ando[1]
[1]University of Exeter, College Of Medicine And Health, Exeter, United Kingdom, [2]The University of Tokyo, Department Of Life Sciences, Tokyo, Japan, [3]University of Plymouth, Faculty Of Health, Plymouth, United Kingdom, [4]University of Exeter, College Of Life And Environmental Sciences, Exeter, United Kingdom

JAKMIP1 was first identified as an Autism spectrum disorder (ASD) candidate gene due to its downregulated expression in both idiopathic and syndromic forms of ASD. A later study then demonstrated that Jakmip1 deficiency results in core ASD-associated behaviours in knockout mice. This suggests that JAKMIP1 may play important roles in nervous system development and that its dysregulation may underlie the development of ASD-related behaviours. However, the molecular functions of JAKMIP1 are not well understood. To investigate its molecular function, we utilised truncated JAKMIP1 constructs tagged with fluorescent proteins. Interestingly, we observed predominantly nuclear localisation of the JAKMIP1 C-terminus, in stark contrast to the microtubular localisation of the N-terminus. To further understand its nuclear role, we employed a dual transcriptomic-proteomic approach utilising RNA-sequencing and immunoprecipitation-mass spectrometry. Our results reveal that JAKMIP1 interacts with cytoskeletal proteins through its N-terminus, and with proteins regulating mRNA splicing and nuclear tRNA export through its C-terminus. Furthermore, JAKMIP1 interacts with various ribosomal and translational regulatory proteins in the cytoplasm. We also identify novel pathways impacted by JAKMIP1 deficiency involved in extracellular matrix organisation and cytokine signalling. These findings suggest that JAKMIP1 may mediate the splicing and processing of mRNAs and tRNAs, facilitate their nuclear export and couple this with the assembly of ribonucleoprotein complexes for cytoplasmic translation through the microtubule network. How these processes affect broader cellular behaviours, such as neuronal responses to cytokines and the composition of the extracellular matrix, will require further investigation.

THE EFFECT OF L. REUTERI ON SOCIAL BEHAVIOR IS INDEPENDENT OF THE ADAPTIVE IMMUNE SYSTEM.

POSTER SESSION 03 - SECTION: NEUROIMMUNE MECHANISMS MEDIATING DYSFUNCTION IN AUTISM

Gut microbes can modulate almost all aspects of host physiology throughout life. As a result, specific microbial interventions are attracting considerable attention as potential therapeutic strategies for treating a variety of conditions. Nonetheless, little is known about the mechanisms through which many of these microbes work. Recently, we and others have found that the commensal bacteria *L. reuteri* reverses social deficits in several mouse models (genetic, environmental and idiopathic) for neurodevelopmental disorders in a vagus nerve-, oxytocin- and biopterin-dependent manner. Given that gut microbes can signal to the brain through the immune system and *L. reuteri* promotes wound healing via the adaptive immune response, we asked whether the prosocial effect mediated by *L. reuteri* also depends on adaptive immunity. Here, we found that the effects of *L. reuteri* on social behavior and related changes in synaptic function are independent of the mature adaptive immune system. Interestingly, these finding indicate that the same microbe (*L. reuteri*) can affect different host phenotypes through distinct mechanisms.

Peripheral sensory neuron injury contributes to neuropathic pain in experimental autoimmune encephalomyelitis.
Multiple sclerosis (MS)-induced neuropathic pain deteriorates quality of life in patients but is often refractory to treatment. In experimental autoimmune encephalomyelitis (EAE), a rodent model of MS, animals develop neuropathy and inflammation-induced tissue acidosis, which suggests the involvement of acid-sensing ion channels (ASICs). Also, peripheral neuropathy is reported in MS patients. However, the involvement of the peripheral nervous system (PNS) in MS neuropathic pain remains elusive. This study investigated the contribution of ASICs and peripheral neuropathy in MS-induced neuropathic pain. Elicited pain levels were as high in Asic1a, Asic2 and Asic3 mice as wild-type mice even though only Asic1a mice showed reduced EAE disease severity, which indicates that pain in EAE was independent of disease severity. We thus adopted an EAE model without pertussis toxin (EAEnp) to restrain activated immunity in the periphery and evaluate the PNS contribution to pain. Both EAE and EAEnp mice showed similar pain behaviors and peripheral neuropathy in nerve fibers and DRG neurons. Moreover, pregabalin significantly reduced neuropathic pain in both EAE and EAEnp mice. Our findings highlight the essential role of the PNS in neuropathic pain in EAE and pave the way for future development of analgesics without side effects in the CNS.

Therapeutic inhibition of mTORC2 rescues the behavioral and neurophysiological abnormalities associated with Pten-deficiency.
Dysregulation of the mammalian target of rapamycin (mTOR) signaling, which is mediated by two structurally and functionally distinct complexes, mTORC1 and mTORC2, has been implicated in several neurological disorders. Individuals carrying loss-of-function mutations in the phosphatase and tensin homolog (PTEN) gene, a negative regulator of mTOR signaling, are prone to developing macrocephaly, autism spectrum disorder (ASD), seizures and intellectual disability. It is generally believed that the neurological symptoms associated with loss of PTEN and other mTORopathies (for example, mutations in the tuberous sclerosis genes TSC1 or TSC2) are due to hyperactivation of mTORC1-mediated protein synthesis. Using molecular genetics, we unexpectedly found that genetic deletion of mTORC2 (but not mTORC1) activity prolonged lifespan, suppressed seizures, rescued ASD-like behaviors and long-term memory, and normalized metabolic changes in the brain of mice lacking Pten. In a more therapeutically oriented approach, we found that administration of an antisense oligonucleotide (ASO) targeting mTORC2's defining component Rictor specifically inhibits mTORC2 activity and reverses the behavioral and

neurophysiological abnormalities in adolescent Pten-deficient mice. Collectively, our findings indicate that mTORC2 is the major driver underlying the neuropathophysiology associated with Pten-deficiency, and its therapeutic reduction could represent a promising and broadly effective translational therapy for neurological disorders where mTOR signaling is dysregulated.

Inappropriate disposal of plastics and plastic particles has been contributed significantly to accumulation in the environment. Under these conditions, a remarkable amount of plastics end up in the aquatic environment where, by natural processes, they are continually fragmented into smaller particles called micro/nanoplastics that can be ingested/absorbed by aquatic organisms and accumulate in different tissues. Once accumulated, these particles can induce several toxic effects. Although several good studies have linked toxic effects with exposure to plastic particles, the whole process is far from be completely understood and almost nothing is known regarding the molecular mechanisms involved. Thus, this study evaluated the effects of PET (polyethylene terephthalate) micro/nanoplastics exposure (at 0.5, 1, 5,10 and 20 mg/L) during six consecutive days on mortality, hatching, spontaneous movement, heart rate, morphology and locomotor behavior of zebrafish embryos/larvae. There was no significant change in the mortality and hatching rate. In the 20 mg/L, spontaneous movement significantly decrease in comparison to the control group. Heart rate was increase at the four highest concentrations when compared to the control group. No significant changes were found in either body length or ocular surface area at any of the concentrations tested. On the other hand, there was a significant decrease in the ocular distance at all concentrations when compared to the control group. No significant alteration were found in the parameters used to assess locomotor behavioral. Additional studies are in course for deeper understanding of the toxic effects of PET micro/nanoplastics exposure.

The use of pesticides has continue grown over recent years, leading to several environmental and health concerns, such as the contamination of surface and groundwater resources and associated biota, potentially affecting populations that are not primary targets of these complex chemical mixtures. In this work, we investigate lethal and sublethal effects of acute exposure of methomyl commercial formulation in zebrafish embryo and larvae. Methomyl is a broad-spectrum carbamate insecticide and acaricide that acts primarily in acetylcholinesterase inhibition (AChE). Methomyl formulation 96h-LC_{50} was determined through the *Fish Embryo Acute Toxicity Test* (FET) and resulted in 1.2 g/L ± 0.04. Sublethal 6-day exposure was performed in six methomyl formulation concentrations (0.5; 1.0; 2.2; 4.8; 10.6; 23.3 mg/L) to evaluate developmental, physiological, morphological, behavioral, biochemical, and molecular endpoints of zebrafish early-development. Methomyl affected embryo hatching and larva morphology and behavior, especially in higher concentrations; resulting in smaller body and eyes size, failure in swimming bladder inflation, hypolocomotor activity, and concentration-dependent reduction of AChE activity; demonstrating methomyl strong acute toxicity and neurotoxic effect.

Long-term consumption of a high-fat diet (HFD) causes obesity and is a risk factor for depression. HFD has a significant impact on the gut microbiota, and dysbiosis of the microbiota is now associated with certain psychiatric disorders such as anxiety and depression. We aimed to investigate whether modulation by antibiotic treatment of the composition of the gut microbiota in diet-induced obese (DIO) mice has an impact on depressive-like behavior. In this study, we analyzed the effects of a 15 weeks HFD consumption by male mice on their depressive-like behavior assessed in the forced swim and sucrose preference tests. Two weeks before beginning the behavioral tests, a group of DIO mice were given a combination of two non-absorbable antibiotics, neomycin and polymyxin B. HFD induced anhedonia, as revealed by the sucrose preference test, and significant changes in gut microbiota composition at the phyla and family levels. On the other hand, there was no significant effect of HFD on the peripheral and brain inflammatory profiles. In DIO mice treated with the antibiotics, an even more pronounced alteration in the composition of the gut microbiota occurred, without any change in anhedonia behavior. Only four families of bacteria were not affected in their abundance by the antibiotic treatment, the *Rikenellaceae*, *Streptococcaceae*, *Erysipelotrichaceae* and *Bifidobacteriaceae*. This stability concomitant with that of anhedonia may suggest that these families were involved in this depression-like behavior.

Introduction: Both human and rodent studies have demonstrated that altered maternal environment influences foetal development, causing impairments in offspring brain. We hypothesise, in the absence of obesity, a maternal high-fat diet (HFD) during gestation/lactation or only during the preimplantation period affects offspring locomotor, explorative and anxiety behaviour. **Methods**: After mating, female-MF1 were allocated to one of three groups: Embryonic-HFD (EHFD: HFD up to E3.5, chow diet after); HFD and control group (NFD), consuming HFD and chow diet throughout pregnancy/lactation periods, respectively. Open field test (OFT) was performed for 10min at 4 (OFT1) and 10 weeks old (OFT2). Comparisons were made between HFD(n=9), EHFD(n=8), and NFD(n=9) groups using a hierarchical linear regression model. **Results:** In OFT1, EHFD males but not females, significantly travelled less (p=0.050), rested more (p=0.043), and had fewer ambulatory (p=0.037) and jump counts (p=0.026) than NFD. HFD males had fewer jump counts (p=0.016) while HFD females spent less time rearing compared to NFD (p=0.014), and EHFD (p=0.009). However, none of these differences were observed in OFT2 (p>0.05). EHFD females spent significantly less time than NFD (p=0.006) and HFD (p=0.007) females in the periphery area in the OFT1, but less time than NFD in the centre area in OFT2 (p=0.044). **Conclusions**: Maternal HFD exposure during only the preimplantation period particularly decreased juvenile male offspring locomotor and exploratory behaviour. This confirms that diet changes during the preimplantation period can affect offspring future health, while also suggesting that exposure to a normal diet can rescue the phenotype in adulthood.

[1]European Molecular Biology Laboratory, Cell Biology And Biophysics, Heidelberg, Germany, [2]Heidelberg University Clinic, Pharmacology, Heidelberg, Germany, [3]European Molecular Biology Laboratory, Epigenetics And Neurobiology Unit, Monterotondo, Italy

Most people face at some point of their life an unpleasant experience of feeling sick, a state that usually combines body aches, fever, lack of appetite, depressed mood and a need to seclude in a warm place. These symptoms are part of an evolutionarily conserved response among vertebrates known as sickness syndrome. The sickness syndrome is triggered by mediators produced by the immune system during systemic inflammation. Among the best studied mediators of sickness is prostaglandin E2 (PGE_2). It remains unclear, though, how different responses to PGE_2 develop over time. To address this question, we delivered PGE_2 intracerebroventricularly in mice and used a supervised machine learning approach to classify mouse behavioral motifs during sickness. Our data show that PGE_2 acting within the central nervous system can induce a rapid modification of both physiology and behavior, and elicit a state that recapitulates many of the symptoms observed during natural sicknesses. We envision that this detailed profiling of sickness-associated behavioral changes will identify key time windows on the action of PGE_2 and guide our future experiments to clarify neuronal mechanisms underlying sickness syndrome.

We aimed to study how a previously characterized calorie-restricted cafeteria diet (CAFR) and moderate treadmill exercise (12-17 m/min) affects the sweet taste and biometrical and metabolic parameters in obese male and female rats. Animals were fed standard chow (STD) or cafeteria (CAF) diet for 8 weeks to induce obesity. Afterwards, animals were either maintained with *ad libitum* CAF or switched to CAFR diet. Dietary groups were subdivided into control (C) and exercise (E) groups. Biometric measures (body weight, Body mass index and abdominal perimeter) were recorded periodically. After 8 weeks of treatment, animals performed a two-bottle preference test, a brief-access licking test and a taste reactivity test with sucrose (0.01M-1M). CAFR feeding decreased all biometrical parameters measured compared with CAF only in females. CAF diet in both sexes decreased sucrose intake compared with STD, while CAFR diet partially reverted this effect in females. Exercise in CAF fed males decreased sucrose intake compared with the CAF-C group. In the brief-access test, CAF feeding decreased sucrose sensitivity and CAFR feeding reverted this effect in both sexes. Exercise also decreased sucrose sensitivity in CAF fed females. Hedonic behaviour elicited by sucrose was decreased in CAF fed males compared to the STD fed. These results indicate that the cafeteria diet-induced obesity decreases intake and sensitivity to sucrose, possibly through the development of an anhedonic state associated with obesity. This effect can be partially reverted by CAFR feeding. Additionally, treadmill exercise might decrease sucrose intake and its rewarding value in CAF-induced obese rats.

Increased training compensates for OX1R blockage-impairment of spatial memory and c-Fos expression in different cortical and subcortical areas.
It has been suggested that the orexin system modulates learning and memory-related processes. However, the possible influence that training could have on the effect of the blockade of orexin-A selective receptor (OX1R) on a spatial memory task has not been explored. Therefore, the present study attempts to compare the effects of OX1R antagonist SB-334867 infusion on spatial memory in two different conditions in the Morris Water Maze (MWM). This experiment evaluated the animals' performance in weak training (2 trials per session) vs strong training (6 trials per session) protocols in a spatial version of the MWM. We found that in the 2-trial condition the post-training SB-334867 infusion had a negative effect on consolidation as well as on the retention and reversal learning of the task 72 h later. This effect was not apparent in the 6-trial condition. In addition, while the strong training groups showed a general increase in c-Fos expression in several brain areas of the hippocampal-thalamic-cortical circuit, SB-334867 administration had the opposite effect in areas that have been previously reported to have a high density of OX1R. Specifically, the SB-infused group in the 2-trial condition showed a decrease in c-Fos immunoreactivity in the dentate gyrus, granular retrosplenial and prelimbic cortices, and centrolateral thalamic nucleus. This was not observed for subjects in the 6-trial condition. The activation of these areas could constitute a neuroanatomical substrate involved in the compensatory mechanisms of training upon SB-334867 impairing effects on a MWM spatial task.

Behavioral and Metabolic Effects of a Calorie-Restricted Cafeteria Diet and Oleuropein Supplementation in Obese Male Rats.

FENS Forum 2022
9-13 July 2022 | Paris, France

Diet-induced obesity models are widely used to investigate dietary interventions for treating obesity. This study was aimed to test whether a dietary intervention based on a calorie-restricted cafeteria diet (CAF-R) and a polyphenolic compound (Oleuropein, OLE) supplementation modified sucrose intake, preference, and taste reactivity in cafeteria diet (CAF)-induced obese rats. CAF diet consists of high-energy, highly palatable human foods. Male rats fed standard chow (STD) or CAF diet were compared with obese rats fed CAF-R diet, alone or supplemented with an olive tree leaves extract (25 mg/kg*day) containing a 20.1% of OLE (CAF-RO). Biometric, food consumption, and serum parameters were measured. CAF diet increased body weight, food and energy consumption and obesity-associated metabolic parameters. CAF-R and CAF-RO diets significantly attenuated body weight gain and BMI, diminished food and energy intake and improved biochemical parameters such as triacylglycerides and insulin resistance which did not differ between CAF-RO and STD groups. The three cafeteria groups diminished sucrose intake and preference compared to STD group. CAF-RO also diminished the hedonic responses for the high sucrose concentrations compared with the other groups. These results indicate that CAF-R diet may be an efficient strategy to restore obesity-associated alterations, whilst OLE supplementation seems to have an additional beneficial effect on sweet taste function.

AIMS: Diet-induced obesity models are widely used to investigate dietary interventions for treating obesity. This study was aimed to test whether a dietary intervention based on a calorie-restricted cafeteria diet (CAF-R) and a polyphenolic compound (Oleuropein, OLE) supplementation modified sucrose intake, preference and taste reactivity in a cafeteria diet (CAF)-induced obese rats. **METHODS:** Male Sprague-Dawley rats fed standard chow (STD) or CAF diet were compared with obese rats fed CAF-R diet, alone or supplemented with an olive tree leaves extract (25 mg/kg*day) containing a 20.1% of OLE (CAF-RO). Two-bottle preference and taste reactivity tests were performed to evaluate the sweet preference and the hedonic responses to sucrose solutions, respectively. Also, biometric, food consumption, and serum parameters were measured. **RESULTS:** As expected, CAF diet increased body weight, food and energy consumption and obesity-associated metabolic parameters. Interestingly, CAF-R and CAF-RO diets significantly attenuated body weight gain and BMI, diminished food and energy intake and improved biochemical parameters such as triacylglycerides and insulin resistance, which did not differ between CAF-RO and STD groups. The three cafeteria groups diminished sucrose intake and preference compared to STD group. CAF-RO also diminished the hedonic responses for the high sucrose concentrations compared with the other groups. **CONCLUSIONS:** These results indicate that CAF-R diet may be an efficient strategy to restore obesity-associated alterations, whilst OLE supplementation seems to have an additional beneficial effect on sweet taste function.

A restricted cafeteria diet ameliorates biometric and metabolic profile in a rat diet-induced obesity model.
The administration of anti-obesity bioactive compounds and/or functional foods in rodents fed energy restriction diets based on chow food can be difficult to interpret. We propose an energy restricted cafeteria (CAF) diet as a dietetic intervention to be combined with other therapies. Postweaning male rats were fed standard chow, CAF diet or 30% energy restricted CAF diet (CAF-R) for 8 weeks. The CAF-R diet lowered energy intake and the increase of body weight and body mass index due to the CAF diet, lead to an intermediate feed efficiency, and dampened the CAF diet-induced alterations on body composition, serum levels of triacylglycerides and NEFAs, and insulin resistance. These effects were associated with diminished , and gene expression in brown adipose tissue. In conclusion, the CAF-R diet ameliorated obesity and related metabolic disorders induced by a regular CAF diet, turning it in a useful tool to study anti-obesity compounds.

CHARACTERISING 'THE MUNCHIES'; EFFECTS OF TETRAHYDROCANNABINOL (THC) VAPOUR INHALATION ON RAT FEEDING BEHAVIOURS AND HOMEOSTATIC APPETITE-REGULATING PATHWAYS

POSTER SESSION 03 - SECTION: GUT-BRAIN AXIS AND THE MODULATION OF APPETITE

There is an urgent drive to assess if cannabis has potential health-related effects. It's known that cannabis promotes food intake ('the munchies') and that tetrahydrocannabinol (THC), the main psychoactive cannabis component, is responsible for driving these effects. The aim of this study is to characterise the effects of THC on feeding patterns and investigate the mechanisms underlying THC-driven feeding. This research uses a THC vapour inhalation rat model which produces a translationally relevant THC dose. Rats are exposed to THC or vehicle vapour for 15-minutes each day, and subsequent food intake measured. We show that THC robustly drives food intake, and this is not dependent on what foods are available, or whether rats are satiated or not. THC also alters food choices, and the preferred food is dependent on the rat's state, where high-fat food is preferred in normal conditions and high-sugar food preferred in satiated conditions. Furthermore, once daily THC exposure does not affect total daily energy intake, suggesting that acute THC-driven feeding does not cause overeating. Our findings also imply that THC acts directly on the brain to drive feeding, as THC does not alter peripheral appetite hormone profiles and THC-driven feeding is not blocked by a peripherally restricted cannabinoid 1 receptor antagonist. Work is underway to assess how THC affects the activity of appetite-regulating brain circuits, to decipher the mechanisms by which THC alters feeding behaviour. Overall, this research sheds light on the physiological effects of THC, information which is critical for the health of cannabis users.

Genetic Variants of Fatty Acid Amide Hydrolase Modulate Acute Inflammatory Responses to Colitis in Adult Male Mice. Cannabinoids, including derived phytocannabinoids and endogenous cannabinoids (endocannabinoids), are typically considered anti-inflammatory. One such endocannabinoid is -arachidonoylethanolamine (anandamide, AEA), which is metabolized by fatty acid amide hydrolase (FAAH). In humans, there is a loss of function single nucleotide polymorphism (SNP) in the FAAH gene (C385A, rs324420), that leads to increases in the levels of AEA. Using a mouse model with this SNP, we investigated how this SNP affects inflammation in a model of inflammatory bowel disease. We administered 2,4,6-trinitrobenzene sulfonic acid (TNBS) intracolonically, to adult male FAAH SNP mice and examined colonic macroscopic tissue damage and myeloperoxidase activity, as well as levels of plasma and amygdalar cytokines and chemokines 3 days after administration, at the peak of colitis. We found that mice possessing the loss of function alleles (AC and AA), displayed no differences in colonic damage or myeloperoxidase activity compared to mice with wild type alleles (CC). In contrast, in plasma, colitis-induced increases in interleukin (IL)-2, leukemia inhibitory factor (LIF), monocyte chemoattractant protein (MCP)-1, and tumor necrosis factor (TNF) were reduced in animals with an A allele. A similar pattern was observed in the amygdala for granulocyte colony stimulating factor (G-CSF) and MCP-1. In the amygdala, the mutant A allele led to lower levels of IL-1α, IL-9, macrophage inflammatory protein (MIP)-1β, and MIP-2 independent of colitis-providing additional understanding of how FAAH may serve as a regulator of inflammatory responses in the brain. Together, these data provide insights into how FAAH regulates inflammatory processes in disease.

Pharmacokinetics and central accumulation of delta-9-tetrahydrocannabinol (THC) and its bioactive metabolites are influenced by route of administration and sex in rats.

Up to a third of North Americans report using cannabis in the prior month, most commonly through inhalation. Animal models that reflect human consumption are critical to study the impact of cannabis on brain and behaviour. Most animal studies to date utilize injection of delta-9-tetrahydrocannabinol (THC; primary psychoactive component of cannabis). THC injections produce markedly different physiological and behavioural effects than inhalation, likely due to distinctive pharmacokinetics. The current study directly examined if administration route (injection versus inhalation) alters metabolism and central accumulation of THC and metabolites over time. Adult male and female Sprague-Dawley rats received either an intraperitoneal injection or a 15-min session of inhaled exposure to THC. Blood and brains were collected at 15, 30, 60, 90 and 240-min post-exposure for analysis of THC and metabolites. Despite achieving comparable peak blood THC concentrations in both groups, our results indicate higher initial brain THC concentration following inhalation, whereas injection resulted in dramatically higher 11-OH-THC concentration, a potent THC metabolite, in blood and brain that increased over time. Our results provide evidence of different pharmacokinetic profiles following inhalation versus injection. Accordingly, administration route should be considered during data interpretation, and translational animal work should strongly consider using inhalation models.

Maternal-fetal transmission of delta-9-tetrahydrocannabinol (THC) and its metabolites following inhalation and injection exposure during pregnancy in rats.
Cannabis use during pregnancy has increased over the past few decades, with recent data indicating that, in youth and young adults especially, up to 22% of people report using cannabis during pregnancy. Animal models provide the ability to study prenatal cannabis exposure (PCE) with control over timing and dosage; however, these studies utilize both injection and inhalation approaches. While it is known that Δ9-tetrahydrocannabinol (THC; primary psychoactive component of cannabis) can cross the placenta, examination of the transmission and concentration of THC and its metabolites from maternal blood into the placenta and fetal brain remains relatively unknown, and the influence of route of administration has never been examined. Pregnant female rats were exposed to either vaporized THC-dominant cannabis extract for pulmonary consumption or subcutaneous injection of THC repeatedly during the gestational period. Maternal blood, placenta, and fetal brains were collected following the final administration of THC for analysis of THC and its metabolites, as well as endocannabinoid concentrations, through mass spectrometry. Both routes of administration resulted in the transmission of THC and its metabolites in placenta and fetal brain. Repeated exposure to inhaled THC vapor resulted in fetal brain THC concentrations that were about 30% of those seen in maternal blood, whereas repeated injections resulted in roughly equivalent concentrations of THC in maternal blood and fetal brain. Neither inhalation nor injection of THC during pregnancy altered fetal brain endocannabinoid concentrations. Our data provide the first characterization of maternal-fetal transmission of THC and its metabolites following both vaporized delivery and injection routes of administration. These data are important to establish the maternal-fetal transmission in preclinical injection and inhalation models of PCE and may provide insight into predicting fetal exposure in human studies.

Neural connectivity between the hypothalamic supramammillary nucleus and appetite- and motivation-related regions of the rat brain.
The supramammillary nucleus (SuM) has an emerging role in appetite control. We have shown that the rat SuM is activated during hunger or food anticipation, or by ghrelin administration. In the present study, we characterised the connectivity between the SuM and key appetite- and motivation-related nuclei in the rat. In adult wild-type rats, or rats expressing Cre recombinase under the control of the tyrosine hydroxylase (TH) promoter (TH-Cre rats), we used c-Fos immunohistochemistry to visualise and correlate the activation of medial SuM (SuMM) with activation in the lateral hypothalamic area (LH), the dorsomedial hypothalamus (DMH) or the ventral tegmental area (VTA) after voluntary consumption of a high-sugar, high-fat food. To determine neuroanatomical connectivity, we used retrograde and anterograde tracing methods to specifically investigate the neuronal inputs and outputs of the SuMM. After consumption of the food there were positive correlations between c-Fos expression in the SuMM and the LH, DMH and VTA ($P = 0.0001$, 0.01 and 0.004). Using Fluoro-Ruby as a retrograde tracer, we demonstrate the existence of inputs from the LH, DMH, VTA and ventromedial hypothalamus (VMH) to the SuMM. The SuMM showed reciprocal inputs to the LH and DMH, and we identified a TH-positive output from SuMM to DMH. We co-labelled retrogradely-labelled sections for TH in the VMH, or for TH, orexin and melanin-concentrating hormone in the LH and DMH. However, we did not observe any colocalisation of immunoreactivity with any retrogradely-labelled cells. Viral mapping in TH-Cre rats confirms the existence of a reciprocal SuMM-DMH connection and shows that TH-positive cells project from the SuMM and VTA to the lateral septal area and cingulate cortex, respectively. These data provide evidence for the connectivity of the SuMM to brain regions involved in appetite control, and form the

foundation for functional and behavioural studies aiming to further characterise the brain circuitry controlling eating behaviours.

Effects of optogenetic stimulation of vasopressinergic retinal afferents on suprachiasmatic neurones.
Physiological circadian rhythms are orchestrated by the hypothalamic suprachiasmatic nucleus (SCN). The activity of SCN cells is synchronised by environmental signals, including light information from retinal ganglion cells (RGCs). We recently described a population of vasopressin-expressing RGCs (VP-RGC) that send axonal projections to the SCN. To determine how these VP-RGCs influence the activity of cells in the SCN, we used optogenetic tools to specifically activate their axon terminals within the SCN. Rats were intravitreally injected with a recombinant adeno-associated virus to express the channelrhodopsin-2 and the red fluorescent protein mCherry under the vasopressin promoter (VP-ChR2mCherry). In vitro recordings in acute brain slices showed that approximately 30% of ventrolateral SCN cells responded to optogenetic stimulation with an increase in firing rate that progressively increased during the first 200 seconds of stimulation and which persisted after the end of stimulation. Finally, application of a vasopressin V1A receptor antagonist dampened the response to optogenetic stimulation. Our data suggest that optogenetic stimulation of VP-RGC axons within the SCN influences the activity of SCN cells in a vasopressin-dependent manner.

Activation of the rat hypothalamic supramammillary nucleus by food anticipation, food restriction or ghrelin administration.
The circulating orexigenic hormone ghrelin targets many brain areas involved in feeding control and signals via a dedicated receptor, the growth hormone secretagogue receptor 1A. One unexplored target area for ghrelin is the supramammillary nucleus (SuM), a hypothalamic area involved in motivation and reinforcement and also recently linked to metabolic control. Given that ghrelin binds to the SuM, we explored whether SuM cells respond to ghrelin and/or are activated when endogenous ghrelin levels are elevated. We found that peripheral ghrelin injection activates SuM cells in rats, reflected by an increase in the number of cells expressing c-Fos protein in this area, as welll as by the predominantly excitatory response of single SuM cells recorded in in vivo electrophysiological studies. Further c-Fos mapping studies reveal that this area is also activated in rats in situations when circulating ghrelin levels are known to be elevated: in food-restricted rats anticipating the consumption of food and in fed rats anticipating the consumption of an energy-dense food. We also show that intra-SuM injection of ghrelin induces a feeding response in rats suggesting that, if peripheral ghrelin is able to access the SuM, it may have direct effects on this brain region. Collectively, our data demonstrate that the SuM is activated when peripheral ghrelin levels are high, further supporting the emerging role for this brain area in metabolic and feeding control.

High-Sugar, but Not High-Fat, Food Activates Supraoptic Nucleus Neurons in the Male Rat.
Oxytocin is a potent anorexigen and is believed to have a role in satiety signaling. We developed rat models to study the activity of oxytocin neurons in response to voluntary consumption or oral gavage of foods using c-Fos immunohistochemistry and in vivo electrophysiology. Using c-Fos expression as an indirect marker of neural activation, we showed that the percentage of magnocellular oxytocin neurons expressing c-Fos increased with voluntary consumption of sweetened condensed milk (SCM). To model the effect of food in the stomach, we gavaged anesthetized rats with SCM. The percentage of supraoptic nucleus and paraventricular nucleus magnocellular oxytocin-immunoreactive neurons expressing c-Fos increased with SCM gavage but not with gastric distention. To further examine the activity of the supraoptic nucleus, we made in vivo electrophysiological recordings from SON neurons, where anesthetized rats were gavaged with SCM or single cream. Pharmacologically identified oxytocin neurons responded to SCM gavage with a linear, proportional, and sustained increase in firing rate, but cream gavage resulted in a transient reduction in firing rate. Blood glucose increased after SCM gavage but not cream gavage. Plasma osmolarity and plasma sodium were unchanged throughout. We show that in response to high-sugar, but not high-fat, food in the stomach, there is an increase in the activity of oxytocin neurons. This does not appear to be a consequence of stomach distention or changes in osmotic pressure. Our data suggest that the presence of specific foods with different macronutrient profiles in the stomach differentially regulates the activity of oxytocin neurons.

Homeostatic responses to palatable food consumption in satiated rats.
Energy intake is regulated by overlapping homeostatic and hedonic systems. Consumption of palatable foods has been implicated in weight gain, but this assumes that homeostatic control systems do not accurately detect this hedonically driven energy intake. This study tested this assumption, hypothesizing that satiated rats would reduce their voluntary food intake

and maintain a stable body weight after consuming a palatable food.

THE LACK OF GHSR SIGNALING ENHANCES THE ANOREXIGENIC AND HYPOGLYCEMIC EFFECTS OF LIRAGLUTIDE IN MICE

POSTER SESSION 03 - SECTION: GUT-BRAIN AXIS AND THE MODULATION OF APPETITE

Gimena Fernandez[1], Daniela Cassano[1], Maria Paula Cornejo[1], Abdella Mohammed Habib[2], Mario Perello[1]

Liraglutide is a GLP-1 receptor agonist that reduces glycemia and appetite and is used as an anti-diabetic medication to treat type 2 diabetes, obesity, and chronic weight management. Ghrelin is an orexigenic peptide hormone that acts via the growth hormone secretagogue receptor (GHSR) and upregulates mechanisms that increase glycemia. Aim: we tested here if the genetic deficiency of GHSR signaling in mice affects the anorexigenic and hypoglycemic effects of Liraglutide. Methods: we treated WT and GHSR-deficient mice with vehicle or Liraglutide (400 microg/Kg) under different experimental conditions, and assessed glycemia and food intake. Results: In *ad libitum* fed condition, Liraglutide did not acutely (0-90 min) affect glycemia of GHSR-deficient vs. WT mice, but induced a stronger reduction of overnight food intake in GHSR-deficient mice than WT mice. In fasted condition, Liraglutide did not acutely affect glycemia of GHSR-deficient vs. WT mice. After refeeding, Liraglutide reduced both fasting-induced hyperphagia and post-prandial increase of glycemia in GHSR-deficient mice and in WT mice but both effects were significantly more pronounced in GHSR-deficient mice. In vehicle-treated WT mice that were refed after fasting with the same amount of food eaten by Liraglutide-treated WT mice, postprandial glycemia was similar as detected in unrestrictedly refed WT mice suggesting that the liraglutide-induced reduction of postprandial glycemia was independent of food intake. After glucose infusion, Liraglutide similarly reduced hyperglycemia in GHSR-deficient vs. WT mice. Conclusion: The genetic deficiency of GHSR enhances the anorexigenic and hypoglycemic effects of liraglutide in mice via independent mechanisms.

Ghrelin Gene Deletion Alters Pulsatile Growth Hormone Secretion in Adult Female Mice.
Using preproghrelin-deficient mice (), we previously observed that preproghrelin modulates pulsatile growth hormone (GH) secretion in post-pubertal male mice. However, the role of ghrelin and its derived peptides in the regulation of growth parameters or feeding in females is unknown. We measured pulsatile GH secretion, growth, metabolic parameters and feeding behavior in adult and male and female mice. We also assessed GH release from pituitary explants and hypothalamic growth hormone-releasing hormone (GHRH) expression and immunoreactivity. Body weight and body fat mass, linear growth, spontaneous food intake and food intake following a 48-h fast, GH pituitary contents and GH release from pituitary explants , fasting glucose and glucose tolerance were not different among adult and male or female mice. , pulsatile GH secretion was decreased, while approximate entropy, that quantified orderliness of secretion, was increased in adult females only, defining more irregular GH pattern. The number of neurons immunoreactive for GHRH visualized in the hypothalamic arcuate nucleus was increased in adult females, as compared to females, whereas the expression of GHRH was not different amongst groups. Thus, these results point to sex-specific effects of preproghrelin gene deletion on pulsatile GH secretion, but not feeding, growth or metabolic parameters, in adult mice.

Ghrelin treatment induces rapid and delayed increments of food intake: a heuristic model to explain ghrelin's orexigenic effects.
Ghrelin is a stomach-derived peptide hormone with salient roles in the regulation of energy balance and metabolism. Notably, ghrelin is recognized as the most powerful known circulating orexigenic hormone. Here, we systematically investigated the effects of ghrelin on energy homeostasis and found that ghrelin primarily induces a biphasic effect on food intake that has indirect consequences on energy expenditure and nutrient partitioning. We also found that ghrelin-induced biphasic effect on

food intake requires the integrity of Agouti-related peptide/neuropeptide Y-producing neurons of the hypothalamic arcuate nucleus, which seem to display a long-lasting activation after a single systemic injection of ghrelin. Finally, we found that different autonomic, hormonal and metabolic satiation signals transiently counteract ghrelin-induced food intake. Based on our observations, we propose a heuristic model to describe how the orexigenic effect of ghrelin and the anorectic food intake-induced rebound sculpt a timely constrain feeding response to ghrelin.

Circulating ghrelin crosses the blood-cerebrospinal fluid barrier via growth hormone secretagogue receptor dependent and independent mechanisms.
Ghrelin is a peptide hormone mainly secreted from gastrointestinal tract that acts via the growth hormone secretagogue receptor (GHSR), which is highly expressed in the brain. Strikingly, the accessibility of ghrelin to the brain seems to be limited and restricted to few brain areas. Previous studies in mice have shown that ghrelin can access the brain via the blood-cerebrospinal fluid (CSF) barrier, an interface constituted by the choroid plexus and the hypothalamic tanycytes. Here, we performed a variety of in vivo and in vitro studies to test the hypothesis that the transport of ghrelin across the blood-CSF barrier occurs in a GHSR-dependent manner. In vivo, we found that the uptake of systemically administered fluorescent ghrelin in the choroid plexus epithelial (CPE) cells and in hypothalamic tanycytes depends on the presence of GHSR. Also, we detected lower levels of CSF ghrelin after a systemic ghrelin injection in GHSR-deficient mice, as compared to WT mice. In vitro, the internalization of fluorescent ghrelin was reduced in explants of choroid plexus from GHSR-deficient mice, and unaffected in primary cultures of hypothalamic tanycytes derived from GHSR-deficient mice. Finally, we found that the GHSR mRNA is detected in a pool of CPE cells, but is nearly undetectable in hypothalamic tanycytes with current approaches. Thus, our results suggest that circulating ghrelin crosses the blood-CSF barrier mainly by a mechanism that involves the GHSR, and also possibly via a GHSR-independent mechanism.

Development of Nonpeptidic Inverse Agonists of the Ghrelin Receptor (GHSR) Based on the 1,2,4-Triazole Scaffold.
GHSR controls, among others, growth hormone and insulin secretion, adiposity, feeding, and glucose metabolism. Therefore, an inverse agonist ligand capable of selectively targeting GHSR and reducing its high constitutive activity appears to be a good candidate for the treatment of obesity-related metabolic diseases. In this context, we present a study that led to the development of several highly potent and selective inverse agonists of GHSR based on the 1,2,4-triazole scaffold. We demonstrate that, depending on the nature of the substituents on positions 3, 4, and 5, this scaffold leads to ligands that exert an intrinsic inverse agonist activity on GHSR-catalyzed G protein activation through the stabilization of a specific inactive receptor conformation. Thanks to an in vivo evaluation, we also show that one of the most promising ligands not only exerts an effect on insulin secretion in rat pancreatic islets but also affects the orexigenic effects of ghrelin in mice.

Fasting induces remodeling of the orexigenic projections from the arcuate nucleus to the hypothalamic paraventricular nucleus, in a growth hormone secretagogue receptor-dependent manner.
Arcuate nucleus (ARC) neurons producing Agouti-related peptide (AgRP) and neuropeptide Y (NPY; ARC neurons) are activated under energy-deficit states. ARC neurons innervate the hypothalamic paraventricular nucleus (PVH), and ARC→PVH projections are recognized as key regulators of food intake. Plasma ghrelin levels increase under energy-deficit states and activate ARC neurons by acting on the growth hormone secretagogue receptor (GHSR). Here, we hypothesized that activation of ARC neurons in fasted mice would promote morphological remodeling of the ARC→PVH projections in a GHSR-dependent manner.

Brain accessibility delineates the central effects of circulating ghrelin.
Ghrelin is a hormone produced in the gastrointestinal tract that acts via the growth hormone secretagogue receptor. In the central nervous system, ghrelin signalling is able to recruit different neuronal targets that regulate the behavioural, neuroendocrine, metabolic and autonomic effects of the hormone. Notably, several studies using radioactive or fluorescent variants of ghrelin have found that the accessibility of circulating ghrelin into the mouse brain is both strikingly low and restricted to some specific brain areas. A variety of studies addressing central effects of systemically injected ghrelin in mice have also provided indirect evidence that the accessibility of plasma ghrelin into the brain is limited. Here, we review these previous observations and discuss the putative pathways that would allow plasma ghrelin to gain access into the brain

together with their physiological implications. Additionally, we discuss some potential features regarding the accessibility of plasma ghrelin into the human brain based on the observations reported by studies that investigate the consequences of ghrelin administration to humans.

Evidence Supporting a Role for the Blood-Cerebrospinal Fluid Barrier Transporting Circulating Ghrelin into the Brain.
The stomach-derived hormone ghrelin mainly acts in the brain. Studies in mice have shown that the accessibility of ghrelin into the brain is limited and that it mainly takes place in some circumventricular organs, such as the median eminence. Notably, some known brain targets of ghrelin are distantly located from the circumventricular organs. Thus, we hypothesized that ghrelin could also access the brain via the blood-cerebrospinal fluid (CSF) barrier, which consists of the choroid plexus and the hypothalamic tanycytes. Using systemic injection of ghrelin or fluorescent-ghrelin in mice, we found that cells of the blood-CSF barrier internalize these molecules. In time-response studies, we found that peripherally injected fluorescent-ghrelin quickly reaches hypothalamic regions located in apposition to the median eminence and more slowly reaches the periventricular hypothalamic parenchyma, adjacent to the dorsal part of the third ventricle. Additionally, we found that CSF ghrelin levels increase after the systemic administration of ghrelin, and that central infusions of either an anti-ghrelin antibody, which immuno-neutralizes CSF ghrelin, or a scrambled version of ghrelin, which is also internalized by cells of the blood-CSF barrier, partially impair the orexigenic effect of peripherally injected ghrelin. Thus, current evidence suggests that the blood-CSF barrier can transport circulating ghrelin into the brain, and that the access of ghrelin into the CSF is required for its full orexigenic effect.

Evidence Supporting a Role for Constitutive Ghrelin Receptor Signaling in Fasting-Induced Hyperphagia in Male Mice.
Ghrelin is a potent orexigenic peptide hormone that acts through the growth hormone secretagogue receptor (GHSR), a G protein-coupled receptor highly expressed in the hypothalamus. In vitro studies have shown that GHSR displays a high constitutive activity, whose physiological relevance is uncertain. As GHSR gene expression in the hypothalamus is known to increase in fasting conditions, we tested the hypothesis that constitutive GHSR activity at the hypothalamic level drives the fasting-induced hyperphagia. We found that refed wild-type (WT) mice displayed a robust hyperphagia that continued for 5 days after refeeding and changed their food intake daily pattern. Fasted WT mice showed an increase in plasma ghrelin levels, as well as in GHSR expression levels and ghrelin binding sites in the hypothalamic arcuate nucleus. When fasting-refeeding responses were evaluated in ghrelin- or GHSR-deficient mice, only the latter displayed an ∼15% smaller hyperphagia, compared with WT mice. Finally, fasting-induced hyperphagia of WT mice was significantly smaller in mice centrally treated with the GHSR inverse agonist K-(D-1-Nal)-FwLL-NH2, compared with mice treated with vehicle, whereas it was unaffected in mice centrally treated with the GHSR antagonists D-Lys3-growth hormone-releasing peptide 6 or JMV2959. Taken together, genetic models and pharmacological results support the notion that constitutive GHSR activity modulates the magnitude of the compensatory hyperphagia triggered by fasting. Thus, the hypothalamic GHSR signaling system could affect the set point of daily food intake, independently of plasma ghrelin levels, in situations of negative energy balance.

Circulating Ghrelin Acts on GABA Neurons of the Area Postrema and Mediates Gastric Emptying in Male Mice.
Ghrelin is known to act on the area postrema (AP), a sensory circumventricular organ located in the medulla oblongata that regulates a variety of important physiological functions. However, the neuronal targets of ghrelin in the AP and their potential role are currently unknown. In this study, we used wild-type and genetically modified mice to gain insights into the neurons of the AP expressing the ghrelin receptor [growth hormone secretagogue receptor (GHSR)] and their role. We show that circulating ghrelin mainly accesses the AP but not to the adjacent nucleus of the solitary tract. Also, we show that both peripheral administration of ghrelin and fasting induce an increase of c-Fos, a marker of neuronal activation, in GHSR-expressing neurons of the AP, and that GHSR expression is necessary for the fasting-induced activation of AP neurons. Additionally, we show that ghrelin-sensitive neurons of the AP are mainly γ-aminobutyric acid (GABA)ergic, and that an intact AP is required for ghrelin-induced gastric emptying. Overall, we show that the capacity of circulating ghrelin to acutely induce gastric emptying in mice requires the integrity of the AP, which contains a population of GABA neurons that are a target of plasma ghrelin.

Des-Acyl Ghrelin Directly Targets the Arcuate Nucleus in a Ghrelin-Receptor Independent Manner and Impairs the Orexigenic Effect of Ghrelin.

Ghrelin is a stomach-derived octanoylated peptide hormone that plays a variety of well-established biological roles acting via its specific receptor known as growth hormone secretagogue receptor (GHSR). In plasma, a des-octanoylated form of ghrelin, named des-acyl ghrelin (DAG), also exists. DAG is suggested to be a signalling molecule that has specific targets, including the brain, and regulates some physiological functions. However, no specific receptor for DAG has been reported until now, and, consequently, the potential role of DAG as a hormone has remained a matter of debate. In the present study, we show that DAG specifically binds to and acts on a subset of arcuate nucleus (ARC) cells in a GHSR-independent manner. ARC cells labelled by a DAG fluorescent tracer include the neuropeptide Y (NPY) and non-NPY neurones. Given the well-established role of the ARC in appetite regulation, we tested the effect of centrally administered DAG on food intake. We found that DAG failed to affect dark phase feeding, as well as food intake, after a starvation period; however, it impaired the orexigenic actions of peripherally administered ghrelin. Thus, we conclude that DAG directly targets ARC neurones and antagonises the orexigenic effects of peripherally administered ghrelin.

Binge-eating (BE) is a behavior characterized by repeated and intermittent overconsumption of palatable food during a short period of time, accompanied by dopaminergic disfunction. Such alterations perpetuate BE and promote obesity, impulsivity, and anxiety-like behaviors. Early-age dietary manipulations alter brain development, modifying feeding behavior and emotional states, increasing animal susceptibility to mood or eating disorders. We aim to describe BE impact in weaning rats' food intake, body and fat depots weight, prefrontal cortex (PFC) and accumbal (NAc) dopaminergic systems, impulsivity, and anxiety-like behavior, during periadolescence. Twenty-one-day old Wistar male rats were subjected to elevated plus maze test weekly. Chow and water were available throughout the study, access to Oreo was limited to two hours, three times per week (BED-group), during 4 weeks. Compared to control rats, body weight and daily chow intake of BED-group were reduced, while Oreo intake escalated until the end of the experiment. Higher caloric intake of BED-group increased brown adipose tissue (BAT) weight. Intermittent access to palatable food induced a gradual reduction in anxiety-like behaviors and more impulsivity. Accumbal dopamine and DOPAC levels decreased in BED-group. Dopamine receptor type 2 expression was decreased in PFC and increased in NAc. Intermittent access to palatable food altered dopaminergic signaling in PFC and NAc which might be responsible for the less anxious and more impulsive behaviors. The increase in BAT depot could be related to the lack of overweight despite high energy intake, nevertheless, other metabolic adaptations in BED-group remain to be elucidated.

OBESITY-DRIVEN MICROGLIAL ACTIVATION – FUNCTIONAL ROLE OF CEREBRAL STEROL METABOLISM

POSTER SESSION 03 - SECTION: GUT-BRAIN AXIS AND THE MODULATION OF APPETITE

Laura Plantera[1], Judith Leyh[1], Madlen Reinicke[2], Uta Ceglarek[2], Ingo Bechmann[1]

Microglia are resident tissue macrophages, long-lived and show signs of aging. Their activation state is affected by obesity and diet, both associated with cognitive decline, impaired learning, memory loss and neurodegeneration. We hypothesize that the accumulation of certain nutrition-derived fatty acids, biologically active lipids and their metabolites in the brain has impact on aging and microglial cell loss. We isolated brain regions from C57BL6/N mice divided into two groups, one on `normal diet´ and one on `high fat diet´ (HFD) for 4, 12 and 24 weeks. RNA was isolated and sequenced using the Illumina NextSeq 2000 sequencing system; lipid content was studied using LC-MS/MS. The main findings are that phytosterols accumulate in the brain with age, moreover phytosterol content in brain and adipose tissue correlates with dietary phytosterol content. As shown by the increase in Iba1-positive cells and an activated morphological phenotype, HFD-related obesity is associated with microglia activation. Moreover, our data show a negative correlation between the amount of phytosterols and the level of pro-inflammatory COX-dependent lipid mediators in the brain. ***Thus, phytosterols may inhibit microglial activation and thus act in an anti-inflammatory way.***

Objective. Obesity is a global health challenge with no effective treatment. Understanding the complex regulation of energy metabolism by the hypothalamus (HpT) is essential to provide new therapeutics. Our team has identified a well-known paracrine system with unknown roles in the brain as a key element of the HpT regulation of energy metabolism. Materials & Methods. Using multiple *in vitro* and *in vivo* models of gain and loss of function, we assessed the functional, cellular and molecular traits of this hypothalamic system, as well as it's therapeutic interest in the paradigm of high-fat diet-induced obesity. Results. We found that our system of interest is predominantly expressed in orexigenic AgRP – neurons in the HpT and that it harnesses the neurons' autophagy machinery to induce AgRP neuropeptide release and promote hunger. We then revealed that selective manipulation of this system protects from various symptoms of HFD-induced obesity, namely fat accumulation. Conclusion. We identified a novel hypothalamic system playing a key role in energy metabolism, generated results with promising clinical applications and open a plethora of perspectives pertaining to the role of this system in other HpT-driven functions.

Sympathetically-innervated adipose tissue (AT) is the primary site of both energy storage and hormone production. Leptin is one such hormone released from AT which suppresses appetite and drives AT lipolysis by activating sympathetic neurons, providing a neuroendocrine feedback loop that controls energy balance. A novel sympathetic associated macrophage (SAM) has recently been implicated in the modulation of extracellular norepinephrine availability at the neuro-adipose junction in obesity, indicating a complex neuro-immune interaction in energy balance. Like SAM, other cellular players present in the neuro-adipose junction may also contribute to energy homeostasis, which is largely unknown. Here, using single-cell RNA sequencing, we transcriptionally profiled heterogenous immune and non-immune cell populations in the mouse sympathetic ganglia and nerve fibers innervating the AT. We identified a novel sympathetic neuron-associated population that is endothelial in nature and is uniquely marked by the expression of leptin receptor ($LepR^+$). We discovered that this population of sympathetic-associated $LepR^+$ cells constitutes the perineurial barrier surrounding sympathetic nerve bundles in fat and ganglia. Moreover, we found that these Sympathetic Associated $LepR^+$Perineurial Cells (SAPCs) express immunomodulatory cytokine, Il-33 which has previously been linked to reducing AT inflammation associated with obesity. SAPCs specific ablation of Il33 results in excessive weight gain and reduction of brown AT activity in mice fed a high-fat diet, suggesting Il33 in SAPCs are essential to protect obesity. Collectively, our study reveals that SAPCs play a crucial role to maintain metabolic homeostasis by sensing the variation at leptin levels and inducing an immune response via Il33.

Maternal overnutrition during critical developmental periods leads to different health adversities in the offspring: relevance of obesity, addiction and schizophrenia.
Maternal overnutrition during sensitive periods of early development increases the risk for obesity and neuropsychiatric disorders later in life. However, it still remains unclear during which phases of early development the offspring is more vulnerable. Here, we investigate the effects of maternal high-fat diet (MHFD) at different stages of pre- or postnatal development and characterize the behavioral, neurochemical and metabolic phenotypes. We observe that MHFD exposure at pre-conception has no deleterious effects on the behavioral and metabolic state of the offspring. Late gestational HFD exposure leads to more prominent addictive-like behaviors with reduced striatal dopamine levels compared to early gestational HFD. Conversely, offspring exposed to MHFD during lactation display the metabolic syndrome and schizophrenia-like phenotype. The latter, is manifested by impaired sensory motor gating, and latent inhibition as well as enhanced sensitivity to amphetamine. These effects are accompanied by higher striatal dopamine levels. Together, our data suggest that MHFD exposure during specific stages of development leads to distinct neuropathological alterations that determine the severity and nature of poor health outcome in adulthood, which may provide insight in identifying effective strategies for early intervention.

Maternal overnutrition programs hedonic and metabolic phenotypes across generations through sperm tsRNAs.
There is a growing body of evidence linking maternal overnutrition to obesity and psychopathology that can be conserved across multiple generations. Recently, we demonstrated in a maternal high-fat diet (HFD; MHFD) mouse model that MHFD induced enhanced hedonic behaviors and obesogenic phenotypes that were conserved across three generations via the paternal lineage, which was independent of sperm methylome changes. Here, we show that sperm tRNA-derived small RNAs (tsRNAs) partly contribute to the transmission of such phenotypes. We observe increased expression of sperm tsRNAs in the F1 male offspring born to HFD-exposed dams. Microinjection of sperm tsRNAs from the F1-HFD male into normal zygotes reproduces obesogenic phenotypes and addictive-like behaviors, such as increased preference of palatable foods and enhanced sensitivity to drugs of abuse in the resultant offspring. The expression of several of the differentially expressed sperm tsRNAs predicted targets such as and GRIN3A, which have been implicated in addiction pathology, are altered in the mesolimbic reward brain regions of the F1-HFD father and the resultant HFD-tsRNA offspring. Together, our findings demonstrate that sperm tsRNA is a potential vector that contributes to the transmission of MHFD-induced addictive-like behaviors and obesogenic phenotypes across generations, thereby emphasizing its role in diverse pathological outcomes.

Maternal Overnutrition Induces Long-Term Cognitive Deficits across Several Generations.
Ample evidence from epidemiological studies has linked maternal obesity with metabolic disorders such as obesity, cardiovascular disease, and diabetes in the next generation. Recently, it was also shown that maternal obesity has long-term effects on the progeny's central nervous system. However, very little is known regarding how maternal overnutrition may affect, in particular, the cognitive abilities of the offspring. We reported that first-generation offspring exposed to a maternal high-fat diet (MHFD) displayed age-dependent cognitive deficits. These deficits were associated with attenuations of amino acid levels in the medial prefrontal cortex and the hippocampus regions of MHFD offspring. Here, we tested the hypothesis that MHFD in mice may induce long-term cognitive impairments and neurochemical dysfunctions in the second and third generations. We found that MHFD led to cognitive disabilities and an altered response to a noncompetitive receptor antagonist of the N-Methyl-D-aspartic acid (NMDA) receptor in adult MHFD offspring in both second and third generations in a sex-specific manner. Our results suggest that maternal overnutrition leads to an increased risk of developing obesity in subsequent generations as well as to cognitive impairments, affecting learning and memory processes in adulthood. Furthermore, MHFD exposure may facilitate pathological brain aging which is not a consequence of obesity. Our findings shed light on the long-term effects of maternal overnutrition on the development of the central nervous system and the underlying mechanisms which these traits relate to disease predisposition.

Transgenerational transmission of hedonic behaviors and metabolic phenotypes induced by maternal overnutrition.
Maternal overnutrition has been associated with increased susceptibility to develop obesity and neurological disorders later in life. Most epidemiological as well as experimental studies have focused on the metabolic consequences across generations following an early developmental nutritional insult. Recently, it has been shown that maternal high-fat diet (HFD) affects third-generation female body mass via the paternal lineage. We showed here that the offspring born to HFD ancestors displayed addictive-like behaviors as well as obesity and insulin resistance up to the third generation in the absence of any further exposure to HFD. These findings, implicate that the male germ line is a major player in transferring phenotypic traits. These behavioral and physiological alterations were paralleled by reduced striatal dopamine levels and increased dopamine 2 receptor density. Interestingly, by the third generation a clear gender segregation emerged, where females showed addictive-like behaviors while male HFD offspring showed an obesogenic phenotype. However, methylome profiling of F1 and F2 sperm revealed no significant difference between the offspring groups, suggesting that the sperm methylome might not be the major carrier for the transmission of the phenotypes observed in our mouse model. Together, our study for the first time demonstrates that maternal HFD insult causes sustained alterations of the mesolimbic dopaminergic system suggestive of a predisposition to develop obesity and addictive-like behaviors across multiple generations.

Cold-induced epigenetic programming of the sperm enhances brown adipose tissue activity in the offspring.
Recent research has focused on environmental effects that control tissue functionality and systemic metabolism. However, whether such stimuli affect human thermogenesis and body mass index (BMI) has not been explored. Here we show retrospectively that the presence of brown adipose tissue (BAT) and the season of conception are linked to BMI in humans. In mice, we demonstrate that cold exposure (CE) of males, but not females, before mating results in improved systemic metabolism and protection from diet-induced obesity of the male offspring. Integrated analyses of the DNA methylome and RNA sequencing of the sperm from male mice revealed several clusters of co-regulated differentially methylated regions (DMRs) and differentially expressed genes (DEGs), suggesting that the improved metabolic health of the offspring was due to enhanced BAT formation and increased neurogenesis. The conclusions are supported by cell-autonomous studies in the offspring that demonstrate an enhanced capacity to form mature active brown adipocytes, improved neuronal density and more norepinephrine release in BAT in response to cold stimulation. Taken together, our results indicate that in humans and in mice, seasonal or experimental CE induces an epigenetic programming of the sperm such that the offspring harbor hyperactive BAT and an improved adaptation to overnutrition and hypothermia.

Changes in body composition during adolescence can increase the appearance of diseases such as obesity or diabetes later in life. In a previous work we found that male but not female rats showed decreased adipose tissue contents after a forced running with “early” (ZT14) and “late” (ZT20) active phase sessions (2 sessions a day). The suprachiasmatic nucleus is a region located in the anterior part of the hypothalamus and is the responsible for most of the circadian rythms of the body. Here, were analyzed the effects of forced running during either “early” (ZT13) or “late” (ZT23) sessions in the adipose and hypothalamic tissues. Adolescent rats were trained by forced running. On P24 and P57, the whole body of the rats was analyzed through computerized tomography. Food and water intake were measured every 24 hours. On P60, the hypothalamic region, the inguinal and the retro-renal fat were removed, and stored at -80C until further analysis. Only the late exercise group showed lower adipose tissue content ($p<0.05$). No differences were observed in the food intake or the orexigenic/anorexigenic genes expression of Pomc, Agrp, Npy, Cartpt ($p>0.05$) from the hypothalamic region. The KEGG pathway analysis revealed the steroid biosynthesis as a potential candidate of the transcriptomic differences between the exercised and sedentary PM rats in the inguinal fat. Our results suggest that the differences could be attributed to the steroid biosynthesis pathway, specifically the cholesterol synthesis. Further studies are required to elucidate the circadian mechanisms responsible for these differential effects of exercise.

Sex-dependent effects of forced exercise in the body composition of adolescent rats.
Determining the body composition during adolescence can predict diseases such as obesity, diabetes, and metabolic syndromes later in life; and physical activity became an effective way to restore changes in body composition. However, current available literature assessing the body composition before, during and after adolescence in female and male rodents by in vivo techniques is scarce. Thus, by using computerized tomography, we aimed to define the baseline of the weight and body composition during the adolescence and young adulthood of female and male Sprague-Dawley rats (on P30, P60 and P90) under standard diet. Then, we determined the effect of 18 days of forced exercise on the body weight and composition during the early adolescence (P27-45). The highest percentual increments in weight, body volume and relative adipose contents occurred during the female and male adolescence. Forced running during the early adolescence decreased weight, body volume and relative adipose delta and increment values in males only. The adolescence of rats is a period of drastic body composition changes, where exercise interventions have sex-dependent effects. These results support a model that could open new research windows in the field of adolescent obesity.

A Handful of Details to Ensure the Experimental Reproducibility on the FORCED Running Wheel in Rodents: A Systematic Review.
A well-documented method and experimental design are essential to ensure the reproducibility and reliability in animal research. Experimental studies using exercise programs in animal models have experienced an exponential increase in the last decades. Complete reporting of forced wheel and treadmill exercise protocols would help to ensure the reproducibility of

training programs. However, forced exercise programs are characterized by a poorly detailed methodology. Also, current guidelines do not cover the minimum data that must be included in published works to reproduce training programs. For this reason, we have carried out a systematic review to determine the reproducibility of training programs and experimental designs of published research in rodents using a forced wheel system. Having determined that most of the studies were not detailed enough to be reproducible, we have suggested guidelines for animal research using FORCED exercise wheels, which could also be applicable to any form of forced exercise.

Dopaminergic Modulation of Forced Running Performance in Adolescent Rats: Role of Striatal D1 and Extra-striatal D2 Dopamine Receptors.
Improving exercise capacity during adolescence impacts positively on cognitive and motor functions. However, the neural mechanisms contributing to enhance physical performance during this sensitive period remain poorly understood. Such knowledge could help to optimize exercise programs and promote a healthy physical and cognitive development in youth athletes. The central dopamine system is of great interest because of its role in regulating motor behavior through the activation of D1 and D2 receptors. Thus, the aim of the present study is to determine whether D1 or D2 receptor signaling contributes to modulate the exercise capacity during adolescence and if this modulation takes place through the striatum. To test this, we used a rodent model of forced running wheel that we implemented recently to assess the exercise capacity. Briefly, rats were exposed to an 8-day period of habituation in the running wheel before assessing their locomotor performance in response to an incremental exercise test, in which the speed was gradually increased until exhaustion. We found that systemic administration of D1-like (SCH23390) and/or D2-like (raclopride) receptor antagonists prior to the incremental test reduced the duration of forced running in a dose-dependent manner. Similarly, locomotor activity in the open field was decreased by the dopamine antagonists. Interestingly, this was not the case following intrastriatal infusion of an effective dose of SCH23390, which decreased motor performance during the incremental test without disrupting the behavioral response in the open field. Surprisingly, intrastriatal delivery of raclopride failed to impact the duration of forced running. Altogether, these results indicate that the level of locomotor response to incremental loads of forced running in adolescent rats is dopamine dependent and mechanistically linked to the activation of striatal D1 and extra-striatal D2 receptors.

Hypothalamic /, Plasmatic Glucose and Lactate Remain Unchanged During Habituation to Forced Exercise.
It has been demonstrated that physical activity contributes to a healthier life. However, there is a knowledge gap regarding the neural mechanisms producing these effects. One of the keystones to deal with this problem is to use training programs with equal loads of physical activity. However, irregular motor and stress responses have been found in murine exercise models. Habituation to forced exercise facilitates a complete response to a training program in all rodents, reaching the same load of physical activity among animals. Here, it was evaluated if glucose and lactate - which are stress biomarkers - are increased during the habituation to exercise. Sprague-Dawley rats received an 8-days habituation protocol with progressive increments of time and speed of running. Then, experimental and control (non-habituated) rats were subjected to an incremental test. Blood samples were obtained to determine plasmatic glucose and lactate levels before, immediately after and 30 min after each session of training. and mRNA expression was determined by two-step qPCR. Our results revealed that glucose and lactate levels are not increased during the habituation period and tend to decrease toward the end of the protocol. Also, and were not chronically activated by the habituation program. Lactate and glucose, determined after the incremental test, were higher in control rats without previous contact with the wheel, compared with habituated and wheel control rats. These results suggest that the implementation of an adaptive phase prior to forced exercise programs might avoid non-specific stress responses.

Aims: Anorexia nervosa (AN) is a complex mental disorder mainly characterized by a voluntary food restriction and excessive physical activity resulting in dramatic weight loss. Changes in the brain-derived neurotropic factor (BDNF) have been described in AN. Besides its function on neuronal survival, synaptic plasticity and mood, BDNF was also reported to have a metabolic effect via both central nervous system (CNS) and peripheral organs, which makes BDNF a candidate for AN diagnosis biomarkers Our goal is to investigate changes in BDNF using mouse AN-like model by measuring BDNF levels in specific brain areas and blood in food-restricted and refeed animals. Methods: We used a mouse model combining a phase of chronic food restriction (50%) followed by an *ad libitum* refeeding period. Female mice have or not access to a running with wheel to create a similar metabolic environment that those of AN patients during restriction and recovery once hospitalised. The BDNF mRNA and protein levels were measured in both blood and brain samples (prefrontal cortex, hippocampus, hypothalamus, dorsal striatum, NAcc, VTA and amygdala) using qPCR and ELISA methods. Results: we expect significant differences of BDNF expression in blood and brain region in the fast animal compared to the levels in the refeed animals. Conclusions: The BDNF could represent a possible biomarker of AN for the diagnostic and the evolution to the remission when weight recover and thus will allow a better understanding of the aetiology of AN. Aims: Nowadays, obesity is one of the most incidence disease in the worldwide and its growth seems to be sharpening in the last decade. Our work has revealed substancial molecular alterations triggered by obesity in the brain of leptin-deficient mice. **Methods**: The present work has used six-week-old male mice (*Mus musculus*) purchased from Charles River Laboratories: eight Wild-type mice (C57BL/6J) and eight leptin-deficient ob/ob mice (B6.V-Lepob/J). Animals were randomly divided into four groups: two untreated control groups, and another two groups treated with 500µg melatonin per kg body weigth during 4 weeks. Controls groups received vehicle at comparable amount, route and treatment duration. The brain tissue processing of each mouse was homogenized following PARIS kit guidelines. The protein expression analysis was carried out using PCR and Western Blot immunoassay techniques. **Results**: Our results showed that leptin-deficience does not alter the melatonin membrane receptor (MT1) neither nuclear receptor (RORα) levels. However, melatonin treatment was able to modulate their expression. The two most important enzymes of the melatonin synthesis pathway were modified by leptin-deficiency, while exogenous melatonin was able to reverse those effects, decreasing protein expression, in the obese mice brain. **Conclusions**: Melatonin administration could be an efficient treatment to modify the melatonin receptors expression in brain and to reduce the impairment in melatonin synthesis induced by leptin deficiency. **Acknowledgments**: PAPI-21-PF-28, FI18/00149, IDI/2021/000033, PI17/02009, PI21/01596.

NASAL ADMINISTRATION OF MENTHAE HERBA EXTRACT IMPROVES LIPID METABOLISM IN OBESE MICE

POSTER SESSION 03 - SECTION: GUT-BRAIN AXIS AND THE MODULATION OF APPETITE

Mi Ryeo Kim, So Young Kim, Moon-Yeol Choi, Mi Hyeong Kim, Kyung A Ko
Daegu Haany University, Physiology, Daegu, Korea, Republic of

Objective: This study was investigated the effect of Menthae Herba volatile extract (MEO) on peripheral and central changes in *ob/ob* mice. **Method**: Mice(7W) were divided into four groups: wild type (WT), WT-MEO and *ob/ob* (OB) and OB-MEO groups. Both the normal lean and OB mice were provided with a standard diet. After MEO treatment for 7 weeks, weight gain, feeding efficiency ratio, blood lipid profiles, abdominal fat weight, histopathological changes, and neurotransmitters in hypothalamus were measured using LC-MS/MS. **Results**: The MEO groups showed a tendency to increase weight and decrease body fat compared to the control group. The levels of serum TG, ALT and AST were decreased in the OB-MEO compared to the OB group. Consistent with the effects on weight gain and fat mass, the levels of TG, TC, and LDL decreased in the MEO compared to the control group. The size of adipocytes was reduced with MEO treatment compared to the control group. As a result of measuring GABA, 5-HT, DA, glutamate, Leu-enkephalin, and Met-enkephalin related to appetite control in the hypothalamus, the WT-MEO group showed a tendency to increase compared to the WT group, and the OB group showed an increase compared to the WT group, but the OB-MEO group showed a tendency to recover to the level of the WT group. **Conclusion**: Our data demonstrate that treatment of MEO volatile extract has anti-obesity effect through changes in markers related to lipid metabolism in peripheral tissue and hypothalamus. THE NEUROPROTECTIVE EFFECT PROMOTED BY THE SUPPLEMENTATION WITH SPRAY-DRIED PORCINE PLASMA INVOLVES THE MICROBIOTA-GUT-BRAIN AXIS.

POSTER SESSION 03 - SECTION: GUT-BRAIN AXIS AND THE MODULATION OF APPETITE

Cristina Rosell-Cardona[1], Lluïsa Miró[1], Concepció Amat[1], Javier Polo[2], Miquel Moretó[1], Anna Pérez Bosque[1]

Alterations on gut microbiota are associated to Alzheimer's disease (AD) progression via the microbiota-gut-brain axis. Dietary supplementation with spray-dried porcine plasma (SDP) prevents neuropathological AD hallmarks in SAMP8 mice. The aim of this work was to study whether changes in the gut microbiota can exert a role in the neuroprotective effects of SDP supplementation. Experiments were performed in 2- and 6-month-old SAMP8 mice fed a control or 8% SDP supplemented diets for 4 months. Cognitive performance was evaluated using the Novel Object Recognition test, BDNF abundance was determined by Western Blot, cytokines were quantified by Real-Time PCR and a commercial kit. Faecal microbiota analysis was performed using Illumina MiSeq platform. Senescence reduced short- and long-term memory as well as cortical BDNF abundance, while SDP supplementation prevented these effects (all, $p<0.05$). Senescence increased the expression of the pro-inflammatory cytokine *Il-1*β and reduced the concentration of the anti-inflammatory IL-10 in the cortex tissue (both, $p<0.05$). Aging also augmented serum concentration of IL-1β and TNF-α and colonic expression of these two cytokines (all, $p<0.05$). SDP prevented these aging effects on brain, systemic and colon inflammation (all, $p<0.05$). Furthermore, aging reduced the abundance of health-promoting bacteria such as *Lactobacillus*, and *Pediococcus*, and increased inflammation-associated bacteria like *Erysipelhotrix* (all, $q<0.05$), while SDP prevented these effects (all, $q<0.05$). In conclusion, the neuroprotective effects of SDP could be exerted by promoting the abundance of probiotic species and enhancing mucosal and systemic anti-inflammatory pathways, thus involving the microbiota-gut-brain axis.

Dietary Spray-Dried Porcine Plasma Reduces Neuropathological Alzheimer's Disease Hallmarks in SAMP8 Mice.
Alzheimer's disease (AD) is characterized by the aberrant processing of amyloid precursor protein (APP) and the accumulation of hyperphosphorylated tau, both of which are accompanied by neuroinflammation. Dietary supplementation with spray-dried porcine plasma (SDP) has anti-inflammatory effects in inflammation models. We investigated whether dietary supplementation with SDP prevents the neuropathological features of AD. The experiments were performed in 2- and 6-month-old SAMP8 mice fed a control diet, or a diet supplemented with 8% SDP, for 4 months. AD brain molecular markers were determined by Western blot and real-time PCR. Senescent mice showed reduced levels of p-GSK3β (Ser9) and an increase in p-CDK5, p-tau (Ser396), sAPPβ, and the concentration of Aβ (all < 0.05). SDP prevented these effects of aging and reduced levels (all < 0.05). Senescence increased the expression of and and pro-inflammatory cytokines (and ; all < 0.05); these changes were prevented by SDP supplementation. Moreover, SDP increased expression (< 0.05). Furthermore, in aged mice, the gene expression levels of the microglial activation markers , , and were increased, and SDP prevented these increases (all < 0.05). Thus, dietary SDP might delay AD onset by reducing its hallmarks in senescent mice.

THE GUT MICROBIOTA REGULATES THE CATECHOLAMINE BIOSYNTHETIC PATHWAY IN THE ADRENAL GLANDS OF STRESSED RATS.

POSTER SESSION 03 - SECTION: GUT-BRAIN AXIS AND THE MODULATION OF APPETITE

Camille Etienne[1], Claire Bernat[2], Catherine Philippe[1], Magali Monnoye[1], Claire Maudet[1], Elise Maximin[1], Laurent Naudon[1], Christine Heberden[1], Nathalie Guerineau[2], Sylvie Rabot[1]

It is now well established that the gut microbiota contributes to the regulation of the hypothalamo-pituitary-adrenal axis. Several studies showed that, following an acute or chronic stress, the plasma concentration of corticosterone is higher in germ-free (GF) rodents than in their conventional (SPF) counterparts. Additionally, the expression of genes encoding the corticotropin releasing hormone in the hypothalamus and the glucocorticoid receptors in several brain regions is altered in GF animals. The possible influence of the gut microbiota on other adrenal stress hormones, *i.e.* the catecholamines (epinephrine and norepinephrine), has comparatively received little attention. We addressed this issue by comparing the expression of genes encoding the enzymes involved in the catecholamine biosynthetic pathway in the adrenal glands of GF and SPF rats, subjected or not to a chronic stress (unpredictable chronic mild stress for 2 weeks) and/or an acute stress (insulin injection). In chronically stressed rats, the adrenal weight is significantly higher (+22% in SPF and +19% in GF rats). Reflecting the contribution of the gut microbiota to the stimulus-secretion coupling in chromaffin cells is the finding that the expression of the gene encoding phenylethanolamine N-methyltransferase (PNMT, enzyme converting norepinephrine to epinephrine) is significantly higher in GF stressed rats compared with SPF stressed counterparts. No significant change was observed for genes encoding tyrosine hydroxylase (TH) and dopamine beta hydroxylase (DbH). We also confirmed the ability of chronic stress to disrupt the composition of the gut microbiota. Collectively, our results unveil the gut microbiota as a new regulator of the adrenomedullary tissue.

SOCIAL ISOLATION IN ADOLESCENCE: CHANGES IN THE GUT MICROBIOTA COMPOSITION AND IN THE HIPPOCAMPAL INFLAMMATION

POSTER SESSION 03 - SECTION: GUT-BRAIN AXIS AND THE MODULATION OF APPETITE

Nicola Lopizzo[1,2], Moira Marizzoni[1], Veronica Begni[2], Monica Mazzelli[1,2], Stefania Provasi[1], Luigi Borruso[3], Marco Riva[2], Annamaria Cattaneo[1,2]

The principal aim of our work was to evaluate, in a preclinical model, changes in the gut microbiota in physiological condition and in response to stress during adolescence. We aimed to correlate the stressed microbiota composition to the inflammatory status in the brain. We used the paradigm of social deprivation in adolescent rats for four weeks after weaning, followed by re-socialization until adulthood. We collected fecal samples at different post-natal days to investigate the short- and long-lasting effects of social isolation on gut microbiota composition and we collected different brain areas at killing to measure a panel of inflammatory and microglia activation mediators. We performed 16S metagenomics sequencing for analyzing the gut microbiota composition and Real-Time PCR to evaluate the expression levels of selected markers. Principal coordinate analysis revealed that microbial changes were influenced by age in both isolated and control rats, regardless of sex, whereas social isolation impacted the microbial composition in a sex-dependent manner. Indeed, a multivariate analysis showed that social isolation induced short-term gut microbiota alterations in females but not in males. LEfSe analysis identified several stress-related bacterial taxa affected by social isolation, whose effect was maintained only for few of them. In the brain we found a specific inflammatory pattern, especially in dorsal hippocampus, significantly correlated with gut microbiota composition. We reported a novel association between gut microbiota community structure and inflammatory status related to social isolation during adolescence, suggesting that stress exposure during this sensitive period of development produces long-lasting effects on different biological systems.

Identification of a miRNAs signature associated with exposure to stress early in life and enhanced vulnerability for schizophrenia: New insights for the key role of miR-125b-1-3p in neurodevelopmental processes.
Epidemiological and clinical studies have provided evidence for a role of both genetic and environmental factors, such as stressful experiences early in life, in the pathogenesis of Schizophrenia (SZ) and microRNAs (miRNAs) have been suggested to play a key role in the interplay between the environment and our genome. In this study, we conducted a miRNOme analysis in different samples (blood of adult subjects exposed to childhood trauma, brain (hippocampus) of rats exposed to prenatal stress and human hippocampal progenitor cells treated with cortisol) and we identified miR-125b-1-3p as a down-regulated miRNA in all the three datasets. Interestingly, a significant down-regulation was observed also in SZ patients exposed to childhood trauma. To investigate the biological systems targeted by miR-125b-1-3p and also involved in the effects of stress, we combined the list of biological pathways modulated by predicted and validated target genes of miR-125b-1-3p, with the biological systems significantly regulated by cortisol in the in vitro model. We found, as common pathways, the CXCR4 signaling, the G-alpha signaling, and the P2Y Purigenic Receptor Signaling Pathway, which are all involved in neurodevelopmental processes. Our data, obtained from the combining of miRNAs datasets across different tissues and species, identified miR-125b-1-3p as a key marker associated with the long-term effects of stress early in life and also with the enhanced vulnerability of developing SZ. The identification of such a miRNA biomarker could allow the early detection of vulnerable subjects for SZ and could provide the basis for the development of preventive therapeutic strategies.

miRNAs in depression vulnerability and resilience: novel targets for preventive strategies.
The exposure to stressful experiences during the prenatal period and through the first years of life is known to affect the brain developmental trajectories, leading to an enhanced vulnerability for the development of several psychiatric disorders later in

life. However, not all the subjects exposed to the same stressful experience develop a pathologic condition, as some of them, activating coping strategies, become more resilient. The disclosure of mechanisms associated with stress vulnerability or resilience may allow the identification of novel biological processes and potential molecules that, if properly targeted, may prevent susceptibility or potentiate resilience. Over the last years, miRNAs have been proposed as one of the epigenetic mechanisms mediating the long-lasting effects of stress. Accordingly, they are associated with the development of stress vulnerability or resilience-related strategies. Moreover, miRNAs have been proposed as possible biomarkers able to identify subjects at high risk to develop depression and to predict the response to pharmacological treatments. In this review, we aimed to provide an overview of findings from studies in rodents and humans focused on the involvement of miRNAs in the mechanisms of stress response with the final goal to identify distinct sets of miRNAs involved in stress vulnerability or resilience. In addition, we reviewed studies on alterations of miRNAs in the context of depression, showing data on the involvement of miRNAs in the pathogenesis of the disease and in the efficacy of pharmacological treatments, discussing the potential utility of miRNAs as peripheral biomarkers able to predict the treatment response.

Glucocorticoids prime the inflammatory response of human hippocampal cells through up-regulation of inflammatory pathways.
Increased pro-inflammatory cytokines and an overactive hypothalamic-pituitary-adrenal (HPA) axis have both been implicated in the pathogenesis of depression. However, these explanations appear contradictory because glucocorticoids are well recognised for their anti-inflammatory effects. Two hypotheses exist to resolve this paradox: the mediating presence of glucocorticoid receptor resistance, or the possibility that glucocorticoids can potentiate inflammatory processes in some circumstances. We sought to investigate these hypotheses in a cell model with significant relevance to depression: human hippocampal progenitor cells. We demonstrated that dexamethasone in vitro given for 24 hours and followed by a 24 hours rest interval before an immune challenge potentiates inflammatory effects in these neural cells, that is, increases the IL-6 protein secretion induced by stimulation with IL-1β (10 ng/mL for 24 hours) by + 49% ($P < 0.05$) at a concentration of 100 nM and by + 70% ($P < 0.01$) for 1 μM. These effects are time- and dose-dependent and require activation of the glucocorticoid receptor. Gene expression microarray assays using Human Gene 2.1st Array Strips demonstrated that glucocorticoid treatment up-regulated several innate immune genes, including chemokines and Nod-like receptor, NLRP6; using transcription factor binding motifs we found limited evidence that glucocorticoid resistance was induced in the cells. Our data suggests a mechanism by which stress may prime the immune system for increased inflammation and suggests that stress and inflammation may be synergistic in the pathogenesis of depression.

Comparison of Bioinformatics Pipelines and Operating Systems for the Analyses of 16S rRNA Gene Amplicon Sequences in Human Fecal Samples.
Amplicon high-throughput sequencing of 16S ribosomal RNA (rRNA) gene is currently the most widely used technique to investigate complex gut microbial communities. Microbial identification might be influenced by several factors, including the choice of bioinformatic pipelines, making comparisons across studies difficult. Here, we compared four commonly used pipelines (QIIME2, Bioconductor, UPARSE and mothur) run on two operating systems (OS) (Linux and Mac), to evaluate the impact of bioinformatic pipeline and OS on the taxonomic classification of 40 human stool samples. We applied the SILVA 132 reference database for all the pipelines. We compared phyla and genera identification and relative abundances across the four pipelines using the Friedman rank sum test. QIIME2 and Bioconductor provided identical outputs on Linux and Mac OS, while UPARSE and mothur reported only minimal differences between OS. Taxa assignments were consistent at both phylum and genus level across all the pipelines. However, a difference in terms of relative abundance was identified for all phyla (< 0.013) and for the majority of the most abundant genera (< 0.028), such as (QIIME2: 24.5%, Bioconductor: 24.6%, UPARSE-linux: 23.6%, UPARSE-mac: 20.6%, mothur-linux: 22.2%, mothur-mac: 21.6%, < 0.001). The use of different bioinformatic pipelines affects the estimation of the relative abundance of gut microbial community, indicating that studies using different pipelines cannot be directly compared. A harmonization procedure is needed to move the field forward.

Whole-blood expression of inflammasome- and glucocorticoid-related mRNAs correctly separates treatment-resistant depressed patients from drug-free and responsive patients in the BIODEP study.

The mRNA expression signatures associated with the 'pro-inflammatory' phenotype of depression, and the differential signatures associated with depression subtypes and the effects of antidepressants, are still unknown. We examined 130 depressed patients (58 treatment-resistant, 36 antidepressant-responsive and 36 currently untreated) and 40 healthy controls from the BIODEP study, and used whole-blood mRNA qPCR to measure the expression of 16 candidate mRNAs, some never measured before: interleukin (IL)-1-beta, IL-6, TNF-alpha, macrophage inhibiting factor (MIF), glucocorticoid receptor (GR), SGK1, FKBP5, the purinergic receptor P2RX7, CCL2, CXCL12, c-reactive protein (CRP), alpha-2-macroglobulin (A2M), acquaporin-4 (AQP4), ISG15, STAT1 and USP-18. All genes but AQP4, ISG15 and USP-18 were differentially regulated. Treatment-resistant and drug-free depressed patients had both increased inflammasome activation (higher P2RX7 and proinflammatory cytokines/chemokines mRNAs expression) and glucocorticoid resistance (lower GR and higher FKBP5 mRNAs expression), while responsive patients had an intermediate phenotype with, additionally, lower CXCL12. Most interestingly, using binomial logistics models we found that a signature of six mRNAs (P2RX7, IL-1-beta, IL-6, TNF-alpha, CXCL12 and GR) distinguished treatment-resistant from responsive patients, even after adjusting for other variables that were different between groups, such as a trait- and state-anxiety, history of childhood maltreatment and serum CRP. Future studies should replicate these findings in larger, longitudinal cohorts, and test whether this mRNA signature can identify patients that are more likely to respond to adjuvant strategies for treatment-resistant depression, including combinations with anti-inflammatory medications.

Alterations in 'inflammatory' pathways in the rat prefrontal cortex as early biological predictors of the long-term negative consequences of exposure to stress early in life.
Early life stress, especially when experienced during the first period of life, affects the brain developmental trajectories leading to an enhanced vulnerability for stress-related psychiatric disorders later in life. Although both clinical and preclinical studies clearly support this association, the biological pathways deregulated by such exposure, and the effects in shaping the neurodevelopmental trajectories, have so far been poorly investigated. By using the prenatal stress (PNS) model, a well-established rat model of early life stress, we performed transcriptomic analyses in the prefrontal cortex of rats exposed or not to PNS and sacrificed at different postnatal days (PNDs 21, 40, 62). We first investigated the long-lasting mechanisms and pathways affected in the PFC. We have decided to focus on the prefrontal cortex because we have previously shown that this brain region is highly sensitive to PNS exposure. We found that adult animals exposed to PNS show alterations in 389 genes, mainly involved in stress and inflammatory signalling. We then wanted to establish whether PNS exposure could also affect the neurodevelopmental trajectories in order to identify the most critical temporal window. We found that PNS rats show the most significant changes during adolescence (between PND 40 versus PND 21), with alterations of several pathways related to stress, inflammation and metabolism, which were maintained until adulthood.

Childhood and Adulthood Severe Stressful Experiences and Biomarkers Related to Glucose Metabolism: A Possible Association?
No study investigated the association between stress exposure in different stages of life and metabolic dysfunction. We explore the association between stress exposure and several biomarkers related to glucose metabolism (insulin, c-peptide, GIP, GLP-1, glucagon) in a group of 72 healthy individuals. We used the Childhood Experience of Care and Abuse-Questionnaire (CECA-Q) and a modified version of the Life Events Scale to define exposure to stress, according to four categories: no exposure to childhood trauma (CT) nor to stressful life events (SLEs) (46%), only to CT (25%), only to SLEs (21%), to both (8%). We found that c-peptide (= 0.006) and insulin (= 0.002) levels differed among the four categories: 0.77 ng/ml (SD 0.27) and 0.21 ng/ml (SD 0.06) for none, 0.77 (SD 0.37) and 0.20 (SD 0.08) for only SLEs, 0.88 (SD 0.39) and 0.27 (SD 0.12) for only CT, 1.33 (SD 0.57) and 0.40 (SD 0.28) for both, respectively. The highest levels of biomarkers were found in subjects exposed to both CT and SLEs. Our preliminary results seem to suggest that CT might be specifically associated with a dysfunction of glucose metabolism, which might increase the risk of poorer health outcomes in adulthood. This association seems to be even stronger in individuals additionally exposed to SLEs in adulthood. In conclusion, if

confirmed in other studies, subjects exposed to both CT and SLEs appear the most vulnerable individuals, for whom preventative interventions, such as healthy lifestyle education programs, might ameliorate the risk of developing metabolic abnormalities.

Social isolation in adolescence and long-term changes in the gut microbiota composition and in the hippocampal inflammation: Implications for psychiatric disorders - Dirk Hellhammer Award Paper 2021.
Exposure to early adverse experiences induces persistent changes in physiological, emotional and behavioural functions predisposing the individual to an enhanced vulnerability to develop different disorders during lifespan. The adverse outcomes depend upon the timing of the stressful experiences, and in this contest, adolescence represents a key sensitive period for brain development. Among the biological systems involved, gut microbiota has recently been proposed to act on the interplay between the stress response, brain functions and immune system, through the gut-brain axis communication. In the current study we aimed to evaluate, in a preclinical model, changes over time in the microbiota community structure in physiological condition and in response to stress during adolescence. We also aimed to correlate the microbiota composition to the inflammatory status in brain. We used the preclinical model of social deprivation in rats during adolescence, based on the lack of all social contacts, for four weeks after weaning, followed by re-socialization until adulthood. We collected fecal samples at different post-natal days to investigate the short- and long-lasting effects of social isolation on gut microbiota composition and we collected brain areas (dorsal and ventral hippocampus) samples at killing to measure a panel of inflammatory and microglia activation markers. 16 S metataxonomic sequencing analysis revealed that microbial changes were influenced by age in both isolated and controls rats, regardless of sex, whereas social isolation impacted the microbial composition in a sex-dependent manner. A multivariate analysis showed that social isolation induced short-term gut microbiota alterations in females but not in males. We also identified several stress-related genera associated with social isolation condition. In brain areas we found a specific inflammatory pattern, in dorsal and ventral hippocampus, that significantly correlated with gut microbiota composition. Overall, in this study we reported a novel sex-specific association between gut microbiota composition and inflammatory response related to social isolation paradigm during adolescence, suggesting that stressful experiences during this sensitive period could have a long-lasting impact on the development of different biological systems that could in turn influence the vulnerability to develop mental disorders later in life.

The Complex Molecular Picture of Gut and Oral Microbiota-Brain-Depression System: What We Know and What We Need to Know.
Major depressive disorder (MDD) is a complex mental disorder where the neurochemical, neuroendocrine, immune, and metabolic systems are impaired. The microbiota-gut-brain axis is a bidirectional network where the central and enteric nervous systems are linked through the same endocrine, immune, neural, and metabolic routes dysregulated in MDD. Thus, gut-brain axis abnormalities in MDD patients may, at least in part, account for the symptomatic features associated with MDD. Recent investigations have suggested that the oral microbiome also plays a key role in this complex molecular picture of relationships. As on one hand there is a lot of what we know and on the other hand little of what we still need to know, we structured this review focusing, in the first place, on putting all pieces of this complex puzzle together, underlying the endocrine, immune, oxidative stress, neural, microbial neurotransmitters, and metabolites molecular interactions and systems lying at the base of gut microbiota (GM)-brain-depression interphase. Then, we focused on promising but still under-explored areas of research strictly linked to the GM and potentially involved in MDD development: (i) the interconnection of GM with oral microbiome that can influence the neuroinflammation-related processes and (ii) gut phageome (bacteria-infecting viruses). As conclusions and future directions, we discussed potentiality but also pitfalls, roadblocks, and the gaps to be bridged in this exciting field of research. By the development of a broader knowledge of the biology associated with MDD, with the inclusion of the gut/oral microbiome, we can accelerate the growth toward a better global health based on precision medicine.

This work uncovered a new microbiota-gut-brain axis involved in metabolism control. In homeostatic conditions, bacterial products are directly sensed by brain neurons, regulating their activity and impacting satiety. MDP, a muropeptide present in all bacteria cell walls, affects hypothalamic inhibitory neurons, and is implicated in feeding and body temperature control. The MDP receptor Nod2 is expressed in neurons from several brain regions, including the hypothalamus. Older female mice lacking Nod2 expression in inhibitory neurons displayed increased weight gain and food consumption. These older females also had reduced propensity to build nests, and, altered temperature regulation. MDP reduced food intake, only when Nod2 was present in inhibitory neurons. Muropeptides, given orally, or produced by intestinal bacteria, reached the brain and regulated neurons of diverse brain areas. Remarkably, the affected regions were distinct, depending on the age and sex of the mice. Only in older females, the arcuate nucleus of the hypothalamus, a main regulator of feeding behavior, was affected by MDP. The activity of inhibitory neurons of the ARC is depressed upon feeding, and it was similarly depressed upon oral administration of MDP. Infusion of MDP into single neurons, demonstrated that MDP-mediated effects were cell-autonomous. Furthermore, the ablation of Nod2 in specific hypothalamic regions, reproduced the phenotype observed in the conditional knockout mice. Oral antibiotic treatment abrogated the Nod2-mediated control over feeding and weight gain, suggesting that the intestinal microbiota is the Nod2 ligand source. Our work reveals a sex- and age-dependent pathway of gut–brain crosstalk, highlighting additional avenues for the treatment of neurological and metabolic disorders

[1]INRAE, Micalis, Jouy-en-Josas, France, [2]Utrecht University, Pharmacology Department, Utrecht, Netherlands

The involvement of the microbiota-gut-brain axis has recently been taken into account in the study of the pathophysiology of autism spectrum disorders (ASD). Preclinical studies have shown that interventions on the gut microbiota, including fecal microbiota transplantations, can modulate behavior in animal models of ASD. The germ-free mouse is a potential model, as it shows impairments in social behavior and increased repetitive behaviors compared to conventional mice. Therefore, our project aimed to test the effect of fecal transplantation of ASD children on behavior and several biological markers in germ-free mice. We hypothesized that behavioral phenotypes impaired in germ-free mice would not be improved, or even be worsened, by fecal microbiota from children with ASD, compared with mice receiving the microbiota from their neurotypical siblings. The experiment was carried out with fecal microbiota from children with or without gastro-intestinal (GI) symptoms as a co-morbidity. We analyzed social behavior, repetitive behavior, anxiety and spatial memory. The latter was impaired in the group receiving microbiota from children with ASD and GI symptoms. We also saw differences between groups in the composition and metabolic activity of the gut microbiota as well as in inflammatory markers. These results show that the microbiota of ASD children, particularly those with GI symptoms, can cause behavioral and biochemical differences in germ-free recipient mice. The current stage of our analyses is to determine whether correlations exist between those differences and the microbial composition and activity of the transferred microbiota.

Introduction: The adolescent period has recently been identified as a critical window in brain, immune, and microbiome development. However, there has been no investigation into the effects that the microbiome has on repetitive mild traumatic brain injury (RmTBI) pathophysiology and microbiome composition at this age. **Methods:** Eighty adolescent and 80 adult rats were used. To deplete the microbiome, half of the rats were administered an antibiotic cocktail in their drinking water for 14 days (80 Female: 80 Male). Microbiome depletion was confirmed via fecal samples. Rats were then randomized to either RmTBI or sham injuries. Fecal samples collected 11 days post-injury were analysed via 16s rRNA sequencing. **Results:** In adolescents, PCoA plots demonstrated clear separations between samples at 11 days post-injury. Analysis of inferred amplicon sequence variants (ASVs) demonstrated differences in composition between placebo+RmTBI and Antibiotic+RmTBI we identified increases in *muribaculaceae* and *lachnospiraceae* in antibiotic+RmTBI, both of which are involved in reducing inflammatory processes. A further 46 significant ASVs were also identified. In adults, PCoA plots demonstrated less separation between groups, with increases reductions in *bacteroides*, *rhodospirillales,* and *bacteroidales* in the Antibiotic+RmTBI which are beneficial bacteria. However, as only 4 ASVs were significantly different in the adult antibiotic+RmTBI compared to placebo+RmTBI, the adult microbiome appears to be more resilient to RmTBI, exhibiting quicker recolonization when compared to adolescents. **Conclusions:** Microbiome recolonization and influences on RmTBI differed between adolescents and adults, which may provide insight as to why adolescents are often more susceptible to poorer mTBI outcomes than adults.

Synchronizing our clocks as we age: the influence of the brain-gut-immune axis on the sleep-wake cycle across the lifespan.
The microbes that colonize the small and large intestines, known as the gut microbiome, play an integral role in optimal brain development and function. The gut microbiome is a vital component of the bidirectional communication pathway between the brain, immune system, and gut, also known as the brain-gut-immune axis. To date, there has been minimal investigation into the implications of improper development of the gut microbiome and the brain-gut-immune axis on the sleep-wake cycle, particularly during sensitive periods of physical and neurological development, such as childhood, adolescence, and senescence. Therefore, this review will explore the current literature surrounding the overlapping developmental periods of the gut microbiome, brain, and immune system from birth through to senescence, while highlighting how the brain-gut-immune axis affects the maturation and organization of the sleep-wake cycle. We also examine how a dysfunction to either the microbiome or the sleep-wake cycle negatively affects the bidirectional relationship between the brain and gut, and subsequently the overall health and functionality of this complex system. Additionally, this review integrates therapeutic studies to demonstrate when dietary manipulations, such as supplementation with probiotics and prebiotics, can modulate the gut microbiome to enhance the health of the brain-gut-immune axis and optimize our sleep-wake cycle.

Gut microbiome depletion and repetitive mild traumatic brain injury differentially modify bone development in male and female adolescent rats.
Dysregulation of the gut microbiome has been shown to disrupt both bone formation and bone resorption in several preclinical and clinical models. However, the role of microbiome in adolescent bone development remains poorly understood. This effect of disrupted bone development may be more pronounced during adolescence, when bone development is vulnerable to environmental stimuli and external insults (e.g., antibiotic treatment and traumatic brain injury), as this is a critical window of development. Therefore, in this study, we sought to investigate the effect of repetitive mild traumatic brain

injury (RmTBI) and gut microbiome depletion by antibiotic treatment on femur length and bone density in male and female adolescent Sprague Dawley rats. Rats were randomly assigned to receive standard or antibiotic autoclaved drinking water and to receive sham or RmTBIs injuries. Using micro-computed tomography (μCT), we found sexually dimorphic changes in adolescent bone development in response to microbiome depletion and RmTBI. Specifically, gut microbiome depletion stunted femur growth in males and altered cross sectional bone area (CSA), bone area fraction, and the bone volume of low and mid density bone in the distal metaphyseal region of the femur. Conversely, RmTBI and antibiotic treatment individually disrupted bone growth, bone area fraction, and bone volume of high-density bone within the distal metaphyseal region of the femur in females, but not when combined. Therefore, findings from this study indicate that gut microbiome and RmTBI may alter bone development in a sex-dependent manner during adolescence.

The Development of Adolescent Chronic Pain following Traumatic Brain Injury and Surgery: The Role of Diet and Early Life Stress.
Pain is evolutionarily necessary for survival in that it reduces tissue damage by signaling the body to respond to a harmful stimulus. However, in many circumstances, acute pain becomes chronic, and this is often dysfunctional. Adolescent chronic pain is a growing epidemic with an unknown etiology and limited effective treatment options. Given that the relationship between acute pain and chronic pain is not straightforward, there is a need to better understand the factors that contribute to the chronification of pain. Since early life factors are critical to a variety of outcomes in the developmental and adolescent periods, they pose promise as potential mechanisms that may underlie the transition from acute to chronic pain. This review examines two early life factors: poor diet and adverse childhood experiences (ACEs); they may increase susceptibility to the development of chronic pain following surgical procedures or traumatic brain injury (TBI). Beyond their high prevalence, surgical procedures and TBI are ideal models to prospectively understand mechanisms underlying the transition from acute to chronic pain. Common themes that emerged from the examination of poor diet and ACEs as mechanisms underlying this transition included: prolonged inflammation and microglia activation leading to sensitization of the pain system, and stress-induced alterations to hypothalamic-pituitary-adrenal axis function, where cortisol is likely playing a role in the development of chronic pain. These areas provide promising targets for interventions, the development of diagnostic biomarkers, and suggest that biological treatment strategies should focus on regulating the neuroinflammatory and stress responses in an effort to modulate and prevent the development of chronic pain.

Investigating the cumulative effects of Δ9-tetrahydrocannabinol and repetitive mild traumatic brain injury on adolescent rats.
The prevalence of mild traumatic brain injury is highest amongst the adolescent population and can lead to complications including neuroinflammation and excitotoxicity. Also pervasive in adolescents is recreational cannabis use. Δ9-Tetrahydrocannabinol, the main psychoactive component of cannabis, is known to have anti-inflammatory properties and serves as a neuroprotective agent against excitotoxicity. Thus, we investigated the effects of Δ9-tetrahydrocannabinol on recovery when administered either prior to or following repeated mild brain injuries. Male and female Sprague-Dawley rats were randomly assigned to receive Δ9-tetrahydrocannabinol or vehicle either prior to or following the repeated injuries. Rats were then tested on a behavioural test battery designed to measure post-concussive symptomology. The hippocampus, nucleus accumbens and prefrontal cortex were extracted from all animals to examine mRNA expression changes (, , , , and). We hypothesized that, in both experiments, Δ9-tetrahydrocannabinol administration would provide neuroprotection against mild injury outcomes and confer therapeutic benefit. Δ9-Tetrahydrocannabinol administration following repeated mild traumatic brain injury was beneficial to three of the six behavioural outcomes affected by injury (reducing anxiety and depressive-like behaviours while also mitigating injury-induced deficits in short-term working memory). Δ9-Tetrahydrocannabinol administration following injury also showed beneficial effects on the expression of , and in the hippocampus, nucleus accumbens and prefrontal cortex. There were no notable benefits of Δ9-tetrahydrocannabinol when administered prior to injury, suggesting that Δ9-tetrahydrocannabinol may have potential therapeutic benefit on post-concussive symptomology when administered post-injury, but not pre-injury.

Neurodegenerative disorders such as Alzheimer's disease (AD) have become a critical public health. Although AD research has made important breakthroughs, the pathogenesis of this disease remains unclear, and specific AD diagnostic biomarkers and therapeutic strategies are still lacking. Meanwhile, the gut microbiota participates in pathogenesis in diseases such as AD, diabetes, obesity and has an impact on aging process. Moreover, the endocannabinoid system (ECS) and the gut microbiota are increasingly emerging as important players in maintaining the general homeostasis and the health status of the host. To understand the role of the gut microbiota and the ECS in AD, induced by diabetes mellitus type 2, we used males and females mice that were subjected to a different diets: control, control & prebiotics, high-fat and high-fat & prebiotics. During 15 months with diets and several behaviour tests, faecal microbiota analysis were performed on particular time points. Additionally, we investigated gene of interest in selected 11 different genus of bacteria. The components of the ECS were examined in different brain and gastrointestinal tract. We showed that specific high-fat diets triggered obesity, leading to diabetes mellitus type 2 and caused Alzheimer‘s disease, which is clinically diagnosed by observing declining cognitive functions and changes in different components of the ECS. In searching for a connection between gut microbiota and AD, we also noticed changes in the gut microbiota throughout the experimental period and observed a different detection of gene, encoding an enzyme involved in the metabolism of nucleotides in different diets and time points.

The gut hosts trillions of microbes, which are key players of the host physiology, such as nutrient metabolism and immunomodulation. Over the past decade, it has become very clear that the microorganisms that inhabit the gastrointestinal tract have also a critical role in orchestrating brain functioning and behavior. Many studies have identified a link between dysbiosis and the pathogenesis of several neuropsychiatric disorders. However, studies on the impact of the gut microbiota on brain and behavioral responses to drugs of abuse have been very limited so far. In this context, our objective was to assess their influence on nicotine addiction-like processes, as tobacco addiction is still responsible for more than 8 million deaths each year. Here we demonstrate that a lack of gut microbiota in mice potentiates nicotine-induced activation of the reward system and reinforcing properties. These effects were not associated with gross behavioral alterations. By contrast, nicotine withdrawal syndrome was not impacted by gut microbiota depletion. Importantly, glial activity has a crucial role in shaping the reward system and its response to drugs. Here we further show that gut microbiota depletion modulates the resident immune cells in the reward system. Notably, it increases astrocyte density in the ventral tegmental area (VTA). Finally, we identify several sub-populations of microglia in the VTA that differ between its sub-parts, and show that they are re-organized in conditions of gut microbiota depletion. The present study suggests that probiotics modulating brain immune cells may be a promising therapeutic strategy for nicotine addiction.

Introduction: Animal studies have confirmed that long-term intake of obesogenic diets and stress exposure impair cognition, especially with regard to aspects that are dependent on the hippocampus, including memory processes and reversal learning. The main aim of our study was to verify the hypothesis that 12-week exposure to stress modifies alterations in the brain proteome induced by western diet in the female rats. Methods: Female Long Evans rats with or without exposure to social stress received standard chow diet, or obesogenic rodent diet (a western diet with human snacks). The cerebrocortical samples from each rat were immediately frozen on dry ice and stored for liquid chromatography-tandem mass spectrometry (LC-MS/ MS) analysis. Results: Based on the discovery analysis, a total of 2,793 proteins were identified and quantified, of which 239 were changed significantly between the temporal cortices across the four animal groups. Statistical analysis showed that western diet consumption alone and in combination with stress exposure resulted in changes only in 5.4% and 3.8% proteins, respectively. Whereas 48% of proteins were affected statistically by chronic stress exposure and this exposition down-regulated 86.3% of them. The most overrepresented biological processes were related to generation of precursor metabolites and energy, synapse transport, and regulation of neurotransmitter levels. Conclusion: Observed changes may contribute to the understanding of functional and morphological brain alterations described in literature as well as behavioral disturbances induced by exposure to the western diet and stress. Grant Support: This research is supported by National Science Center grant no. 2015/19/D/NZ7/02408.

THE IMPACT OF MATERNAL HIGH-FAT DIET ON OFFSPRING NEURODEVELOPMENT

POSTER SESSION 03 - SECTION: GUT-BRAIN AXIS AND THE MODULATION OF APPETITE

Gintare Urbonaite[1], Adomas Smalskys[1], Urte Neniskyte[1,2]

Aims: A typical Western diet is excessively fatty, leading to a rapid increase in human obesity worldwide, including the women of reproductive age. There is growing evidence that maternal high-fat diet (mHFD) may cause neurodevelopmental disorders in the offspring, in part due to the changes in the microbiota. Our aim was to determine how mHFD alters the microbiota in the mothers and their offspring and how these changes affect the behavior in offspring using a mouse model. *Methods:* Female C57Bl/6 mice were fed a control diet (CD, 10% fat) or high-fat diet (HFD, 60%) from weaning to lactation. Before mating, the metabolic status of the dams was evaluated by the body mass and glucose and insulin tolerance tests. The offspring were weaned to CD. We investigated the behavioral phenotype of the offspring in the open field, three-chamber, novel object recognition, marble burying, and Barnes maze tests. Microbiota composition of the cecum of the dams and their offspring were analyzed using 16S rRNA gene sequencing. *Results:* We determined that the consumption of HFD causes metabolic dysfunction in the dams. mHFD changed gut microbiota diversity and composition in both dams and offspring. Microbiota alterations at the phylum, genus, and species level were more prominent in mHFD female versus male offspring. In contrast, mHFD disturbed the behavior more in male offspring than in females. *Conclusions:* Our findings show, that mHFD altered the composition of the offspring gut microbiota which may contribute to abnormal behavior in a sex-specific manner.

DNA-Damaging Effect of Different Wavelength (206 and 257 nm) Femtosecond Laser Pulses.
The purpose of this study was to investigate the possible cytotoxic and genotoxic impact of new-generation 206 nm femtosecond solid-state laser irradiation on murine skin cells in vitro, and to compare the cell and DNA damage caused by different wavelength (206 vs. 257 nm) femtosecond laser pulses. The first attempts to evaluate the possible genotoxic impact of ultrashort laser pulses on the murine bone marrow cells in vitro revealed the unlooked-for DNA-damaging effect. However, the impact of far-ultraviolet (UV) radiation on genetic material of internal and external organs' cells may differ due to differences in size, structure, and biochemical composition of the cells. Mouse skin cells were exposed to different doses of 206 and 257 nm wavelength femtosecond laser, and 254 nm UV lamp irradiation. Comet assay in two versions-the standard alkaline and the enzyme-linked-was used for the evaluation of DNA damage. The irradiation determined by different parameters demonstrated intensity-dependent genotoxic impact. The pyrimidine dimers made up the greater part of DNA photodamage, but with rising exposure dose the increase of relative amount of more energy-consuming primary damage-DNA strand breaks-was detected. The 206 nm femtosecond laser irradiation was much more cytotoxic but caused less primary DNA damage than the same pulse duration longer wavelength (257 nm) laser irradiation. DNA-damaging effect of 206 nm femtosecond laser pulses with extremely low penetration force may highly depend on the size, structure, and biochemical composition of the cells of organ or tissue targets.

REGULATION OF FEEDING BY OPTOGENETIC ACTIVATION AND INHIBITION OF LILLIPUTIAN GENE IN DROSOPHILA MELANOGASTER LARVAE

POSTER SESSION 03 - SECTION: GUT-BRAIN AXIS AND THE MODULATION OF APPETITE

Ilenia Meloni[1], Astrid Rohwedder[2], Alexandra Großjohann[2], Andreas Thum[2], Caroline Murawski[1]
[1]Kurt-Schwabe-Institut Meinsberg e.V., Organophotonic Sensing, Waldheim, Germany, [2]Institute of Biology, Universität Leipzig, Department Of Genetics, Leipzig, Germany

Optogenetics is a tool that allows controlling cells with light. Here, we studied the effect of optogenetic activation and inhibition in *lilli*^{189Y} transgenic larvae. The *lilliputian* gene encodes for a DNA binding transcription factor. It is involved in several different biological processes.

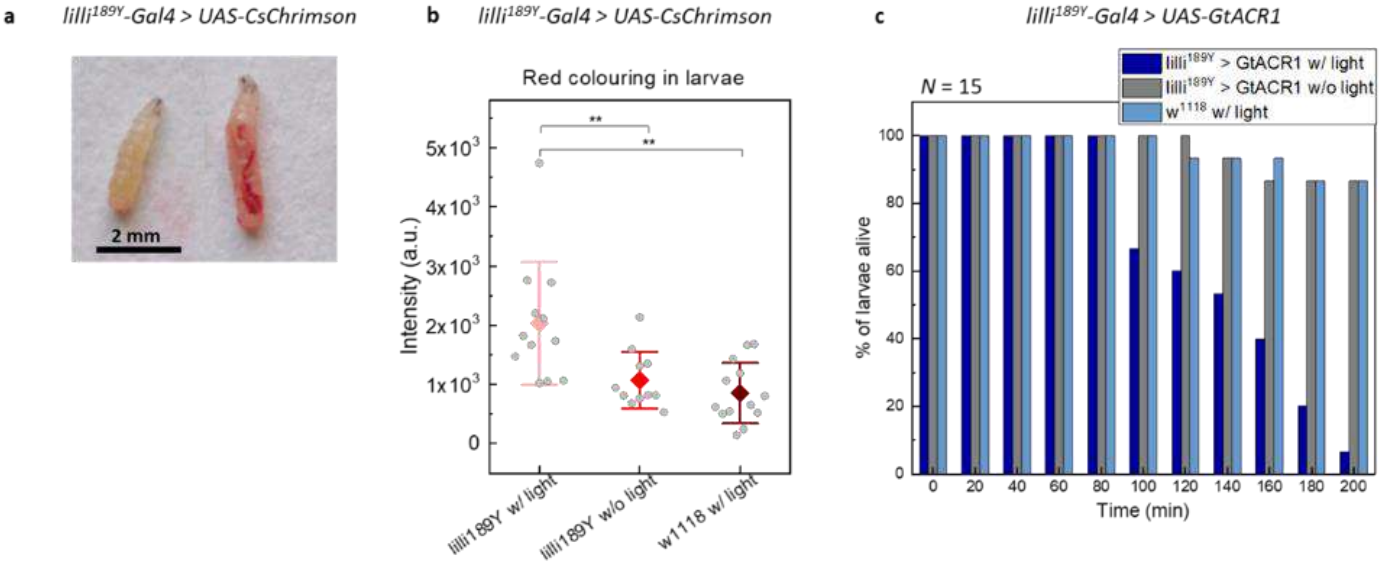

Figure 1. Behavioral response of *lilli*^{189Y} upon optogenetic stimulation. a) Comparison of apple agarose uptake (colored with red food dye) between w^{1118} (left) and *lilli*^{189Y}*-Gal4 > UAS-CsChrimson* (right) upon optogenetic activation. b) Intensity of ingested red color of larvae from a) after 200 min with and without optogenetic activation. c) Percentage of larvae alive over time during optogenetic inhibition. We observed that the optogenetic stimulation of *lilli*^{189Y}*-Gal4 > UAS-CsChrimson* larvae caused aggregation of larvae when located on agarose. In the absence of agarose, the larvae became aggressive showing cannibalistic behavior. We noticed a significant increase in food uptake due to activation with red light (Fig. 1a,b). On the other hand, inhibition of *lilli*^{189Y}*-Gal4 > UAS-GtACR1* caused larvae to die after 100 min of stimulation suggesting optogenetically induced dehydration (Fig. 1c). Fluorescence imaging of *lilli*^{189Y}*-Gal4* larvae showed expression in the salivary glands and in a few neurons of the larval central nervous system, pronounced in a few pairs of antennal lobe interneurons. We hypothesized that optogenetic control of the salivary glands caused the described feeding regulation. Repetition of our experiments with *SGS-Gal4*, a driver with sole expression in the salivary glands, led to the same results. In conclusion, our observations showed that the salivary glands contribute to regulating food uptake and may lead to collective behavior in *D. melanogaster* larvae.

Controlling the behaviour of Drosophila melanogaster via smartphone optogenetics.
Invertebrates such as Drosophila melanogaster have proven to be a valuable model organism for studies of the nervous system. In order to control neuronal activity, optogenetics has evolved as a powerful technique enabling non-invasive stimulation using light. This requires light sources that can deliver patterns of light with high temporal and spatial precision.

Currently employed light sources for stimulation of small invertebrates, however, are either limited in spatial resolution or require sophisticated and bulky equipment. In this work, we used smartphone displays for optogenetic control of Drosophila melanogaster. We developed an open-source smartphone app that allows time-dependent display of light patterns and used this to activate and inhibit different neuronal populations in both larvae and adult flies. Characteristic behavioural responses were observed depending on the displayed colour and brightness and in agreement with the activation spectra and light sensitivity of the used channelrhodopsins. By displaying patterns of light, we constrained larval movement and were able to guide larvae on the display. Our method serves as a low-cost high-resolution testbench for optogenetic experiments using small invertebrate species and is particularly appealing to application in neuroscience teaching labs.

THE IMPACT OF INHIBITORY TRAINING ON IMPLICIT ATTITUDE AND FOOD CONSUMPTION IN RESTRICTIVE EATERS

POSTER SESSION 03 - SECTION: GUT-BRAIN AXIS AND THE MODULATION OF APPETITE

Shir Berebbi
The Hebrew University, Psychology, Jerusalem, Israel

Restrained eaters are people that regularly limit their food consumption to control their weightγ They are at risk of developing eating disorders. Behaviorally, they showed inconsistent inhibition patterns, e.g., better inhibition when they were exposed to food stimuli and worsened inhibition when stimuli were neutral. Cognitively, restrained eaters show more negative thoughts about eating, weight, and shape than healthy patients. The implications of those beliefs help them to avoid all "threatening" stimuli, like high-calorie food, that could disturb them to achieve their goal that is weight loss. The current study used the stop-signal task as a training task and implicit association task and food intake test as measures to evaluate the effectiveness of the training. The participants were divided into 3 training conditions. In the first group, food stimuli were paired with the "stop" sign (stop-condition), in the second they attached to the "go" sign (go-condition) and in the third, they attached evenly for both signs (control-condition). The results of the study showed that food consumption was similar in the three groups. However, in the stop condition, participants endorsed more positive attitudes toward high-calorie food, and they reported the highest improvement of food-anxiety levels (in comparison to both other conditions). It could be that the training with stop condition creates a coupling between inhibition and food, in the broadest sense of the word. That is, the training helps participants to inhibit their intrusive thoughts about food, and thus to decrease their anxiety and to increase their positive attitude toward high-calorie food.

COMPARATIVE IN SILICO ANALYSIS OF MICROBIAL DYSBIOSIS DISCERN POTENTIAL METABOLIC LINK IN NEURODEGENERATIVE DISEASES

POSTER SESSION 03 - SECTION: GUT-BRAIN AXIS AND THE MODULATION OF APPETITE

V Vipin[1], Nitin Chauhan[2], Somit Dutta[1], Upendra Nongthomba[3]
[1]INDIAN INSTITUTE OF SCIENCE, Molecular Reproduction, Development And Genetics, BENGALURU, India, [2]Jawaharlal Nehru University, School Of Computational And Integrative Sciences, New Delhi, India, [3]Indian Institute of Science, Molecular Reproduction, Development And Genetics, Bengaluru, India

A healthy gut flora contains a diverse and stable commensal group of microorganisms, whereas, in disease conditions, there is a shift towards pathogenic microbes, termed microbial dysbiosis. Many studies associate microbial dysbiosis with neurodegenerative disorders, including Alzheimer's, Parkinson's, Multiple sclerosis and Amyloid lateral sclerosis. Although several studies document microbial dysbiosis in neurodegenerative diseases, an overall comparative analysis of microbes and their metabolic involvement in these diseases is lacking. In this study, we performed a comparative analysis of microbial composition changes occurring in these 4 neurodegenerative disorders. Our analysis showed a high resemblance of microbial dysbiosis signatures between AD, PD and MS. However ALS appeared dissimilar in microbial dysbiosis signatures. The functional analysis of these dysbiotic microbes showed several potential metabolic links which can be involved in the altered microbiome-gut-brain axis in neurodegenerative diseases. The microbes with elevated populations lack pathways for synthesizing SCFA, butyrate, and Propionate. Also, these microbes have a high capacity for producing L-glutamate, an excitatory neurotransmitter and precursor of GABA. On the other hand, Tryptophan, a precursor for serotonin and other neuroactive molecules has a lower representation in the annotated genome of elevated microbes. Similarly, histamine, a crucial neuro-immuno-modulatory compound, was also less expressed in microbes found in elevated conditions. Finally, the neuroprotective compound spermidine was also less represented in the genome of elevated microbes. Together, our study showed the potential metabolic involvement of dysbiotic microbes in neurodegenerative disorders. Further, this can lead to microbiome-based therapeutic and diagnostic approaches in neurodegenerative diseases including AD, PD, MS and ALS.

A NON-INVASIVE BRAIN-MACHINE INTERFACE SYSTEM FOR THE CONTROL OF HAND PROSTHESES

POSTER SESSION 03 - SECTION: BRAIN COMPUTER INTERFACE

Corentin Piozin[1,2], Catherine Simon[3], Brice Lavrard[3], Jean-Yves Audran[1], Florian Waszak[2], Selim Eskiizmirliler[2]
[1]Otto Bock, Otto Bock France, Courtaboeuf, France, [2]Université de Paris, CNRS, Integrative Neuroscience And Cognition Center, Paris, France, [3]Institut Robert Merle d'Aubigné, Pôle Appareillage Du Membre Supérieur, Valenton, France

In this work we present the current results we obtained in our ongoing project aiming at the development of a non-invasive Brain-Machine Interface (BMI) for the sensorimotor control of a commercially available myoelectric prosthesis (Myobock©, Ottobock) in collaboration with its manufacturer (Ottobock France) and the rehabilitation center IRMA. The new system uses as input the ElectroEncephaloGraphy (EEG) signals of the user as well as vibrations produced by a bracelet containing vibrating motors whose frequencies are proportional to the forces measured by the force sensors installed on the fingertips of the prosthesis. EEG signals were collected by two different recording systems with different number of electrodes during the experiments performed by two groups composed of able-bodied and amputee subjects, in which they were asked to grasp and displace different objects, either performing or mimicking the grip of the prosthesis. A combination of the Common Spatial Patterns and Wavelet Decomposition techniques have been used to construct the feature vector's content. The classification/prediction performances of three machine-learning algorithms (Artificial Neural Network, Support Vector Machine with two different kernels) were first tested off-line for a preliminary glimpse at the system performance and for different system parameters adjustment. The real-time performance was then computed during the online tests done with both groups using the whole system; the able bodied subjects using the prosthesis with the help of a 3D printed apparatus. The obtained results advocate for a proof of concept regarding the use of a wireless BMI dedicated to the control of a myoelectric prosthesis.

A CALCIUM IMAGING BASED BRAIN-MACHINE INTERFACE FOR VIRTUAL NAVIGATION

POSTER SESSION 03 - SECTION: BRAIN COMPUTER INTERFACE

Ethan Sorrell[1], Daniel Wilson[2], M. Rule[1], Helen Yang[2], Fulvio Forni[1], Christopher Harvey[2], Timothy O'Leary[1]
[1]University of Cambridge, Department Of Engineering, Cambridge, United Kingdom, [2]Harvard Medical School, Department Of Neurobiology, Boston, United States of America

Modern calcium-imaging techniques allow for the simultaneous recording of large populations of neurons over extended periods of time. Using these techniques, scientists can decode task relevant variables from recorded neural activity. By further providing continuous feedback of decoded neural activity, we can ask more probing questions about learning, plasticity, and function in the brain. This can be done by implementing a brain-machine interface (BMI) that decodes neural activity and provides feedback of the output to the subject in real-time. We present a calcium-imaging based BMI for whole body navigation of mice through a virtual T-maze task. We recorded neural signals from the posterior parietal cortex of mice using 2-photon calcium imaging, and decoded continuous kinematic variables from these signals using linear decoding. We provided visual feedback in real-time by updating the kinematics of the mice in the virtual environment using the decoder output. Segmentation of individual neurons from images was not required, and we decoded directly from downsampled and filtered images. Mice successfully completed trials using this interface, and continued to do so with a fixed decoder over several days. We propose that such an interface could be used to bypass standard neural pathways, and make direct connections between neural signals and control outputs, to explore new questions about the brain.

M/EEG NETWORKS INTEGRATION TO ELICIT PATTERNS OF MOTOR IMAGERY-BASED BCI TRAINING

POSTER SESSION 03 - SECTION: BRAIN COMPUTER INTERFACE

Marie-Constance Corsi[1], Mario Chavez[2], Denis Schwartz[3], Nathalie George[4], Laurent Hugueville[4], Ari Kahn[5], Sophie Dupont[6], Danielle Bassett[5], Fabrizio De Vico Fallani[7]
[1]Paris Brain Institute, Aramis Team, Paris, France, [2]CNRS, Charpier Lab, Paris, France, [3]Inserm, Paris Brain Institute, Cenir, Paris, France, [4]CNRS, Cenir, Paris, France, [5]University of Pennsylvania, Department Of Bioengineering, Philadelphia, United States of America, [6]AP-HP, Hôpital De La Pitié Salpêtrière, Paris, France, [7]Inria Paris, Aramis Team-project, Paris, France

Despite its clinical application, voluntarily modulating brain activity appears to be a learned skill that affects the usability of brain-computer interfaces (BCIs) systems. The involved learning process induces a brain network reorganization that remains poorly understood. We hypothesized that integrating information from electroencephalography (EEG) and magnetoencephalography (MEG) data, provides a better description of the network changes occurring during the BCI training. We performed experiments on a group of 20 naive healthy subjects during a BCI training consisting of four sessions over two weeks in which both EEG and MEG signals were recorded. The task consisted in controlling the vertical position of a moving cursor through the α/β modulation to reach a target displayed on a screen. We adopted a multilayer approach to integrate brain network properties from EEG and MEG data. Regardless the chosen modality, a progressive increase in the integration of somatosensory areas in the α band was paralleled by a decrease of the integration of visual processing and working memory areas in the β band. Only brain network properties in multilayer network correlated with future BCI scores in the α_2 band ($p < 0.01$): positively in somatosensory and decision-making related areas (gyrus rectus & subcentral gyrus) and negatively in associative areas (superior occipital gyrus). Our results constitute the first proof of a learning process from the integration of M/EEG networks properties. Integrating multimodal brain network properties could be considered as a potential marker of BCI learning.

Integrating EEG and MEG Signals to Improve Motor Imagery Classification in Brain-Computer Interface.
We adopted a fusion approach that combines features from simultaneously recorded electroencephalogram (EEG) and magnetoencephalogram (MEG) signals to improve classification performances in motor imagery-based brain-computer interfaces (BCIs). We applied our approach to a group of 15 healthy subjects and found a significant classification performance enhancement as compared to standard single-modality approaches in the alpha and beta bands. Taken together, our findings demonstrate the advantage of considering multimodal approaches as complementary tools for improving the impact of noninvasive BCIs.

Magnetoencephalography With Optically Pumped He Magnetometers at Ambient Temperature.
In this paper, we present the first proof of concept confirming the possibility to record magnetoencephalographic (MEG) signals with optically pumped magnetometers (OPMs) based on the parametric resonance of He atoms. The main advantage of this kind of OPM is the possibility to provide a tri-axis vector measurement of the magnetic field at room-temperature (the He vapor is neither cooled nor heated). The sensor achieves a sensitivity of 210 fT/ √ Hz in the bandwidth [2-300 Hz]. MEG simulation studies with a brain phantom were cross-validated with real MEG measurements on a healthy subject. For both studies, MEG signal was recorded consecutively with OPMs and superconducting quantum interference devices (SQUIDs) used as reference sensors. For healthy subject MEG recordings, three MEG proofs of concept were carried out: auditory evoked fields, visual evoked fields, and spontaneous activity. M100 peaks have been detected on evoked responses recorded by both OPMs and SQUIDs with no significant difference in latency. Concerning spontaneous activity, an attenuation of the signal power between 8-12 Hz (alpha band) related to eyes opening has been observed with OPM similarly to SQUID. All these results confirm that the room temperature vector He OPMs can record MEG signals and provide reliable information on brain activity.

EEG evidence of compensatory mechanisms in preclinical Alzheimer's disease.
Early biomarkers are needed to identify individuals at high risk of preclinical Alzheimer's disease and to better understand the pathophysiological processes of disease progression. Preclinical Alzheimer's disease EEG changes would be non-invasive and cheap screening tools and could also help to predict future progression to clinical Alzheimer's disease. However, the impact of amyloid-β deposition and neurodegeneration on EEG biomarkers needs to be elucidated. We included participants from the INSIGHT-preAD cohort, which is an ongoing single-centre multimodal observational study that was designed to identify risk factors and markers of progression to clinical Alzheimer's disease in 318 cognitively normal individuals aged 70-85 years with a subjective memory complaint. We divided the subjects into four groups, according to their amyloid status (based on 18F-florbetapir PET) and neurodegeneration status (evidenced by 18F-fluorodeoxyglucose PET brain metabolism in Alzheimer's disease signature regions). The first group was amyloid-positive and neurodegeneration-positive, which corresponds to stage 2 of preclinical Alzheimer's disease. The second group was amyloid-positive and neurodegeneration-negative, which corresponds to stage 1 of preclinical Alzheimer's disease. The third group was amyloid-negative and neurodegeneration-positive, which corresponds to 'suspected non-Alzheimer's pathophysiology'. The last group was the control group, defined by amyloid-negative and neurodegeneration-negative subjects. We analysed 314 baseline 256-channel high-density eyes closed 1-min resting state EEG recordings. EEG biomarkers included spectral measures, algorithmic complexity and functional connectivity assessed with a novel information-theoretic measure, weighted symbolic mutual information. The most prominent effects of neurodegeneration on EEG metrics were localized in frontocentral regions with an increase in high frequency oscillations (higher beta and gamma power) and a decrease in low frequency oscillations (lower delta power), higher spectral entropy, higher complexity and increased functional connectivity measured by weighted symbolic mutual information in theta band. Neurodegeneration was associated with a widespread increase of median spectral frequency. We found a non-linear relationship between amyloid burden and EEG metrics in neurodegeneration-positive subjects, either following a U-shape curve for delta power or an inverted U-shape curve for the other metrics, meaning that EEG patterns are modulated differently depending on the degree of amyloid burden. This finding suggests initial compensatory mechanisms that are overwhelmed for the highest amyloid load. Together, these results indicate that EEG metrics are useful biomarkers for the preclinical stage of Alzheimer's disease.

Functional disconnection of associative cortical areas predicts performance during BCI training.
Brain-computer interfaces (BCIs) have been largely developed to allow communication, control, and neurofeedback in human beings. Despite their great potential, BCIs perform inconsistently across individuals and the neural processes that enable humans to achieve good control remain poorly understood. To address this question, we performed simultaneous high-density electroencephalographic (EEG) and magnetoencephalographic (MEG) recordings in a motor imagery-based BCI training involving a group of healthy subjects. After reconstructing the signals at the cortical level, we showed that the reinforcement of motor-related activity during the BCI skill acquisition is paralleled by a progressive disconnection of associative areas which were not directly targeted during the experiments. Notably, these network connectivity changes reflected growing automaticity associated with BCI performance and predicted future learning rate. Altogether, our findings provide new insights into the large-scale cortical organizational mechanisms underlying BCI learning, which have implications for the improvement of this technology in a broad range of real-life applications.

Learning in brain-computer interface control evidenced by joint decomposition of brain and behavior.
Motor imagery-based brain-computer interfaces (BCIs) use an individual's ability to volitionally modulate localized brain activity, often as a therapy for motor dysfunction or to probe causal relations between brain activity and behavior. However, many individuals cannot learn to successfully modulate their brain activity, greatly limiting the efficacy of BCI for therapy and for basic scientific inquiry. Formal experiments designed to probe the nature of BCI learning have offered initial evidence that coherent activity across spatially distributed and functionally diverse cognitive systems is a hallmark of individuals who can successfully learn to control the BCI. However, little is known about how these distributed networks interact through time to support learning.

Network-based brain-computer interfaces: principles and applications.
Brain-computer interfaces (BCIs) make possible to interact with the external environment by decoding the mental intention of

individuals. BCIs can therefore be used to address basic neuroscience questions but also to unlock a variety of applications from exoskeleton control to neurofeedback rehabilitation. In general, BCI usability depends on the ability to comprehensively characterize brain functioning and correctly identify the user's mental state. To this end, much of the efforts have focused on improving the classification algorithms taking into account localized brain activities as input features. Despite considerable improvement BCI performance is still unstable and, as a matter of fact, current features represent oversimplified descriptors of brain functioning. In the last decade, growing evidence has shown that the brain works as a networked system composed of multiple specialized and spatially distributed areas that dynamically integrate information. While more complex, looking at how remote brain regions functionally interact represents a grounded alternative to better describe brain functioning. Thanks to recent advances in network science, i.e. a modern field that draws on graph theory, statistical mechanics, data mining and inferential modeling, scientists have now powerful means to characterize complex brain networks derived from neuroimaging data. Notably, summary features can be extracted from brain networks to quantitatively measure specific organizational properties across a variety of topological scales. In this topical review, we aim to provide the state-of-the-art supporting the development of a network theoretic approach as a promising tool for understanding BCIs and improve usability.

BCI learning induces core-periphery reorganization in M/EEG multiplex brain networks.
Brain-computer interfaces (BCIs) constitute a promising tool for communication and control. However, mastering non-invasive closed-loop systems remains a learned skill that is difficult to develop for a non-negligible proportion of users. The involved learning process induces neural changes associated with a brain network reorganization that remains poorly understood.To address this inter-subject variability, we adopted a multilayer approach to integrate brain network properties from electroencephalographic and magnetoencephalographic data resulting from a four-session BCI training program followed by a group of healthy subjects. Our method gives access to the contribution of each layer to multilayer network that tends to be equal with time.We show that regardless the chosen modality, a progressive increase in the integration of somatosensory areas in theband was paralleled by a decrease of the integration of visual processing and working memory areas in theband. Notably, only brain network properties in multilayer network correlated with future BCI scores in theband: positively in somatosensory and decision-making related areas and negatively in associative areas.Our findings cast new light on neural processes underlying BCI training. Integrating multimodal brain network properties provides new information that correlates with behavioral performance and could be considered as a potential marker of BCI learning.

A machine learning approach to screen for preclinical Alzheimer's disease.
Combining multimodal biomarkers could help in the early diagnosis of Alzheimer's disease (AD). We included 304 cognitively normal individuals from the INSIGHT-preAD cohort. Amyloid and neurodegeneration were assessed on F-florbetapir and F-fluorodeoxyglucose PET, respectively. We used a nested cross-validation approach with non-invasive features (electroencephalography [EEG], APOE4 genotype, demographic, neuropsychological and MRI data) to predict: 1/ amyloid status; 2/ neurodegeneration status; 3/ decline to prodromal AD at 5-year follow-up. Importantly, EEG was most strongly predictive of neurodegeneration, even when reducing the number of channels from 224 down to 4, as 4-channel EEG best predicted neurodegeneration (negative predictive value [NPV] = 82%, positive predictive value [PPV] = 38%, 77% specificity, 45% sensitivity). The combination of demographic, neuropsychological data, APOE4 and hippocampal volumetry most strongly predicted amyloid (80% NPV, 41% PPV, 70% specificity, 58% sensitivity) and most strongly predicted decline to prodromal AD at 5 years (97% NPV, 14% PPV, 83% specificity, 50% sensitivity). Thus, machine learning can help to screen patients at high risk of preclinical AD using non-invasive and affordable biomarkers.

Phase/Amplitude Synchronization of Brain Signals During Motor Imagery BCI Tasks.
In the last decade, functional connectivity (FC) has been increasingly adopted based on its ability to capture statistical dependencies between multivariate brain signals. However, the role of FC in the context of brain-computer interface applications is still poorly understood. To address this gap in knowledge, we considered a group of 20 healthy subjects during an EEG-based hand motor imagery (MI) task. We studied two well-established FC estimators, i.e. spectral- and imaginary-coherence, and we investigated how they were modulated by the MI task. We characterized the resulting FC networks by extracting the strength of connectivity of each EEG sensor and we compared the discriminant power with respect to standard power spectrum features. At the group level, results showed that while spectral-coherence based network features were increasing in the sensorimotor areas, those based on imaginary-coherence were significantly decreasing. We demonstrated that this opposite, but complementary, behavior was respectively determined by the increase in amplitude and phase

synchronization between the brain signals. At the individual level, we eventually assessed the potential of these network connectivity features in a simple off-line classification scenario. Taken together, our results provide fresh insights into the oscillatory mechanisms subserving brain network changes during MI and offer new perspectives to improve BCI performance.

Towards multimodal BCIs: the impact of peripheral control on motor cortex activity and sense of agency.

In the recent years, brain computer interfaces (BCI) using motor imagery have shown some limitations regarding the quality of control. In an effort to improve this promising technology, some studies intended to develop hybrid BCI with other technologies such as eye tracking which shows more reliability. However, the use of an eye tracker in the control of a robot might affect by itself the sense of agency (SoA) and the brain activity in the regions used for motor imagery (MI). Here, we explore the link between the sense of agency and the activity of the motor cortex. For this purpose, we used of a virtual arm projected on a surface which is either controlled by motion capture or controlled by gaze using an eye tracker. We found out that there is an activity in the motor cortex during the task of control by gaze and that having control over a projected robotic arm presents significant differences with the situation of observing the robot moving.

CHRONIC STABILITY OF 1024-CHANNEL UTAH-ARRAY-BASED NEUROPROSTHESIS IN MONKEYS

POSTER SESSION 03 - SECTION: BRAIN COMPUTER INTERFACE

Xing Chen[1], Feng Wang[1], Roxana Kooijmans[1], Pieter Roelfsema[1,2,3]

Electrical stimulation of visual cortex via a neuroprosthesis generates the perception of dots of light known as 'phosphenes,' allowing perception of simple shapes, even after decades of blindness. We evaluated the efficacy and stability of a 1024-channel neuroprosthesis system in non-human primates (NHPs) over >3 years to assess its suitability for long-term vision restoration. We implanted two rhesus macaques (M. mulatta) with 16 Utah arrays in primary visual cortex (V1) and visual area 4 (V4). The monkeys performed a stimulus detection task and were perfused after 3-3.5 years for histological analysis. We monitored the animals' health and measured electrode impedances, neuronal signal quality, and current thresholds for phosphene generation. The monkeys remained healthy throughout the implantation period and the 1024-channel device retained its mechanical integrity and electrical conductivity. Over time, however, we observed decreases in 1) signal-to-noise ratios (SNR) of visually evoked responses, 2) peak-to-peak voltages of recorded neuronal signals, 3) the number of high-amplitude channels (peak-to-peak voltage >100 uV) and 4) the number of channels through which phosphenes could be evoked, as well as impaired visual perception at locations corresponding to implanted areas. Tissue dissections and histological analysis revealed encapsulation of the arrays, and associated cortical degeneration. In conclusion, long-term implantation of a high-channel-count device in NHP visual cortex was accompanied by deformation of cortical tissue and decreased stimulation efficacy and signal quality over time, implying that improvement of device biocompatibility and/or refinement of implantation techniques is needed before future clinical use is feasible.

Shape perception via a high-channel-count neuroprosthesis in monkey visual cortex.
Blindness affects 40 million people across the world. A neuroprosthesis could one day restore functional vision in the blind. We implanted a 1024-channel prosthesis in areas V1 and V4 of the visual cortex of monkeys and used electrical stimulation to elicit percepts of dots of light (called phosphenes) on hundreds of electrodes, the locations of which matched the receptive fields of the stimulated neurons. Activity in area V4 predicted phosphene percepts that were elicited in V1. We simultaneously stimulated multiple electrodes to impose visible patterns composed of a number of phosphenes. The monkeys immediately recognized them as simple shapes, motions, or letters. These results demonstrate the potential of electrical stimulation to restore functional, life-enhancing vision in the blind.

Population receptive fields in nonhuman primates from whole-brain fMRI and large-scale neurophysiology in visual cortex.
Population receptive field (pRF) modeling is a popular fMRI method to map the retinotopic organization of the human brain. While fMRI-based pRF maps are qualitatively similar to invasively recorded single-cell receptive fields in animals, it remains unclear what neuronal signal they represent. We addressed this question in awake nonhuman primates comparing whole-brain fMRI and large-scale neurophysiological recordings in areas V1 and V4 of the visual cortex. We examined the fits of several pRF models based on the fMRI blood-oxygen-level-dependent (BOLD) signal, multi-unit spiking activity (MUA), and local field potential (LFP) power in different frequency bands. We found that pRFs derived from BOLD-fMRI were most similar to MUA-pRFs in V1 and V4, while pRFs based on LFP gamma power also gave a good approximation. fMRI-based pRFs thus reliably reflect neuronal receptive field properties in the primate brain. In addition to our results in V1 and V4, the whole-brain fMRI measurements revealed retinotopic tuning in many other cortical and subcortical areas with a consistent increase in pRF size with increasing eccentricity, as well as a retinotopically specific deactivation of default mode network nodes similar to previous observations in humans.

Perceptual learning of fine contrast discrimination changes neuronal tuning and population coding in macaque V4.
Perceptual learning, the improvement in perceptual abilities with training, is thought to be mediated by an alteration of neuronal tuning. It remains poorly understood how tuning properties change as training progresses, whether improved stimulus tuning directly links to increased behavioural readout of sensory information, or how population coding mechanisms change with training. Here, we recorded continuously from multiple neuronal clusters in area V4 while macaque monkeys learned a fine contrast categorization task. Training increased neuronal coding abilities by shifting the steepest point of contrast response functions towards the categorization boundary. Population coding accuracy of difficult discriminations resulted largely from an increased information coding of individual channels, particularly for those channels that in early learning had larger ability for easy discriminations, but comparatively small encoding abilities for difficult discriminations. Population coding was also enhanced by specific changes in correlations. Neuronal activity became more indicative of upcoming choices with training.

Stimulus roving and flankers affect perceptual learning of contrast discrimination in Macaca mulatta.
'Stimulus roving' refers to a paradigm in which the properties of the stimuli to be discriminated vary from trial to trial, rather than being kept constant throughout a block of trials. Rhesus monkeys have previously been shown to improve their contrast discrimination performance on a non-roving task, in which they had to report the contrast of a test stimulus relative to that of a fixed-contrast sample stimulus. Human psychophysics studies indicate that roving stimuli yield little or no perceptual learning. Here, we investigate how stimulus roving influences perceptual learning in macaque monkeys and how the addition of flankers alters performance under roving conditions. Animals were initially trained on a contrast discrimination task under non-roving conditions until their performance levels stabilized. The introduction of roving contrast conditions resulted in a pronounced drop in performance, which suggested that subjects initially failed to heed the sample contrast and performed the task using an internal memory reference. With training, significant improvements occurred, demonstrating that learning is possible under roving conditions. To investigate the notion of flanker-induced perceptual learning, flanker stimuli (30% fixed-contrast iso-oriented collinear gratings) were presented jointly with central (roving) stimuli. Presentation of flanker stimuli yielded substantial performance improvements in one subject, but deteriorations in the other. Finally, after the removal of flankers, performance levels returned to their pre-flanker state in both subjects, indicating that the flanker-induced changes were contingent upon the continued presentation of flankers.

Perceptual learning of contrast discrimination in macaca mulatta.
Rhesus monkeys underwent training in a contrast discrimination task, in which grating stimuli were presented at parafoveal and peripheral visual field locations. Subjects had to compare a sample stimulus that had a fixed contrast of 30% to a test stimulus that varied in contrast from trial to trial. Extensive practice yielded improvements in contrast discrimination that were observed across the full range of test stimulus contrasts. These improvements occurred across multiple sessions, as well as across trials within individual sessions. The finer the contrast discriminations required, the longer it took for subjects to improve. Improvements in psychophysical performance resulted in the steepening of psychometric functions and/or shifts in the point of subjective equality towards the contrast of the sample stimulus. Enhancement in discrimination was especially pronounced around the contrast level of the sample stimulus, to which the subject was consistently exposed. The changes resulted in increased accuracy overall, lower discrimination thresholds, and faster response times. Partial transfer of learning, from vertically oriented training stimuli to horizontally oriented testing stimuli, was observed, while transfer to stimuli with different spatial frequencies was less pronounced. The results demonstrate the existence of perceptual learning in the contrast domain, whereby learning affects multiple performance-related psychophysical metrics.

Effect of feature-selective attention on neuronal responses in macaque area MT.
Attention influences visual processing in striate and extrastriate cortex, which has been extensively studied for spatial-, object-, and feature-based attention. Most studies exploring neural signatures of feature-based attention have trained animals

to attend to an object identified by a certain feature and ignore objects/displays identified by a different feature. Little is known about the effects of feature-selective attention, where subjects attend to one stimulus feature domain (e.g., color) of an object while features from different domains (e.g., direction of motion) of the same object are ignored. To study this type of feature-selective attention in area MT in the middle temporal sulcus, we trained macaque monkeys to either attend to and report the direction of motion of a moving sine wave grating (a feature for which MT neurons display strong selectivity) or attend to and report its color (a feature for which MT neurons have very limited selectivity). We hypothesized that neurons would upregulate their firing rate during attend-direction conditions compared with attend-color conditions. We found that feature-selective attention significantly affected 22% of MT neurons. Contrary to our hypothesis, these neurons did not necessarily increase firing rate when animals attended to direction of motion but fell into one of two classes. In one class, attention to color increased the gain of stimulus-induced responses compared with attend-direction conditions. The other class displayed the opposite effects. Feature-selective activity modulations occurred earlier in neurons modulated by attention to color compared with neurons modulated by attention to motion direction. Thus feature-selective attention influences neuronal processing in macaque area MT but often exhibited a mismatch between the preferred stimulus dimension (direction of motion) and the preferred attention dimension (attention to color).

Visual percepts evoked with an intracortical 96-channel microelectrode array inserted in human occipital cortex.
BACKGROUNDA long-held goal of vision therapy is to transfer information directly to the visual cortex of blind individuals, thereby restoring a rudimentary form of sight. However, no clinically available cortical visual prosthesis yet exists.METHODSWe implanted an intracortical microelectrode array consisting of 96 electrodes in the visual cortex of a 57-year-old person with complete blindness for a 6-month period. We measured thresholds and the characteristics of the visual percepts elicited by intracortical microstimulation.RESULTSImplantation and subsequent explantation of intracortical microelectrodes were carried out without complications. The mean stimulation threshold for single electrodes was 66.8 ± 36.5 μA. We consistently obtained high-quality recordings from visually deprived neurons and the stimulation parameters remained stable over time. Simultaneous stimulation via multiple electrodes was associated with a significant reduction in thresholds ($P < 0.001$, ANOVA) and evoked discriminable phosphene percepts, allowing the blind participant to identify some letters and recognize object boundaries.CONCLUSIONSOur results demonstrate the safety and efficacy of chronic intracortical microstimulation via a large number of electrodes in human visual cortex, showing its high potential for restoring functional vision in the blind.TRIAL REGISTRATIONClinicalTrials.gov identifier NCT02983370.FUNDINGThe Spanish Ministerio de Ciencia Innovación y Universidades, the Generalitat Valenciana (Spain), the Europan Union's Horizon 2020 programme, the Bidons Egara Research Chair of the University Miguel Hernández (Spain), and the John Moran Eye Center of the University of Utah.

Stimulus-induced dissociation of neuronal firing rates and local field potential gamma power and its relationship to the resonance blood oxygen level-dependent signal in macaque primary visual cortex.
The functional magnetic resonance imaging (fMRI) blood oxygenation level-dependent (BOLD) signal is regularly used to assign neuronal activity to cognitive function. Recent analyses have shown that the local field potential (LFP) gamma power is a better predictor of the fMRI BOLD signal than spiking activity. However, LFP gamma power and spiking activity are usually correlated, clouding the analysis of the neural basis of the BOLD signal. We show that changes in LFP gamma power and spiking activity in the primary visual cortex (V1) of the awake primate can be dissociated by using grating and plaid pattern stimuli, which differentially engage surround suppression and cross-orientation inhibition/facilitation within and between cortical columns. Grating presentation yielded substantial V1 LFP gamma frequency oscillations and significant multi-unit activity. Plaid pattern presentation significantly reduced the LFP gamma power while increasing population multi-unit activity. The fMRI BOLD activity followed the LFP gamma power changes, not the multi-unit activity. Inference of neuronal activity from the fMRI BOLD signal thus requires detailed a priori knowledge of how different stimuli or tasks activate the cortical network.

Significant research is made towards the restoration of upper limb function through prostheses controlled by brain-machine interfaces (BMI). This research calls for tractable experimental models. Although the mouse model is increasingly used for BMI developments, a mouse upper limb prosthesis with the correct anatomy and scale is lacking. Also, it is still unclear if mice would be able to embody a limb prosthesis, even though encouraging results have been obtained by testing the embodiment of a fake tail (Wada et al., 2016, J Neurosci). Here, we aimed to develop a mouse forelimb neuroprosthesis to explore different BMI-based control and feedback strategies, as well as an assay to probe its embodiment in the mouse body representation. Our 3D-printed forelimb prosthesis includes four degrees of freedom, a closed-loop control to ensure accuracy and robustness, and provides position and contact feedback to the closed-loop BMI. To explore the induction of an embodiment-like behaviour towards the prosthesis, we have reproduced the rubber hand illusion (Botvinick & Cohen, 1998, Nature) in the mouse. Tactile stimulations were applied to both a visible static forelimb prosthesis and the hidden real paw, either synchronously or asynchronously. At the end of the stimulation, we threatened the prosthesis and quantified the animal's reaction through the analysis of its facial expressions. Overall, these developments will enable us to better understand the role of somatosensory feedback on embodiment. Moreover, these tools will consolidate the mouse model in the field of neuroprosthetic research.

Paris-Saclay Institute of Neuroscience, Université Paris Saclay, CNRS, Department Of Integrative And Computational Neuroscience, Saclay, France

Neuroprosthetics offer great hope for motor-impaired human patients. One obstacle is that fine motor control requires near-instantaneous, rich somatosensory feedback. Such distributed touch feedback may be recreated in a brain-machine interface using distributed artificial stimulation across the primary somatosensory cortex surface. Here, we hypothesized that this neuronal stimulation must be contiguous in its spatial organization and temporal dynamics in order to be efficiently integrated by sensorimotor circuits. Using a closed-loop brain-machine interface, we trained head-fixed mice to control a virtual cursor by modulating the activity of motor cortex neurons. We provided artificial feedback in real time, consisting of distributed optogenetic stimulation patterns in the primary somatosensory cortex. We found that the mice only developed a specific motor strategy and sustained task performance when the optogenetic feedback pattern was contiguous while it moved across the topography of the somatosensory cortex. These results reveal new properties of cortical integration, and set new constraints on the design of neuroprosthetics.

A BRAIN-MACHINE INTERFACE BASED ON COTICAL MESOSCALE DYNAMICS

POSTER SESSION 03 - SECTION: BRAIN COMPUTER INTERFACE

Anton Dogadov, Daniel Shulz, Isabelle Ferezou, Valérie Ego-Stengel, Luc Estebanez
Paris-Saclay Institute of Neuroscience, Université Paris Saclay, CNRS, Department Of Integrative And Computational Neuroscience, Saclay, France

In the cerebral cortex, activity dynamics measured at a mesoscopic (0.1 to 1 mm) scale are characterized by both spontaneous and task-related dynamical waves of neuronal synchrony that travel through the cortical network. The dynamics of these waves include the spread of neuronal depolarization from a stationary bump to traveling waves that can follow complex trajectories. The function of these traveling waves, which are thought to participate in information propagation and processing in primary sensory areas, remains poorly understood. To test whether cortical waves can be actively generated and controlled, we are implementing a goal-directed task for head-fixed mice based on the online processing of wide-field calcium imaging signals. Transgenic mice expressing GCaMP6f in excitatory cortical neurons (Ai-95 x EMX-Cre) are implanted with 6 mm optical windows covering the left primary somatosensory and motor cortex. Calcium-dependent optical signals are analyzed in real time in order to track the trajectory of propagating mesoscale waves, which allows to condition the delivery of water rewards to the detection of waves depending of their specific spatiotemporal features. This methodological framework provides a unique opportunity to better understand how neuronal assemblies can orchestrate the flow of information within cortical networks while an animal is actively performing a task. Our preliminary experiments suggest that mice can be trained to voluntary control the emergence of waves of activity. If confirmed, this will represent an important proof-of-concept of the feasibility of using mesoscale cortical dynamics for building brain-machine interfaces.

Neuroprostheses aim to restore the lost function after a limb amputation or severe neural injuries. Within a peripheral neuroprosthesis, the interface between nerve and machine is intended to record neural signals and stimulate selective populations of nerve fibers, constituting a bidirectional interface. In this work, a new generation of neural interfaces that replaces metals by engineered graphene has been tested. This new device is based on modified reduced-graphene oxide, named EGNITE. The biocompatibility of EGNITE devices was tested *in vitro* and *in vivo*. *In vitro*, cell viability of dorsal root ganglia and cortical neurons seed on top of the material was analyzed. *In vivo*, polyimide devices coated with EGNITE were longitudinally implanted in the sciatic nerve of rats for 8 weeks. EGNITE had no impact on cell viability and did not produce any significant functional deficit or axonal damage in the implanted animals. To test the functionality of EGNITE devices, transverse intrafascicular multichannel electrodes containing 16 EGNITE active sites were implanted in the sciatic nerve of rats for 90 days. EGNITE devices were able to stimulate nerve fascicles to produce selective muscle activation. Compared with standard electrodes using metal conductors, EGNITE devices needed about 3 times less current to produce the same muscle activation. The biocompatibility of EGNITE together with its superior electrical capabilities may have relevant implications in the field of neuroprostheses by reducing potential tissue damage and lowering the energy consumption of the devices, thus extending the window of effective stimulation after implantation.

All-Polymer Printed Low-Cost Regenerative Nerve Cuff Electrodes.
Neural regeneration after lesions is still limited by several factors and new technologies are developed to address this issue. Here, we present and test in animal models a new regenerative nerve cuff electrode (RnCE). It is based on a novel low-cost fabrication strategy, called "Print and Shrink", which combines the inkjet printing of a conducting polymer with a heat-shrinkable polymer substrate for the development of a bioelectronic interface. This method allows to produce miniaturized regenerative cuff electrodes without the use of cleanroom facilities and vacuum based deposition methods, thus highly reducing the production costs. To fully proof the electrodes performance we assessed functional recovery and adequacy to support axonal regeneration after section of rat sciatic nerves and repair with RnCE. We investigated the possibility to stimulate the nerve to activate different muscles, both in acute and chronic scenarios. Three months after implantation, RnCEs were able to stimulate regenerated motor axons and induce a muscular response. The capability to produce fully-transparent nerve interfaces provided with polymeric microelectrodes through a cost-effective manufacturing process is an unexplored approach in neuroprosthesis field. Our findings pave the way to the development of new and more usable technologies for nerve regeneration and neuromodulation.

OPTOGENETIC AND MACHINE LEARNING STRATEGIES FOR AN AUDITORY CORTICAL IMPLANT.

POSTER SESSION 03 - SECTION: BRAIN COMPUTER INTERFACE

Antonin Verdier
Institut Pasteur, Institut De L'audition, Paris, France

Aim: Cochlear implants are among the most successful sensory restoration devices, drastically improving hearing in impaired patients via auditory nerve stimulation. However, they still have limitations and require a functional auditory nerve. To explore new ways of solving these limits, we are currently developing methodologies to demonstrate, in mice, the feasibility of auditory rehabilitation using a cortical optogenetic implant. Methods: We first established benchmarks of mouse hearing using a Go/NoGo discrimination for 5 important features of hearing. Frequency discrimination, amplitude modulation, robustness to noise, frequency modulation and harmonics discrimination. These benchmarks will be compared to perceptions obtained with the implant. Concomitantly, we implemented algorithms to convert sounds into tonotopic activation patterns which we can test in behavioral discrimination tasks using a video projector system through cranial chronic windows before implementing them on the 2D implant prototype. Results: Behavioral experiments allowed us to measure frequency perception accuracy for 16 different stimuli of tone frequencies and 16 AM frequencies. Also, background noise diminishes discrimination capacities. Regarding encoding models, we use tonotopic maps of the auditory cortex obtained through intrinsic imaging, to construct a linear model, which computes projections of the sound spectrum onto a tonotopic axis. Alternatively, we've also developed an autoencoder network model that heavily compresses sound representations while keeping nearly all spectro-temporal information. Conclusions: These results pave the way for generating artificial auditory perception via cortical stimulation and benchmark them against auditory discrimination performances of normally-hearing mice.

THE ROLE OF AFFERENT INPUT IN NEUROPROSTHETIC LEARNING

POSTER SESSION 03 - SECTION: BRAIN COMPUTER INTERFACE

Antoine Philippides[1], Mario Prsa[2], Gregorio Galinanes[3], Daniel Huber[4]
[1]University of Geneva, Basic Neurosciences, Geneva, Switzerland, [2]University of Fribourg, Faculty Of Science And Medicine, Fribourg, Switzerland, [3]University of Geneva, Basic Neuroscience, Geneva, Switzerland, [4]University of Geneva, Neurosciences Foundamentales, Geneva, Switzerland

Brain-Machine-Interfaces can potentially provide powerful means to replace impaired motor functions. To improve currently available devices, it is important to gain a better understanding of the neuronal mechanisms underlying neuroprosthetic control. We have demonstrated that learning-related changes in neuronal firing can be highly specific to the conditioned neuron. Independent of the type of plasticity involved, what is the origin and nature of the synaptic input driving the conditioned neuron? To identify the afferent activity driving neuroprosthetic learning, we designed a novel two-photon microscope capable of imaging multiple cortical layers simultaneously while we condition a chosen neuron. By labeling the conditioned neurons (L2/3) and afferent incoming axons (L1) with spectrally different calcium indicators, this optical approach allows us to image the in- and output of specific synaptic interactions simultaneously. Our first goal was to characterize the role of the motor thalamus (VM) and premotor areas in the learning process. Both regions show high correlations with the conditioned neuron, and with their signals we can easily reconstruct the activity patterns of conditioned neurons and its neighbors. However, calcium dynamics of buttons from the two regions also show differences. Thalamic activity is slowly evolving over a learning session suggesting a stable input contribution, which could be important for long-term memory consolidation. In contrast we observed that input from premotor areas showed more transient changes which might be related to early phases of learning. Taken togther, these experiments suggest a differential role of the two afferent input sources in the process of neuroprosthetic learning.

Wireless closed-loop optogenetics across the entire dorsoventral spinal cord in mice.
Optoelectronic systems can exert precise control over targeted neurons and pathways throughout the brain in untethered animals, but similar technologies for the spinal cord are not well established. In the present study, we describe a system for ultrafast, wireless, closed-loop manipulation of targeted neurons and pathways across the entire dorsoventral spinal cord in untethered mice. We developed a soft stretchable carrier, integrating microscale light-emitting diodes (micro-LEDs), that conforms to the dura mater of the spinal cord. A coating of silicone-phosphor matrix over the micro-LEDs provides mechanical protection and light conversion for compatibility with a large library of opsins. A lightweight, head-mounted, wireless platform powers the micro-LEDs and performs low-latency, on-chip processing of sensed physiological signals to control photostimulation in a closed loop. We use the device to reveal the role of various neuronal subtypes, sensory pathways and supraspinal projections in the control of locomotion in healthy and spinal-cord injured mice.

ERROR-RELATED POTENTIALS DETECTION WITH DRY AND WET EEG ELECTRODES

POSTER SESSION 03 - SECTION: BRAIN COMPUTER INTERFACE

Aline Xavier Fidêncio[1,2], Christian Klaes[2], Ioannis Iossifidis[1]
[1]Ruhr West University of Applied Sciences, Computer Science, Mülheim an der Ruhr, Germany, [2]Universitätsklinikum Knappschaftskrankenhaus Bochum, Neurosurgery, Bochum, Germany

Electroencephalography (EEG) is a non-invasive technique for measuring brain electrical activity from electrodes placed on the scalp surface. Improvements in this technology are particularly relevant because they also boost brain-machine interfaces (BMI) development. Commonly, gel-based electrodes are used since they guarantee a high-quality signal. Alternatively, dry electrodes have been introduced, more suitable for daily use. In this work, we compare conventional dry and wet electrode systems specifically for the detection of error-related potentials (ErrPs). ErrPs are elicited as a reaction to both self-made and external errors. There has been increased interest in the integration of these signals into BMIs to improve their performance since they provide a convenient source of feedback to the system with no extra workload for the subject. These signals can be used, e.g., to correct errors or even for system adaptation. ErrP-based BMIs in the literature have consistently used wet electrodes. Therefore, even though both electrodes types have been compared for other event-related potentials (e.g., P300), it is relevant to know whether the signal quality for the detection of ErrPs is comparable among them. In this work, we implement a simple game to elicit ErrPs and compare the quality of the measured signals. We tested the feasibility of the experimental protocol to elicit ErrP and the measured ErrP displayed a similar waveshape in terms of observed peaks. However, differences exist in both latencies as well as in their amplitude. These variations and other relevant characteristics have to be further verified with more subjects.

Investigating the keys of performance in Brain Computer interface is like falling down the rabbit hole, a huge number of relevant parameters to study covering completely different fields such as semantic (instructions given), psychology (subject's profiling), machine learning (classification) or interface ergonomics (feedback representation). Each of those domains interact to ease the subject to achieve of demanding tasks such as motor imagery (MI). Following the trend of multi-modality in MI BCI context, we propose to put the subject into an engaging environment where it will control a robotic arm by its eyes and brain to grasp real objects. We aim to study the importance of ergonomics as a key of performances in MI BCI. Our method has different strategies regarding the timing of the task in a new enriched environment where the task is oriented towards a target. We compare between strategies the spatiotemporal EEG features used in MI BCI (Power spectrum between condition, R^2 statistical test) and classification accuracy to assess the overall experimentation's performance. We found out encouraging results for our three preliminary test-pilots (1F, 25 ± 1 year) who all presented good desynchronization in the alpha or beta bands that translated into high statistical differences between resting and motor imagery states and into good classification performances. In the Testing session, two strategies seem to give better results in terms both of statistical differences and classification accuracy. To conclude, the engaging environment with embodiment provides good constant performance and timing seems to be a relevant parameter to study.

SPATIALLY AND TEMPORALLY CONTINUOUS OPTOGENETIC FEEDBACK IN A CLOSED-LOOP CORTICAL BRAIN-MACHINE INTERFACE

POSTER SESSION 03 - SECTION: BRAIN COMPUTER INTERFACE

Dorian Goueytes, Henri Lassagne, Daniel Shulz, Valérie Ego-Stengel, Luc Estebanez
Paris-Saclay Institute of Neuroscience, Université Paris Saclay, CNRS, Department Of Integrative And Computational Neuroscience, Saclay, France

Distributed microstimulations at the cortical surface can efficiently communicate feedback to a subject during control of a prosthesis through a brain-machine interface. Such feedback can potentially convey vast amounts of information, although the ability of the targeted cortical circuits to integrate arbitrary neuronal activations may constrain the dynamical patterns that can be used to convey this feedback. Here, we explore in mice a novel class of closed-loop brain-machine interface where distributed cortical feedback on the primary somatosensory cortex encodes the instantaneous angular position of a prosthesis joint in a spatially continuous way. We tested the ability of the mice to decode the rotary joint angle and optimize its trajectory based on a patterned rotary bar microstimulation applied online through optogenetics on the primary somatosensory cortex of mice. We showed that mice are able to use this continuous, rotating feedback in an active behaving context to increase the rate of rewards. Mice achieved this outcome by efficiently detecting reward opportunities, but also by moving the joint faster towards the rewarded angular zone while maintaining the cursor in a rewarded area comparatively longer than in a no-feedback condition. These findings indicate a path towards providing distributed cortical feedback with arbitrary shapes and topology, with a direct application to the control of a rotary joint — a frequent occurrence in many robotic posthesis.

SPONTANEOUS CORRELATION STRUCTURE IN THE VISUAL CORTEX OF A BLIND HUMAN PATIENT

POSTER SESSION 03 - SECTION: BRAIN COMPUTER INTERFACE

Karolína Korvasová[1], Cristina Soto-Sánchez[2], Tibor Rózsa[3], Eduardo Fernández[2], Ján Antolík[3]
[1]Charles University, Faculty Of Mathematics And Physics, Prague, Czech Republic, [2]Miguel Hernandez University, Neuroengineering Medical Group, Elche (Alicante), Spain, [3]Charles University, Prague, Department Of Software And Computer Science Education, Prague, Czech Republic

The development of penetrating cortical visual prostheses has recently advanced by the successful induction of visual percepts with various shapes in a blind human patient [1]. This achievement raises the natural question of how to control the evoked shape by stimulating a particular subset of electrodes from the micro-electrode array. However, such ideas rely on the assumption that the functional structure of the cortical circuit is still at least to some extent preserved despite the long-lasting blindness of the patient. As no visually evoked activity can be recorded from the primary visual cortex of a blind patient, we test the idea whether its functional structure can be inferred from spontaneous activity. As shown by imaging studies in several animal species [2,3], cells with similar orientation tuning tend to be more correlated during spontaneous activity than average and the orientation preference map can be retrieved from the spontaneous activity. However, so far it is unclear whether the Utah array used as the cortical visual prosthesis is sufficiently dense to permit such inference and whether the correlation structure is present after long-lasting blindness. We developed an algorithm based on a self-organizing map that retrieves a relatively robust correlation structure from the spontaneous activity of a blind patient recorded with a Utah array, with a longer reach of correlations compared to a sighted monkey. Collective motion of dimers.
We consider a discrete agent-based model on a one-dimensional lattice and a two-dimensional square lattice, where each agent is a dimer occupying two sites. Agents move by vacating one occupied site in favor of a nearest-neighbor site and obey either a strict simple exclusion rule or a weaker constraint that permits partial overlaps between dimers. Using indicator variables and careful probability arguments, a discrete-time master equation for these processes is derived systematically within a mean-field approximation. In the continuum limit, nonlinear diffusion equations that describe the average agent occupancy of the dimer population are obtained. In addition, we show that multiple species of interacting subpopulations give rise to advection-diffusion equations. Averaged discrete simulation data compares very well with the solution to the continuum partial differential equation models. Since many cell types are elongated rather than circular, this work offers insight into population-level behavior of collective cellular motion.

Investigating the Turing conditions for diffusion-driven instability in the presence of a binding immobile substrate.
Turing's diffusion-driven instability for the standard two species reaction-diffusion system is only achievable under well-known and rather restrictive conditions on both the diffusion rates and the kinetic parameters, which necessitates the pairing of a self-activator with a self-inhibitor. In this study we generalize the standard two-species model by considering the case where the reactants can bind to an immobile substrate, for instance extra-cellular matrix, and investigate the influence of this dynamics on Turing's diffusion-driven instability. Such systems have been previously studied on the grounds that binding of the self-activator to a substrate may effectively reduce its diffusion rate and thus induce a Turing instability for species with equal diffusion coefficients, as originally demonstrated by Lengyel and Epstein (1992) under the assumption that the bound state dynamics occurs on a fast timescale. We, however, analyse the full system without any separation of timescales and demonstrate that the full system also allows a relaxation of the standard constraints on the reaction kinetics for the Turing instability, increasing the type of interactions that could give rise to spatial patterning. In particular, we show that two self-

activators can undertake a diffusively driven instability in the presence of a binding immobile substrate, highlighting that the interactions required of a putative biological Turing instability need not be associated with a self-activator-self-inhibitor morphogen pair.

A didactical note on the advantage of using two parameters in Hopf bifurcation studies.
In order to maximize the information that a linearized stability analysis provides, one should work with two free parameters rather than one. Moreover, it is recommended to first consider coefficients in the characteristic equation as parameters and in a second step (try to) invert the map that defines the coefficients in terms of the parameters as they occur in the original equation. Our aim is to substantiate these claims by way of a delay equation example taken from the literature.

A CONTINUUM OF BIOPHYSICAL TIME SCALES OF NEURONS IN THE INTERMEDIATE NUCLEUS OF THE LATERAL LEMNISCUS

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Kathrin Wicke, Felix Felmy
University of Veterinary Medicine Hannover, Institute Of Zoology, Hannover, Germany

The intermedial nucleus of the lateral lemniscus (INLL) integrates auditory information from the cochlear and superior olivary nuclei and feeds output to the inferior colliculus. This connectivity suggests that INLL neurons process complex auditory information, potentially including frequency, temporal pattern content and sound source location, prior to the midbrain processing. The tonotopic pattern of the INLL has been suggested to be patchy or organized along a dorso-ventral axis. Besides possible cross-frequency integration, little is known about the functional role of the INLL or the biophysical characteristics of its neuronal population. Here we describe the biophysical and synaptic properties of INLL neurons. Patch-clamp recordings in acute brain slices showed that nearly all membrane properties correlate with the membrane time constant (τ_{mem}), which spans over three magnitudes to generate a large continuum of cellular integration times. The postsynaptic current size and kinetic increase with τ_{mem}, and thereby amplify the continuum of integration times. The lack of correlation between τ_{mem} and cell morphology suggests that varying intrinsic membrane properties underlie this heterogeneity. Recovery of the location of each recorded neuron did not reveal an organizational principle. Therefore, the biophysical heterogeneity seems to be independent of the INLLs tonotopy. Overall, INLL neurons process inputs over a broad range of timescales, supported by their biophysical and synaptic properties. Thus, INLL neurons might be able to process multiple features of auditory information over a broad range of timescales, and possibly serve as a temporal filterbank across the range of perceived frequencies.

IMPAIRED PROCESSING OF AMPLITUDE-MODULATED TONES IN THE INFERIOR COLLICULUS IN CACNA2D3 MICE - A RISK GENE FOR AUTISM SPECTRUM DISORDERS IN HUMANS

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Gerhard Bracic[1], Katrin Hegmann[2], Jutta Engel[1], Simone Kurt[1]
[1]Saarland University, Department Of Biophysics & Cipmm, Hearing Research, Homburg, Germany, [2]Ulm University, Institute Of Neurobiology, Ulm, Germany

Temporal processing of complex sounds is a fundamental and intricate task in hearing and a prerequisite for processing and understanding vocalization, speech, and prosody. Here we examined response properties of neurons of the inferior colliculus (IC) in mice lacking *Cacna2d3*, a risk gene for autism spectrum disorders. The $\alpha_2\delta3$ auxiliary Ca^{2+} channel subunit encoded by *Cacna2d3* is essential for proper function of the endbulb of Held synapse in the auditory brainstem (Pirone et al., 2014). Recent evidence has shown that much of auditory feature extraction is being performed in the auditory brainstem and the auditory midbrain, the IC, including processing of amplitude modulation. We determined spectral and temporal response properties of single and multi-unit responses in IC neurons of anesthetized mice. IC units of $\alpha_2\delta3^{-/-}$ mice showed normal tuning properties yet increased spontaneous rates compared with wildtype. When stimulated with amplitude-modulated (AM) tones, $\alpha_2\delta3^{-/-}$ units exhibited less precise temporal coding and reduced evoked rates to higher modulation frequencies (f_m). Population peak latencies were increased for f_m up to 100 Hz in $\alpha_2\delta3^{-/-}$ compared with wildtype units. The loss of precision of temporal coding with increasing f_m from 70 Hz to 160 Hz was characterized using a normalized offset-corrected (Pearson-like) correlation coefficient, which appeared more appropriate than the metrics of vector strength. The processing deficits of AM sounds that we analyzed at the level of the IC indicate that $\alpha_2\delta3^{-/-}$ mice exhibit a subcortical auditory processing disorder. Similar deficits may be present in other mouse models for autism spectrum disorders.

Aims The functional molecular data available to date in the cochlea has been obtained through the identification of the causal genes for deafness, a total of 140 genes responsible for isolated deafness and 300-400 genes for syndromic deafness. These advances open the way for curing deafness by gene therapy approaches, a clinical domain in which only prostheses can be presently proposed to patients. However, progress in the development of gene therapy requires a complete inventory of the cochlear cell types and an exhaustive characterisation of the genes expressed by each cochlear cell type with their developmental dynamics. To this purpose, we constructed a transcriptomic atlas including more than 110,000 cochlear cells and nuclei. **Methods** The cochleae were extracted from C57bl6J mice before and upon hearing onset, and on P20 when the cochlea is mature. After tissue dissociation, the cochlear cells and nuclei were sorted by flow cytometry and underwent RNA-sequencing. **Results** Our dataset provides a comprehensive map of deafness genes and transcription factors expressed in all cochlear cell types, the identification of new markers for poorly characterized cell types, and evidence for a yet unidentified cell type based on transcriptomic signatures and hybridization assays. In addition, overlooked candidate diseased cochlear cell types for several monogenic forms of deafness were also revealed. **Conclusion** Our study provides an exhaustive and highly detailed map of gene expression in the mouse cochlea in a timeframe corresponding to the postnatal development of the human ear compatible with gene therapy.

The optogenetic cochlear implants strives to overcome the problems of large current spread and limited dynamic range of electrical cochlear implants (Dieter et al., 2020). F-Chrimson is a promising Channelrhodopsin(ChR) for this technology, combining fast kinetics and less phototoxic red-shifted light absorption. We investigated the effect of emitter size and pulse properties on the inferior colliculus (IC) activity elicited by f-Chrimson mediated optogenetic stimulation of the auditory nerve following prior experiments on blue-light sensitive CatCh (Dieter et al., 2019). We injected adeno-associated virus carrying f-Chrimson (AAV2/6-hSyn-f-Chrimson-EYFP) into the cochlea of neonatal Mongolian gerbils. Eight to fifteen weeks after injection, we inserted laser (594 nm)-coupled optical fibers (50/200µm diameter) into the basal, medial and/or apical turns of cochlea via a cochleostomy. We recorded optically evoked auditory brainstem responses verifying functional f-Chrimson expression. Following placement of a 32-channel electrode array in the contralateral IC, we drove optogenetic stimulation of the auditory nerve by light pulses of varying intensities, durations, and stimulation frequencies. Preliminary results from five gerbils show shorter latencies of IC responses of f-Chrimson mediated optogenetic stimulation of the auditory nerve than reported for CatCh-injected animals. IC responses followed optogenetic stimulation up to frequencies of 180 Hz (n=2) and the response strength increased with energy input. Preliminary analysis of cochlear spread of excitation suggests more spectrally selective stimulation with the 50µm diameter optical fiber (NA 0.22) than with the 200µm fiber (NA 0.39) (n=2). These results indicate that f-Chrimson is a promising ChR for optogenetic stimulation of the auditory nerve.

Multiple PDZ domain containing protein (MPDZ or Mupp1) is a large cytosolic polarity protein with thirteen PDZ domains present in neurons and epithelial cells. Mutations in *MPDZ* gene have been reported in patients with autosomal recessive congenital hydrocephalus (HYC2, OMIM #603785) with brain and eye anomalies and with some patients displaying sensorineural hearing loss and mild Intellectual Disability (*Shaheen et al.,* 2017). Also, genetic variations within *Mpdz* have been associated with alcohol and sedative dependence in both mice and humans, which suggest that it may regulate responses to multiple drug abuse (PMID35095607). MPDZ is found at the tight junction of epithelial cells (*Marivin et al., 2019*; *Jarysta et al.,* 2021), but also at the postsynaptic density of synapses in the brain (*Krapivinsky et al*., 2004; *Jones et al.,* 2009). In both systems it functions as a scaffolding protein, interacting with different partners to control the development and function of the cell and tissues. Here we characterized a conditional *Mpdz* mouse mutant for inner ear and cognitive deficits. We identified both epithelial and synaptic disruptions behind the hearing deficits of our model, supporting a role for the protein in both compartments. To evaluate the role of MPDZ on cognitive (notably learning and memory), we developed brain-specific mutants and evaluated reference and working memory, so far never assessed in absence of *Mpdz* in a rodent model. Our result show both brain and sensory organ dysfunctions in absence of MPDZ, supporting a peripheral and a central function for MPDZ in hearing and cognition.

FGFR1-mediated protocadherin-15 loading mediates cargo specificity during intraflagellar transport in inner ear hair-cell kinocilia.
The mechanosensory hair cells of the inner ear are required for hearing and balance and have a distinctive apical structure, the hair bundle, that converts mechanical stimuli into electrical signals. This structure comprises a single cilium, the kinocilium, lying adjacent to an ensemble of actin-based projections known as stereocilia. Hair bundle polarity depends on kinociliary protocadherin-15 (Pcdh15) localization. Protocadherin-15 is found only in hair-cell kinocilia, and is not localized to the primary cilia of adjacent supporting cells. Thus, Pcdh15 must be specifically targeted and trafficked into the hair-cell kinocilium. Here we show that kinocilial Pcdh15 trafficking relies on cell type-specific coupling to the generic intraflagellar transport (IFT) transport mechanism. We uncover a role for fibroblast growth factor receptor 1 (FGFR1) in loading Pcdh15 onto kinociliary transport particles in hair cells. We find that on activation, FGFR1 binds and phosphorylates Pcdh15. Moreover, we find a previously uncharacterized role for clathrin in coupling this kinocilia-specific cargo with the anterograde IFT-B complex through the adaptor, DAB2. Our results identify a modified ciliary transport pathway used for Pcdh15 transport into the cilium of the inner ear hair cell and coordinated by FGFR1 activity.

PURINERGIC RECEPTOR AGONISTS ACTIVATED CA2+ SIGNALING IN THE DEITERS' CELLS IN THE ORGAN OF CORTI IN DIFFERENT POSTNATAL DEVELOPMENTAL STAGES FROM PREHEARING TO MATURED

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Eszter Berekméri[1,2], Louise Moysan[2], Ann-Kathrin Lutz[2], János Farkas[1,3], Ádám Fekete[4], László Köles[1,3], Beata Sperlagh[5], Tibor Zelles[1,3,5]

The supporting cells of the organ of Corti and their ATP activated Ca^{2+} signaling are studied extensively in cochlear explants of newborn mice (1-2 days old (P1-2)) and the fundamental role of the ATP-dependent spontaneous activity in cochlear development has been shown. However, information on purinergic Ca^{2+} signaling during cochlear development and in mature stage are much sparse. We have investigated the ATP and UTP-evoked Ca^{2+} signals in Deiters' cells in the hemicochlea preparation in different postnatal developmental-stages from P5, deaf mice to > P18, hearing mice. Single-cell electroporation of Deiters' cells with Ca^{2+} sensitive dyes and their fluorescent imaging showed that the ATP and UTP-induced Ca^{2+} transients have different amplitude, duration and area under the curve characteristics. For mathematical modeling the intracellular Ca^{2+} dynamics of the Deiters' cells we set up a closed cell model to investigate the UTP induced Ca^{2+} responses, and an open cell model to simulate the ATP induced ones. Our results showed that extracellular Ca^{2+} dependent P2X and intracellular Ca^{2+} store dependent P2Y receptors were involved in the ATP and UTP-evoked Ca^{2+} transients in each developmental stages. The UTP induced responses were smaller than ATP induced ones. This was also predicted by our models.

Aims: Spiral ganglion neurons (SGNs) inside the cochlea play a pivotal role in hearing and are subdivided in type 1 (T1) and type 2 (T2) SGNs. Optogenetic tools to modulate SGN activity display a promising approach to decipher their exact role in hearing and adaptation to varying sound intensities. However, strong and SGN type specific expression of a transgene is still demanding. Therefore, the characterization of potential promoters that drive target gene expression in either T1 or T2 SGNs is essential to specifically investigate the function of these cell types. **Methods:** In order to achieve this goal, RNAseq data (umgear.org) were screened for genes specifically and highly expressed in T1 or T2 SGNs, corresponding promoter elements were cloned and their *in vitro* activity was analyzed by luciferase assay. Successfully evaluated promoters were used to drive transgene expression of f-Chrimson, a channelrhodopsin, in murine cochlea after early postnatal adenovirus associated virus injection. Promotor function was examined *in vivo*, by recording functional responses to optogenetic stimulation (optically evoked auditory brainstem responses, oABR) followed by analysis of cochlear f-Chrimson expression by immunohistology. **Results:** Preliminary data shows that the selected promoters are capable to drive transgene expression sufficiently to enable oABRs. Additionally, histological analysis revealed cell type specific expression of the transgene in SGNs. **Conclusions:** Taken together, our data indicates that we can specifically target SGNs *in vivo* and this will further support research to elucidate the specific role of T1 and T2 SGNs.

NEURAL CIRCUITRY FOR OXYTOCIN RELEASE AND MATERNAL BEHAVIOR

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Silvana Valtcheva[1,2], Habon Issa[2], Kathleen Martin[2], Chloe Bair-Marchall[2], Kanghoon Jung[3], Hyung-Bae Kwon[3], Robert Froemke[2]
[1]University of Cologne, Faculty Of Medicine, Cologne, Germany, [2]New York University School of Medicine, Skirball Institute, New York, United States of America, [3]Johns Hopkins University School of Medicine, Solomon H. Snyder Department Of Neuroscience, Baltimore, United States of America

Parenting behaviors emerge from complex neural circuits conferring sensitivity to infant needs to ensure survival of the species. One important molecular signal for the maternal brain is the hypothalamic neuropeptide oxytocin. Oxytocin is believed to powerfully enhance parental behaviors by increasing the salience of sensory cues from the offspring but it remains unexplored what sensory cues from infants can activate oxytocin neurons in new mothers. Here we describe a neural circuit routing auditory information about infant vocalizations to the oxytocin system in maternal mice (dams). We found that oxytocin neurons, but not other hypothalamic cells, are activated following playback of pup distress vocalizations. Using anatomical tracing approaches and slice physiology, we identified the a subcortical pathway relaying auditory information to oxytocin neurons. In hypothalamic brain slices, we found that optogenetic activation of PIL fibers led to long-term depression of synaptic inhibition in OT neurons mediated by postsynaptic internalization of GABAARs via dynamin signaling. Using a genetically-encoded oxytocin sensor, we demonstrated that pup calls, but not pure tones, were efficient in triggering central oxytocin release. Finally, inhibiting PIL projections to hypothalamus with chemogenetics, perturbed pup retrieval behavior in dams by decreasing the amount of pups retrieved and increasing the latency of retrieval over multiple trials. These findings suggest that the thalamus-hypothalamus noncanonical auditory pathway may be a specific circuit for the detection of social sounds, important for disinhibiting oxytocin neurons, gating oxytocin release in downstream brain areas, and sustaining maternal performance over time.

ELUCIDATING THE NEURONAL POPULATION CODE OF SOUND LOCATION AT THE INFERIOR COLLICULUS OF AWAKE MICE USING A FAST VOLUMETRIC CALCIUM IMAGING APPROACH.

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Juan Carlos Boffi[1], Brice Bathellier[2], Hiroki Asari[3], Robert Prevedel[1,3,4]
[1]European Molecular Biology Laboratory, Cell Biology And Biophysics Unit, Heidelberg, Germany, [2]Institut Pasteur, INSERM, Institut De L'audition, Paris, France, [3]European Molecular Biology Laboratory, Epigenetics And Neurobiology Unit, Rome, Italy, [4]European Molecular Biology Laboratory, Molecular Medicine Partnership Unit, Heidelberg, Germany

Sound location is proposed to be encoded by neuronal population activity patterns at the mammalian inferior colliculus (IC). However, simultaneous recordings of IC population responses are lacking to capture these population dynamics and characterize the underlying neural code. Using a bespoke scanned temporal focusing two-photon microscope, we performed fast volumetric calcium imaging in awake mice, and simultaneously recorded the activity of unprecedentedly large populations of IC neurons in response to sounds delivered from 13 different frontal horizontal locations (azimuths). The responses of IC neurons showed marked trial-to-trial variability. Nevertheless, our information theoretic analysis identified that individual IC neurons carried a small but significant amount of information about stimulus azimuth, suggesting that the azimuth information is distributed over IC populations. To better understand a potential population code, we compared the performance of theoretical decoding models on the simultaneously recorded IC population responses. We found that a decoding model based on an ensemble of binary classifiers outperformed previously proposed single-architecture models when operating on simultaneously recorded single-trial responses. These findings support the existence of IC activity patterns that encode sound location on the single-trial basis. Our simultaneous recordings showed significant noise correlations, but they did not impact the decoder accuracy. Finally, our volumetric imaging approach revealed the presence of azimuth tuned neurons in a previously unexplored anatomical subdivision of IC: the dorsal cortex. Altogether these findings point out a role of IC as a key relay of the mammalian auditory pathway in sound source localization via parallel distributed processing.

INVESTIGATING THE ROLE OF THE CEREBELLUM IN BIRDSONG SENSORIMOTOR LEARNING

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Roman Ursu[1], Ludivine Pidoux[2], Eduarda Centeno[3], Arthur Leblois[4]
[1]Universite de Bordeaux, Neurosciences, Bordeaux, France, [2]IPMC, Pharmacologie, Valbonne, France, [3]Université de Bordeaux, Neurosciences, Bordeaux, France, [4]CNRS - Université de Bordeaux, Neuroscience, Bordeaux, France

Aims: Vocal communication relies on the precise timing of vocalizations. In particular, songbirds learn to produce vocalization with tight temporal precision. The cerebellum is thought to be involved in sensorimotor learning and particularly in controlling and learning the timing of motor actions. However, its possible contribution to song timing and its acquisition in songbird remains unknown. Here we investigate the role of the cerebellum in the control and plasticity of song production in zebra finches. **Methods**: We recorded extracellular neuronal activity in the cerebellum of zebra finches during singing and auditory stimulation. We induced song plasticity through a closed-loop auditory perturbation protocol. Chemical lesions are realised through ibotenic acid injections. Finally, we performed anatomical tracing (dextran dye injections) and electrical brain stimulation. **Results**: Anatomical and electrophysiological data support the existence of a connection between the deep cerebellar nuclei (DCN) and the pallial nuclei involved in song timing via the thalamus. Neurons in the lobules IV/V of the cerebellum modulate their firing rate during singing and are sensitive to auditory stimulation during rest and auditory perturbation during singing. However, lesions of the lateral DCN do not affect the plasticity of syllable durations in adult birds. **Conclusions**: Our data show that the lobule IV/V of the cerebellum displays auditory and singing-related activity in zebrafinches. However, the lateral cerebellum doesn't seem to be involved in adult song plasticity.

KV3.3 SUBUNITS CONTROL PRESYNAPTIC WAVEFORM AND IMPROVE TIMING AT A CENTRAL EXCITATORY SYNAPSE

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Mihai Stancu[1], Amy Richardson[2], Victoria Ciampani[2], Ian Forsythe[2], Conny Kopp-Scheinpflug[1]
[1]Ludwig-Maximilian University, Biology, Munchen, Germany, [2]University of Leicester, Psychology & Behaviour, Leicester, United Kingdom

Aims It has been shown that Medial Nucleus of the Trapezoid Body 'MNTB' neurons possess functional Kv3 channels that are composed of either Kv3.1 and/or Kv3.3, and the deletion of either subunit caused a small increase in postsynaptic AP duration, consistent with functional redundancy of either subunit in the postsynaptic MNTB cell body. Here we test for Kv3 subunit-specific roles at the presynaptic calyx of Held terminal innervating MNTB neurons using *in vivo* single unit recordings in Kv3.3 knockout mice. Methods Adult Kv3.3 KO mice of both sexes (n=5) and 5 age-matched CBA wild-type (WT) mice were anaesthetised and stabilized in a sound-proof chamber, in a custom stereotaxic device. Single unit recordings were acquired while presenting pure tone stimuli (100ms duration, 5ms rise/fall, at varying intensities 0-90dB SPL) to the contralateral ear. Results Extracellular recordings from MNTB neurons exhibited a typical complex waveform, comprised of a presynaptic and a postsynaptic component. The time between the peak and trough of extracellular action potentials (APs) are compelling markers for AP half-width and showed that the presynaptic APs and synaptic delays were significantly longer in Kv3.3 knockouts compared to WT recordings. Conclusion These results suggest that Kv3.3 is the presynaptic ‘delayed rectifier', enabling fast presynaptic APs and precisely timed synaptic delays. The changes in presynaptic AP duration and synaptic delay in the Kv3.3 knockout are likely to affect temporal processing in the MNTB output, like first-spike latency and jitter. However, the longer presynaptic APs will also affect transmitter release and hence spontaneous and sound driven firing rates.

Chemogenetic Recruitment of Specific Interneurons Suppresses Seizure Activity.
Current anti-epileptic medications that boost synaptic inhibition are effective in reducing several types of epileptic seizure activity. Nevertheless, these drugs can generate significant side-effects and even paradoxical responses due to the broad nature of their action. Recently developed chemogenetic techniques provide the opportunity to pharmacologically recruit endogenous inhibitory mechanisms in a selective and circuit-specific manner. Here, we use chemogenetics to assess the potential of suppressing epileptiform activity by enhancing the synaptic output from three major interneuron populations in the rodent hippocampus: parvalbumin (PV), somatostatin (SST), and vasoactive intestinal peptide (VIP) expressing interneurons. To target different neuronal populations, promoter-specific cre-recombinase mice were combined with viral-mediated delivery of chemogenetic constructs. Targeted electrophysiological recordings were then conducted in an model of chronic, drug-resistant epilepsy. In addition, behavioral video-scoring was performed in an model of acutely triggered seizure activity. Pre-synaptic and post-synaptic whole cell recordings in brain slices revealed that each of the three interneuron types increase their firing rate and synaptic output following chemogenetic activation. However, the interneuron populations exhibited different effects on epileptiform discharges. Recruiting VIP interneurons did not change the total duration of epileptiform discharges. In contrast, recruiting SST or PV interneurons produced robust suppression of epileptiform synchronization. PV interneurons exhibited the strongest effect per cell, eliciting at least a fivefold greater reduction in epileptiform activity than the other cell types. Consistent with this, we found that chemogenetic recruitment of PV interneurons suppressed convulsive behaviors by more than 80%. Our findings support the idea that selective chemogenetic enhancement of inhibitory synaptic pathways offers potential as an anti-seizure strategy.

GOOD INTERAURAL TIME DIFFERENCE (ITD) SENSITIVITY WITH BILATERAL COCHLEAR IMPLANTS REQUIRES ITDS IN PULSE TIMING, NOT ENVELOPES

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Nicole Rosskothen-Kuhl[1], Alexa Buck[2], Lakshay Khurana[3], Jan Schnupp[2]
[1]Medical Center - University of Freiburg, Department Of Oto-rhino-laryngology, Freiburg, Germany, [2]City University of Hong Kong, Neuroscience, Hong Kong, Hong Kong PRC, [3]University Medical Center Goettingen, Institute For Auditory Neuroscience, Goettingen, Germany

Interaural time difference (ITD) discrimination is a major challenge for bilateral cochlear implant (biCIs) patients, especially after early deafness. Our recent work demonstrating that neonatally deafened (ND) rats with synchronized biCIs develop excellent ITD sensitivity may therefore come as surprise. Today's clinical CI processors employ asynchronous pulsatile stimulation in each ear, so that biCI users only experience ITDs in pulse train envelopes (envITD). It seems possible that uninformative pulse-timing ITDs (ptITDs) will swamp envITDs. This motivated us to investigate the relative effectiveness of ptITDs and envITDs in well-controlled behavioral animal experiments. ND biCI rats were trained to lateralize sinusoidally enveloped pulse trains in which envITD and ptITDs co-varied. Animals were tested with envITDs and ptITDs, which were drawn independently from {-100, 0, +100} µs. Various combinations of two pulse rates {900, 4500} pps and three envelope modulation rates {5, 20, 100} Hz were tested. Probit analysis was used to quantify how strongly animals based their lateralization judgments on envITDs or ptITDs at each condition. Animals learned to lateralize ITDs with high accuracy when envITDs and ptITDs were congruent. When envITDs and ptITDs conflicted, ptITDs completely dominated the lateralization judgments. At none of the conditions tested did envITDs significantly influence lateralization behavior. Our results suggest that the auditory pathway cannot process envITDs in biCI stimulation effectively. Healthy ears can be highly sensitive to acoustic envITDs but the situation in biCI stimulation is radically different. To make rich binaural hearing available to biCI patients, pulse timing has to be considered more strongly.

SOUND LOCALIZATION TUNING OF THE MEDIAL SUPERIOR OLIVE IN MONGOLIAN GERBILS AFTER HEARING ONSET

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Martijn Sierksma, Gerard Borst
Erasmus MC, Neuroscience, Rotterdam, Netherlands

Sound sources can be localized in the horizontal plane by comparing their arrival times at both ears. A specialized brainstem circuit that converges on the medial superior olive (MSO) computes these interaural time differences (ITDs) in arrival. This computation depends on the unique biophysical properties of MSO neurons and on the time it takes the signals to travel to the MSO from both ears. How the ITD tuning of MSO neurons develops is still unknown. Aim. We compared ITD tuning and monaural travel delays for MSO neurons in anesthetized, two to four weeks old Mongolian gerbils. Methods. We made juxtacellular or single-unit recordings of principal MSO neurons using glass pipettes. ITD tuning and monaural delays were measured using sound stimulation with an in-ear speaker. Results. We observed that young MSO neurons received excitatory inputs from both ears. The firing of MSO neurons was facilitated by binaural stimulation and showed the highest firing rate ('best ITD') when sounds were presented much earlier at the contralateral ear. This excess delay became smaller during the fourth week. First spike latencies to monaural clicks decreased during the third and fourth week. The difference in monaural first spike latencies was in line with the excess contralateral delay, and was strongly correlated with the best ITD of the same neuron ($r = 0.8$). Conclusions. We conclude that, unlike the rapid development of other features, the MSO's ITD tuning and the monaural travel delays to the MSO mature beyond the third week in Mongolian gerbils.

HOW DO INTERAURAL TIME AND INTERAURAL LEVEL DIFFERENCES INTERACT IN SPATIAL HEARING WITH COCHLEAR IMPLANTS?

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Sarah Buchholz[1], Felix Kleinschroth[1], Heika Hildebrandt-Schönfeld[1], Theresa Preyer[1], Jan Schnupp[2], Nicole Rosskothen-Kuhl[1]
[1]Medical Center - University of Freiburg, Department Of Oto-rhino-laryngology, Freiburg, Germany, [2]City University of Hong Kong, Neuroscience, Hong Kong, Hong Kong PRC

Sound localization in the horizontal plane is based on two binaural cues: interaural level differences (ILDs) and interaural time differences (ITDs). For bilateral cochlear implant (biCI) users, sound localization and spatial hearing are major challenges, and ITD sensitivity is particularly poor, with most biCI patients relying almost exclusively on ILDs. However, our recent work demonstrates that neonatally deafened (ND) rats with synchronized biCIs can develop excellent ITD sensitivity. Here, we investigate how the sensitivities to ILDs and ITDs compare and interact in ND rats which are supplied with synchronized biCI input from the outset. ND biCI rats were trained to lateralize pulse trains at a pulse rate of 900 pps with either solitary ILDs (range of ±6 dB) or co-varying ITDs and ILDs of {+/- 100, 80, 60, 0} µs and {+/-6, 4, 1, 0.5, 0} dB. Trials in which ITDs and ILDs varied independently from each other were used to determine the relative strength and interaction of these two spatial cues. Our biCI animals developed excellent ILD as well as ITD sensitivities, and the two types of cues interacted additively. Importantly, very small pulse timing ITDs of ~80 µs could influence an animal's lateralization judgment as powerfully as relatively very large electrical pulse amplitude ILDs of ~4 dB. These results add to the growing evidence that the inability of CI processing strategies in current clinical use to encode auditory information in precise pulse timing constitute a very significant technical limitation.

Standard cochlear implants as electrochemical sensors: Intracochlear oxygen measurements in vivo.
Cochlear implants are the most successful neural prostheses worldwide and routinely restore sensorineural hearing loss by direct electrical stimulation of the auditory nerve. Enhancing this standard implant by chemical sensor functionality opens up new possibilities, ranging from access to the biochemical microenvironment of the implanted electrode array to the long-term study of the electrode status. We developed an electrochemical method to turn the platinum stimulation microelectrodes of cochlear implants into electrochemical sensors. The electrodes showed excellent and stable chemical sensor properties, as demonstrated by in vitro characterizations with combined amperometric and active potentiometric dissolved oxygen and hydrogen peroxide measurements. Linear, stable and highly reproducible sensor responses within the relevant concentration ranges with negligible offset were shown. This approach was successfully applied in vivo in an animal model. Intracochlear oxygen dynamics in rats upon breathing pure oxygen were reproducibly and precisely measured in real-time from the perilymph. At the same time, correct implant placement and its functionality was verified by measurements of electrically evoked auditory brainstem responses with clearly distinguishable peaks. Acute measurements indicated no adverse influence of electrical stimulation on electrochemical measurements and vice versa. Our work is ground-breaking towards advanced implant functionality, future implant lifetime monitoring, and implant-life-long in situ investigation of electrode degradation in cochlear implant patients.

NEUROPATHOLOGICAL ALTERATIONS IN INDIVIDUALS WITH TINNITUS: A POST-MORTEM STUDY

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Faris Almasabi[1], Faisal Alosaimi[1], Anouk Walters[1], Minerva Terrón[1], Jasper Smit[2], Yasin Temel[1], Marcus Janssen[3], Ali Jahanshahi[1]
[1]Maastricht University, Department Of Neurosurgery, School For Mental Health And Neuroscience, Faculty Of Health, Medicine And Life Sciences, Maastricht, Netherlands, [2]Zuyderland Medical Center, Department Of Ear, Nose, Throat, Head And Neck Surgery, Heerlen, Netherlands, [3]Maastricht University Medical Center, Department Of Clinical Neurophysiology, Maastricht, Netherlands

Introduction Tinnitus is a phantom perception of sound. Degenerative or inflammatory processes as well as changes in the monoaminergic systems have been suggested as potential underlying mechanisms. To our knowledge however, no post-mortem study was conducted on tinnitus patients. Here, we aimed to study the pathological changes in the auditory and non-auditory brain regions of tinnitus patients. **Methods** Brain specimens were obtained from tinnitus patients and matched controls. The paraffin-embedded tissue blocks contained the medial geniculate body (MGB), inferior colliculus (IC) and dorsal raphe nucleus (DRN). Nissl staining was performed to access cell density and cell/area measurements. The number of glial cells was assessed using anti-GFAP and iba-1 antibodies. In addition, the DRN was stained using antibodies raised against phenylalanine hydroxylase-8 (PH8) and tyrosine-hydroxylase (TH) to detect serotonergic and dopaminergic neurons, respectively. **Results** Quantitative analysis of Nissl stained sectioned revealed a significant reduction in neuronal cell density in the MGB and IC of tinnitus subjects. Although cell size was not changed between groups. Moreover, a lower number of astrocytes were found in the IC of tinnitus cases. No significant cell loss was found in the DRN in Nissl stained sections. However, the number of PH8 positive cells was significantly reduced in tinnitus cases, while the number of TH positive neurons did not differ between groups. **Conclusion** This study suggests that both neurodegenerative and inflammatory processes may be involved in the neuropathophysiology of tinnitus, and point towards a potential role for raphe serotonergic system in this complex neuro-otologic disorder.

EFFECT OF GROUP I MGLUR ACTIVATION ON SYNAPTIC TRANSMISSION AND NEURON EXCITABILITY IN THE AUDITORY MIDBRAIN OF FXS MOUSE MODEL

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Michał Wojcik, Thorsten Becker, Ursula Koch
Free University Berlin, Biology, Berlin, Germany

Metabotropic glutamate receptors (mGluRs) play a critical role in the developmental shaping of sensory pathways. In spite of combined efforts to understand their role, the exact involvement in this process remains elusive. Dysfunctional overactivity of pathways activated by mGluRs may contribute to multiple debilitating conditions, an example of which is Fragile X Syndrome (FXS) - the most inherited cause of autism. In this work, the effects of acute mGluR1/5 activation on neural circuit function are dissected and compared between genotypes of the FXS mouse model in the central nucleus of the inferior colliculus - a major integratory hub of the auditory pathway - around the critical period of hearing development. Our results obtained using whole-cell patch-clamp in acute murine brain slices indicate a range of group I mGluR-related phenomena, affecting both excitatory and inhibitory synaptic transmission in a cell-type-specific manner. Local mGluR agonist administration (3,5-DHPG) also led to temporary changes in the neuronal membrane properties, increasing input resistance and lowering the firing threshold in a majority of recorded neurons. Additionally, an increase in rebound spiking and changes in neuronal firing patterns were observed. The effects of mGluR activation seem to be less profound in animals missing the fragile X mental retardation protein (FMRP) and increase with age, persisting even after a critical period of auditory circuit development. These phenomena may underlie the behavioural and sensory processing deficits for which the loss of FMRP is a prerequisite and give new insight into factors shaping the ontogenesis of the auditory pathway.

Phasic Neuronal Firing in the Rodent Nucleus of the Solitary Tract .
Phasic pattern of neuronal activity has been previously described in detail for magnocellular vasopressin neurons in the hypothalamic paraventricular and supraoptic nuclei. This characteristic bistable pattern consists of alternating periods of electrical silence and elevated neuronal firing, implicated in neuropeptide release. Here, with the use of multi-electrode array recordings , we aimed to study the firing pattern of neurons in the nucleus of the solitary tract (NTS) - the brainstem hub for homeostatic, cardio-vascular, and metabolic processes. Our recordings from the mouse and rat hindbrain slices reveal the phasic activity pattern to be displayed by a subset of neurons in the dorsomedial NTS subjacent to the area postrema (AP), with the inter-spike interval distribution closely resembling that reported for phasic magnocellular vasopressin cells. Additionally, we provide interspecies comparison, showing higher phasic frequency and firing rate of phasic NTS cells in mice compared to rats. Further, we describe daily changes in their firing rate and pattern, peaking at the middle of the night. Last, we reveal these phasic cells to be sensitive to adrenergic receptors activation and to respond to electrical stimulation of the AP. This study provides a comprehensive description of the phasic neuronal activity in the rodent NTS and identifies it as a potential downstream target of the AP noradrenergic system.

Circadian actions of orexins on the retinorecipient lateral geniculate complex in rat.
Rhythmic processes in living organisms are controlled by biological clocks. The orexinergic system of the lateral hypothalamus carries circadian information to provide arousal for the brain during the active phase. Here, we show that orexins exert an excitatory action in three parts of the lateral geniculate nucleus (LGN), in particular upon directly retinorecipient neurons in the non-image forming visual structures. We provide evidence for the high nocturnal levels of orexins with stable circadian expression of predominant orexin receptor 2 in the LGN. Our data additionally establish the convergence of orexinergic and pituitary adenylate cyclase (PAC)-activating peptide/PAC1 receptor systems (used by melanopsin-expressing retinal ganglion cells), which directly regulates responses to the retinal input. These results help us better understand circadian orexinergic control over the non-image forming subcortical visual system, forming the animal's preparedness for the behaviourally active night.

Evaluation of ultrasonic vocalizations in a neurodevelopmental model of schizophrenia during the early life stages of rats.
In an animal neurodevelopmental model of schizophrenia, we investigated ultrasonic communication and social behavior in male and female rats. Pregnant dams were treated with methylazoxymethanol acetate (MAM; 22 mg/kg) at 17 days of gestation. First, we examined the ultrasonic vocalizations (USVs) emitted by 8-day-old pups isolated from their mothers and placed in a familiar or an unfamiliar environment. Second, we assessed tickling-induced USVs, social play (SP) behavior and accompanying USVs in 30-day-old juveniles. Independent of the prenatal treatment, sex differences were noted at both ages. In the pups isolated from their mothers, compared to the females, the males produced flatter calls with a lower frequency. Compared to the females, the tickling-induced male USVs were characterized by a higher frequency, and the male SP-induced USVs showed a broader bandwidth and more modulated structure. Additionally, the numbers of both SP-induced USVs and SP episodes in the males were higher than those in the females. In contrast, the MAM exposure reduced the ultrasonic communication and social behavior independent of age almost equally in the male and female rats. The MAM-exposed isolated pups and juveniles experiencing tickling and social interaction displayed lower USV bandwidths, suggesting that the complexity of their ultrasonic communication was reduced. In addition, the MAM-exposed juveniles demonstrated a lower number of 50-kHz "happy calls" and decreased SP duration, which is suggestive of social withdrawal or negative-like symptoms. These data demonstrate that young MAM-exposed rats display an atypical repertoire of USVs and reduced play behavior suggestive of communication deficits associated with schizophrenia.

Aims: Sodium salicylate is commonly used as a pharmacological model for tinnitus in laboratory animals. The effects of salicylate on the detection of amplitude modulated (AM) sound are unknown. Here, we assessed the salicylate-induced effect on behavioural AM detection thresholds and neuronal AM coding in the inferior colliculus (IC). **Methods:** Six B6CBAF1/J mice were trained and tested in a Go-No-Go AM detection task. The detection thresholds for 16 Hz and 512 Hz AM noise were assessed in blocks of 3 consecutive days both before, during and after injections with salicylate (daily 250 mg/kg i.p., 2 hours before first session). Acute electrophysiological recordings were performed in the IC of 10 mice under ketamine/xylazine anaesthesia using multichannel silicon arrays. Spike sorting was performed using Kilosort2 to isolate single units. Pure tone, AM noise and dynamic random chord (DRC) stimuli were presented. After a baseline recording period, sodium salicylate was injected, and its effect on the responses was evaluated in the same units. DiO-stained electrode tracks were retrieved in histology to estimate subregional localization of recorded units. Plasma salicylate concentrations were measured. **Results:** Salicylate improved the behavioural sensitivity of mice to amplitude modulations. Upon salicylate, most IC neurons showed lower spontaneous activity, elevated pure-tone thresholds and improved responses to AM stimuli as measured by spike rate and vector strength; spectral-temporal receptive fields became more predictive of the response to DRCs. **Conclusion:** Salicylate unexpectedly improved AM sensitivity in mice, reflected both in neuronal activity in the auditory midbrain and in lower behavioural detection thresholds.

SOUND REPRESENTATIONS IN THE AUDITORY BRAINSTEM OF AWAKE MICE

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Etienne Gosselin[1], Jérôme Bourien[2], Jean-Luc Puel[3], Brice Bathellier[4]
[1]Institut Pasteur, Institut De L'audition, Paris, France, [2]University of Montpellier - Inserm, Institute For Neurosciences Of Montpellier - Inserm U1298, Montpellier cedex , France, [3]Inserm - University of Montpellier, Institute For Neuroscience Of Montpellier, Montpellier, France, [4]Institut Pasteur, INSERM, Institut De L'audition, Paris, France

Sound information is shaped along the auditory pathway to generate sound perception. Yet, even the transformation occurring at the first processing steps remain incompletely understood due to the difficulty to record large number of neurons in the auditory brainstem areas in awake freely listening animals. Here, we used the length and high contact density of Neuropixels 1.0 probes to record neurons from the cochlear nucleus (CN), superior olivary complex (SOC) and inferior colliculus (IC) regions together in head-fixed, awake mice listening passively to a set of 307 short (<500ms) artificial sounds and 10 long (30s) sounds from natural environments. The set of sounds was designed to include sounds of increasing complexity: diverse categories of simple sounds, complex sounds (bird songs, music), as well as partial and complete reconstructions of the complex sounds. We compared the responses recorded with known properties in anesthetized animals and confirmed the presence of primary-like and onset responses. While the responses to more complex sounds remain to be analyzed, we also developed models to capture the transformations from a precise biophysical model of the cochlea to brainstem.

Chrysoula Giasafaki* [1], Noelia Antón-Bolaños* [1,2] and Guillermina López-Bendito [1]
[1] Instituto de Neurociencias de Alicante, UMH-CSIC, Sant Joan d´ Alacant, Spain [2] Department of Stem Cell and Regenerative Biology, Harvard University, Cambridge, MA, USA The majority of sensory and motor information is conveyed to the cerebral cortex through the thalamocortical axons (TCAs). Thalamocortical connectivity is very precise and formed prenatally, thus it plays a crucial role in several aspects of cortical development such as cortical area specification, identity and wiring. However, the mechanisms by which TCAs regulate the establishment and plasticity of these cortical features remain largely unknown. To this end, our aim is to determine the capacity of TCAs to compete for neocortical space and impose a sensory input when the thalamus has been genetically manipulated. To achieve this, we have developed a genetic approach to selectively ablate the medial geniculate body (MGB) of the auditory thalamus very early in embryonic development before thalamic axons reach the cortical plate. As a result, these mice develop normally receiving peripheral sensory input, but lacking a specific thalamic relay station. We found a rewired auditory pathway with misrouted auditory TCAs passing through the somatosensory thalamic nucleus as well as an increased primary somatosensory cortex. Furthermore, we observed additional inter-modal and intra-modal changes occurring in our ablated model. This study will provide essential information not only for the development of thalamocortical projections, but also for the capacity of spared sensory circuits to rewire following an early thalamic manipulation.

Cross-hierarchical plasticity of corticofugal projections to dLGN after neonatal monocular enucleation.
Perception is the result of interactions between the sensory periphery, thalamus, and cerebral cortex. Inputs from the retina project to the first-order dorsal lateral geniculate nucleus (dLGN), which projects to the primary visual cortex (V1). In return, the cortex innervates the thalamus. While layer 6 projections innervate all thalamic nuclei, cortical layer 5 neurons selectively project to the higher order lateral posterior nucleus (LP) and not to dLGN. It has been demonstrated that a subpopulation of layer 5 (Rbp4-Cre+) projections rewires to dLGN after monocular or binocular enucleation in young postnatal mice. However, the exact cortical regional origin of these projections was not fully determined, and it remained unclear whether these changes persisted into adulthood. In this study, we report gene expression changes observed in the dLGN after monocular enucleation at birth using microarray, qPCR at P6, and in situ hybridization at P8. We report that genes that are normally enriched in dLGN, but not LP during development are preferentially downregulated in dLGN following monocular enucleation. Comparisons with developmental gene expression patters in dLGN suggest more immature and delayed gene expression in enucleated dLGN. Combined tracing and immuno-histochemical analysis revealed that the induced layer 5 fibers that innervate enucleated dLGN originate from putative primary visual cortex and they retain increased VGluT1+ synapse formation into adulthood. Our results indicate a new form of plasticity when layer 5 driver input takes over the innervation of an originally first-order thalamic nucleus after early sensory deficit.

CORTICO-FUGAL REGULATION OF PREDICTIVE CODING

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Alexandria Lesicko[1], Christopher Angeloni[1], Jennifer Blackwell[2], Mariella De Biasi[3], Maria Geffen[1]
[1]University of Pennsylvania, Departments Of Otorhinolaryngology, Neuroscience And Neurology, Philadelphia, United States of America, [2]Stony Brook University, Department Of Neurobiology And Behavior, Stony Brook, United States of America, [3]University of Pennsylvania, Departments Of Psychiatry, Systems Pharmacology And Experimental Therapeutics, And Neuroscience, Philadelphia, United States of America

Sensory cues are differentially encoded depending on the contextual stream in which they are embedded. This adaptation can be understood through a predictive coding framework, in which responses to predictable stimuli become attenuated (repetition suppression), while unexpected cues elicit a prediction error response. In the auditory system, prediction error first appears at the level of the auditory midbrain, or inferior colliculus (IC), and is most prominent in the auditory cortex (AC). To determine the role of descending connections from AC to IC in predictive coding, we selectively suppressed the cortico-collicular (CC) pathway while recording responses to predictable and unpredictable stimuli in IC. To selectively target auditory CC cells, we made bilateral injections of a retro AAV-Cre construct in IC, while injecting an AAV-Flex-ArchT construct in AC. We performed extracellular recordings in IC in awake mice while playing tone sequences designed to parse prediction error and repetition suppression effects, suppressing CC cells on a fraction of trials. We found that suppression of the CC pathway led to a decrease in prediction error but did not affect repetition suppression. We also discovered populations of IC neurons that exhibit repetition enhancement, an increase in firing with stimulus repetition, and negative prediction error, a stronger response to a tone in a predictable rather than unpredictable context, both of which were suppressed during CC inactivation. Neurons in IC responded more similarly to each context in the absence of cortical input, suggesting that AC provides cues about the statistical context of sound to subcortical brain regions.

BRAIN-WIDE MAPPING OF AUDITORY-EVOKED RESPONSES IN DANIONELLA

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Joerg Henninger, Maximilian Hoffmann, Mykola Kadobianskyi, Benjamin Judkewitz
Charite, Judkewitz Lab, Berlin, Germany

Our understanding of how auditory information is transformed along the auditory pathway is still limited and would greatly benefit from dense recordings of neuronal population activity across brain areas. Yet, the size and opacity of vertebrate brains make it technically challenging to monitor brain-wide activity at a temporally and spatially high resolution. To fill this gap, we recently introduced a novel model organism, the teleost fish Danionella cerebrum. Danionella combines small size, genetic tractability, and brain transparency with the complexity of a mature vertebrate and thereby enables new ways to explore distributed neuronal circuits. At the same time our data show that Dc exhibit complex behaviours including acoustic communication. Here, we developed a custom-tailored microscope (image transfer oblique plane microscope, ITOPM) to enable the recording of quasi-synchronous neural activity across the majority of the Danionella brain with single-cell resolution at 1 Hz volume rate during auditory stimulation. Using whole-brain oblique plane microscopy we identify Danionella's major auditory processing areas spanning hindbrain, midbrain and forebrain. Our data demonstrates that the acoustic processing of pure tones and pulses is already segregated at the level of the acoustic nuclei in the hindbrain. Finally, we show how tuning specificity and sensitivity of cells increases with the transition from hindbrain to midbrain and how reponses to vocalisation mimics systematically vary along the whole acoustic pathway.

GABAERGIC NEURONS OF THE POSTERIOR NUCLEUS BASALIS MODULATE INFORMATION PROCESSING IN THE AUDITORY PATHWAY

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Kevin Thomas, Hamid Azimi, Pilar Vaca Sánchez, Michael Harvey, Gregor Rainer
University of Fribourg, Department Of Medicine, Fribourg, Switzerland

The posterior Nucleus Basalis (pNB) is a subset of the basal forebrain (BF) regulating the auditory pathway, that contains extensively documented cholinergic projections, but also GABAergic neurons projecting to cortex as well as thalamus. Here, we study how optogenetic manipulation of pNB GABAergic neurons impacts auditory neural circuit responses and auditory based behavior. We designed an auditory detection paradigm in which animals had to detect a relevant target stimulus in the presence of auditory noise. Freely moving rats were trained to hold down a lever and release it upon presentation of a narrow bandpass-filtered auditory stimulus in the presence of a broad-band masking noise. When inhibiting the pNB- parvalbumin expressing (PV) neurons only, we observed robust impairment of stimulus detection. While activating the same population did not modify detection abilities, more general activation of the entire pNB-GABAergic population using mDlx improved detection. In parallel, we recorded LFP and single-unit activity under isoflurane anesthesia in pNB, primary auditory cortex (A1), and the auditory responsive thalamic medial geniculate nucleus (MGN), during similar optogenetics manipulations. We document suppression of neural responses to the target stimulus in the presence of masking noise in MGN and A1. PV specific 40Hz stimulation elicited frequency-specific modulation of neural activity in MGN and A1. In addition, we observed 40Hz entrainment in A1 following pNB-GABAergic population activation using mDlx. Our studies suggest that distinct populations of pNB-GABAergic neurons may exert important influences on auditory information processing, complementing neuromodulatory effects due to cholinergic projections.

Role of the Thalamus in Basal Forebrain Regulation of Neural Activity in the Primary Auditory Cortex.
Many studies have implicated the basal forebrain (BF) as a potent regulator of sensory encoding even at the earliest stages of or cortical processing. The source of this regulation involves the well-documented corticopetal cholinergic projections from BF to primary cortical areas. However, the BF also projects to subcortical structures, including the thalamic reticular nucleus (TRN), which has abundant reciprocal connections with sensory thalamus. Here we present naturalistic auditory stimuli to the anesthetized rat while making simultaneous single-unit recordings from the ventral medial geniculate nucleus (MGN) and primary auditory cortex (A1) during electrical stimulation of the BF. Like primary visual cortex, we find that BF stimulation increases the trial-to-trial reliability of A1 neurons, and we relate these results to change in the response properties of MGN neurons. We discuss several lines of evidence that implicate the BF to thalamus pathway in the manifestation of BF-induced changes to cortical sensory processing and support our conclusions with supplementary TRN recordings, as well as studies in awake animals showing a strong relationship between endogenous BF activity and A1 reliability. Our findings suggest that the BF subcortical projections that modulate MGN play an important role in auditory processing.

HIDDEN HEARING-LOSS AND INFORMATION TRANSMISSION IN THE AUDITORY MIDBRAIN

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Juan Fuentes[1], Roland Schaette[2], David Mcalpine[1]
[1]Australian Hearing Hub, Linguistics, Macquarie Park, Australia, [2]University College London, Ear Institute, London, United Kingdom

Hidden hearing-loss (HHL) refers to listening difficulties in noisy environments, suggested to arise from over-exposure to loud sounds that spares hearing sensitivity but damages high-threshold auditory nerve fibres. Perceptual and physiological effects haven't been fully understood, and as there's no measure to quantify them, our goal is to investigate primitives for an electrophysiological measure of HHL and its consequences to perception. Here we adapt a recently developed framework that combines normative theories and population spike-train data to predict the optimal state in which neural populations of the inferior colliculus (IC) are inferred (via maximum likelihood estimation) to operate. We assessed single- and multi-neuron IC recordings of mice and gerbils, and explored the sample of fitted neural parameters (thresholds and slopes of input-output functions) through a maximum-entropy continuum of models. Relative to unexposed animals, animals exposed to loud sounds sufficient to generate HHL showed increased average coding utility (defined over mutual information) only for quiet acoustic contexts, but the reverse this effect for louder contexts, i.e., unexposed animals achieving increased average coding utility, among other stable differences in more population parameters. This is consistent with exposed animals having an overrepresentation of low-threshold fibres and a compensatory change in neural gain following selective damage to high-threshold auditory fibres. The normative model employed here, the way it is combined with spike-train data, and the consistent effect across different types of auditory stimuli, suggests a potential means of developing an information-theoretic approach to hearing problems not evident in standard hearing tests.

Improving EEG Muscle Artifact Removal With an EMG Array.
Removal of artifacts induced by muscle activity is crucial for analysis of the electroencephalogram (EEG), and continues to be a challenge in experiments where the subject may speak, change facial expressions, or move. Ensemble empirical mode decomposition with canonical correlation analysis (EEMD-CCA) has been proven to be an efficient method for denoising of EEG contaminated with muscle artifacts. EEMD-CCA, likewise the majority of algorithms, does not incorporate any statistical information of the artifact, namely, electromyogram (EMG) recorded over the muscles actively contaminating the EEG. In this paper, we propose to extend EEMD-CCA in order to include an EMG array as information to aid the removal of artifacts, assessing the performance gain achieved when the number of EMG channels grow. By filtering adaptively (recursive least squares, EMG array as reference) each component resulting from CCA, we aim to ameliorate the distortion of brain signals induced by artifacts and denoising methods. We simulated several noise scenarios based on a linear contamination model, between real and synthetic EEG and EMG signals, and varied the number of EMG channels available to the filter. Our results exhibit a substantial improvement in the performance as the number of EMG electrodes increase from 2 to 16. Further increasing the number of EMG channels up to 128 did not have a significant impact on the performance. We conclude by recommending the use of EMG electrodes to filter components, as it is a computationally inexpensive enhancement that impacts significantly on performance using only a few electrodes.

CELL TYPE SPECIFIC AUDITORY RESPONSES IN THE AUDITORY STRIATUM

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Mélanie Druart, Megha Kori, Corryn Chaimowitz, Jan Klee, Tanya Sippy
NYU School of Medicine, Psychiatry - Neuroscience Institut, New York, United States of America

Despite its importance in health and disease, we know remarkably little about sensorimotor transformation (i.e how we assign meaning to and use sensory stimuli to guide behavior). The dorsal striatum is thought to be particularly important for the formation of sensorimotor associations during reinforcement learning due to the dopaminergic inputs it receives, as well as a diverse array of cortical and subcortical inputs. There are two cell types that make up the two output pathways of the dorsal striatum, direct pathway striatal projection neurons (dSPNs) and indirect pathway striatal neurons (iSPNs). While much work has focused on how these pathways might function to initiate movements, very little is known about how sensory learning influences the neuronal activity of these neurons and what effect this has on behavior. In this study, we focus on a the posterior, or auditory striatum (AudStr), that receives dense auditory inputs from both the medial geniculate body (MGB) of the thalamus and primary auditory cortex (A1). We first investigated the sensory response of dSPNs and iSPNs in AudStr by examining the membrane potential (Vm) fluctuation *in vivo* in awake head-fixed animal in response to auditory cues. Interestingly, our results reveal cell-type specific differences: dSPNs show significant subthreshold responses more frequently than iSPNs. We hypothesized these differences are the result of differential connectivity from MGB or A1, and are currently assaying the probability and strength of these connections. In future work, we plan to understand how auditory learning shapes auditory responses onto dSPNs and iSPNs.

Emerging Roles of Complement in Psychiatric Disorders.
The complement system consists of more than 30 proteins that have long been known to participate to the immune defence against pathogens and to the removal of damaged cells. Their role, however, extends beyond immunity and clearance of altered "self" components in the periphery. In particular, complement proteins can be induced by all cell types in the brain. Recent discoveries highlight the role of complement in normal and pathological brain development. Specifically, the complement system mediates synaptic pruning, a developmental process whereby supernumerary synapses are eliminated in the immature brain. The complement system has been implicated in pathological synapse elimination in schizophrenia, West Nile virus infection, and lupus, all of which are associated with psychiatric manifestations. Complement also contributes to synapse loss in neurodegenerative conditions. This review provides a brief overview of the well-studied role of complement molecules in immunity. The contribution of complement to embryonic and adult neurogenesis, neuronal migration, and developmental synaptic elimination in the normal brain is reviewed. We discuss the role of complement in synapse loss in psychiatric and neurological diseases and evaluate the therapeutic potential of complement-targeting drugs for brain disorders.

An Etiological Foxp2 Mutation Impairs Neuronal Gain in Layer VI Cortico-Thalamic Cells through Increased GABA/GIRK Signaling.
A rare mutation affecting the Forkhead-box protein P2 (FOXP2) transcription factor causes a severe monogenic speech and language disorder. Mice carrying an identical point mutation to that observed in affected patients (Foxp2 mice) display motor deficits and impaired synaptic plasticity in the striatum. However, the consequences of the mutation on neuronal function, in particular in the cerebral cortex, remain little studied. Foxp2 is expressed in a subset of Layer VI cortical neurons. Here, we used Ntsr1-EGFP mice to identify Foxp2+ neurons in the mouse auditory cortex We studied the functional impact of the R552H mutation on the morphologic and functional properties of Layer VI cortical neurons from Ntsr1-EGFP; Foxp2 male and female mice. The complexity of apical, but not basal dendrites was significantly lower in Foxp2 cortico-thalamic neurons than in control Foxp2 neurons. Excitatory synaptic inputs, but not inhibitory synaptic inputs, were decreased in Foxp2 mice. In response, homeostatic mechanisms would be expected to increase neuronal gain, i.e., the conversion of a synaptic input into

a firing output. However, the intrinsic excitability of Foxp2+ cortical neurons was lower in Foxp2 neurons. A-type and delayed-rectifier (DR) potassium currents, two putative transcriptional targets of Foxp2, were not affected by the mutation. In contrast, GABA/GIRK signaling, another presumed target of Foxp2, was increased in mutant neurons. Blocking GIRK channels strongly attenuated the difference in intrinsic excitability between wild-type (WT) and Foxp2 neurons. Our results reveal a novel role for Foxp2 in the control of neuronal input/output homeostasis. Mutations of the Forkhead-box protein 2 (FOXP2) gene in humans are the first known monogenic cause of a speech and language disorder. The Foxp2 mutation may directly affect neuronal development and function in neocortex, where Foxp2 is expressed. Brain imaging studies in patients with a heterozygous mutation in FOXP2 showed abnormalities in cortical language-related regions relative to the unaffected members of the same family. However, the role of Foxp2 in neocortical neurons is poorly understood. Using mice with a Foxp2 mutation equivalent to that found in patients, we studied functional modifications in auditory cortex neurons We found that mutant neurons exhibit alterations of synaptic input and GABAB/GIRK signaling, reflecting a loss of neuronal homeostasis.

Elevated expression of complement C4 in the mouse prefrontal cortex causes schizophrenia-associated phenotypes. Accumulating evidence supports immune involvement in the pathogenesis of schizophrenia, a severe psychiatric disorder. In particular, high expression variants of C4, a gene of the innate immune complement system, were shown to confer susceptibility to schizophrenia. However, how elevated C4 expression may impact brain circuits remains largely unknown. We used in utero electroporation to overexpress C4 in the mouse prefrontal cortex. We found reduced glutamatergic input to pyramidal cells of juvenile and adult, but not of newborn C4-overexpressing (C4-OE) mice, together with decreased spine density, which mirrors spine loss observed in the schizophrenic cortex. Using time-lapse two-photon imaging in vivo, we observed that these deficits were associated with decreased dendritic spine gain and elimination in juvenile C4-OE mice, which may reflect poor formation and/or stabilization of immature spines. In juvenile and adult C4-OE mice, we found evidence for NMDA receptor hypofunction, another schizophrenia-associated phenotype, and synaptic accumulation of calcium-permeable AMPA receptors. Alterations in cortical GABAergic networks have been repeatedly associated with schizophrenia. We found that functional GABAergic transmission was reduced in C4-OE mice, in line with diminished GABA release probability from parvalbumin interneurons, lower GAD67 expression, and decreased intrinsic excitability in parvalbumin interneurons. These cellular abnormalities were associated with working memory impairment. Our results substantiate the causal relationship between an immunogenetic risk factor and several distinct cortical endophenotypes of schizophrenia and shed light on the underlying cellular mechanisms.

RESPONSES TO ACOUSTIC STIMULI IN THE VENTRAL TEGMENTAL AREA OF FREELY-MOVING MICE

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Samira Souffi, Israel Nelken
The Hebrew University of Jerusalem, Edmond And Lily Safra Center For Brain Sciences, Jerusalem, Israel

In humans, the neuronal substrates of pleasure-inducing effects of music were described as an interaction between ancient reward mechanisms, believed to be related to dopamine release, and cortical systems which are highly modifiable by individual experience and culture. However, little is known about the encoding of both simple and complex auditory stimuli in the reward system in rodents. Here, we recorded the neuronal activity by using fiber photometry in an important relay of the reward system, the ventral tegmental area (VTA), in freely-moving mice. We compared these responses to the well-understood responses in auditory cortex in anesthetized mice. We compared the temporal patterns of calcium responses in both structures at the presentation of broadband noise, pure tones and music excerpts. We found that VTA neurons responded to all acoustic stimuli but with clear differences compared to auditory cortical responses. In response to broadband noise and pure tones, VTA responses seemed to have somewhat longer latencies than A1 responses. Moreover, A1 responses were often biphasic, with a short-latency component that corresponds to the onset responses in A1 and a later component that peaks a few hundreds of ms after sound onset. In contrast, the responses in VTA consisted of a single component whose duration was significantly longer than the early responses in A1. These data indicate that non-music acoustic stimuli can activate the reward system in awake mice but with different temporal properties compared to the auditory cortex.

UNRAVELLING THE FUNCTIONAL HETEROGENEITY OF RIBBON SYNAPSES FROM COCHLEAR INNER HAIR CELLS

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Lina María Jaime Tobón[1,2,3,4], Tobias Moser[1,2,3,4]
[1]Max Planck Institute for Multidisciplinary Sciences, Auditory Neuroscience Group And Synaptic Nanophysiology Group, Göttingen, Germany, [2]University of Göttingen, Cluster Of Excellence "multiscale Bioimaging: From Molecular Machines To Networks Of Excitable Cells", Göttingen, Germany, [3]University Medical Center Göttingen, Institute For Auditory Neuroscience & Innerearlab, Göttingen, Germany, [4]University Medical Center Göttingen, Collaborative Research Center 889, Göttingen, Germany

Synaptic heterogeneity can expand the encoding capacity of individual neurons or sensory cells. In the auditory system, the ribbon synapses between cochlear inner hair cells (IHCs) and spiral ganglion neurons (SGNs) exhibit a high degree of heterogeneity. At the presynaptic level, one individual IHC contains 10 to 30 active zones that differ in their size as well as in the number and function of Ca^{2+} channels. This presynaptic heterogeneity follows a particular gradient along the neural/abneural axis of the IHC. Synapses from the neural side have larger active zones and Ca^{2+} channel clusters, yet require stronger depolarizations to elicit Ca^{2+} influx. At the postsynaptic level, SGNs exhibit differences in their spontaneous activity, spike rate adaptation and operating range. However, the connection between presynaptic IHC's heterogeneity and postsynaptic SGN's response diversity has remained elusive. Here, we studied the *synaptic* heterogeneity of murine IHC ribbon synapses using paired pre- and postsynaptic bouton recordings at near physiological conditions. Our results emphasize that IHC synapses have differences in the spontaneous rate (SR) of release that depend on the topographical position of the synapses. High SR synapses were located predominantly at the abneural side of the IHC and displayed spontaneous EPSCs of higher amplitude and more compact waveform. High SR synapses also had lower thresholds for evoked neurotransmitter release, shorter response latencies and stronger initial release rates. This study reveals that IHCs employ heterogeneous synapses to provide different input into SGNs that collectively code the wide range of audible sound intensities.

Endophilin-A regulates presynaptic Ca influx and synaptic vesicle recycling in auditory hair cells.
Ribbon synapses of cochlear inner hair cells (IHCs) operate with high rates of neurotransmission; yet, the molecular regulation of synaptic vesicle (SV) recycling at these synapses remains poorly understood. Here, we studied the role of endophilins-A1-3, endocytic adaptors with curvature-sensing and curvature-generating properties, in mouse IHCs. Single-cell RT-PCR indicated the expression of endophilins-A1-3 in IHCs, and immunoblotting confirmed the presence of endophilin-A1 and endophilin-A2 in the cochlea. Patch-clamp recordings from endophilin-A-deficient IHCs revealed a reduction of Ca influx and exocytosis, which we attribute to a decreased abundance of presynaptic Ca channels and impaired SV replenishment. Slow endocytic membrane retrieval, thought to reflect clathrin-mediated endocytosis, was impaired. Otoferlin, essential for IHC exocytosis, co-immunoprecipitated with purified endophilin-A1 protein, suggestive of a molecular interaction that might aid exocytosis-endocytosis coupling. Electron microscopy revealed lower SV numbers, but an increased occurrence of coated structures and endosome-like vacuoles at IHC active zones. In summary, endophilins regulate Ca influx and promote SV recycling in IHCs, likely via coupling exocytosis to endocytosis, and contributing to membrane retrieval and SV reformation.

The synaptic ribbon is critical for sound encoding at high rates and with temporal precision.
We studied the role of the synaptic ribbon for sound encoding at the synapses between inner hair cells (IHCs) and spiral ganglion neurons (SGNs) in mice lacking RIBEYE (RBE). Electron and immunofluorescence microscopy revealed a lack of synaptic ribbons and an assembly of several small active zones (AZs) at each synaptic contact. Spontaneous and sound-

evoked firing rates of SGNs and their compound action potential were reduced, indicating impaired transmission at ribbonless IHC-SGN synapses. The temporal precision of sound encoding was impaired and the recovery of SGN-firing from adaptation indicated slowed synaptic vesicle (SV) replenishment. Activation of Ca-channels was shifted to more depolarized potentials and exocytosis was reduced for weak depolarizations. Presynaptic Ca-signals showed a broader spread, compatible with the altered Ca-channel clustering observed by super-resolution immunofluorescence microscopy. We postulate that RIBEYE disruption is partially compensated by multi-AZ organization. The remaining synaptic deficit indicates ribbon function in SV-replenishment and Ca-channel regulation.

OPTIMIZING STIMULUS PARAMETERS FOR ULTRAFAST COCHLEAR OPTOGENETIC ENCODING

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Artur Mittring, Tobias Moser, Antoine Huet
University Medical Center Goettingen, Institute For Auditory Neuroscience, Goettingen, Germany

Spatially confined optogenetic stimulation of the spiral ganglion neurons (SGNs) represents a prospective alternative to electrical stimulation currently used in cochlear implants (CI) and opens up new perspective to study neural networks in the auditory pathway. Identifying the optimal stimulation parameters (light pulse duration and repetition rate) is critical to optogenetically control the SGNs firing, to develop the sound coding strategies of the future optical cochlear implant, and to computationally model the biophysical parameters of optogenetically driven SGN firing *in vivo*. Those parameters can be empirically measured by *in vivo* single SGN juxta-cellular recordings in response to optical stimulation delivered into the cochlea. Nonetheless, those recordings are limited in time and, hence, measuring all combinations of interests per SGN using deterministic stimulus is challenging. Therefore, we developed and validated an optical stochastic stimulus paradigm containing the combination of pulse duration and repetition rate of interest. The validation was done by recording *in vivo* from mice single SGNs expressing targeting optimized Chronos (Keppeler et al., 2018) and transduced using a viral approach (AAV-PHP.B, human synapsin promoter, titer = 3.3-8.4 x 10^{12} GC/ml, early postnatal injection). This stimulus paradigm allowed us to identify optimal illumination parameters of SGNs in minutes. Our results will be used to analyze neural network function in the auditory brainstem and to design coding strategies for the future optical CI.

EVOLUTIONARY DEVELOPMENT OF EXCITATORY PROJECTION NEURONS IN MAMMALIAN SOUND LOCALIZATION CIRCUITS

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Denise Krissel
Carl von Ossietzky University, Department For Neuroscence, Oldenburg, Germany

Three neuronal populations in the mammalian auditory brainstem enable sound localization: the Dorsal Cochlear Nucleus, the Lateral Superior Olive and the Medial Superior Olive. Fusiform VGluT2-positive excitatory neurons make up the major projection neurons in these populations and simultaneously emerge from the rhombic lip of rhombomere 5 at embryonic day 10. This study aims to determine the evolutionary and developmental relationship between these subpopulations. By single nucleus mRNA sequencing of these Vglut2-positive cells the underlying gene regulatory networks are to be reconstructed. To ensure unambiguous identification of the cells of interest the *VGluT2::Cre;H2BmCherry* mouse line is utilized which expresses the fluorescent histone-bound protein *H2BmCherry* specifically in all VGluT2-positive cells. Starting with established, publicly available protocols the procedures were adjusted and scaled to suit our particular needs and to obtain high quality single nuclei of all three neuronal subpopulations. Many steps of the initial sample processing were adjusted to gain a higher yield or a better quality of nuclei from fresh, unfixed mouse brain tissue; from the preparation of the tissue to dissection, digestion, isolation and storage of the single nuclei towards final protocol modifications to fit size and age of the input material. At this step of the project I conclude that murine brain tissue is best stored in a high-salt solution at 4°C for a maximum of two days. Further, gradient centrifugation gently and efficiently separates nuclei from debris. Any alteration of the centrifugation times or -forces during these steps can cause severe loss or damage to the sample.

THE INTERPLAY BETWEEN SENSORY AND COGNITIVE NEURODEGENERATION: COCHLEAR VULNERABILITY TO NOISE EXPOSURE IN A MODEL OF ALZHEIMER'S DISEASE.

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Anna Pisani[1], Fabiola Paciello[2], Rolando Rolesi[1], Raffaele Montuoro[1], Gaetano Paludetti[1], Claudio Grassi[2], Anna Rita Fetoni[1,3]

Aim: Recent epidemiological evidence suggests a strong association between hearing loss and cognitive decline with increased risk for the onset of neurodegenerative disorders, including Alzheimer's disease (AD). Several hypotheses have been proposed to explain the relationship between auditory deprivation and cognitive impairment, but such association remains still controversial. We previously reported that noise exposure can accelerate cognitive decline in an AD animal model (3×Tg-AD mice). Here, we wondered if cochlear structures in AD mice could be most vulnerable to noise-induced hearing loss. **Methods:** Wild type (WT) and 3×Tg-AD mice were exposed to noise (100 dB, 10 kHz, 60 min/day, 10 days) at 2 months of age (M), before the cognitive phenotype is manifested. Functional and morphological evaluations were performed to assess auditory threshold and cochlear structure alterations (hair cells, spiral ganglion neurons, afferent nerve fibers). Analyses of AD hallmarks (increased Tau phosphorylation, inflammatory and oxidative stress makers) were carried out. **Results:** Morphological analyses showed a significant neuronal damage (reduction of spiral ganglion neurons and afferent fibers) in noise-exposed AD mice. Western Blot results displayed an increase of phosphorylation levels of Tau (ser396) following noise, probably mediated by Cdk5 up-regulation. Also, an increase of oxidative stress and inflammatory markers expression (TNFα and NF-κB) confirmed the high susceptibility of cochlear tissue to noise-insult in the neurodegenerative model. **Conclusion:** Our findings demonstrates that 3×Tg-AD mice are more vulnerable to cochlear damage induced by noise exposure, and supports the hypothesis that hearing loss can affect both sensory and cognitive neurodegenerative processes, exacerbating AD pathology.

ROLE OF THE FERRITIN LIGHT-CHAIN IN THE LOGIC OF SOUND CODING

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Chloé Petit[1], Sahia Mahaman Bachir Dodo[1], Anne-Gabrielle Harrus[1], Cécilia Souyris[1], Jing Wang[1], Jérôme Bourien[2], Rémy Pujol[1], Frédéric Venail[1], Ruben Vidal[3], Jean-Luc Puel[1], Régis Nouvian[1]

Hearing relies on the recruitment of two populations of cochlear sensory cells, the outer hair cells (OHCs) and the inner hair cells (IHCs). While the pool of outer hair cells amplifies incoming sound-stimulation to achieve exquisite frequency selectivity, the inner hair cells transduce the mechanical pressure into release of glutamate onto the postsynaptic receptors of the auditory nerve fibers. Hair cells active zones harbor a synaptic ribbon, an electron-dense organelle surrounded by a monolayer of glutamate-filled vesicles. Using yeast-two hybrid assay, we isolated the ferritin light-chain (FTL1), known to store intracellular iron, as an interacting partner of RIBEYE, the major component of the ribbon body. Here, our objective is to probe the function of FTL1 in the logic of sound coding. In the FTL1 knock-out mouse, we found-out an auditory threshold shift in 20% of the homozygous mice associated with the loss of the distortion product of otoacoustic emissions, as a proxy of the OHC's activity. Consistently, light and electron microscopy show a progressive massive degeneration of the OHCs. In addition, we found-out splayed hair bundle in IHCs in the fraction of $FTL1^{-/-}$ with threshold shift. However, the loss of FTL1 did not change the number and size of the hair cell's synaptic ribbons. We propose that ferritin may protect up to some extent the hair cells against iron-induced oxidative stress. Moreover, the interaction between FTL1 and RIBEYE might suggest that ribbon synapse is vulnerable to free radicals.

KV4.2 KNOCKOUT MICE HAVE INCREASED AUDITORY SUPRATHRESHOLD RESPONSES BUT POOR GAP DETECTION

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Dora Persic, Pim Van Dijk, Sonja Pyott
University Medical Center Groningen, Otorhinolaryngology, Groningen, Netherlands

Aims. Type I spiral ganglion neurons transmit acoustic information from cochlear inner hair cells to the auditory brainstem. An important regulator of their function are potassium channels. We set out to determine the influence of the potassium channel Kv4.2 on hearing, susceptibility to noise-induced hearing loss, and auditory temporal processing using measurements of auditory brainstem responses and gap detection in Kv4.2 knockout (KO) and wildtype (WT) animals. Methods. Auditory brainstem responses (ABR) were collected from C57BL/6 and Kcnd2-/- animals at baseline (6 weeks old) and one week following acoustic overexposure. Auditory temporal acuity was assessed by gap prepulse inhibition of the acoustic startle reflex (GPIAS). Results. KO animals showed greater wave I amplitudes at most tested frequencies. Following acoustic overexposure, KO animals lost these advantages and showed no difference in either thresholds or wave I amplitudes from WT animals. Preliminary GPIAS results indicate poor temporal acuity in Kv4.2 KO animals based on an inability to supress startle responses by silent gaps, in spite of otherwise normal prepulse inhibition. Conclusion. The lack of Kv4.2 leads to increased wave I suprathreshold responses without greatly affecting auditory thresholds, presumably as a result of spiral ganglion neuron hyperexcitability. This increased excitability rendered KO animals more susceptible to noise-induced hearing loss. However, the increased suprathreshold responses did not lead to improved temporal acuity; in contrary, KO animals appear to have poor gap detection. Further experiments should resolve whether this deficit is arising from peripheral or central hyperexcitability.

FUNCTIONAL CHARACTERIZATION OF THE BASAL COCHLEAR INNER HAIR CELLS UPON NOISE EXPOSURE

POSTER SESSION 03 - SECTION: COCHLEAR & SUBCORTICAL AUDITORY PROCESSING

Mauro Alfonso Malpede[1,2], David Oestreicher[1,3], Annalena Reitmeier[1], Tina Pangrsic[1]
[1]Experimental Otology Group, InnerEarLab, Department of Otolaryngology, University Medical Center Göttingen, Göttingen, Germany, Göttingen, Germany, [2]Collaborative Research Center 889, University of Göttingen, Göttingen, Germany., Göttingen, Germany, [3]Auditory Neuroscience Group, Max Planck Institute of Experimental Medicine, Göttingen, Germany, Göttingen, Germany

Acoustic overexposures are the primary cause of hearing loss nowadays. In animal models, histological analysis of the cochlea after exposure to acoustic trauma revealed damages of cellular structures, such as stereocilia and ribbon synapses of the inner hair cells (IHCs).
Unlike the extensive knowledge on the anatomical aspects, much less is known about the noise-induced functional changes on the IHC ribbon synapses and synaptic transmission to the spiral ganglion neurons (SGNs). Despite the basal region of the cochlea being recognized as the most vulnerable to noise overexposure, the only data on the effects of noise exposure on the IHC synaptic function so far come from patch-clamp recordings of the apical end of the cochlea.
Here we show for the first time patch-clamp recordings of basal IHCs (bIHCs) after noise trauma protocols that caused a permanent threshold shift (PTS) of the auditory brainstem response (ABR). Anaesthetized mice were exposed to 8-16 kHz noise at different sound pressure levels and used for both patch-clamp recordings and immunohistochemistry of ribbon synapses immediately after and two weeks after exposure. While significant increase in ABR thresholds was observed after exposure across all tested noise intensities and lasted for at least 2 weeks afterwards, this was accompanied by no IHC synaptic loss. In line with this notion, no functional alterations have been found either in the Ca^{2+} -dependent exocytosis of bIHCs or in the voltage-dependent whole-cell calcium influx. Further experiments are needed to better investigate the functional properties of the bIHCs synapses after noise trauma.

INFORMATION CONTENT AND ROUTING OF VISUOMOTOR SIGNALS IN THE CORTEX

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Anderson Speed, Bilal Haider
Georgia Institute of Technology, Biomedical Engineering, Atlanta, United States of America

Flexible sensorimotor transformations are a hallmark of complex cognitive behaviors. It remains unclear if specific sensory information gets routed to motor areas of the cortex, or if motor areas dispense with detailed sensory representations. By simultaneously measuring neural activity in both sensory and premotor areas during a flexible sensorimotor transformation, we can begin to identify principles governing the information content and routing of signals relevant for sensorimotor behaviors. We developed a novel behavioral task where head-fixed mice report detection of different visual stimuli with different actions (N = 5 mice). Mice licked left to report stimuli detected in the central (binocular) visual field, and licked right when detecting stimuli in the right (monocular) visual field. Stimuli were presented in blocks of 15-35 trials in the same location before switching. Behavioral performance varied psychometrically with contrast at each stimulus location. We next performed acute recordings with Neuropixels probes in primary visual cortex (V1) and anterolateral motor cortex (ALM). Peristimulus time histograms from both areas showed clear short-latency (<0.2 s) effects of stimulus location and trial outcome (hit vs miss). To assess the specificity of visual information routed to ALM, we leveraged simultaneous recordings from V1 and ALM. ALM and V1 neurons whose stimulus preference matched showed stronger and more temporally reliable [HB1] pairwise correlations than ALM and V1 neurons with opposite stimulus preferences. These trial-by-trial relationships exhibited both location and visual contrast specificity[HB2] . We are currently investigating whether these functional relationships flexibly change in the context of updated stimulus-reward contingencies.

Probing mechanisms of visual spatial attention in mice.
The role of spatial attention for visual perception has been thoroughly studied in primates, but less so in mice. Several behavioral tasks in mice reveal spatial attentional effects, with similarities to observations in primates. Pairing these tasks with large-scale, cell-type-specific techniques could enable deeper access to underlying mechanisms, and help define the utility and limitations of resolving attentional effects on visual perception and neural activity in mice. In this Review, we evaluate behavioral and neural evidence for visual spatial attention in mice; assess how specializations of the mouse visual system and behavioral repertoire impact interpretation of spatial attentional effects; and outline how several measurement and manipulation techniques in mice could precisely test and refine models of attentional modulation across scales.

Spatial modulation of dark versus bright stimulus responses in the mouse visual system.
A fundamental task of the visual system is to respond to both increases and decreases of luminance with action potentials (ON and OFF responses). OFF responses are stronger, faster, and more salient than ON responses in primary visual cortex (V1) of both cats and primates, but in ferrets and mice, ON responses can be stronger, weaker, or balanced in comparison to OFF responses. These discrepancies could arise from differences in species, experimental techniques, or stimulus properties, particularly retinotopic location in the visual field, as has been speculated; however, the role of retinotopy for ON/OFF dominance has not been systematically tested across multiple scales of neural activity within species. Here, we measured OFF versus ON responses across large portions of visual space with silicon probe and whole-cell patch-clamp recordings in mouse V1 and lateral geniculate nucleus (LGN). We found that OFF responses dominated in the central visual field, whereas ON and OFF responses were more balanced in the periphery. These findings were consistent across local field potential (LFP), spikes, and subthreshold membrane potential in V1, and were aligned with spatial biases in ON and OFF responses in LGN. Our findings reveal that retinotopy may provide a common organizing principle for spatial modulation of

OFF versus ON processing in mammalian visual systems.

Diminished Cortical Excitation and Elevated Inhibition During Perceptual Impairments in a Mouse Model of Autism.
Sensory impairments are a core feature of autism spectrum disorder (ASD). These impairments affect visual perception and have been hypothesized to arise from imbalances in cortical excitatory and inhibitory activity. There is conflicting evidence for this hypothesis from several recent studies of transgenic mouse models of ASD; crucially, none have measured activity from identified excitatory and inhibitory neurons during simultaneous impairments of sensory perception. Here, we directly recorded putative excitatory and inhibitory population spiking in primary visual cortex (V1) while simultaneously measuring visual perceptual behavior in CNTNAP2-/- knockout (KO) mice. We observed quantitative impairments in the speed, accuracy, and contrast sensitivity of visual perception in KO mice. During these perceptual impairments, stimuli evoked more firing of inhibitory neurons and less firing of excitatory neurons, with reduced neural sensitivity to contrast. In addition, pervasive 3-10 Hz oscillations in superficial cortical layers 2/3 (L2/3) of KO mice degraded predictions of behavioral performance from neural activity. Our findings show that perceptual deficits relevant to ASD may be associated with elevated cortical inhibitory activity along with diminished and aberrant excitatory population activity in L2/3, a major source of feedforward projections to higher cortical regions.

Spatial attention enhances network, cellular and subthreshold responses in mouse visual cortex.
Internal brain states strongly modulate sensory processing during behaviour. Studies of visual processing in primates show that attention to space selectively improves behavioural and neural responses to stimuli at the attended locations. Here we develop a visual spatial task for mice that elicits behavioural improvements consistent with the effects of spatial attention, and simultaneously measure network, cellular, and subthreshold activity in primary visual cortex. During trial-by-trial behavioural improvements, local field potential (LFP) responses to stimuli detected inside the receptive field (RF) strengthen. Moreover, detection inside the RF selectively enhances excitatory and inhibitory neuron responses to task-irrelevant stimuli and suppresses noise correlations and low frequency LFP fluctuations. Whole-cell patch-clamp recordings reveal that detection inside the RF increases synaptic activity that depolarizes membrane potential responses at the behaviorally relevant location. Our study establishes that mice display fundamental signatures of visual spatial attention spanning behavioral, network, cellular, and synaptic levels, providing new insight into rapid cognitive enhancement of sensory signals in visual cortex.
Nat Commun, 2020; 11
30865879: Speed A, Del Rosario J, Burgess CP, Haider B
Cortical State Fluctuations across Layers of V1 during Visual Spatial Perception.
Many factors modulate the state of cortical activity, but the importance of cortical state variability for sensory perception remains debated. We trained mice to detect spatially localized visual stimuli and simultaneously measured local field potentials and excitatory and inhibitory neuron populations across layers of primary visual cortex (V1). Cortical states with low spontaneous firing and correlations in excitatory neurons, and suppression of 3- to 7-Hz oscillations in layer 4, accurately predicted single-trial visual detection. Our results show that cortical states exert strong effects at the initial stage of cortical processing in V1 and can play a prominent role for visual spatial behavior in mice.

A novel device for real-time measurement and manipulation of licking behavior in head-fixed mice.
The mouse has become an influential model system for investigating the mammalian nervous system. Technologies in mice enable recording and manipulation of neural circuits during tasks where they respond to sensory stimuli by licking for liquid rewards. Precise monitoring of licking during these tasks provides an accessible metric of sensory-motor processing, particularly when combined with simultaneous neural recordings. There are several challenges in designing and implementing lick detectors during head-fixed neurophysiological experiments in mice. First, mice are small, and licking behaviors are easily perturbed or biased by large sensors. Second, neural recordings during licking are highly sensitive to electrical contact artifacts. Third, submillisecond lick detection latencies are required to generate control signals that manipulate neural activity at appropriate time scales. Here we designed, characterized, and implemented a contactless dual-port device that precisely measures directional licking in head-fixed mice performing visual behavior. We first determined the optimal characteristics of our detector through design iteration and then quantified device performance under ideal conditions. We then tested performance during head-fixed mouse behavior with simultaneous neural recordings in vivo. We finally demonstrate our device's ability to detect directional licks and generate appropriate control signals in real time to rapidly suppress licking behavior via closed-loop inhibition of neural activity. Our dual-port detector is cost effective and easily replicable, and it should enable a wide variety of applications probing the neural circuit basis of sensory perception, motor

action, and learning in normal and transgenic mouse models. NEW & NOTEWORTHY Mice readily learn tasks in which they respond to sensory cues by licking for liquid rewards; tasks that involve multiple licking responses allow study of neural circuits underlying decision making and sensory-motor integration. Here we design, characterize, and implement a novel dual-port lick detector that precisely measures directional licking in head-fixed mice performing visual behavior, enabling simultaneous neural recording and closed-loop manipulation of licking.

[1]University of Coimbra, Faculty Of Sciences And Technology (fctuc), Coimbra, Portugal, [2]University of Coimbra, Coimbra Institute For Biomedical Imaging And Translational Research (cibit), Coimbra, Portugal, [3]CIBIT, Institute Of Nuclear Sciences Applied To Health (icnas), Coimbra, Portugal, [4]University of Coimbra, Faculty Of Medicine (fmuc), Coimbra, Portugal

Introduction: Dimetiltriptamina (DMT) is an indole alkaloid widely found in nature, best known by its presence in ayahuasca. It is a psychedelic tryptamine associated with intense visual hallucinatory phenomena, perceptual changes and profound spiritual experiences. **Aims:** In this work we questioned if populations of visual neurons do reorganize along eccentricity in response to inhaled DMT. **Methods:** In order to study population receptive field (pRF) properties of visual neurons, whose alterations can be indicative of visual neuronal reorganization in response to inhaled DMT, a cross-sectional study investigating control and DMT condition was conducted at ICNAS/CIBIT. We acquired anatomical and functional MRI data from two groups of individuals 14 naïve for the control condition and 7 DMT experienced individuals for the active condition. Experienced individuals inhaled DMT immediately before acquisition. We used a visual technique called population receptive field (pRF) mapping, an optimized alternative to traditional retinotopy, to estimate the average sizes of pRF in V1 visual area along eccentricity for each participant. **Results:** Since normality assumption was not assured we performed the non parametric Mann-whitney U test. We found statistically significant differences for the central bins of eccentricity, between 0º and 5º (see Table 1 for details). **Discussion and Conclusion:** The average pRF size of V1 was statistically significantly higher for the central bins of eccentricity in active condition (inhaled DMT) which suggests that there is a early level visual reorganization due to inhaled DMT and this reorganization differs for central and peripheral locations.

Table 1 *- Test Statistics (group variable: naive vs DMT).*

	0º and 5º of eccentricity (central)	5º and 10º of eccentricity (peripheral)

The Effects of Tryptamine Psychedelics in the Brain: A meta-Analysis of Functional and Review of Molecular Imaging

Studies.
There is an increasing interest in the neural effects of psychoactive drugs, in particular tryptamine psychedelics, which has been incremented by the proposal that they have potential therapeutic benefits, based on their molecular mimicry of serotonin. It is widely believed that they act mainly through 5HT2A receptors but their effects on neural activation of distinct brain systems are not fully understood. We performed a quantitative meta-analysis of brain imaging studies to investigate the effects of substances within this class (e.g., LSD, Psilocybin, DMT, Ayahuasca) in the brain from a molecular and functional point of view. We investigated the question whether the changes in activation patterns and connectivity map into regions with larger 5HT1A/5HT2A receptor binding, as expected from indolaemine hallucinogens (in spite of the often reported emphasis only on 5HT2AR). We did indeed find that regions with changed connectivity and/or activation patterns match regions with high density of 5HT2A receptors, namely visual BA19, visual fusiform regions in BA37, dorsal anterior and posterior cingulate cortex, medial prefrontal cortex, and regions involved in theory of mind such as the surpramarginal gyrus, and temporal cortex (rich in 5HT1A receptors). However, we also found relevant patterns in other brain regions such as dorsolateral prefrontal cortex. Moreover, many of the above-mentioned regions also have a significant density of both 5HT1A/5HT2A receptors, and available PET studies on the effects of psychedelics on receptor occupancy are still quite scarce, precluding a metanalytic approach. Finally, we found a robust neuromodulatory effect in the right amygdala. In sum, the available evidence points towards strong neuromodulatory effects of tryptamine psychedelics in key brain regions involved in mental imagery, theory of mind and affective regulation, pointing to potential therapeutic applications of this class of substances.

THE ORIENTATION COLUMN AS A WHOLE PROCESSING UNIT : A FALSE IDEA ?

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Rudy Lussiez, Afef Ouelhazi, Stéphane Molotchnikoff
University of Montreal, Biological Sciences, Montreal, Canada

Numerous studies have shown that the cat's secondary visual cortex (V2) is functionally organized, following an orientation column structure similar to V1. This structure is characterized by a uniform orientation selectivity throughout cortical layers, where supragranular and infragranular neurons share the same preferred orientation. This organization relies heavily on the existing functional connections between superficial and deep layers within V2, with the emergence of a stimulus-evoked connectome. This interlayer connectome is the basis of the orientation column, as communications between layers play a large role in unifying the tuning properties. Previous investigations in our lab have shown that the neurons' orientation tuning can be changed using visual adaptation, with a differential effect between superficial and deep layers of V2 (Lussiez, 2020). Moreover, it has been demonstrated that connectomes can change depending on the presented stimulus (Bharmauria,2015). Using electrophysiological recordings in V2, this study aims to observe the effects of adaptation on stimulus-evoked connectomes within and between cortical layers. Our study shows that before adaptation, functional connections between supragranular and infragranular layers are largely dominant compared to intralayer connections, in perfect accordance with the orientation column concept. However, as neurons have changed their orientation preference after adaptation, interlayers connections are greatly reduced, to the benefice of intralayer communication. We hypothesize that while the orientation column may function as a whole processing unit in control conditions, it is comprised of two different « tissues » that can function independently after adaptation, and consequently, it seems that adaptation ruptures the orientation column.

BEHAVIOURAL AND IN VITRO STUDIES ON PROCESSING OF BISTABLE STIMULI IN THE MOUSE VISUAL SYSTEM

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Richard Van Wezel, Laurens Kirkels, Wenjun Zhang, Rezvani Zhara, Naoki Kogo
Donders Institute for Brain, Cognition and Behaviour, Biophysics, Nijmegen, Netherlands

Visual decision mechanisms are often studied using bistable stimuli. In a bistable visual stimulus the evidence for one visual percept is as strong as the evidence for the other percept, but only one of the percepts appears. We studied the basic mechanisms how the brain decides what percept arises. In behavioural experiments we placed mice head-fixed on an air-floating ball at the center of a large dome on the inside of which we projected moving random dot patterns for two seconds. Rightward or leftward moving random dot patterns causes the mice to change their running direction in the direction of the moving pattern. We investigated the behavioural response under conditions with motion patterns in two different motion directions at the same time (’transparency”) that evoke bistable perception. The results show that the mice follow the average motion directions. In an in-vitro set-up we further investigated the fundamental mechanisms of bistable perception. We developed a “hybrid” system where two pyramidal neurons in a mouse visual cortical brain slice interact through a computer-simulated mutual inhibition circuit. Simultaneous activation of the mutually inhibiting pyramidal neurons leads to bi-stable activity. We show that this in-vitro circuit exhibits characteristics strikingly similar to the properties of bistable visual perception.

KETAMINE AFFECTS ADAPTATION-INDUCED CHANGES IN PREFERRED ORIENTATION AND NETWORK DYNAMICS

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Afef Ouelhazi, Rudy Lussiez, Stéphane Molotchnikoff
Udem, Sciences Biologiques, Montréal, Canada

Ketamine affects adaptation-induced changes in preferred orientation and network dynamics Ouelhazi Afef, Lussiez Rudy, Molotchnikoff Stéphane **Abstract** Primary visual cortex features a well demonstrated selectivity by virtue of which neurons respond maximally to specific attributes of stimulus characteristics. However, the imposition of a non-preferred stimulus for many minutes (visual adaptation), or the application of an antidepressant, such as ketamine, shifts the preferred orientation. That is, the neuron acquires a new orientation selectivity. The mechanism of the change of stimulus selectivity is not yet ascertained. This investigation explores, in mouse and cat, the modification of orientation selectivities and its outcome on correlations between neurons. Electrophysiological recordings of monocular stimulations in control, post-adaptation, and post-ketamine conditions revealed that ketamine impacts post-adaptation effects by altering neuronal tuning curves and segregating them into two neuronal groups with distinct effects: it facilitates recovery in cells exhibiting large shifts after adaptation, whereas in units displaying small shifts, the drug potentiates the shifts. Moreover, pair-wise cross correlogram analyses show that ketamine disrupts post-adaptation neuronal circuits, potentiating functional connectivity between neurons in cats, but not mice. In cat, ketamine significantly increases the number of connections and their strengths and enhances neuronal synchrony. We conclude that ketamine affects adaptation-induced changes in preferred orientation and network correlations by reorganizing pre-existing neuronal networks.

Aims: Repressor Element 1-Silencing Transcription Factor (REST) regulates the expression of a wide array of neuronal genes implicated in differentiation, development and plasticity. We set out to investigate the effect of REST inhibition on primary visual cortex (V1b) plasticity in the adult mouse. **Methods:** Employing the monocular deprivation paradigm in a $REST^{lox/lox}$ conditional knockout (cKO) model, we studied the effects of stereotaxically delivering Cre recombinase into V1b via adeno-associated virus vectors (AAVs) on ocular dominance plasticity *in vivo.* To this end, we recorded visual evoked potentials (VEPs) with chronic multi-electrode implants in the awake animal, vision-correlated behavior via the optomotor response (OMR) and molecular changes in *ex vivo* brain tissue with immunofluorescence and RT-PCR. We also employed these techniques in wild type C57BL/6 mice to study the effects of engineered chimeric REST inhibitors based on the photo-activated *Avena sativa* light-oxygen-voltage-sensing 2-phototrophin 1 (*As*LOV2). **Results:** Electrophysiology shows that 3 days of monocular deprivation in REST-inhibited animals produce a significant shift in ocular dominance towards the non-deprived eye in the V1b, mirrored by a lowered OMR score. RT-PCR and immunofluorescence demonstrate a concurrent increase in the expression of plasticity-related genes BDNF, Nav1.2, SYN1 and NPAS4, normally targeted by REST repression. **Conclusions:** Our data demonstrates that inhibition of REST activity *in vivo* can result in reactivation of ocular dominance plasticity in the adult visual cortex after the end of the critical period, paving the way for new therapeutic strategies for the correction of amblyopia in adults.

A fully organic retinal prosthesis restores vision in a rat model of degenerative blindness.
The degeneration of photoreceptors in the retina is one of the major causes of adult blindness in humans. Unfortunately, no effective clinical treatments exist for the majority of retinal degenerative disorders. Here we report on the fabrication and functional validation of a fully organic prosthesis for long-term in vivo subretinal implantation in the eye of Royal College of Surgeons rats, a widely recognized model of retinitis pigmentosa. Electrophysiological and behavioural analyses reveal a prosthesis-dependent recovery of light sensitivity and visual acuity that persists up to 6-10 months after surgery. The rescue of the visual function is accompanied by an increase in the basal metabolic activity of the primary visual cortex, as demonstrated by positron emission tomography imaging. Our results highlight the possibility of developing a new generation of fully organic, highly biocompatible and functionally autonomous photovoltaic prostheses for subretinal implants to treat degenerative blindness.

Subretinally injected semiconducting polymer nanoparticles rescue vision in a rat model of retinal dystrophy.
Inherited retinal dystrophies and late-stage age-related macular degeneration, for which treatments remain limited, are among the most prevalent causes of legal blindness. Retinal prostheses have been developed to stimulate the inner retinal network; however, lack of sensitivity and resolution, and the need for wiring or external cameras, have limited their application. Here we show that conjugated polymer nanoparticles (P3HT NPs) mediate light-evoked stimulation of retinal

neurons and persistently rescue visual functions when subretinally injected in a rat model of retinitis pigmentosa. P3HT NPs spread out over the entire subretinal space and promote light-dependent activation of spared inner retinal neurons, recovering subcortical, cortical and behavioural visual responses in the absence of trophic effects or retinal inflammation. By conferring sustained light sensitivity to degenerate retinas after a single injection, and with the potential for high spatial resolution, P3HT NPs provide a new avenue in retinal prosthetics with potential applications not only in retinitis pigmentosa, but also in age-related macular degeneration.

Neuronal firing modulation by a membrane-targeted photoswitch.
Optical technologies allowing modulation of neuronal activity at high spatio-temporal resolution are becoming paramount in neuroscience. In this respect, azobenzene-based photoswitches are promising nanoscale tools for neuronal photostimulation. Here we engineered a light-sensitive azobenzene compound (Ziapin2) that stably partitions into the plasma membrane and causes its thinning through trans-dimerization in the dark, resulting in an increased membrane capacitance at steady state. We demonstrated that in neurons loaded with the compound, millisecond pulses of visible light induce a transient hyperpolarization followed by a delayed depolarization that triggers action potential firing. These effects are persistent and can be evoked in vivo up to 7 days, proving the potential of Ziapin2 for the modulation of membrane capacitance in the millisecond timescale, without directly affecting ion channels or local temperature.

Leber congenital amaurosis (LCA) is an inherited retinal disease that causes early-onset blindness in infants and children. A possible strategy to recover vision in late stages of disease is the introduction of light-sensitive channel proteins in bipolar cells to compensate for photoreceptor cell loss. However, it is largely unknown whether the newly-generated signal from light-sensitive bipolar cells is sufficient to re-establish behaviorally relevant visual perception. Therefore, the aim of our study is to assess how intraocular expression of an engineered light-sensitive protein (Opto-mGluR6) affects primary visual cortex function in a mouse model of early-onset retinal degeneration (*Lca5*$^{-/-}$). To answer this objective, three groups of mice (untreated *Lca5*$^{-/-}$, *Lca5*$^{-/-}$ intraocularly treated with Opto-mGluR6 and wild type C57BL/6J mice) were chronically implanted with high-density silicon probes targeting primary visual cortex. Mice were head-fixed and trained to perform a virtual-reality visual discrimination task by running on a spherical treadmill. Local field potentials and single unit responses were recorded throughout task performance. Our initial analyses of behavioral data indicate lower learning performance in treated and untreated *Lca5*$^{-/-}$ mice compared to C57BL/6J control mice. We are currently analyzing the electrophysiological data to assess whether this trend is also reflected in primary visual cortex activity. Overall, we currently do not find recovery of visually-guided behavior in Lca5-/- mice that underwent treatment with an optogenetic construct to produce light-sensitivity in retinal bipolar cells.

HIGH-DIMENSIONAL GEOMETRY OF POPULATION RESPONSES IN SECONDARY VISUAL CORTEX

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Ali Haydaroglu[1,2], Matteo Carandini[3], Kenneth Harris[2]
[1]University College London, Sainsbury Wellcome Center, London, United Kingdom, [2]University College London, Ucl Queen Square Institute Of Neurology, London, United Kingdom, [3]University College London, Ucl Institute Of Ophthalmology, London, United Kingdom

[Aims] Population responses in the mouse primary visual cortex follow a high-dimensional geometry characterized by a covariance eigenspectrum with a power law coefficient around 1.04. This structure allows codes to be decorrelated, optimizing efficiency while maintaining smoothness (Stringer et al., *Nature* 2019). Is this structure maintained across the visual hierarchy? [Methods] We used 2-photon imaging to record simultaneously from 4000-6000 neurons in visual cortical areas AM and V1 of awake mice on a spherical treadmill. 1800 natural image stimuli were presented twice each. We calculated the eigenspectra of stimulus responses with cross-validated PCA. [Results] Replicating the original finding, the V1 power law coefficient was 1.12 (n=2: 1.09, 1.16). AM population response eigenspectra are also well-approximated by a power law with a coefficient of 1.27 (n=3: 1.30, 1.27, 1.25), higher than in V1 ($P < 0.05$, unpaired t-test). Additionally, the distribution of the fraction of neural variance that is stimulus-related in AM is lower than in V1, with a larger fraction of AM neurons having lower stimulus responsiveness. AM population responses also perform worse at decoding stimulus identity (9 +/- 1% stimulus decoding accuracy) compared to V1 neurons (15 +/- 2%). Furthermore, a larger fraction of neural activity is predictable by behavioral data from face videos of mice in AM than in V1. [Conclusions] Our results suggest less reliable, lower-dimensional population responses to natural images in AM than in V1, possibly due to larger behavioral influences in higher visual areas.

A NOVEL AND HIGHLY SENSITIVE STATISTICAL TEST FOR CALCIUM IMAGING

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Jorrit Montijn, J Alexander Heimel
Netherlands Institute for Neuroscience, Cortical Structure And Function, Amsterdam, Netherlands

Aims In neurophysiological studies, such as those using calcium imaging data, a standard approach is to test all cells for stimulus responsiveness and include only those that are significantly modulated. We recently proposed a statistical test for spiking data: the ZETA-test. This test outperforms model-based approaches, t-tests, and ANOVAs, but unfortunately can only be applied to point events, such as spike times. Here, we present a new method that solves this drawback: the time-series (TS)-ZETA test. **Methods** We construct a reference time vector over the window of interest, using stochastic across-trial delay variations to achieve a temporal resolution higher than the frame acquisition speed. For each trial, we interpolate the values to this reference vector. We average across all trials, calculate the cumulative sum, and subtract a linear null-hypothesis distribution. We jitter the stimulus onsets and repeat the above procedure to sample null-hypothesis curves. Applying extreme value theory to these samples, we calculate the statistical significance of the observed neuronal response. **Results** We quantified the sensitivity of the TS-ZETA test on V1 neuronal responses to drifting gratings recorded with calcium imaging (fig. 1). We compared this to commonly used approaches, such as t-tests and ANOVAs using an ROC analysis (TS-ZETA AUC=0.946; ANOVA AUC=0.923; T-test AUC=0.841; Mann-Whitney AUC tests, all comparisons, $p<10^{-9}$).

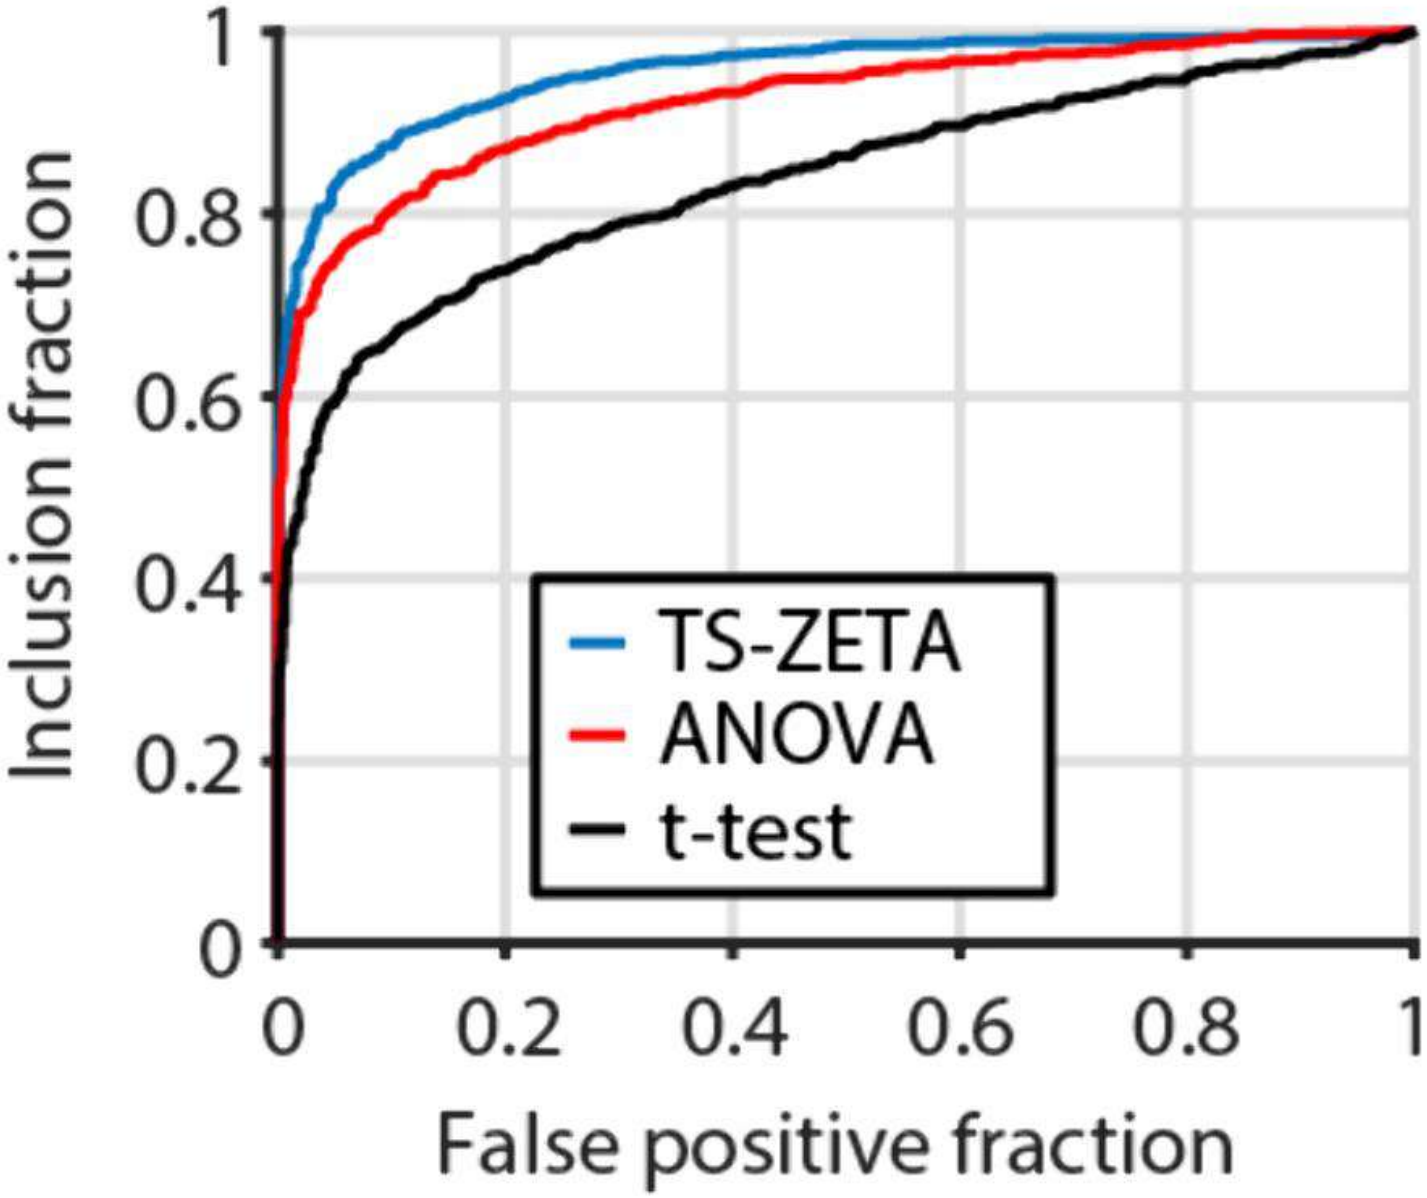

Figure 1. Benchmarking of the performance of TS-ZETA, ANOVA, and t-test on 1055 V1 cells. **Conclusions** The binning-free and parameter-free TS-ZETA test includes more cells than a t-test or ANOVA for similar false positive rates.

Neuronal activity in the primary visual cortex (V1) is governed by feedforward information processing in each neuron's receptive field (RF) and by contextual information in surrounding regions. Ongoing feedforward responses are rapidly affected by contextual inputs, so it is challenging to dissociate their functional roles. We used full and occluded views of natural scenes to reveal the impact of contextual mechanisms on V1 representations in the absence of information in the RF, as well as the effect of training on the selectivity and response dynamics of V1 neurons. We presented partially occluded and full (non-occluded) natural scenes while recording V1 activity from monkeys using electrophysiology (24 images per condition; 211 sites in two macaques) and from mice using chronic widefield and two-photon calcium imaging (6 images per condition; ~900 neurons in six animals). In mice, V1 activity was recorded both before and after perceptual training to detect 4 full natural scenes. We successfully decoded stimulus identity from V1 activity in both species without visual stimulation in neuronal RFs. In monkeys, decoding was significant in the sustained phase of the response, from ~75ms after stimulus onset. In mice, we found significant decoding both before and after perceptual training (all *p*s < 0.05, permutation test), and training mice on fullscreen images weakened V1 responses to these images but strengthened responses to occluded images. Our results support predictive coding theories of neuronal activity and lay the groundwork for investigating the precise contextual features that drive and modify V1 responses.

Aims: Nonverbal social communication relies heavily on visual analysis of body movements. fMRI studies have identified body patches in the macaque inferotemporal (IT) cortex. However, the organization of "dynamic" body patches activated by dynamic bodies, and their feature selectivity at the single-cell level, are unknown. Here we investigated the neural representations underlying the visual processing of dynamic bodies in macaque anterior IT. **Methods**: We used a set of 1 s long videos of dynamic monkey bodies, dynamic monkey faces, and dynamic artificial objects to localize the dynamic body patches with fMRI in two monkeys. We found several dynamic body patches along and ventral to the Superior Temporal Sulcus (STS). Then, we recorded body-selective single cells identified with the same videos used for fMRI mapping in anterior IT, ventral to the STS, in the same two monkeys. **Results**: The majority of neurons responded only during a specific segment of the video and demonstrated high selectivity for different body videos. Most neurons responded similarly to the original videos and a version in which the body was reduced to a silhouette. Many neurons responded to both static snapshots and the original videos, while others only responded to the videos, requiring motion. The latter cells were also sensitive about the order in which video frames were displayed. **Conclusion**: These findings suggest that the majority of anterior IT body-selective cells are shape-selective, and that some of these cells, located ventral to the STS, also encode the snapshot sequence.

WHEN THE VISUAL CORTEX STOPS CARING ABOUT ORIENTATION: FEATURE AND CATEGORY REPRESENTATION IN V1 DURING ORIENTATION DISCRIMINATION

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Julien Corbo[1], Batuhan Erkat[1,2], John Mcclure[1,2], Hussein Khdour[1,2], Pierre-Olivier Polack[1]
[1]Rutgers University, Center For Molecular And Behavioral Neuroscience, Newark, United States of America, [2]Rutgers University, Behavioral And Neural Sciences Graduate Program, Newark, United States of America

A prerequisite to visual discrimination is that two different sensory stimuli should evoke distinct population activities, or representations. However, the mechanisms by which sensory processing is adapted to a visual discrimination task computational constraints remains poorly understood. Here, we investigated the relationship between orientation discrimination and orientation representations in the primary visual cortex (V1) using calcium imaging in mice performing a Go/NoGo task with oriented drifting gratings throughout six consecutive days. Each day, the orientation of the NoGo stimulus was made closer to the Go orientation (from +90° to +15°), increasing the task's difficulty. As the angle between the Go and NoGo cue decreased, the response profiles in the orientation space stopped corresponding to the presented orientations. NoGo cues activated the same 'NoGo region' of the orientation space day after day, despite the change of presented orientation. Additionally, the NoGo cues activated neurons tuned for the Go orientation, creating a bimodal activation in the orientation space. The ratio between the activation of the Go and NoGo regions of the orientation space was correlated to the behavioral choice probability. Additionally, presenting pure tones simultaneously to the visual stimuli improved the orientation discrimination performance, and changed the Go/NoGo activation ratio accordingly. Our results therefore show that V1 can abandon feature representation in favor of categorical representation (Go or NoGo) to improve discrimination performance. This categorical representation seems to be generated by attractors in the orientation space that are activated by the sensory inputs.

Cortical Merging in S1 as a Substrate for Tactile Input Grouping.
Perception is a reconstruction process guided by rules based on knowledge about the world. Little is known about the neural implementation of the rules of object formation in the tactile sensory system. When two close tactile stimuli are delivered simultaneously on the skin, subjects feel a unique sensation, spatially centered between the two stimuli. Voltage-sensitive dye imaging (VSDi) and electrophysiological recordings [local field potentials (LFPs) and single units] were used to extract the cortical representation of two-point tactile stimuli in the primary somatosensory cortex of anesthetized Long-Evans rats. Although layer 4 LFP responses to brief costimulation of the distal region of two digits resembled the sum of individual responses, approximately one-third of single units demonstrated merging-compatible changes. In contrast to previous intrinsic optical imaging studies, VSD activations reflecting layer 2/3 activity were centered between the representations of the digits stimulated alone. This merging was found for every tested distance between the stimulated digits. We discuss this laminar difference as evidence that merging occurs through a buildup stream and depends on the superposition of inputs, which increases with successive stages of sensory processing. These findings show that layers 2/3 are involved in the grouping of sensory inputs. This process that could be inscribed in the cortical computing routine and network organization is likely to promote object formation and implement perception rules.

Sensory-evoked propagating waves of activity in the primary sensory cortices: poorly understood, yet ubiquitous.
Any sensory stimulus evokes a propagating wave of activity in the corresponding sensory cortex that exceeds its topographical boundaries within the primary sensory map. Hama and colleagues (Hama N, Kawai M, Ito S-I, Hirota A. J Neurophysiol 119: 1934-1946, 2018) provided a first study, in the tactile modality, of the interactions between two successively evoked waves. We argue that the difficulty in finding a simple rule to account for all the various observed interactions calls for an effort to clarify the mechanisms and substrates of the propagating waves and their role in sensory processing.

Neuronal Encoding of Multisensory Motion Features in the Rat Associative Parietal Cortex.
Motion perception is facilitated by the interplay of various sensory channels. In rodents, the cortical areas involved in multisensory motion coding remain to be identified. Using voltage-sensitive-dye imaging, we revealed a visuo-tactile convergent region that anatomically corresponds to the associative parietal cortex (APC). Single unit responses to moving visual gratings or whiskers deflections revealed a specific coding of motion characteristics strikingly found in both sensory modalities. The heteromodality of this region was further supported by a large proportion of bimodal neurons and by a classification procedure revealing that APC carries information about motion features, sensory origin and multisensory direction-congruency. Altogether, the results point to a central role of APC in multisensory integration for motion perception.

ONGOING ACTIVATION OF VISUAL CORTEX AND SUPERIOR COLLICULUS IN THE RD10 MOUSE MODEL OF RETINITIS PIGMENTOSA

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Thomas Rüland[1,2,3], Kerstin Doerenkamp[2,3,4], Peter Graff[2,3], Simon Musall[3,5], Björn Kampa[2,3,6], Frank Müller[1]
[1]Forschungszentrum Jülich, Molekular- Und Zellphysiologie (ibi-1), Jülich, Germany, [2]RWTH Aachen University, Molecular And Systemic Neurophysiology - Institute Of Biology 2, Aachen, Germany, [3]RWTH Aachen University, Rtg 2416 - Multisenses Multiscales, Aachen, Germany, [4]Forschungszentrum Jülich, Computational And Systems Neuroscience (inm-6), Jülich, Germany, [5]Forschungszentrum Jülich, Bioelectronics - Institute Of Biological Information Processing, Jülich, Germany, [6]Forschungszentrum Jülich, Institute Of Neuroscience And Medicine (inm-2), Jülich, Germany

Restoring vision in patients suffering from retinal degeneration has been an ongoing effort in the last decades. Retinal implants have been shown to be a promising approach, but the fidelity of evoked visual impression is still very limited and general success is not guaranteed. While technical limitations might be one of the reasons for these ongoing issues, we investigated whether functional changes in visual cortex (V1) e.g., based on cross-modal plasticity upon loss of visual input might lead to an impairment in the processing of retinally evoked stimuli. First, we used optomotor reflex testing to ascertain complete blindness of experimental animals and found that behavioural responses to visual stimulation were completely abolished at up to 30 weeks of age, much later than previously suggested by histological investigations. Next, we performed high-density Neuropixels recordings in V1 and superior colliculus (SC) of awake and behaviourally blind *rd10* mice while presenting auditory, tactile, and visual stimuli. As expected, meaningful responses to visual stimulation were non-existent in V1 as well as SC of *rd10* mice. However, auditory and tactile neuronal responses were either slightly enhanced (SC) or unchanged (V1), showing no evidence for cross-modal plasticity in these visual areas. Furthermore, retinally degenerated mice showed characteristic oscillatory activity in V1 and SC very similar to activity previously found in extracted *rd10* retinae. This pathological input might prevent visual areas from enhancing their responses to other modalities and likely retain their responsivity to stimulation by artificial retinal implants.

ATTENTION-DEPENDENT MODULATION OF MONKEY V1 EPIDURAL FIELD POTENTIALS IS CLOSELY LINKED TO BEHAVIORAL PERFORMANCE

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Dan Qi Priscilla Oh
University of Bremen, Cognitive Neurophysiology, Brain Research Institute, University Of Bremen, Bremen, Germany

Epidural multielectrode arrays constitute a key technique for future clinical applications and offer interesting options for basic science research, because of their reduced invasiveness and high coverage density. Visual epidural field potentials (EFPs) were recently shown to possess high selectivity regarding basic visual stimulus features, but selectivity during cognitive processing has only rarely been studied. We here investigate neural signatures of selective visual attention in EFPs and their correlation to signatures of attention in behavioral data by recording EFPs from monkey primary visual cortex (V1) during a covert-attention task. Monkeys were allowed to respond to a slight orientation change in both the cued and uncued object. A non-binary rewarding scheme (Fischer & Wegener, 2019) was used to support either more distributed or more selective attention. We hypothesized that attentional modulation of the EFP should follow the strength of behavioral effects in the two reward regimes. Reaction time (RT) differences for responses to cued and uncued changes were found to be significantly larger in the regime supporting more selective attention. Accordingly, gamma-band power of EFPs showed an attentional modulation of about 50% with selective attention but only a weak modulation with distributed attention. Attentional modulation was strongest in trials with fast responses as compared to trials with medium or slow responses. The strength of attentional modulation significantly decreased with increasing distance from the attended object, consistent with a spatial attention field. The results show that EFPs from monkey V1 are strongly modulated by attention and closely linked to behavioral performance.

HISTOLOGICAL VALIDATION OF THE ACCURACY OF DIFFUSION TENSOR IMAGING FOR TRACING FIBRE TRACTS IN MACAQUE EXTRASTRIATE VISUAL CORTEX.

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Danielle Sams[1], Jackson Smith[2], Corentin Gaillard[1], Bashir Ahmed[3], Kristine Krug[1]
[1]Otto-von-Guericke-University, Department In Sensory Physiology, Magdeburg, Germany, [2]Ernst Strüngmann Institue, Neuroscience, Frankfurt am Main, Germany, [3]University of Oxford, Department Of Physiology, Anatomy And Genetics, Oxford, United Kingdom

Diffusion tensor methods in magnetic resonance imaging (DTI) are increasingly used with probabilistic tractography to plot white matter pathways in human and animal brains. Here we compare the use of DTI against histological visualization of neuronal connections with the aim of validating DTI plus tractography against the 'gold standard' methods of neuronal tract tracing. BDA tracer was injected into the left hemispheric extrastriate cortical area V5/MT+ of two anaesthetized rhesus macaque monkeys, for which DTI measurements had been previously made under anaesthesia. The path of the tracer was hand-drawn and the digital output was aligned and overlaid onto the fractional anisotropy (FA) image using FSL software. Tractography was conducted on the FA images of both brains using ProbtrackX from the FSL FDT toolbox starting from seed points at the injection site. Tracer and tractography data were normalised and spatially cross-correlated slice by slice in MATLAB to compare the extent to which DTI reveals brain connectivity between regions compared with histology. The highest correlations were found in the neighbourhood of the injection site. Errors in alignment could be categorised as systematic (revealed by a non-zero peak of the correlogram) or random (revealed by the width of the correlogram), but in addition, there were brain sites where only one of the tracing methods reported any connectivity. We conclude that over short distances the results of the two methods are reasonably concordant but longer-range trajectories are harder to assess.

BROADBAND VISUAL STIMULI ENGAGE NEW NEURONAL POPULATIONS IN THE MOUSE VISUAL CORTEX AND FACILITATE VISUAL DISCRIMINATION

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Elisabeta Balla[1,2,3], Christopher Wiesbrock[1,3], Jenice Linde[1,3], Björn Kampa[1,2,3]
[1]RWTH Aachen University, Research Training Group 2416 Multisenses – Multiscales, Aachen, Germany, [2]Institute of Neuroscience and Medicine (INM-10), Forschungszentrum Jülich, Jara-brain, Jülich, Germany, [3]RWTH Aachen University, Systemic Neurophysiology, Aachen, Germany

The visual system has evolved in congruence to its core function of making useful representations of the visual features of an animal's environment. Many of these visual features (e.g. orientation of edges) are present in natural sceneries at a broad variability of distributions. Identifying what computations are implemented for coping with this variability, is, therefore, pertinent in acquiring a better understanding of signal processing in the visual system and how natural statistics ultimately affects visual perception of the environment. This study aimed to explore this effect in mice in respect to their capability to discriminate between orientations and spatial frequencies in bandwidth-enriched naturalistic stimuli. For this purpose, we designed a mouse touchscreen-chamber-based 2AFC visual discrimination task, whereby we tested the effect of different spatial frequency bandwidths on the capability of mice to discriminate orientations of the presented visual stimuli and the effect of varying orientation bandwidths on visual stimulus spatial frequency discrimination capability of these mice. We observed that the spatial frequency discrimination capability of our mice was significantly improved by broadening the orientation bandwidth. Next, we used *in vivo* multiphoton imaging to address how bandwidth-enriched naturalistic stimuli activate neurons in visual cortex. Pseudo-random sequences of orientation bandwidth-enriched and spatial frequency bandwidth-enriched stimuli were presented to a passively viewing animal. Upon enrichment of stimulus bandwidth in the orientation domain, new cohorts of neurons of different orientation preferences were engaged. We conclude that the additional computational power provided by these newly engaged channels facilitates the perception of the visual stimulus.

Directed evolution of an acid Yersinia mollaretii phytase for broadened activity at neutral pH.
Phytases are phosphohydrolases that initiate the sequential hydrolysis of phosphate from phytate, which is the main storage form of phosphorous in numerous plant seeds, especially in cereals and grains. Phytate is indigestible for most monogastric animals, such as poultry, swine, fish, and humans; therefore, microbial phytases have been widely used in plant (specially soy)-based animal feeding to improve nutrition by enhanced phosphorus, mineral, and trace element absorption, and reducing phosphorus pollution by animal waste. Most phytases used as animal feed additives have an acid pH optimum (pH 2.5 and 5.5 for Aspergillus and pH 4.5 for E. coli phytases) and show a sharp decrease in performance at neutral pH, correlating with intestinal digestion. Directed evolution of phytases has been previously reported to improve enzyme thermostability, pH, or specific activity. In this manuscript, we report a directed evolution campaign of the highly active bacterial phytase from Yersinia mollaretii (YmPh) towards a broadened pH activity spectrum. Directed evolution identified the key positions T44 and K45 for increased YmPh activity at neutral pH. Both positions are located in the active site loop of the phytase and have a synergistic effect on activity with a broadened pH spectrum. Kinetic characterization of the improved variants, YmPh-M10 and -M16, showed up to sevenfold increased specific activity and up to 2.2-fold reduced K at pH 6.6 under screening conditions compared to Yersinia mollaretii phytase wild type (YmPhWT).

Aims: Visual information from body movements and facial expressions are essential elements of non-verbal social communication and action recognition. To understand the neural substrate underlying the visual processing of dynamic monkey bodies (DB) and dynamic monkey faces (DF) we conducted fMRI studies in two macaques. Methods & Results: First, 1 s long videos of DB, DF, dynamic artificial objects (DO) and phase scrambled (P) versions of these videos were presented on a dynamic white noise background during passive fixation. Nine body patches were localized along and ventral to the STS with the contrast [(DB > PB) & (DB > DF) & (DB > DO)]. Using the contrast [(DF > PF) & (DF > DO)] we localized 9 face patches in both animals. In a follow-up scan session, we presented the original movies and 2 static images from each movie for 500 ms in a random order, using a block design. Comparing the percent signal change in the previously defined 9 body patches, we found a higher activation for dynamic than static stimuli and a preserved category selectivity for the static stimuli. When comparing the activations in the 9 face patches, the category selectivity was preserved for the static stimuli, whereas the activation for dynamic and static stimuli was similar. Conclusion: These results suggest that movements have a stronger effect on the body patch system. To understand how the shape and motion information is coded in dynamic body patches single-unit recordings are ongoing (Raman et al FENS 2022).

LINEAR DECODING APPLIED TO V5/MT NEURONAL ACTIVITY ON PAST TRIALS PREDICTS CURRENT SENSORY CHOICES

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Sameh Ben Hadj Hassan[1], Corentin Gaillard[1], Andrew Parker[1,2], Kristine Krug[1,2]
[1]Institute of Biology, Otto-von-Guericke-Universitaet, Department Of Sensory Physiology, Magdeburg, Germany, [2]University of Oxford, Dept Physiology, Anatomy & Genetics, oxford, United Kingdom

Perceptual decisions about sequences of sensory stimuli often show serial dependence. The behavioural choice on one trial is often affected by the choice on previous trials. We investigated whether neuronal signals in extrastriate visual area V5/MT on preceding trials might influence choice on the current trial and thereby reveal the neuronal mechanisms of sequential choice effects. We analysed data from 30 single neurons recorded from V5/MT in three Rhesus monkeys making sequential choices about the rotation direction of a three-dimensional cylinder. We focused on the responses of neurons that showed significant choice-related firing (mean choice probability=0.73) while the monkey viewed perceptually ambiguous stimuli. Application of wavelet analysis to the early choice-related firing (80–500 ms) revealed differences in the frequency bands of neuronal activity. When the previous unambiguous trial had resulted in a correct choice that was the same as the current choice, there was a pattern of high theta, low alpha & low beta, whereas when the choices were different the opposite pattern was seen. To probe this in further detail, we applied a regularized linear decoder to predict the choice for an ambiguous trial by referencing the neuronal activity of the preceding unambiguous trial. Neuronal activity on a previous trial significantly predicted the current choice (61% correct, 95%CI ~52%), even when limiting analysis to preceding trials that were correct and rewarded. These findings provide a potential neuronal signature of sequential choice strategy (win-stay; win-switch) in primate visual cortex with differences in the spectral profile for persistent responses.

Prefrontal Control of Proactive and Reactive Mechanisms of Visual Suppression.
In everyday life, we are continuously struggling at focusing on our current goals while at the same time avoiding distractions. Attention is the neuro-cognitive process devoted to the selection of behaviorally relevant sensory information while at the same time preventing distraction by irrelevant information. Distraction can be prevented proactively, by strategically prioritizing task-relevant information at the expense of irrelevant information, or reactively, by suppressing the ongoing processing of distractors. The distinctive neuronal signature of these suppressive mechanisms is still largely unknown. Thanks to machine-learning decoding methods applied to prefrontal cortical activity, we monitor the dynamic spatial attention with an unprecedented spatial and temporal resolution. We first identify independent behavioral and neuronal signatures for long-term (learning-based spatial prioritization) and short-term (dynamic spatial attention) mechanisms. We then identify distinct behavioral and neuronal signatures for proactive and reactive suppression mechanisms. We find that while distracting task-relevant information is suppressed proactively, task-irrelevant information is suppressed reactively. Critically, we show that distractor suppression, whether proactive or reactive, strongly depends on the implementation of both long-term and short-term mechanisms of selection. Overall, we provide a unified neuro-cognitive framework describing how the prefrontal cortex deals with distractors in order to flexibly optimize behavior in dynamic environments.

Prefrontal attentional saccades explore space rhythmically.
Recent studies suggest that attention samples space rhythmically through oscillatory interactions in the frontoparietal network. How these attentional fluctuations coincide with spatial exploration/displacement and exploitation/selection by a dynamic attentional spotlight under top-down control is unclear. Here, we show a direct contribution of prefrontal attention selection mechanisms to a continuous space exploration. Specifically, we provide a direct high spatio-temporal resolution prefrontal population decoding of the covert attentional spotlight. We show that it continuously explores space at a 7-12 Hz rhythm. Sensory encoding and behavioral reports are increased at a specific optimal phase w/ to this rhythm. We propose that this prefrontal neuronal rhythm reflects an alpha-clocked sampling of the visual environment in the absence of eye

movements. These attentional explorations are highly flexible, how they spatially unfold depending both on within-trial and across-task contingencies. These results are discussed in the context of exploration-exploitation strategies and prefrontal top-down attentional control.

Atomoxetine improves attentional orienting in a predictive context.
The role of norepinephrine (NE) in visuo-spatial attention remains poorly understood. Our goal was to identify the attentional processes influenced by atomoxetine (ATX) injections, a NE-reuptake inhibitor that boosts the level of NE in the brain, and to characterize these influences. We tested the effects of ATX injections, on seven monkeys performing a saccadic cued task in which cues and distractors were used to manipulate spatial attention. We found that when the cue accurately predicted the location of the upcoming cue in 80% of the trials, ATX consistently improved attentional orienting, as measured from reaction times (RTs). These effects were best accounted for by a faster accumulation rate in the valid trials, rather than by a change in the decision threshold. By contrast, the effect of ATX on alerting and distractor interference was more inconsistent. Finally, we also found that, under ATX, RTs to non-cued targets were longer when these were presented separately from cued targets. This suggests that the impact of NE on visuo-spatial attention depends on the context, such that the adaptive changes elicited by the highly informative value of the cues in the most frequent trials were accompanied by a cost in the less frequent trials.

Two leading theories, the Global Neural Workspace (GNW) and the Integrated Information Theory (IIT), make diverging predictions concerning the role of the prefrontal cortex (PFC) in consciousness. PFC is activated when reporting conscious perception but it has been argued that PFC is only involved in an introspective process occurring after consciousness (post-perception). In the present study, we measured the timing of visual information available to the ventrolateral-lateral PFC (vlPFC) using Utah arrays in macaque monkeys instructed to passively watch a stream of flashing images. Linear classifiers could predict above chance the identity of some images as early as 60 milliseconds after stimulus onset. Moreover, after 150 milliseconds the classifiers reached a peak accuracy when all images could be discriminated from each other. To test whether the vlPFC activity was reflecting introspection, we also let the monkeys watch streams of images quickly succeeding each other at a pace of 10 Hz (RSVP condition). At this rate, post-perception was unlikely for every image in the stream but classifiers accuracy continued to peak at the same time and as high as in the condition where each image was presented at a slow pace. Our results suggest that vlPFC is involved in visual processing earlier than, and independently from post-perception. Such early decoding of stimulus identity in the PFC might be related to phenomenal consciousness. We also show that the RSVP condition alters the dynamics of sensory representations in vlPFC. Our results challenge and might refine both the IIT and GNW theory of consciousness.

FACE-BODY INTEGRATION IN ANTERIOR INFEROTEMPORAL CORTEX

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Yordanka Zafirova[1,2], Rufin Vogels[1,2]
[1]KU Leuven, Department Of Neuroscience, Leuven, Belgium, [2]KU Leuven, Leuven Brain Institute, Leuven, Belgium

Aims: Socially relevant stimuli recruit different brain areas but little is known about the integrative mechanisms allowing for whole-agent perception. Therefore, we conducted fMRI and electrophysiological experiments in two macaque monkeys, by employing greyscale images and comparing responses to natural (head at its anatomical position) and unnatural (head attached to a different part of the upper body) monkey composites with the sum of their corresponding parts (faces and bodies, presented separately). Methods & Results: First, we localized the areas activated more by monkeys than manmade objects. In these areas in anterior inferotemporal (IT) cortex, activations to the natural composites were higher than to the unnatural ones, and that difference could not be explained by the summed activations of their corresponding parts. Importantly, the activation to the natural composites equaled the summed face-body activations, while the activation to the unnatural ones was subadditive. Second, we localized the IT patches activated more by the natural than the unnatural composites while accounting for differences in stimulus eccentricity. In these patches, we recorded single neurons in several tests, changing the position of the stimuli (monkey- or face-centered, face or body left or right of fixation) or face-body distance (0°, 0.2°, 0.4°). In all tests, responses to the natural composites were higher and approximated the face-body sums, while responses to the unnatural ones were subadditive. Detaching the head from the body resulted in comparable natural-unnatural responses at the longest distance. Conclusion: These results suggest that face-body integration depends on the configuration of the two parts.

NEURONAL BASES OF EFFICIENT CODING OF MULTIPOINT CORRELATIONS IN RAT VISUAL CORTEX

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Riccardo Caramellino[1], Eugenio Piasini[1], Valeriya Zelenkova[1], Daria Ricci[1], Vijay Balasubramanian[2], Davide Zoccolan[1]

Efficient processing of sensory data requires adapting the neuronal encoding strategy to the statistics of natural stimuli. One area where this concept has been applied is the perceptual saliency of textures: multiple works have shown that humans are most sensitive to textures containing multipoint correlations that vary the most across natural images. The neuronal mechanisms underlying such adaptation are not understood but investigating them in depth requires invasive experiments that are impossible in humans. We have shown that rats can be trained to discriminate between binary textures containing unstructured random noise and textures defined by single- to four-point correlations among nearby pixels. We observed a decrease in sensitivity from 2- to 4-point correlations and a further decrease from 4- to 3-point, fully reproducing results obtained on humans. Building on this result, we started performing extracellular recordings of neural activity from primary visual cortex (V1) and extrastriate areas of anaesthetized rats passively viewing textures containing multi-point correlations or unstructured noise. We found that, in V1, the highest fraction of selective units (p-value<0.05, ANOVA) was tuned for 1-point correlations, followed by 2-,4- and 3-point. In extrastriate cortex, we found the largest fraction of units to be selective for 1-point, followed by 4-, 2- and 3-point correlations. Finally, we confirmed a difference in neural representations of texture statistics between striate and extrastriate cortex with a population decoding analysis. These results provide an early indication of the relative contribution to this process by distinct visual cortical areas.

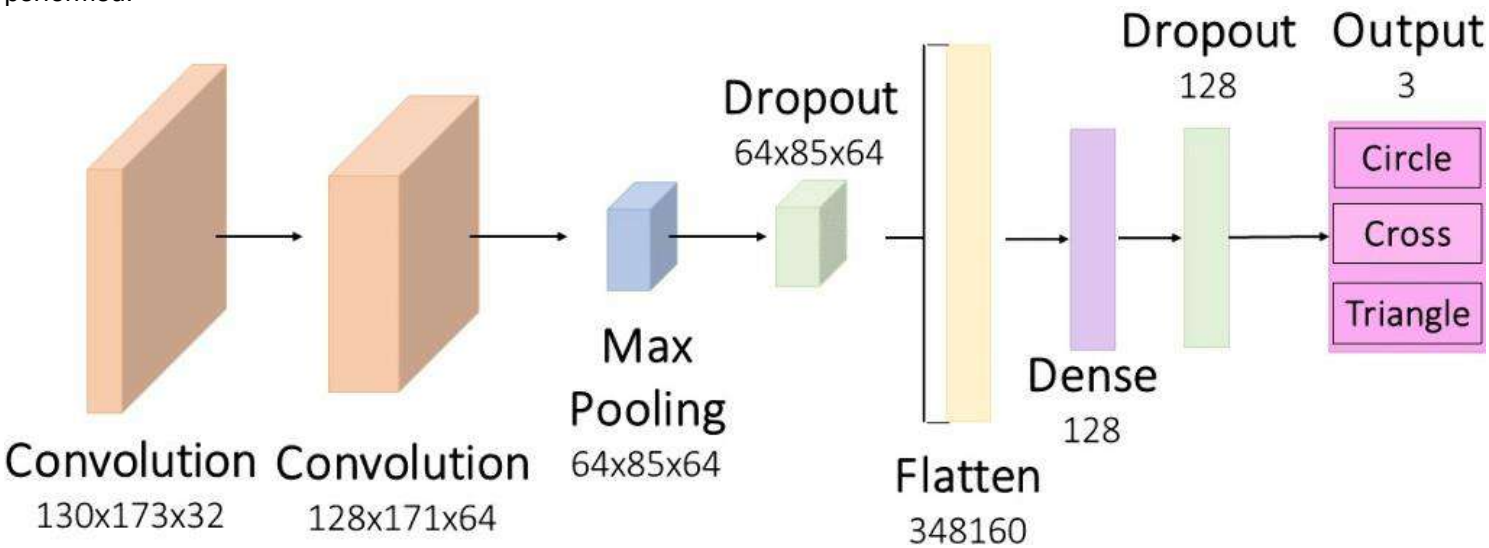
[1]Scuola Superiore Sant'Anna, The Biorobotics Institute, Pontedera (PI), Italy, [2]Scuola Normale Superiore, Laboratory Of Biology, Pisa, Italy, [3]Stella Maris Foundation, Neuroscience, Calambrone PI, Italy, [4]École Polytechnique Fédérale de Lausanne, Bertarelli Foundation Chair In Translational Neural Engineering, Geneve, Switzerland

Optic nerve stimulation holds great potential for visual prostheses. Its effectiveness depends on the stimulation protocol, which can be optimized to achieve cortical activation similar to that recorded in response to visual stimuli. To identify a target cortical activation, it is necessary to characterize the cortical response. We here propose a convolutional neural network (CNN) to do it exploiting widefield calcium brain images. A mouse was presented with 3 types of visual stimuli (circle, cross, triangle) for one second each, and the activity from its primary visual cortex (V1) was recorded using widefield calcium imaging. This technique allows large-scale visualization of cortical activity with a high signal-to-noise ratio. A dataset of 45 images (15 per stimulus) with a size of 656x875 pixels was collected. Each image was classified into the 3 stimuli by a CNN with 9 layers (Fig). The CNN was trained minimizing categorical cross-entropy with Adadelta for 100 epochs. Offline data augmentation was applied to the training set. The best model among epochs was selected according to the highest accuracy on the validation set. For robust testing, 5-fold stratified cross-validation was performed.



The CNN achieved an accuracy of 86.67%±9.30%. Although very preliminary, this interesting result shows that a shallow CNN can decode a visual stimulus from V1 neural activity of a mouse, and that deep learning can associate cortical activation to visual perception. This can be leveraged not only to properly drive optic nerve stimulation but also as a useful insight for applications that exploit visual cortex activity.

VARIATION OF CONTRAST INDUCES MUSCARINIC-DEPENDENT CHANGES IN OSCILLATORY ACTIVITY OF THE PRIMARY VISUAL CORTEX

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Elvire Vaucher, Marie-Charlotte Higgins, Christian Casanova, Nelson Cortes Hernandez
Université de Montréal, Ecole D'optométrie, Montréal, Canada

Aims. Cholinergic/ muscarinic stimulation can enhance oscillatory activity in the primary visual cortex (V1). How this modulation mediates oscillatory processing associated with visual signals in V1 is still unknown. Therefore, in the present study, cortical oscillatory responses to variation of visual contrast were examined and the effect of acetylcholine and muscarinic receptors on such evoked rhythms was analyzed. **Methods**. Eight long Evans Rats (300-350g) were used. Evoked local field potentials were acquired at 30 kHz using linear 16-channel multiunit electrodes implanted in V1. A luminance based sinusoidal grating (0.12cpd, 3Hz drift in the preferred direction, 0%, 6%, 12%, 25%, 50%, 60% and 100% contrast) was displayed (2sec on/2sec off, 20 repetitions) on a CRT screen. Wavelet analysis was used to calculate spectral estimates normalized by condition with Matlab (*Cortes Hernandez et al., Vision, 2021*). The response under scopolamine (0.3 mg/kg. i.p.), a muscarinic antagonist, was also measured. **Results**. Cortical alpha- and gamma-band oscillations were increased as a function of contrast, as shown by spectral time-frequency analysis in layers 2/3, 4, and 5. The scopolamine shifted linearly gamma-waves responses associated with contrast in supragranular and granular layers. It also shifted linearly alpha rhythms in supragranular layer, but responses to visual contrast in the granular layer were abolished by scopolamine. **Conclusions**. In the gamma-band range, the acetylcholine produces a contrast gain control in layers 2/3 and 4, which might influence perceptual sensitivity to contrast.

EXTENSIVE DIMENSIONALITY OF NEURAL CIRCUIT MANIFOLDS ASSOCIATED WITH A SALT-AND-PEPPER ORGANIZATION OF CORTICAL STIMULUS PREFERENCES

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Michael Sternbach[1,2,3], Fred Wolf[1,2,3,4]
[1]Max Planck Institute for Dynamics and Self-Organization, Goettingen Campus Institute For Dynamics Of Biological Networks, Göttingen, Germany, [2]Georg-August-Universität Göttingen, Goettingen Campus Institute For Dynamics Of Biological Networks, Göttingen, Germany, [3]Georg-August-Universität Göttingen, Bernstein Center For Computational Neuroscience, Göttingen, Germany, [4]Institute for Dynamics of Complex Systems, Georg-august University, Göttingen, Germany

In rodent sensory cortex, cortical circuits include a dense blanket of inhibition (Bopp et al. 2014). If cortical principal cells acquire their stimulus preferences by selecting afferent connections through Hebbian mechanisms. Then strong feedback inhibition can force neurons to adopt maximally dissimilar selectivities (Rubner&Schulten1990). Here we introduce and examine a set of idealized models to investigate manifolds of stable network configurations in inhibition dominated circuits. Biological neural circuits are expected to converge to one of many stable network configurations. For the form vision core circuit of primate/carnivore V1 prior work indicates that stable network configurations form high-dimensional continua (Wolf 2005, Kaschube et al. 2010). Similar results for network configurations in rodents V1, called salt-and-pepper organizations (SaP), are currently not available. We utilize techniques from the study of spin liquid states (Chalker2015) to construct and examine mathematically tractable models with SaP optimal states. We demonstrate that these models can exhibit ground state manifolds with extensive dimensionality for uniform, range-dependent and selectivity-dependent neuronal connectivity. This result is consistent with the general expectation that there are a very high number of equivalent SaP configurations. Disordered SaP states result even for dense and uniform connectivity patterns and do not require any structural source of disorder. These studies expand the toolbox for analyzing the multiplicity of stable cortical circuit configurations. Our results suggest that the evolutionary transition from a rodent ancestral circuit configurations of V1 to a primate/carnivore V1 architecture was accompanied by a radical reduction of the dimensionality of the cortical circuit state manifold.

The primary visual cortex, V1, of mammals contains orientation selective neurons. Previously only two types of spatial organisation was observed: orientation preference pinwheels and salt-and-pepper patterns. Furthermore a recent analysis in primates including the smallest living primate, the mouse lemur (Microcebus murinus), revealed that primate orientation domains are nearly incompressible, scaling weakly with brain and body size. Thus it has been argued that brains with small visual cortices such as the approximately 5 mm^2 V1 of the mouse and ancestral mammals (Keil et al. 2012, Kaschube 2014) should not be able to contain orientation domains. Here we present evidence for the relatively large orientation domains in an extremely small V1. We performed intrinsic signal imaging in the visual cortex of the fat-tailed dunnart, Sminthopsis crassicaudata, a marsupial with a V1 size of 5.6 mm2 (Tyler et.al. 1998). Despite this, we observed well expressed orientation domains. This makes the dunnart the smallest mammal studied to possess orientation domains. Dunnart orientation domains seemingly differ in layout substantially from those found in primates and carnivores. In particular the dunnart maps lack a quasi-periodic structure and exhibit no pinwheel singularities. Dunnart orientation domains are variable in size with the largest domains considerably larger than column sizes found in the mouse lemur (Ho 2021). Our studies suggest that a third type of V1 functional architecture emerged in marsupial V1. Moreover, the novel arrangement and small brain size of the dunnart means key principles of sensory cortex theories, such as the coverage-continuity-compromise, can be critically tested.

FUNCTIONAL PARCELLATION OF THE HUMAN FACE-SELECTIVE AREAS: A RESTING-STATE CONNECTIVITY HOMOGENEITY ANALYSIS.

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Federica Bencivenga[1,2], Elaheh Akbarifathkouhi[1], Gaspare Galati[1,2]
[1]Sapienza University of Rome, Department Of Psychology, Rome, Italy, [2]Santa Lucia Foundation, Cognitive And Motor Rehabilitation And Neuroimaging Unit, Rome, Italy

Although different functional parcellations of human face-selective areas in the ventral visual stream have been proposed, the extent to which such regions share similar properties is still unclear[1]. Using a subset of 165 subjects from the HCP1200 functional magnetic resonance imaging dataset, we combined task-based definition of face-selective areas and resting-state connectivity homogeneity analysis to reach a finer-grained parcellation of face-selective areas. We segmented individual surface-based statistical maps of activation during vision of faces vs places through a watershed algorithm, identifying three parcels lying between the fusiform and the middle occipital gyrus. We then computed a connectivity fingerprint of each face-selective surface vertex, defined as the correlation between its resting-state timeseries and that of all vertices outside the face parcels. Finally, we computed a homogeneity measure between the connectivity fingerprints of each pair of vertices within and between the face parcels. The connectivity homogeneity between face vertices was inversely proportional to the anatomical distance between them measured on the individual cortical surface. Having accounted for distance effects, homogeneity was higher within than between face parcels. This result shows that three face regions are distinguishable based on their resting-state functional connectivity fingerprints. Despite needing validation, our method shows the possibility of segregating parcels with similar functional properties using the profile of their functional connectivity at rest. 1. Grill-Spector, K., Weiner, K. S., Kay, K., & Gomez, J. (2017). The functional neuroanatomy of human face perception. Annual review of vision science, 3, 167-196.

Assessing the effective connectivity of premotor areas during real vs imagined grasping: a DCM-PEB approach.
The parieto-frontal circuit underlying grasping, which requires the serial involvement of the anterior intraparietal area (aIPs) and the ventral premotor cortex (PMv), has been recently extended enlightening the role of the dorsal premotor cortex (PMd). The supplementary motor area (SMA) has been also suggested to encode grip force for grasping actions; furthermore, both PMd and SMA are known to play a crucial role in motor imagery. Here, we aimed at assessing the dynamic couplings between left aIPs, PMv, PMd, SMA and primary motor cortex (M1) by comparing executed and imagined right-hand grasping, using Dynamic Causal Modelling (DCM) and Parametrical Empirical Bayes (PEB) analyses. 24 subjects underwent an fMRI exam (3T) during which they were asked to perform or imagine a grasping movement visually cued by photographs of commonly used objects. We tested whether the two conditions a) exert a modulatory effect on both forward and feedback couplings among our areas of interest, and b) differ in terms of strength and sign of these parameters. Results of the real condition confirmed the serial involvement of aIPs, PMv and M1. PMv also exerted a positive influence on PMd and SMA, but received an inhibitory feedback only from PMd. Our results suggest that a general motor program for grasping is planned by the aIPs-PMv circuit; then, PMd and SMA encode high-level features of the movement. During imagery, the connection strength from aIPs to PMv was weaker and the information flow stopped in PMv; thus, a less complex motor program was planned. Moreover, results suggest that SMA and PMd cooperate to prevent motor execution. In conclusion, the comparison between execution and imagery reveals that during grasping premotor areas dynamically interplay in different ways, depending on task demands.

Neural representations underlying mental imagery as unveiled by representation similarity analysis.
It is commonly acknowledged that visual imagery and perception rely on the same content-dependent brain areas in the high-level visual cortex (HVC). However, the way in which our brain processes and organizes previous acquired knowledge to allow the generation of mental images is still a matter of debate. Here, we performed a representation similarity analysis of

three previous fMRI experiments conducted in our laboratory to characterize the neural representation underlying imagery and perception of objects, buildings and faces and to disclose possible dissimilarities in the neural structure of such representations. To this aim, we built representational dissimilarity matrices (RDMs) by computing multivariate distances between the activity patterns associated with each pair of stimuli in the content-dependent areas of the HVC and HC. We found that spatial information is widely coded in the HVC during perception (i.e. RSC, PPA and OPA) and imagery (OPA and PPA). Also, visual information seems to be coded in both preferred and non-preferred regions of the HVC, supporting a distributed view of encoding. Overall, the present results shed light upon the spatial coding of imagined and perceived exemplars in the HVC.

TOWARDS AN OPTIMIZATION OF FUNCTIONAL LOCALIZERS IN NON-HUMAN PRIMATE IMAGING WITH (FMRI) FREQUENCY-TAGGING

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Marie-Alphée Laurent[1], Pauline Audurier[2], Vanessa De Castro[2], Xiaoqing Gao[3], Jean-Baptiste Durand[2], Jacques Jonas[4], Bruno Rossion[1], Benoit R. Cottereau[2]
[1]University of Lorraine, CNRS - UMR7039, Cran, Vandoeuvre-lès-Nancy, France, [2]University of Paul Sabatier (UPS), CNRS - UMR5549, Cerco, Toulouse, France, [3]Center for Psychological Sciences, Zhejiang University, Zhejiang, China, [4]Université de Lorraine, Chru-nancy, Service De Neurologie, Nancy, France

Aims Non-human primate (NHP) neuroimaging can provide essential insights into the neural basis of human cognitive functions. While functional fMRI localizers can play an essential role in reaching this objective (Russ et al., 2021), they often differ substantially across species in terms of paradigms, measured signals and data analysis, biasing the comparisons. Here we introduce a functional frequency-tagging face localizer for NHP imaging, successfully developed in humans and outperforming standard “face localizers” (Gao et al., 2018). **Methods** FMRI recordings were performed in two awake macaques. Within a rapid 6Hz stream of natural images of non-face objects, 7 human or monkey face stimuli were presented in bursts every 9s during a 243s run. We also included control conditions with phase-scrambled versions of all images. As in humans, runs were analyzed in the frequency domain where face-selective responses were objectively identified and quantified at the peak of the face-stimulation frequency (0.111Hz) and its second harmonic (0.222Hz). **Results** Focal activations with high signal-to-noise ratio were observed in regions previously described as face-selective, mainly in the STS (clusters PL, ML, MF; also, AL, AF), both for human and monkey faces. Robust activations were also found in the prefrontal cortex of one monkey in the PVL and PO clusters. **Conclusions** Face-selective responses were highly reliable, excluding all contributions from low-level visual cues contained in the amplitude spectrum of the images. These observations indicate that fMRI frequency-tagging provides a valid approach to objectively compare human and monkey neural face recognition systems within the same framework.

IMPAIRMENT OF EVIDENCE ACCUMULATION UNDERLIES VISUOMOTOR DEFICITS IN MOUSE MODELS OF AUTISM.

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Laura Burnett, Peter Koppensteiner, Olga Symonova, Tomas Vega-Zuniga, Gaia Novarino, Maximilian Joesch
Institute of Science and Technology, Life Sciences, Klosterneuburg, Austria

Individuals with autism spectrum disorders (ASDs) often exhibit impairments in gaze fixation, visual attention, and hyper- or hyposensitivity to visual stimuli. However, the neural mechanisms underlying these problems remain unclear. Here we show that the mechanism of evidence accumulation required to initiate efficient threat responses is disrupted in Setd5(+/-) mice, a model of ASD. Although mutant animals can quickly detect visual threats, on average they require longer to evaluate and respond to them compared to their wild-type (WT) siblings. Other behavioural dynamics, as well as visual and threat evoked responses in the medial superior colliculus (mSC) remain unaffected, indicating cognitive rather than motor or sensory impairments. These behavioural deficits were recapitulated following optogenetic activation of excitatory vGlut2+ mSC neurons, known to initiate threat responses by exciting the dorsal periaqueductal grey (dPAG). In vitro patch-clamp recordings of Setd5(+/-) dPAG neurons revealed a stark reduction in firing rates in response to high, but not low, current injections. This change appears to be mediated by misregulation of Kv1.1 channels, suggesting a disruption in homeostatic mechanisms. In accordance with these intrinsic firing changes, a low saliency threat stimuli known to drive dPAG cells weakly, elicits WT behavioural responses in Setd5(+/-) mice. Finally, we observed similar phenotypic changes across two other independent ASD models, Cul3(+/-) and Ptchd1(-/y), suggesting that SC to PAG pathway might be a key node in ASD-related visuomotor deficits. Overall, our results provide a mechanistic model of cognitive dysfunction from gene to behaviour.

Role of JNK, MEK and adenylyl cyclase signalling in speed and directionality of enteric neural crest-derived cells.
Cells derived from the neural crest colonize the developing gut and give rise to the enteric nervous system. The rate at which the ENCC population advances along the bowel will be affected by both the speed and directionality of individual ENCCs. The aim of the study was to use time-lapse imaging and pharmacological activators and inhibitors to examine the role of several intracellular signalling pathways in both the speed and the directionality of individual enteric neural crest-derived cells in intact explants of E12.5 mouse gut. Drugs that activate or inhibit intracellular components proposed to be involved in GDNF-RET and EDN3-ETB signalling in ENCCs were used.

Transplantation of enteric nervous system stem cells rescues nitric oxide synthase deficient mouse colon.
Enteric nervous system neuropathy causes a wide range of severe gut motility disorders. Cell replacement of lost neurons using enteric neural stem cells (ENSC) is a possible therapy for these life-limiting disorders. Here we show rescue of gut motility after ENSC transplantation in a mouse model of human enteric neuropathy, the neuronal nitric oxide synthase (nNOS) deficient mouse model, which displays slow transit in the colon. We further show that transplantation of ENSC into the colon rescues impaired colonic motility with formation of extensive networks of transplanted cells, including the development of nNOS neurons and subsequent restoration of nitrergic responses. Moreover, post-transplantation non-cell-autonomous mechanisms restore the numbers of interstitial cells of Cajal that are reduced in the nNOS colon. These results provide the first direct evidence that ENSC transplantation can modulate the enteric neuromuscular syncytium to restore function, at the organ level, in a dysmotile gastrointestinal disease model.

Mosaic Analysis with Double Markers Reveals Distinct Sequential Functions of Lgl1 in Neural Stem Cells.
The concerted production of neurons and glia by neural stem cells (NSCs) is essential for neural circuit assembly. In the developing cerebral cortex, radial glia progenitors (RGPs) generate nearly all neocortical neurons and certain glia lineages.

RGP proliferation behavior shows a high degree of non-stochasticity, thus a deterministic characteristic of neuron and glia production. However, the cellular and molecular mechanisms controlling RGP behavior and proliferation dynamics in neurogenesis and glia generation remain unknown. By using mosaic analysis with double markers (MADM)-based genetic paradigms enabling the sparse and global knockout with unprecedented single-cell resolution, we identified Lgl1 as a critical regulatory component. We uncover Lgl1-dependent tissue-wide community effects required for embryonic cortical neurogenesis and novel cell-autonomous Lgl1 functions controlling RGP-mediated glia genesis and postnatal NSC behavior. These results suggest that NSC-mediated neuron and glia production is tightly regulated through the concerted interplay of sequential Lgl1-dependent global and cell intrinsic mechanisms.

IMPLICIT LEARNING OF VISUAL TRACKING IS SPECIFIC TO RESPONSE MODALITY AND RELIES ON IMPROVEMENT OF SIGNAL PREDICTION

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Simon Boylan, Alexandre Zénon
INCIA, Gironde, Bordeaux CEDEX, France

There is no consensus on the conditions under which implicit learning of visual tracking occurs. Here, we assessed the occurrence of such learning in eye and hand tracking tasks .We used an information-theoretic framework to gain better insight into the nature of the learning process. In experiment 1, 20 volunteers tracked a signal (order-2 autoregressive) composed of five segments, two of which repeated across trials . Individuals tracked with the eye or with a joystick in counter-balanced blocks. We found that tracking performance was better on the repeated than on the random segments but only in the joystick condition. This learning was improved on the next day. Subjects had no conscious awareness of the repetition. Through information-theoretic measures, we showed that improved performance in the joystick condition was caused by a better capacity to predict future positions of the signal. In Experiment 2 (N= 24), we replicated these findings and accounted for confounding factors. We also assessed the capacity of the subjects to generate the signal spontaneously when the target disappeared during five seconds. Preliminary results suggest that volunteers were not able to generate the signal during the blanks, despite their capacity to use their implicit knowledge of the signal to improve tracking performance. These findings show clearly that visual tracking signals can be learned implicitly, allowing individuals to improve their capacity to predict future signal values. The motor specificity of the learning process suggests that learning takes place at the level of the motor control circuit.

FLEXIBLE, CONTEXT-DEPENDENT, HIERARCHY OF EYE-HEAD COORDINATION

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Ofer Karp[1], Ehud Ahissar[2]
[1]Weizmann Institute of science, Brain Science, Rehovot, Israel, [2]Weizmann Institute of science, Brain Sciences, Rehovot, Israel

Visual orienting responses had traditionally been studied in head-fixed conditions. It had been shown that when the head is free to move, eye movements exhibit complex behavior, such as multisaccadic gaze-shifts. Here we show that head-eye coordination exhibits a flexible hierarchy, in which either the eye or the head can lead the orienting movement, depending on the context. We tested 20 human subjects in a virtual reality (VR) environment consisting of a neutral background and a ball. The subjects were asked to track the ball with their gaze and were free to move their head and body. Each trial started with the ball appearing at the same (virtual) allocentric position. After 2 seconds the ball jumped 15-55 deg horizontally, and the subject's gaze followed it ("exogenous orientation"). After 4 seconds the ball disappeared. The subjects, then, typically oriented their gaze back to the approximate area of trial initiation (without explicit instructions, "endogenous orientation"). We found that the hierarchy of head-eye coordination switched between these two orienting movements: the eye was leading during exogenous orientation (29±10ms), and the head was leading during endogenous orientation (16±10ms). Endogenous orientations involved 57±6% more saccades than exogenous orientations, with the first saccade being smaller by 29±7%. We model orientation control by a system of eye and head sensory-motor closed-loops, competing for action, based on visual, proprioceptive and context information. The model replicates our data, can replicate an opto-kinetic reflex and suggests that both saccades and smooth-pursuit movements are controlled by the same loop.

LOCUS COERULEUS BROADCASTS VISUOMOTOR PREDICTION ERRORS ACROSS THE NEOCORTEX

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Rebecca Jordan, Georg Keller
Friedrich Miescher Institute for Biomedical Research, Neurobiology, Basel, Switzerland

We have a remarkable ability to distinguish sensory inputs caused by our own actions, and those caused by the external environment. To achieve this, the brain must continually learn the relationships between motor actions and their sensory consequences. One way the brain may do this is to calculate prediction errors – deviations between predicted and actual sensory outcomes – in order to drive learning. If such prediction errors activate widely-projecting neuromodulatory systems, this would enable a coordinated and global modulation of learning rates by prediction errors. The noradrenergic locus coeruleus is one system that is known to promote cortical plasticity and has been shown to be responsive to unexpected sensory stimuli. To test if the mouse locus coeruleus responds to visuomotor prediction errors, we use a virtual reality system to generate visuomotor mismatches. Using two-photon calcium imaging and widefield imaging of noradrenaline sensors, we find that cortical locus coeruleus axons respond to visuomotor mismatches, of both the positive (more visual flow than expected) and negative (less visual flow than expected) type. These responses are widespread and found in different cortical regions, including visual cortex, somatosensory cortex, and motor cortex. Our results are consistent with the locus coeruleus broadcasting unsigned sensorimotor prediction errors.

DENDRITIC SIGNALING IN CORTICAL PYRAMIDAL CELLS DURING VISUAL DISCRIMINATION

POSTER SESSION 03 - SECTION: CODING IN VISUAL CORTEX

Borbála Kertész[1], Eszter Báthory[2], Zoltán Szadai[3], Martin Stacho[4], Lídia Popara[3], Tamás Tompa[1], Katalin Ócsai[1], Gergely Szalay[1], István Takács[1], Andrius Plauska[1], Linda Sulcz-Judák[1], Gergely Katona[3], Balázs Rózsa[1]
[1]Institute of Experimental Medicine - Eötvös Loránd Research Network, 3d Functional Network And Dendritic Imaging, Budapest, Hungary, [2]Budapest University of Technology and Economics, Faculty Of Electrical Engineering And Informatics, Budapest, Hungary, [3]Faculty of Information Technology and Bionics, Pázmány Péter Catholic University, Mta-ppke Itk-nap B 2p Measurement Technology Group, Budapest, Hungary, [4]Institute of Cognitive Neuroscience, Faculty of Psychology, Ruhr-University Bochum, Department Of Biopsychology, Bochum, Germany

The role of dendritic calcium spikes in the neocortex is unsettled as yet, not least because dendritic arborization is extensive and branches can reach several hundred micrometers, causing recordings in vivo to stay technically challenging. It is demonstrated that dendritic signaling takes part in the formation of perception by associating feed-forward and feedback information streams arriving to different cortical layers. A different hypothesis suggests that dendrites could also participate in associative learning by carrying information – an 'error signal' – backwards. Here we look into how stimulus properties and behavioral performance affect dendritic signaling, and perhaps by doing so also gain further insight on the current theories regarding the functional involvements of dendritic activity. We used 3D two-photon laser scanning microscopy with acousto-optical deflectors to examine calcium activity in the somata and apical dendrites of pyramidal neurons in V1 of mice performing visual discrimination tasks. Controlled water-access animals were trained to discriminate between two types of drifting grating visual stimuli, one followed by a drop of water as a reward while the other was unrewarded. Learning progression was assessed on the ratio of anticipatory lick rates during stimulation. The discrepancy between the expected and the actual outcomes offers an opportunity to investigate prediction error signaling. Calcium measurements were obtained with 3-dimensional ribbon scanning, a composite imaging field covering the whole length of neurons. Here we present the signals recorded on the pyramidal neurons' dendrites and somata, as well as an observed functional grouping of pyramidal cells based on signal types.

GABAERGIC MECHANISMS OF LOCALIZED FAST NEURONAL OSCILLATIONS IN THE MOUSE HIPPOCAMPAL CA1 AREA DURING ACTIVE EXPLORATION

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Ece Sakalar, Alexander Wallerus, Thomas Klausberger, Balint Lasztoczi
Center for Brain Research, Medical University of Vienna, Division Of Cognitive Neurobiology, Vienna, Austria

During exploratory behaviour the brain processes diverse information streams, integrating multiple sensory modalities with mnemonic and motivational cues to guide adaptive behaviour. In the CA1 area of hippocampus online brain states are characterized by continuous 8 - 12 Hz theta oscillations. Layer-specific slow (30 - 50 Hz), mid-frequency (60 - 90 Hz) and fast (100 - 150 Hz) gamma oscillations occur at distinct phases of theta waves, and together they provide a temporal framework that orchestrates network operations such as integration and segregation of information streams. Here we explore the contribution of identified GABA*ergic* cell types to this complex temporal framework. We recorded local field potentials from the hippocampal CA1 area of head fixed mice with multisite linear silicon probes, while animals performed unidirectional runs in a virtual corridor for a small water reward. Layer specific gamma oscillations were separated by applying current source density analysis. Simultaneously, we recorded spike timing of individual pyramidal cells and interneurons using multi shank silicon probes and firing of GABA*ergic* cells by glass microelectrodes filled with neurobiotin. A subset of recorded cells was subsequently labelled with neurobiotin using the juxtacellular method, and their affiliation to identified cell types was established based on their axonal and dendritic distribution and protein content. We found that the spike timing of GABA*ergic* cells is selectively modulated by different gamma oscillations contingent on cell type affiliations. Our data suggest that GABA*ergic* cells make cell-type specific contributions in establishing the temporal framework that orchestrates hippocampal network operations. (Funding: FWF P29744-B27).

WHAT IS THE MECHANICAL BASIS OF BETA OSCILLATIONS AND WAVES OF NEURAL ACTIVITY OBSERVED IN THE MOTOR CORTEX?

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Ling Kang, Jonas Ranft, Vincent Hakim
Ecole Normale Superieure, Biophysique Et Neuroscience Theoriques, Paris, France

Modeling the nonlinear dynamics of neural networks can help to make sense of phenomena observed in neural recordings. We focus on beta frequency (~20Hz) oscillations that are observed in motor cortex during movement preparation. In experiments, local field potentials (LFPs) recorded with multi-electrode arrays have been observed to display transient oscillations and organize into a variety of traveling waves (planar, radial, rotating,..). We model beta oscillation as arising from reciprocal interactions between randomly connected excitatory (E) pyramidal cells and local inhibitory interneurons (I). We use a rate model (mean-field) description of the local neural activity that has been shown to provide an accurate population-level description of network simulations based on coupled spiking neurons. Using distance-dependent interactions and delays matching those reported from experiments, we study this model in 2D to investigate possible origins of transient bursts of beta oscillations and of the observed spatial waves. Stochastic local entries are introduced to mimic inputs to the motor cortex from other neural areas. We compare our simulation results to electrophysiological datasets recorded in motor cortex of macaque monkey during an instructed delayed reach-to-grasp task [4]. We find that our model closely agrees with the recordings. It reproduces the observed power spectrum of the local field potential, beta oscillation burst statistics and produces a variety of traveling waves of speed and types similar to those seen in experiments. Our results suggest that both time-varying external entries and intrinsic network architecture shape the LFP dynamics of motor

cortex.

DEND MUTATION DISRUPTS HIPPOCAMPAL NETWORK ACTIVITY AND NOCTURNAL γ SHIFT

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Marie-Elisabeth Burkart[1], Josephine Kurzke[1], Jorge Vera[2], Frances Ashcroft[3], Jens Eilers[1], Kristina Lippmann[1]
[1]University of Leipzig, Carl-ludwig-institute For Physiology, Leipzig, Germany, [2]Albert Einstein College of Medicine, Dominick P. Purpura Department Of Neuroscience, New York, United States of America, [3]University of Oxford, Department Of Physiology, Anatomy And Genetics, Oxford, United Kingdom

Aims ATP-sensitive potassium (K_{ATP}) channels mediate cell metabolism and electrical activity by coupling intracellular ATP levels to membrane K^+-conductance. The activating mutation V59M in the $K_{ir}6.2$ subunit of the K_{ATP} channel causes developmental **d**elay and **e**pilepsy with **n**eonatal **d**iabetes, i.e., DEND syndrome. While the origin of neonatal diabetes is well understood, the pathophysiology of the neurological symptoms remains to be elucidated. Inhibitory parvalbumin$^+$-interneurons (PV-INs) play a pivotal role in generating cognition-associated hippocampal sharp-wave ripples (SWRs) and gamma oscillations (30-100 Hz) as well as epileptogenesis. Therefore, we asked whether constitutively open K_{ATP} channels in PV-INs may contribute to the neurological symptoms of the DEND syndrome. **Methods** We performed *in vivo* and *in vitro* local field potential as well as patch-clamp recordings of PV-INs in the hippocampal area CA1 in control mice and mice with the V59M mutation expressed in PV-INs (PV-V59M). **Results** We found that *in vitro* SWRs and gamma oscillations are similarly impaired in PV-V59M mice and control mice with pharmacologically opened K_{ATP} channels. Patch-clamp recordings of PV-INs in PV-V59M mice revealed a decreased power of intrinsic gamma oscillations and fewer PV-INs with gamma resonance behaviour. Moreover, PV-V59M mice showed seizures and a reduced power of gamma oscillations during wakefulness in *in vivo* LFP recordings. **Conclusions** Our findings provide evidence that the K_{ATP} channel mutation Kir6.2-V59M, expressed only in PV-INs, leads to altered network oscillations and seizures that potentially underly the neurological symptoms of DEND syndrome and highlight the crucial role of PV-INs in oscillatory activity and network inhibition.

Hippocampal activity is organized by a collection of network oscillators on multiple time scales. Of these, theta oscillations reflect rhythmic inputs, occurring typically during exploratory or memory-guided behaviour or REM sleep. Recent studies revealed an unexpected diversity of theta cycles. In rodents performing memory tasks, cycle-by-cycle variations were found based on beta-gamma frequency theta-nested spectral components (tSCs), likely related to distinct spiking dynamics with different contributions to memory processes. The medial septum (MS) has been identified as responsible for generation of theta oscillations while gamma rhythms mostly have been associated with entorhinal cortex (EC) and CA3 inputs or local CA1 networks. To examine the possible contribution of the MS theta generator to the wave-by-wave spectral heterogeneity of theta, we recorded septal neurons simultaneously with the hippocampal local field potential in mice moving freely in a linear track and in anesthetized mice and rats, and used optogenetics to stimulate parvalbumin-expressing MS neurons in PV-IRES-Cre mice. We found that MS neurons' firing rate and phase-locking to theta waves were correlated to the presence of different CA1 tSCs. Furthermore, most MS neurons not only showed strong phase-coupling to tSCs but also preceded them. Optogenetic activation of MS parvalbumin-expressing neurons with theta-modulated stimulation bursts proved that the MS is capable of eliciting theta-nested beta-gamma oscillations in the CA1. In conclusion, these results suggest that septal firing is not only involved in the generation of the hippocampal theta oscillations but also modulate the higher frequency spectral components nested in individual theta cycles.

Virtual museum of congenital heart defects: digitization and establishment of a database for cardiac specimens.
Education and training of morphology for medical students, and professionals specializing in pediatric cardiology and surgery has traditionally been based on hands-on encounter with congenitally malformed cardiac specimens. Large international archives are no longer widely available due to stricter data protection rules, a reduced number of autopsies, attrition rate of existing specimens, and most importantly due to a higher survival rate of patients. Our Cardiac Archive houses about 400 cardiac specimens with congenital heart disease. The collection spans almost 60 years and thus goes back to pre-surgical era. Unfortunately, attrition rate due to desiccation has led to an increased natural decay in recent years. The present multi-institutional project focuses on saving the collection by digitization. Specimens are scanned by high-resolution micro-CT/MRI. Virtual 3D-models are segmented and a comprehensive database is built. We now report an initial feasibility study with six test specimens that provided promising results, however, adequate presentation of the intracardiac anatomy, including septa and cardiac valves requires further refinements. Computer assisted design methods are necessary to overcome consequences of pathological examination, shrinkage and/or distortion of the specimens. For a next step, we anticipate an expandable web-based virtual museum with interactive reference and training tools. Web access for professional third parties will be provided by registration/subscription. In a future phase, segmental wall motion data could be added to virtual models. 3D-printed models may replace actual specimens and serve as hands-on surgical training to elucidate complex morphologies, promote surgical emulation, and extract more accurate procedural knowledge based on such a collection.

Pyrophosphate therapy prevents trauma-induced calcification in the mouse model of neurogenic heterotopic ossification.
Trauma-induced calcification is the pathological consequence of complex injuries which often affect the central nervous system and other parts of the body simultaneously. We demonstrated by an animal model recapitulating the calcification of the above condition that adrenaline transmits the stress signal of brain injury to the calcifying tissues. We have also found that although the level of plasma pyrophosphate, the endogenous inhibitor of calcification, was normal in calcifying animals, it could not counteract the acute calcification. However, externally added pyrophosphate inhibited calcification even when it was administered after the complex injuries. Our finding suggests a potentially powerful clinical intervention of calcification triggered by polytrauma injuries which has no effective treatment.

In vivo localization of chronically implanted electrodes and optic fibers in mice.
Electrophysiology provides a direct readout of neuronal activity at a temporal precision only limited by the sampling rate. However, interrogating deep brain structures, implanting multiple targets or aiming at unusual angles still poses significant challenges for operators, and errors are only discovered by post-hoc histological reconstruction. Here, we propose a method combining the high-resolution information about bone landmarks provided by micro-CT scanning with the soft tissue contrast of the MRI, which allowed us to precisely localize electrodes and optic fibers in mice in vivo. This enables arbitrating the success of implantation directly after surgery with a precision comparable to gold standard histology. Adjustment of the recording depth with micro-drives or early termination of unsuccessful experiments saves many working hours, and fast 3-dimensional feedback helps surgeons avoid systematic errors. Increased aiming precision enables more precise targeting of small or deep brain nuclei and multiple targeting of specific cortical or hippocampal layers.

BASAL GANGLIA FEEDBACK LOOPS AS POSSIBLE CANDIDATES FOR GENERATION OF BETA OSCILLATION

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Shiva Azizpourlindi[1,2], Arthur Leblois[1,2]
[1]CNRS UMR 5293, Institut Des Maladies Neurodégénératives, Bordeaux, France, [2]Université de Bordeaux, Institut Des Maladies Neurodégénératives, Bordeaux, France

An increase in beta-band frequency (13-30 Hz) activity has been observed in different nuclei of the basal ganglia in Parkinson's disease (PD). However, which neural circuits give rise to these oscillations remains unclear. In this study, we computationally investigate the mechanisms responsible for the generations of beta oscillations that happen persistently in Dopamine depletion and also transiently in healthy rats. Our results show that using a rate model with realistic time constants, the classical STN-GPe recurrent network produces higher frequencies than the beta range and consequently is unlikely to be the source of these oscillations alone. We then propose two alternative circuits made of pallidostriatal feedback loops that can generate network oscillations close to this range. The dynamics of the loops are modeled using both the rate model as well as a spiking neural network with more precise time constants derived from experiments. We explore how each of these loops behaves around the point of transition between stable fixed point to the oscillatory regime depending on synaptic connection strengths. Then, one by one, we add the aforementioned loops together and explore how the frequency of the neural oscillations changes as a function of relative synaptic gains of the loops. Moreover, we show that with the pathophysiological changes due to Dopamine depletion in PD, the network can transition from a steady-state firing rate to the state of oscillating in beta-band frequencies. Our results show that it is plausible that the oscillations are a product of the interactions between multiple feedback loops.

A Disynaptic Circuit in the Globus Pallidus Controls Locomotion Inhibition.
The basal ganglia (BG) inhibit movements through two independent circuits: the striatal neuron-indirect and the subthalamic nucleus-hyperdirect pathways. These pathways exert opposite effects onto external globus pallidus (GPe) neurons, whose functional importance as a relay has changed drastically with the discovery of two distinct cell types, namely the prototypic and the arkypallidal neurons. However, little is known about the synaptic connectivity scheme of different GPe neurons toward both motor-suppressing pathways, as well as how opposite changes in GPe neuronal activity relate to locomotion inhibition. Here, we optogenetically dissect the input organizations of prototypic and arkypallidal neurons and further define the circuit mechanism and behavioral outcome associated with activation of the indirect or hyperdirect pathways. This work reveals that arkypallidal neurons are part of a novel disynaptic feedback loop differentially recruited by the indirect or hyperdirect pathways and that broadcasts inhibitory control onto locomotion only when arkypallidal neurons increase their activity.

Experimental investigation of the stability of the floating water bridge.
When a high voltage is applied between two beakers filled with deionized water, a floating bridge of water is formed in between exceeding the length of 2 cm when the beakers are pulled apart. Currently two theories regarding the stability of the floating water bridge exist, one suggesting that the tension caused by electric field in the dielectric medium is holding the bridge and the other suggesting surface tension to be responsible for the vertical equilibrium. We construct experiments in which the electric field and the geometry of the bridge are measured and compared with predictions of theories of the floating water bridge stability. We use a numerical simulation for estimation of the electric field. Our results indicate that the two forces of dielectric and surface tensions hold the bridge against gravity simultaneously and, having the same order of magnitude, neither of the two forces are negligible. In bridges with larger diameters, the effect of dielectric tension is slightly more in the vertical equilibrium than surface tension. Results show that the stability can be explained by macroscopic forces, regardless

of the microscopic changes in the water structure.

TRANSVERS-PLANE-SNAPSHOT OF SIGNAL PROPAGATING NEURONAL PATHWAYS REVEALS RELATIONSHIP BETWEEN SPONTANEOUS AND EVOKED ACTIVITY IN A CULTURED NEURONAL CIRCUIT.

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Hiroki Asada[1], Suguru Kudoh[2]
[1]Kwansei Gakuin Universtiy, Department Of Engineering, Sanda-shi, Hyougo, Japan, [2]Kwansei Gakuin University, Department Of Engineering, Sanda-shi, Hyougo, Japan

In cultured neuronal networks, a single current stimulus often evokes a relatively reproducible spike pattern. In the neuronal network, not only evoked response activity but also spontaneous electrical activity is expressed. The physical neural pathways expressing this spontaneous activity are thought to include multiple neuronal pathways expressing evoked responses. Therefore, the spatial pattern of spontaneous activity is a slice of the state in which several neural pathways are propagating signals in a fixed time window. In this study, rat hippocampal neurons from 18-day old Wistar Rat embryos were cultivated over 30 days on a MED probe provided with 64-multi-electrodes array. Firstly, we summarized the reproducible response activity, then all responses evoked by repeated electro stimulation were sliced into 1-ms-width-time-windows, which cannot include one or more transmitted signals between neurons. As a result, spikes were detected simultaneously at several channels in a 1-ms-width-timewindow, indicating that the signals evoked by a stimulus were propagating in a branched manner, and were transmitted along parallel pathways. The spatial pattern of spontaneous activity was snapshot of the signals propagating the neuronal pathways and composed of several transverse plane of branched and parallels pathways undertaking evoked activity. It suggests the possibility that evoked activity pattern based on spontaneous activity pattern.

The main inhibitory synaptic currents, gated by gamma-aminobutyric acid (GABA), are mediated by Cl^--conducting channels, and are therefore sensitive to changes in the chloride electrochemical gradient. As GABAergic activity dictates neuronal firing, the intracellular chloride concentration ($[Cl^-]_i$) plays a major role in the regulation of neuronal activity. We measured $[Cl^-]_i$ with 2-photon LSSmClopHensor imaging in anaesthetized young adult mice, and we found a large physiological diurnal fluctuation of baseline $[Cl^-]_i$ in pyramidal neurons. This equates to a ~15mV positive shift in chloride equilibrium potential at times when mice are typically active (midnight), relative to their sleep phase (midday). Accordingly, the KCC2 chloride extruder shows reduced membrane expression and increased inactivating phosphorylation at night, when the NKCC1 chloride importer shows increased activating phosphorylation. We then demonstrated that at midnight: 1) optogenetic activation of parvalbumin interneurons in the visual cortex displays a more variable effect compared to the stable inhibiting activity observed at midday; 2) visually evoked gamma-band oscillations are reduced, and this can be rescued by the NKCC1 blocker bumetanide; 3) the brain cortex is more sensitive to the pro-epileptic drug 4-ammino pyridine, and this raised epileptogenicity is rescued by bumetanide.
These results shed light on a new scenario in which GABAergic transmission changes its efficacy according to $[Cl]_i$ also in the cortex of adult mammals following diurnal oscillations. As GABA exerts plenty of physiological actions, further analysis will be carried out to assess the implications of this finding.

A Map of the microRNA Regulatory Networks Identified by Experimentally Validated microRNA-Target Interactions in Five Domestic Animals: Cattle, Pig, Sheep, Dog, and Chicken.
Domestic animals are members of the broader ecological context, in which humans are situated. Yet, genomics and systems science research have lagged behind and been relatively underappreciated in domestic animals compared to human genetics/genomics. Harnessing big data calls for omics data mapping studies in a broad range of mammals. To this end, microRNAs (miRNAs) regulate posttranscriptional expression of target genes, hence, governing different biological pathways and physiological processes. The knowledge of miRNA regulatory networks and maps is important for understanding regulation of gene expression and functions in both humans and domestic animals. However, complete miRNA regulatory networks have not yet been described in all species, particularly in domestic animals. We report here an original analysis so as to map the miRNA regulatory networks in domestic animals based on miRNA-target interactions (MTIs). Validated MTIs for five species; cattle, pig, sheep, dog, and chicken were extracted from the miRTarBase. miRNA regulomes were visualized using the Cytoscape software. The data in cattle, chicken, and pig were sufficient to visualize networks, identify central molecules, and subnetworks associated with the same phenotype; however, the MTI data in dog and sheep are still limited. We found several hub genes with large number of interactions, for example, 1 miRNA (bta-miR-17-5p) interacting with 27 genes and 7 miRNAs interacting with the same gene (tumor necrosis factor []) in cattle. In addition, two single-nucleotide polymorphisms were identified within the seed region of a previously demonstrated MTI, namely, between (high mobility group box 3) gene and bta-miR-17-5p. In summary, this miRNA regulome mapping study will enable and guide further studies of genome function in mammals with a view to applications in human as well as veterinary medicine. Furthermore, these miRNA regulomes can help to clarify fundamental pathways in cell biology and reveal molecular insights on phenotypic trait variability in common complex diseases and response phenotypes of drugs or other health interventions for precision

medicine in the future.

GENERATING SLEEP OSCILLATIONS USING PRIMARY AND HIPSC-DERIVED THALAMO-CORTICAL CULTURES

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Mojtaba Bandarabadi, David Pamies, Marie-Gabrielle Zurich, Anne Vassalli, Mehdi Tafti
University of Lausanne, Department Of Biomedical Sciences, Lausanne, Switzerland

Slow oscillations, delta waves, and spindles are the major brain oscillations during non-rapid eye movement (NREM) sleep, arising from the thalamo-cortical circuitries. Whether the generation of these oscillatory patterns requires subcortical neuromodulatory inputs remain unknown. Using a high-density microelectrode array with 26400 electrodes, we recorded both single-unit activity and local field potential (LFP) of primary and hiPSC-derived cortical, thalamic, and thalamo-cortical co-cultures. We found that cell assemblies of these *in vitro* networks mimic oscillatory patterns of slow oscillations (<1Hz), delta waves (2-4 Hz), and spindles (9-16 Hz), respectively, similar to NREM sleep. Interestingly, spindles of thalamo-cortical co-cultures show strong coupling to the slow waves as *in vivo*, and slow waves travel across the cortical culture and are accompanied with fast gamma oscillations, as in the intact brain. Addition to cortical cultures of an antagonist of calcium-activated potassium channels suppressed the slow oscillation, suggesting a subcellular pathway for travelling of these oscillations. Furthermore, stimulation of these networks using wake-promoting neuromodulators induced desynchronized wake-like states in cultures. Our results demonstrate that NREM sleep with its oscillatory characteristics is the default state of the cortical and thalamo-cortical networks and highlight the potential applications of developing *in vitro* sleep models to answer basic questions in the field of sleep research.

Slow Waves Promote Sleep-Dependent Plasticity and Functional Recovery after Stroke.
Functional recovery after stroke is associated with a remapping of neural circuits. This reorganization is often associated with low-frequency, high-amplitude oscillations in the peri-infarct zone in both rodents and humans. These oscillations are reminiscent of sleep slow waves (SW) and suggestive of a role for sleep in brain plasticity that occur during stroke recovery; however, direct evidence is missing. Using a stroke model in male mice, we showed that stroke was followed by a transient increase in NREM sleep accompanied by reduced amplitude and slope of ipsilateral NREM sleep SW. We next used 5 ms optical activation of Channelrhodopsin 2-expressing pyramidal neurons, or 200 ms silencing of Archeorhodopsin T-expressing pyramidal neurons, to generate local cortical UP, or DOWN, states, respectively, both sharing similarities with spontaneous NREM SW in freely moving mice. Importantly, we found that single optogenetically evoked SW (SW) in the peri-infarct zone, randomly distributed during sleep, significantly improved fine motor movements of the limb corresponding to the sensorimotor stroke lesion site compared with spontaneous recovery and control conditions, while motor strength remained unchanged. In contrast, SW during wakefulness had no effect. Furthermore, chronic SW during sleep were associated with local axonal sprouting as revealed by the increase of anatomic presynaptic and postsynaptic markers in the peri-infarct zone and corresponding contralesional areas to cortical circuit reorganization during stroke recovery. These results support a role for sleep SW in cortical circuit plasticity and sensorimotor recovery after stroke and provide a clinically relevant framework for rehabilitation strategies using neuromodulation during sleep. Brain stroke is one of the leading causes of death and major disabilities in the elderly worldwide. A better understanding of the pathophysiological mechanisms underlying spontaneous brain plasticity after stroke, together with an optimization of rehabilitative strategies, are essential to improve stroke treatments. Here, we investigate the role of optogenetically induced sleep slow waves in an animal model of ischemic stroke and identify sleep as a window for poststroke intervention that promotes neuroplasticity and facilitates sensorimotor recovery.

A role for spindles in the onset of rapid eye movement sleep.
Sleep spindle generation classically relies on an interplay between the thalamic reticular nucleus (TRN), thalamo-cortical (TC) relay cells and cortico-thalamic (CT) feedback during non-rapid eye movement (NREM) sleep. Spindles are hypothesized to stabilize sleep, gate sensory processing and consolidate memory. However, the contribution of non-sensory thalamic nuclei

in spindle generation and the role of spindles in sleep-state regulation remain unclear. Using multisite thalamic and cortical LFP/unit recordings in freely behaving mice, we show that spike-field coupling within centromedial and anterodorsal (AD) thalamic nuclei is as strong as for TRN during detected spindles. We found that spindle rate significantly increases before the onset of rapid eye movement (REM) sleep, but not wakefulness. The latter observation is consistent with our finding that enhancing spontaneous activity of TRN cells or TRN-AD projections using optogenetics increase spindle rate and transitions to REM sleep. Together, our results extend the classical TRN-TC-CT spindle pathway to include non-sensory thalamic nuclei and implicate spindles in the onset of REM sleep.

REM sleep stabilizes hypothalamic representation of feeding behavior.
During rapid eye movement (REM) sleep, behavioral unresponsiveness contrasts strongly with intense brain-wide neural network dynamics. Yet, the physiological functions of this cellular activation remain unclear. Using in vivo calcium imaging in freely behaving mice, we found that inhibitory neurons in the lateral hypothalamus (LH) show unique activity patterns during feeding that are reactivated during REM, but not non-REM, sleep. REM sleep-specific optogenetic silencing of LH cells induced a reorganization of these activity patterns during subsequent feeding behaviors accompanied by decreased food intake. Our findings provide evidence for a role for REM sleep in the maintenance of cellular representations of feeding behavior.

Loss of Snord116 alters cortical neuronal activity in mice: a preclinical investigation of Prader-Willi syndrome.
Prader-Willi syndrome (PWS) is a neurodevelopmental disorder that is characterized by metabolic alteration and sleep abnormalities mostly related to rapid eye movement (REM) sleep disturbances. The disease is caused by genomic imprinting defects that are inherited through the paternal line. Among the genes located in the PWS region on chromosome 15 (15q11-q13), small nucleolar RNA 116 (Snord116) has been previously associated with intrusions of REM sleep into wakefulness in humans and mice. Here, we further explore sleep regulation of PWS by reporting a study with PWScrm+/p- mouse line, which carries a paternal deletion of Snord116. We focused our study on both macrostructural electrophysiological components of sleep, distributed among REMs and nonrapid eye movements. Of note, here, we study a novel electroencephalography (EEG) graphoelements of sleep for mouse studies, the well-known spindles. EEG biomarkers are often linked to the functional properties of cortical neurons and can be instrumental in translational studies. Thus, to better understand specific properties, we isolated and characterized the intrinsic activity of cortical neurons using in vitro microelectrode array. Our results confirm that the loss of Snord116 gene in mice influences specific properties of REM sleep, such as theta rhythms and, for the first time, the organization of REM episodes throughout sleep-wake cycles. Moreover, the analysis of sleep spindles present novel specific phenotype in PWS mice, indicating that a new catalog of sleep biomarkers can be informative in preclinical studies of PWS.

Assessing Epileptogenicity Using Phase-Locked High Frequency Oscillations: A Systematic Comparison of Methods.
High frequency oscillations (HFOs) are traditional biomarkers to identify the epileptogenic tissue during presurgical evaluation in pharmacoresistant epileptic patients. Recently, the resection of brain tissue exhibiting coupling between the amplitude of HFOs and the phase of low frequencies demonstrated a more favorable surgical outcome. Here we compare the predictive value of ictal HFOs and four methods for quantifying the ictal phase-amplitude coupling, namely mean vector length, phase-locked high gamma, phase locking value, and modulation index (MI). We analyzed 32 seizures from 16 patients to identify the channels that exhibit HFOs and phase-locked HFOs during seizures. We compared the resection ratio, defined as the percentage of channels exhibiting coupling located in the resected tissue, with the postsurgical outcome. We found that the MI is the only method to show a significant difference between the resection ratios of patients with good and poor outcomes. We further show that the whole seizure, not only the onset, is critical to assess epileptogenicity using the phase-locked HFOs. We postulate that the superiority of MI stems from its capacity to assess coupling of discrete HFO events and its independence from the HFO power. These results confirm that quantitative analysis of HFOs can boost presurgical evaluation and indicate the paramount importance of algorithm selection for clinical applications.

Dynamic modulation of theta-gamma coupling during rapid eye movement sleep.
Theta phase modulates gamma amplitude in hippocampal networks during spatial navigation and rapid eye movement (REM) sleep. This cross-frequency coupling has been linked to working memory and spatial memory consolidation; however, its

spatial and temporal dynamics remains unclear. Here, we first investigate the dynamics of theta-gamma interactions using multiple frequency and temporal scales in simultaneous recordings from hippocampal CA3, CA1, subiculum, and parietal cortex in freely moving mice. We found that theta phase dynamically modulates distinct gamma bands during REM sleep. Interestingly, we further show that theta-gamma coupling switches between recorded brain structures during REM sleep and progressively increases over a single REM sleep episode. Finally, we show that optogenetic silencing of septohippocampal GABAergic projections significantly impedes both theta-gamma coupling and theta phase coherence. Collectively, our study shows that phase-space (i.e. cross-frequency coupling) coding of information during REM sleep is orchestrated across time and space consistent with region-specific processing of information during REM sleep including learning and memory.

SPINDLE: End-to-end learning from EEG/EMG to extrapolate animal sleep scoring across experimental settings, labs and species.
Understanding sleep and its perturbation by environment, mutation, or medication remains a central problem in biomedical research. Its examination in animal models rests on brain state analysis via classification of electroencephalographic (EEG) signatures. Traditionally, these states are classified by trained human experts by visual inspection of raw EEG recordings, which is a laborious task prone to inter-individual variability. Recently, machine learning approaches have been developed to automate this process, but their generalization capabilities are often insufficient, especially across animals from different experimental studies. To address this challenge, we crafted a convolutional neural network-based architecture to produce domain invariant predictions, and furthermore integrated a hidden Markov model to constrain state dynamics based upon known sleep physiology. Our method, which we named SPINDLE (Sleep Phase Identification with Neural networks for Domain-invariant LEearning) was validated using data of four animal cohorts from three independent sleep labs, and achieved average agreement rates of 99%, 98%, 93%, and 97% with scorings from five human experts from different labs, essentially duplicating human capability. It generalized across different genetic mutants, surgery procedures, recording setups and even different species, far exceeding state-of-the-art solutions that we tested in parallel on this task. Moreover, we show that these scored data can be processed for downstream analyzes identical to those from human-scored data, in particular by demonstrating the ability to detect mutation-induced sleep alteration. We provide to the scientific community free usage of SPINDLE and benchmarking datasets as an online server at https://sleeplearning.ethz.ch. Our aim is to catalyze high-throughput and well-standardized experimental studies in order to improve our understanding of sleep.

Lauflumide (NLS-4) Is a New Potent Wake-Promoting Compound.
Psychostimulants are used for the treatment of excessive daytime sleepiness in a wide range of sleep disorders as well as in attention deficit hyperactivity disorder or cognitive impairment in neuropsychiatric disorders. Here, we tested in mice the wake-promoting properties of NLS-4 and its effects on the following sleep as compared with those of modafinil and vehicle. C57BL/6J mice were intraperitoneally injected with vehicle, NLS-4 (64 mg/kg), or modafinil (150 mg/kg) at light onset. EEG and EMG were recorded continuously for 24 h after injections and vigilance states as well as EEG power densities were analyzed. NLS-4 at 64 mg/kg induced significantly longer wakefulness duration than modafinil at 150 mg/kg. Although no significant sleep rebound was observed after sleep onset for both treatments as compared with their vehicles, modafinil-treated mice showed significantly more NREM sleep when compared to NLS-4. Spectral analysis of the NREM EEG after NLS-4 treatment indicated an increased power density in delta activity (0.75-3.5 Hz) and a decreased power in theta frequency range (6.25-7.25 Hz), while there was no differences after modafinil treatment. Also, time course analysis of the delta activity showed a significant increase only during the first 2 time intervals of sleep after NLS-4 treatment, while delta power was increased during the first 9 time intervals after modafinil. Our results indicate that NLS-4 is a highly potent wake-promoting drug with no sign of hypersomnia rebound. As opposed to modafinil, recovery sleep after NLS-4 treatment is characterized by less NREM amount and delta activity, suggesting a lower need for recovery despite longer drug-induced wakefulness.

Thalamic dual control of sleep and wakefulness.
Slow waves (0.5-4 Hz) predominate in the cortical electroencephalogram during non-rapid eye movement (NREM) sleep in mammals. They reflect the synchronization of large neuronal ensembles alternating between active (UP) and quiescent (Down) states and propagating along the neocortex. The thalamic contribution to cortical UP states and sleep modulation remains unclear. Here we show that spontaneous firing of centromedial thalamus (CMT) neurons in mice is phase-advanced to global cortical UP states and NREM-wake transitions. Tonic optogenetic activation of CMT neurons induces NREM-wake

transitions, whereas burst activation mimics UP states in the cingulate cortex and enhances brain-wide synchrony of cortical slow waves during sleep, through a relay in the anterodorsal thalamus. Finally, we demonstrate that CMT and anterodorsal thalamus relay neurons promote sleep recovery. These findings suggest that the tonic and/or burst firing pattern of CMT neurons can modulate brain-wide cortical activity during sleep and provides dual control of sleep-wake states.

STATE-SPECIFIC ACTIVITY OF PYRAMIDAL CELLS AND INTERNEURONS IN SUPRAGRANULAR NEOCORTICAL LAYERS DURING NATURAL SLEEP AND WAKEFULNESS

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

János Horváth, Robert Averkin, Sándor Bordé, Boglárka Bozsó, Viktor Szemenyei, Gábor Tamás
University of Szeged, Department Of Physiology, Anatomy And Neuroscience, Szeged, Hungary

Rhythmic population activity of neocortical neurons is linked to behavioral states. We applied a drug-free technique of juxtacellular recording/labeling to determine contributions of neocortical pyramidal cells (PYR) regular spiking interneurons (RSIs) and fast spiking interneurons (FSIs) in neural oscillations in freely behaving rats during natural sleep and awake states. In general, layer2 and 3 PYRs (n=40) showed sporadic activity in non-REM sleep with moderate spindle phase coupled firing detected in layer3 PYRs. Sporadic and phase unrelated firing was characteristic of layer2 PYRs during theta oscillations in REM sleep with a moderate increase in firing in theta oscillations of quiet wakefulness. Layer3 PYRs showed phase related packets of sporadic firing in REM theta with a decreased activity in quiet wakefulness. Rhythmic activity was observed in all FSIs (n=32) and most RSIs (n=27 out of 34) during spindles with FSI and RSI firing locked to different phases of spindle cycles, respectively. RSIs (n=14) showed elevated firing during REM sleep theta relative to nonREM episodes and theta phase relatedness in REM was preserved during awake theta in n=4 cells. Most interneurons (both FSI, n=18 and RSI, n=20) showed a shift in phase preference in spindle vs. theta oscillations, but a minority of individual FSIs (n=3) and RSIs (n=5) fired at the same phase of spindle and theta. In conclusion, the sporadic firing of layer2 and 3 PYRs is accompanied by heterogeneous involvement of FSIs and RSIs during nonREM, REM sleep and revealed a prominent contribution of RSIs to theta periods relative to FSIs.

GABA-A RHYTHMIC INHIBITION IN THE CLAUSTRUM DRIVES NETWORK OSCILLATION

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Gilles Ouanounou, Ambre Ledoux, Thierry Bal
Université Paris-Saclay, CNRS,, Neuropsi, Institut Des Neurosciences Paris-saclay, Saclay, France

The claustrum and the endopiriform nucleus (DEN) form a sheet-like structure below the insular cortex. Thanks to a variety of interneurons and far-projecting excitatory claustrocortical neurons, it is the most connected structure in the forebrain. This brain hub is not well understood yet, despite its presence in amniotes, including reptiles and mammals (Norimoto et al., 2020). It modulates neocortical sleep slow-wave synchronization (Narikiyo et al., 2020) and may mediate the unified sense of cognition (Crick and Koch, 2005) and attention (Atlan et al., 2018; Fodoulian et al., 2021). In mouse brain slices containing portions of the claustrum/DEN and insula, we found that claustral principal cells undergo a 0,3-1 Hz network oscillation under cholinergic modulation. To examine the mechanisms underlying this oscillation we performed voltage-clamp protocols in neurons from wild-type and transgenic mice. In putative principal claustral neurons, we found a clear rhythmicity of inhibitions, while excitatory post-synaptic currents distribution remained mostly non-rhythmic. Rhythmic inhibitions were driven through chloride and not potassium conductances, suggesting the involvement of GABA-A receptors. In current-clamp, rhythmic burst firing of action potentials in principal cells was generated by excitatory inputs and terminated by inhibitions. These experiments suggest a pacemaker role for inhibitory neurons under cholinergic modulation of the network. We also recorded a subset of claustral neurons with endogenous rhythmic behavior. Whether these (inter)neurons play a pacemaker role in the network oscillation, and what kinds of synaptic loops there are within the claustrum and/or between the claustrum and the adjacent insular cortex, remains to be examined.

Memory consolidation is a process of stabilisation of information in two stages: the fast synaptic consolidation and the gradual system consolidation. The latter consists in the reorganisation of information and its transfer from temporary storage in the hippocampus to long-term storage in the neocortex. Sleep, and in particular its deepest stage called slow wave sleep, is thought to play a crucial role in memory consolidation. Evidence suggest that information transfer could occur through the temporal coupling of hippocampal ripples and cortical spindles. We recently showed that midline thalamic neurons synchronise neocortical slow oscillations during slow wave sleep. Here, we hypothesise that through synchronising cortical activity, midline thalamus mediates coordination of spindles and ripples. To investigate the role of midline NECAB-1 thalamic neurons in hippocampo-cortical coupling, and its role in memory consolidation during slow wave sleep, we conducted a spatial memory task called displaced object recognition. After exposing the mice to a set of objects, we optogenetically or chemogenetically inhibited NECAB-1 thalamic neurons during the first hours of sleep, while recording the local field potential signals in multiple cortices and hippocampus. We hypothesize that inhibiting NECAB-1 thalamic neurons will impede spindles-ripples coordination and thus hindering the memory consolidation of spatial memory.

ARE SPONTANEOUS SPIKES OF THE MITRAL CELLS OF THE RODENT OLFACTORY BULB MODULATED BY INTRINSIC THETA OSCILLATIONS?

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Luna Jammal Salameh
University of Regensburg, Biology, Regensburg, Germany

Both spontaneous and odor-evoked network activity in rodent olfactory bulbs (OB) are patterned by respiration, resulting in oscillations within the theta regime. Previously, we observed theta rhythms in local field potential recordings (LFP) in semi-intact nose-brain preparations of rats that are uncoupled from respiration (Perez et al. 2015). Thus, we hypothesize that the respiratory theta rhythm taps into an intrinsic theta resonance of the bulbar network.
Here we investigate the properties of these intrinsic theta rhythms. First, we frequently observed harmonics of theta, as recently reported from hippocampal LFPs . We also observed that both frequency and power of theta rhythms were stable, persisting for at least one hour (average frequency 2.1 ± 0.3 Hz, n=10).
Moreover, theta frequency did not change across all bulbar locations recorded from (up to nine), suggesting that the frequency is homogenous within the entire OB network (n=14). Next, we asked if the spontaneous spiking activity recorded near the mitral cell layer is correlated with the ongoing theta rhythm. We developed an algorithm to isolate the spikes to determine their phase relative to the LFP theta, and applied circular statistical tests to check for preferred phases of firing. We observed significant correlations between spike-phase distributions and LFP theta within subsets of one-minute recording intervals. Moreover, our results align well with in vivo recordings showing a correlation between mitral cell spontaneous activity and breathing (Fukunaga et al., 2012) and prove that the preparation allows to investigate rhythmic bulbar activity at the single cell level.

Learning-induced modulation of the effect of neuroglial transmission on synaptic plasticity.
Training rats in a complex olfactory discrimination task results in acquisition of "rule learning" (learning how to learn), a term describing the capability to perform the task superbly. Such rule learning results in strengthening of both excitatory and inhibitory synaptic connections between neurons in the piriform cortex. Moreover, intrinsic excitability is also enhanced throughout the pyramidal neuron population. Surprisingly, the cortical network retains its stability under these long-term modifications. In particular, the susceptibility for long-term potentiation (LTP) induction, while decreased for a short time window, returns to almost its pretraining value, although significant strengthening of AMPA receptor-mediated glutamatergic transmission remains. Such network balance is essential for maintaining the single-cell modifications that underlie long-term memory while preventing hyperexcitability that would result in runaway synaptic activity. However, the mechanisms underlying the long-term maintenance of such balance have yet to be described. In this study, we explored the role of astrocyte-mediated gliotransmission in long-term maintenance of learning-induced modifications in susceptibility for LTP induction and control of the strength of synaptic inhibition. We show that blocking connexin 43 hemichannels, which form gap junctions between astrocytes, decreases significantly the ability to induce LTP by stimulating the excitatory connections between piriform cortex pyramidal neurons after learning only. In parallel, spontaneous miniature inhibitory postsynaptic current amplitude is reduced in neurons from trained rats only, to the level of prelearning. Thus gliotransmission has a key role in maintaining learning-induced cortical stability by a wide-ranged control on synaptic transmission and plasticity. NEW & NOTEWORTHY We explore the role of astrocyte-mediated gliotransmission in maintenance of olfactory discrimination learning-induced modifications. We show that blocking gap junctions between astrocytes decreases significantly the ability to induce long-term potentiation in the piriform cortex after learning only. In parallel, synaptic inhibition is reduced in neurons from trained rats only, to the level of prelearning. Thus gliotransmission has a key role in maintaining learning-induced cortical stability by a wide-ranged control on synaptic transmission and plasticity.

Learning-induced modulation of the GABAB-mediated inhibitory synaptic transmission: mechanisms and functional

significance.
Complex olfactory-discrimination (OD) learning results in a series of intrinsic and excitatory synaptic modifications in piriform cortex pyramidal neurons that enhance the circuit excitability. Such overexcitation must be balanced to prevent runway activity while maintaining the efficient ability to store memories. We showed previously that OD learning is accompanied by enhancement of the GABAA-mediated inhibition. Here we show that GABAB-mediated inhibition is also enhanced after learning and study the mechanism underlying such enhancement and explore its functional role. We show that presynaptic, GABAB-mediated synaptic inhibition is enhanced after learning. In contrast, the population-average postsynaptic GABAB-mediated synaptic inhibition is unchanged, but its standard deviation is enhanced. Learning-induced reduction in paired pulse facilitation in the glutamatergic synapses interconnecting pyramidal neurons was abolished by application of the GABAB antagonist CGP55845 but not by blocking G protein-gated inwardly rectifying potassium channels only, indicating enhanced suppression of excitatory synaptic release via presynaptic GABAB-receptor activation. In addition, the correlation between the strengths of the early (GABAA-mediated) and late (GABAB-mediated) synaptic inhibition was much stronger for each particular neuron after learning. Consequently, GABAB-mediated inhibition was also more efficient in controlling epileptic-like activity induced by blocking GABAA receptors. We suggest that complex OD learning is accompanied by enhancement of the GABAB-mediated inhibition that enables the cortical network to store memories, while preventing uncontrolled activity.
J Neurophysiol, 2014; 111
27449811: Jammal L, Whalley B, Ghosh S, Lamrecht R, Barkai E
Physiological expression of olfactory discrimination rule learning balances whole-population modulation and circuit stability in the piriform cortex network.
Once trained, rats are able to execute particularly difficult olfactory discrimination tasks with exceptional accuracy. Such skill acquisition, termed "rule learning", is accompanied by a series of long-lasting modifications to three cellular properties which modulate pyramidal neuron activity in piriform cortex; intrinsic excitability, synaptic excitation, and synaptic inhibition. Here, we explore how these changes, which are seemingly contradictory at the single-cell level in terms of their effect on neuronal excitation, are manifested within the piriform cortical neuronal network to store the memory of the rule, while maintaining network stability. To this end, we monitored network activity via multisite extracellular recordings of field postsynaptic potentials (fPSPS) and with single-cell recordings of miniature inhibitory and excitatory synaptic events in piriform cortex slices. We show that although 5 days after rule learning the cortical network maintains its basic activity patterns, synaptic connectivity is strengthened specifically between spatially proximal cells. Moreover, while the enhancement of inhibitory and excitatory synaptic connectivity is nearly identical, strengthening of synaptic inhibition is equally distributed between neurons while synaptic excitation is particularly strengthened within a specific subgroup of cells. We suggest that memory for the acquired rule is stored mainly by strengthening excitatory synaptic connection between close pyramidal neurons and runaway synaptic activity arising from this change is prevented by a nonspecific enhancement of synaptic inhibition.

TEMPORAL DISPARITY OF ACTION POTENTIALS TRIGGERED IN AXON INITIAL SEGMENTS AND DISTAL AXONS IN THE NEOCORTEX

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Martin Tóth[1], Márton Rózsa[1], Gáspár Oláh[1], Judith Baka[1], Pal Barzo[2], Gábor Tamás[1]
[1]University Of Szeged, Department Of Physiology, Anatomy And Neuroscience, Szeged, Hungary, [2]University of Szeged, Department Of Neurosurgery, Szeged, Hungary

Neural population activity determines the timing of synaptic inputs, which arrive to dendrites, cell bodies and axon initial segments (AISs) of cortical neurons. Action potentials in the AIS (AIS-APs) are driven by input integration, and the phase preference of AIS-APs during network oscillations is characteristic to cell classes. Distal regions of cortical axons do not receive synaptic inputs, yet experimental induction protocols can trigger reatroaxonal action potentials (RA-APs) in axons distal from the soma. We report spontaneously occurring RA-APs in human and rodent cortical interneurons that appear uncorrelated to inputs and population activity. Network linked triggering of AIS-APs versus network independent timing of RA-APs of the same interneurons result in disparate temporal contribution of a single cell to in vivo network operation through perisomatic and distal axonal firing.

SIMULTANEOUS LFP RECORDING AND CALCIUM IMAGING OF CORTICAL LAYER I NDNF+ INTERNEURONS IN FREELY-MOVING MICE DURING SLEEP

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Gaëlle Mailhos, Y Audrey Hay, Yuqi Li, Ole Paulsen
University of Cambridge, Department Of Physiology, Development, And Neuroscience, Cambridge, United Kingdom

Cortical layer I (L1) contains a sparse population of interneurons expressing NDNF. They receive long-range projections from association cortices, higher-order thalamic nuclei and neuromodulatory nuclei and control the local cortical activity through extensive projections on the distal dendrites of pyramidal cells located in deeper layers. Previous studies have identified L1 NDNF+ interneurons as key for long-term associative memory. Because oscillations in the Local Field Potential (LFP) during sleep – namely Sharp-Wave Ripples, thalamic spindles and slow oscillations – are thought to play a causal role in memory consolidation, we hypothesise that L1 interneurons could take part in coordinating these oscillations. To do so, we use a miniaturised wide-field fluorescence microscope to image calcium activity of L1 NDNF+ interneurons in the parietal and retrosplenial cortices while simultaneously recording LFP in CA1 hippocampus, prefrontal and somatosensory cortices in freely-moving mice during sleep. We aim to study the calcium activity of L1 NDNF+ interneurons relative to SWR and spindles, and how the relationships between their calcium activity and sleep oscillations may evolve throughout a progressive learning task.

A5-CONTAINING NICOTINIC ACETYLCHOLINE RECEPTOR REGULATION OF FAST GABAA-MEDIATED INHIBITION DURING UP AND DOWN STATES

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Ani Kaplanian[1,2], Michael Vinos[2,3], Irini Skaliora[2,3]
[1]University of Patras, Biology, Patras, Greece, [2]Biomedical Research Foundation of Academy of Athens, Basic Research, Athens, Greece, [3]National and Kapodistrian University of Athens (NKUA), Department Of History And Philosophy Of Science, Athens, Greece

AIMS: Cortical “slow oscillations”, a form of spontaneous network activity, observed during quiescent brain states, are successive epochs of a depolarized “Up state” and a hyperpolarized “Down state”. Up and Down state (UDS) activity is a feature of both developing and mature cortical networks and is considered the default activity of the cerebral cortex. The aim of this study was to investigate the role of a5-containing nicotinic acetylcholine receptor (nAChR) in regulating GABAa-mediated inhibition during UDS in young mice. METHODS: Our study was conducted in acute brain slices (Layer II/III, S1bf cortex) of wild type (WT) and ACNA5 (a5-nAChR knock out) mice (18-25 days old) and UDSs were assessed by simultaneous local field potential (LFP) and intracellular (IC) recordings. 200nM of gabazine was used for the blockade of GABAa receptors, and voltage clamp (VC) recordings of pyramidal neurons were conducted to further investigate GABAa-mediated currents (sIPSCs and mIPSCs). RESULTS: We show that the effect of gabazine was genotype-dependent; under GABAa blockade, the presence of a5-nAChR in WT mice leads to shrinkage of UDSs and transition of network activity into epileptiform spike-and-wave discharges (SWDs); however ACNA5 mice retain UDS activity and exhibit a low occurrence of SWDs. Our VC recordings showed that pyramidal neurons of layer II/III receive differential inhibitory input, which depends on the presence (WT) or absence (ACNA5) of a5-nAChR. CONCLUSIONS: These results indicate that a5-subunit-mediated cholinergic regulation of GABAa receptors is crucial for the maintenance of UDS.

NORADRENERGIC MEDIATION OF HIPPOCAMPAL THETA RHYTHM INDUCED BY VAGAL NERVE STIMULATION

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Renata Bocian[1], Adam Broncel[2], Jan Konopacki[1]
[1]University of Lodz, Faculty of Biology and Environmental Protection, Department Of Neurobiology, Lodz, Poland, [2]Neuromedical, Research Department, Lodz, Poland

Noradrenergic mediation of hippocampal theta rhythm induced by vagal nerve stimulation Aim: Vagal nerve stimulation (VNS) is recognized as a low risk therapy for patients suffering from a broad spectrum of central nervous system disturbances. We demonstrated that theta rhythm can be an effective biomarker of central VNS disorders. Specifically, VNS was found to produce hippocampal (HPC) theta rhythm. We also provided data demonstrating that VNS-induced theta is mediated by cholinergic and GABAergic nature. The noradrenergic mediation of VNS-induced theta rhythm has never been tested. Hence, the present study was undertaken to identify the noradrenergic receptors profile mediating the production of VNS-induced theta in anesthetized rats. **Methods:** The experiments were performed on urethanized male Wistar rats. All animals were implanted with a VNS cuff electrode on the left vagal nerve, a tungsten microelectrode for recording the hippocampal field activity, and a cannula for the drug injections. **Results:** The intrahimpocampal microinjection of selective $alpha_1$-, $alpha_2$-, $beta_1$-adrenergic agonists (phenylephrine, tizanidine and dobutamine respectively) diminish VNS-induced theta rhythm in HPC. Injection of fenoterol and BRL37344 ($beta_2$-and $beta_3$-adrenergic agonists) did not affect theta field activity. **Conclusion**: These data provide evidences that only $alpha_1$, $alpha_2$, $beta_1$-adrenergic receptors localized in HPC are involved in the pharmacological mechanisms responsible for the production of VNS-induced theta rhythm. The remaining hippocampal noradrenergic receptors ($beta_2$- and $beta_3$) do not seem to be directly involved in the mechanism responsible for VNS-induced hippocampal theta rhythm. *This research project was supported by Neuromedical Ltd.*

MULTIELECTRODE RECORDINGS IN THE POSTERIOR HYPOTHALAMUS OF FREELY MOVING RATS: THETA RHYTHM IN THE SUPRAMAMMILLARY AND POSTERIOR HYPOTHALAMIC NUCLEI

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

University of Lodz, Faculty of Biology and Environmental Protection, Neurobiology Department, Lodz, Poland

Rodent theta rhythm is best known for its appearance in the hippocampus (HPC). The presence of HPC theta is a result of the activation of the supramammillary (SuM) and posterior hypothalamic (PH) nuclei. They both send projections to the HPC and facilitate the appearance of theta rhythm in the structure. Additionally, theta rhythm can also be recorded locally from both the SuM and PH. However, very little is known about this posterior hypothalamic theta rhythm, its role and how the SuM and PH differently contribute to its local or hippocampal oscillation genesis. AIMS Investigation of the differences in theta oscillations between the SuM and PH nuclei in freely moving rats. METHODS Eight adult Wistar rats were implanted with a 16-channel multielectrode for chronic local field potential recordings. The recording sites were the supramammillary and posterior hypothalamic nuclei. Basic parameters of theta oscillations, i.e. frequency, amplitude, power of dominant frequency, were later analyzed and compared between the SuM and PH nuclei. RESULTS Clear oscillations in theta range (3-12 Hz) were observed in all rats tested in both the SuM and PH nuclei. No evident differences were observed in terms of theta rhythm parameters depending on the recording site. CONCLUSIONS Lack of clear differences between SuM and PHa local theta characteristics raises the question about the mechanism of posterior hypothalamic theta rhythm generation and its role in driving the HPC theta rhythm. *Supported by National Science Centre Poland: UMO-2017/25/B/NZ4/01476.*

Lamotrigine Attenuates Neuronal Excitability, Depresses GABA Synaptic Inhibition, and Modulates Theta Rhythms in Rat Hippocampus.
Theta oscillations generated in hippocampal (HPC) and cortical neuronal networks are involved in various aspects of brain function, including sensorimotor integration, movement planning, memory formation and attention. Disruptions of theta rhythms are present in individuals with brain disorders, including epilepsy and Alzheimer's disease. Theta rhythm generation involves a specific interplay between cellular (ion channel) and network (synaptic) mechanisms. HCN channels are theta modulators, and several medications are known to enhance their activity. We investigated how different doses of lamotrigine (LTG), an HCN channel modulator, and antiepileptic and neuroprotective agent, would affect HPC theta rhythms in acute HPC slices (in vitro) and anaesthetized rats (in vivo). Whole-cell patch clamp recordings revealed that LTG decreased GABA-fast transmission in CA3 cells, in vitro. In addition, LTG directly depressed CA3 and CA1 pyramidal neuron excitability. These effects were partially blocked by ZD 7288, a selective HCN blocker, and are consistent with decreased excitability associated with antiepileptic actions. Lamotrigine depressed HPC theta oscillations in vitro, also consistent with its neuronal depressant effects. In contrast, it exerted an opposite, enhancing effect, on theta recorded in vivo. The contradictory in vivo and in vitro results indicate that LTG increases ascending theta activating medial septum/entorhinal synaptic inputs that over-power the depressant effects seen in HPC neurons. These results provide new insights into LTG actions and indicate an opportunity to develop more precise therapeutics for the treatment of dementias, memory disorders and epilepsy.

The Role of the Posterior Hypothalamus in the Modulation and Production of Rhythmic Theta Oscillations.
Theta rhythm recorded as an extracellular synchronous field potential is generated in a number of brain sites including the hippocampus. The physiological occurrence of hippocampal theta rhythm is associated with the activation of a number of structures forming the ascending brainstem-hippocampal synchronizing pathway. Experimental evidence indicates that the supramammillary nucleus and posterior hypothalamic nuclei, considered as the posterior hypothalamic area, comprise a critical node of this ascending pathway. The posterior hypothalamic area plays an important role in movement control, place-learning, memory processing, emotion and arousal. In the light of multiplicity of functions of the posterior hypothalamic area and the influence of theta field oscillations on a number of neural processes, it is the authors' intent to summarize the data

concerning the involvement of the supramammillary nucleus and posterior hypothalamic nuclei in the modulation of limbic theta rhythmicity as well as the ability of these brain structures to independently generate theta rhythmicity.

Inhibition of Matrix Metalloproteinase 9 Activity Promotes Synaptogenesis in the Hippocampus.
Information coding in the hippocampus relies on the interplay between various neuronal ensembles. We discovered that the application of a cholinergic agonist, carbachol (Cch), which triggers oscillatory activity in the gamma range, induces the activity of matrix metalloproteinase 9 (MMP-9)-an enzyme necessary for the maintenance of synaptic plasticity. Using electrophysiological recordings in hippocampal organotypic slices, we show that Cch potentiates the frequency of miniature inhibitory and excitatory postsynaptic currents (mIPSCs and mEPSCs, respectively) in CA1 neurons and this effect is MMP-9 dependent. Interestingly, though MMP-9 inhibition prevents the potentiation of inhibitory events, it further boosts the frequency of excitatory mEPSCs. Such enhancement of the frequency of excitatory events is a result of increased synaptogenesis onto CA1 neurons. Thus, the function of MMP-9 in cholinergically induced plasticity in the hippocampus is to maintain the fine-tuned balance between the excitatory and the inhibitory synaptic transmission.

Postnatal Development of the Posterior Hypothalamic Theta Rhythm and Local Cell Discharges in Rat Brain Slices.
Theta rhythms have been recorded from rat brain slices of the posterior hypothalamic area (PHa), including the supramammillary and posterior hypothalamic nuclei. Additionally, in numerous studies theta-related neurons were identified in the PHa according to the classification of Bland and Colom (Progress in Neurobiology, 41, 157-208, 1993). It is currently widely accepted that the PHa contributes to the process of HPC theta frequency programming at least in certain behavioral states. The postnatal development of the HPC and its ability to generate theta has also been a subject of studies. Specifically, it was found that theta oscillations are present in the HPC of 8-10 days old rat pups and turn into a well-synchronized and high-amplitude activity in the following few days. In our current study, we therefore focused on the postnatal development of cholinergically-induced theta rhythm and theta-related neuronal activity in PHa slices obtained from 8 to 24 days old rat pups. Theta activity was observed in the PHa preparations at the age of 8-10 days and then progressively increased its probability of occurrence, amplitude and synchrony up to the age of 22-24 days when it reached a plateau phase. A steady increase in the number of recorded neurons correlated with local theta oscillations was also observed.

Is electrical coupling involved in the generation of posterior hypothalamic theta rhythm?
Data obtained in in vitro experiments and urethane anaesthetized animals have revealed that the mechanisms responsible for the generation of hippocampal cholinergic theta rhythm are specifically affected by the administration of broad spectrum gap junctions (GJs) blocker - carbenoxolone (CBX). The aim of this study was to examine the effect of GJs modulation on the production of posterior hypothalamic theta. Specifically, we were interested in evaluating whether CBX could attenuate the theta rhythm recorded from the supramammillary nucleus and posterior hypothalamic nuclei, in both in vitro and in vivo preparations. The data we obtained from in vitro and in vivo preparations demonstrated that the administration of CBX did not suppress cholinergically induced theta in posterior hypothalamic area (PHa) slices nor the theta rhythm observed in the PHa of urethane anaesthetized rats. Moreover, the application of trimethylamine, while very effective in the enhancement of hippocampal theta rhythm, did not produce any changes in theta oscillations observed in either in vitro or in vivo posterior hypothalamic area preparations. These data show that electrical coupling via GJs is not involved in theta rhythm generation in the PHa. Surprisingly, we observed a significant enhancement of theta activity in response to the carbenoxolone administration in both in vitro and in vivo PHa preparations. The theta rhythm enhancement detected in those experiments was attenuated by the application of spironolactone (mineralocorticoid receptors antagonist). We suggest that the observed excitatory effects of CBX on posterior hypothalamic oscillatory activity in the theta band could be mediated by mineralocorticoid receptors.

Cell discharge correlates of posterior hypothalamic theta rhythm recorded in anesthetized rats and brain slices.
Kowalczyk et al. (Hippocampus 2014; 24:7-20) were probably the first to conduct a systemic study of posterior hypothalamic area (PHa) theta rhythm in anesthetized rats. They demonstrated that local PHa theta field potentials were tail-pinch resistant and could be generated in urethane-anesthetized rats independently of ongoing hippocampal formation theta rhythm. These in vivo data were also confirmed in PHa slice preparations perfused with cholinergic agonist, carbachol. In the current experiments we extend our earlier observations concerning PHa theta rhythm. Specifically, PHa field potentials were analyzed in relation to the ongoing local cell firing repertoire. Single-unit discharge patterns of cells localized in the posterior hypothalamic and supramammillary nuclei were characterized according to the criteria that was developed previously to classify theta-related cells in the hippocampal formation. The present study demonstrated that in addition to the earlier described theta-related cells (theta-on, theta-off and gating cells) the PHa also contains cells discharging in a very regular manner, which were labelled "timing cells". This type of neuron has not been previously documented. We suggest that "timing cells" form a part of the ascending brainstem synchronizing pathway, provideing a regular rhythmic signal which facilitates the transduction of tonic discharges of cells localized in the brain stem into theta-frequency rhythmic discharges. © 2016 Wiley Periodicals, Inc.

Atropine-sensitive theta rhythm in the posterior hypothalamic area: in vivo and in vitro studies.
Theta rhythm is the largest, most prominent, and well-documented electroencephalography activity present in a number of mammals, including humans. Spontaneous theta activity recorded locally in the posterior hypothalamic area (PHa) has never been the subject of detailed studies. The authors have shown that local theta field potentials could be generated in urethane-anesthetized rats in the supramammillary (SuM) nuclei and posterior hypothalamic (PH) nuclei. Theta recorded in the PHa was produced independently of simultaneously occurring hippocampal theta. These data were confirmed in the PHa maintained in vitro. Local theta field activity was recorded in the SuM and PH nuclei of PHa slice preparations perfused with cholinergic agonist carbachol. Both in vivo and in vitro recorded PHa theta rhythmicity had a cholinergic-muscarinic profile, that is, it was antagonized by muscarinic antagonist atropine sulfate.

Spatiotemporal characterization of mTOR kinase activity following kainic acid induced status epilepticus and analysis of rat brain response to chronic rapamycin treatment.
Mammalian target of rapamycin (mTOR) is a protein kinase that senses nutrient availability, trophic factors support, cellular energy level, cellular stress, and neurotransmitters and adjusts cellular metabolism accordingly. Adequate mTOR activity is needed for development as well as proper physiology of mature neurons. Consequently, changes in mTOR activity are often observed in neuropathology. Recently, several groups reported that seizures increase mammalian target of rapamycin (mTOR) kinase activity, and such increased activity in genetic models can contribute to spontaneous seizures. However, the current knowledge about the spatiotemporal pattern of mTOR activation induced by proconvulsive agents is rather rudimentary. Also consequences of insufficient mTOR activity on a status epilepticus are poorly understood. Here, we systematically investigated these two issues. We showed that mTOR signaling was activated by kainic acid (KA)-induced status epilepticus through several brain areas, including the hippocampus and cortex as well as revealed two waves of mTOR activation: an early wave (2 h) that occurs in neurons and a late wave that predominantly occurs in astrocytes. Unexpectedly, we found that pretreatment with rapamycin, a potent mTOR inhibitor, gradually (i) sensitized animals to KA treatment and (ii) induced gross anatomical changes in the brain.

Theta-related gating cells in hippocampal formation: in vivo and in vitro study.
In this study we extended our earlier in vitro findings concerning the discovery of a novel type of theta-related cells, which we have termed gating cells. There were two main objectives of our present investigations. The first was to determine the distribution of theta gating cells in the separated CA1 and CA3 generators in three different pharmacological conditions: (i) the presence of a cholinergic agonist-carbachol, (ii) the presence of carbachol and GABA(A) ergic antagonist-bicuculline, (iii) the presence of carbachol and GABA(B) ergic antagonist-2-hydroxysaclofen. The second objective of our studies was to verify our earlier in vitro findings and to demonstrate, for the first time, gating cells in intact hippocampus during the generation of Type II theta in urethane anaesthetized rats. Two hundred ninety-nine theta-related cells were isolated and recorded from in vivo and in vitro hippocampal formation. Twenty out of all 299 neurons (6.6%) were classified as gating cells. The neuron was classified as a gating cell if it met one of the following criteria: (i) the cell discharges occurred precisely in the beginning and at the end of each theta epoch (gating cell A); (ii) the cell began to discharge just before the transition from

non-theta interval/LIA into the theta epoch (gating cell B); (iii) the cell began to discharge just after the transition from the theta epoch into non-theta interval/LIA (gating cell C). Our data demonstrates that the appearance of theta epochs and their length, as well as the appearance of non-theta states (in vivo recorded LIA or in vitro recorded intervals between theta epochs) and their length, may require the existence of a specific population of hippocampal neurons which we termed gating cells.

MULTIELECTRODE RECORDINGS IN THE POSTERIOR HYPOTHALAMUS OF FREELY MOVING RATS: MOVEMENT-RELATED AND IMMOBILITY-RELATED THETA RHYTHM

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Tomasz Kowalczyk, Bartosz Caban
University of Lodz, Faculty of Biology and Environmental Protection, Neurobiology Department, Lodz, Poland

It is well-established that hippocampal theta rhythms can be divided into two distinct subtypes according to their pharmacological profile and relation to different animal's behavior. Our recent studies have revealed that well-synchronized theta rhythm can also successfully be recorded from the posterior hypothalamic area (PHa) in anesthetized rats and isolated brain slices of PHa maintained in vitro. AIMS: The aim of the present study was to investigate the possible differences in theta band oscillations recorded locally in the posterior hypothalamic area of freely-moving rats during different types of behavior. METHODS: The experiments were performed in eight adult rats. Animals were anesthetized with ketamine and 16-channel multielectrodes were implanted into the region of posterior hypothalamus. After recovery period animals were tested in the open field. Radio-transmitted EEG recordings form supramammillary and posterior hypothalamic nuclei were taken simultaneously with video recordings. RESULTS: Multielectrode recordings performed in freely moving rats have shown that both posterior hypothalamic and supramammillary nuclei are capable of generating movement-related theta activity. It was shown that PHa theta activity recorded during voluntary movements differs in frequency and amplitude parameters from theta rhythm observed during immobility or automatic activities. CONCLUSIONS: Two subtypes of theta rhythmic oscillations can be recorded from the posterior hypothalamic area of freely moving rats expressing different locomotor activities. SILENT JUXTACELLULAR FIELD POTENTIALS CORRESPOND TO NEURONAL CELL TYPES

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Robert Averkin, Sándor Bordé, János Horváth, Boglárka Bozsó, Viktor Szemenyei, Gábor Tamás
University of Szeged, Department Of Physiology, Anatomy And Neuroscience, Szeged, Hungary

Extracellular recording techniques characterize single neurons based on firing characteristics of monitored cells in relation to field potentials generated by population activity. Thus, silent network states or subthreshold periods of individual cells make cell identification difficult if not impossible with extracellular approaches. Juxtacelluar recordings provide means to record the suprathreshold activity of individual neurons together with local field potentials while allowing anatomical labeling of the recorded cells. In freely behaving rats, we juxtacellularly recorded pyramidal cells (PYRs), fast spiking interneurons (FSIs) and regular spiking interneurons (RSIs). The three cell types were distinguished based on morphology and firing characteristics during nonREM sleep packets, sleep spindles and down to up (DU) state transitions. We observed that down states (DSs) preceding DU transitions were different in FSIs than those in RSI and PYR cells and hypothesized that silent periods of local field potentials might express complex cell type specific characteristics. Indeed, simultaneous triple juxtacellular recordings confirmed heterogeneous DSs in neighboring cells. We developed a workflow for clustering individually recorded silent DSs (n>23000) based on principal component analysis, unsupervised learning algorithms and self-organizing maps (SOMs). Cell groups of PYRs, FSIs and RSIs showed significant difference in SOM profiles constructed from silent DSs. We conclude that local field potentials recorded juxtacellular to nonspiking individual cells are cell type specific. This suggests that field potentials in the network are highly compartmentalized and retain identities of cellular units in space and time even if neuronal populations are in a silent state.

PATHWAY SPECIFIC REGULATION OF CONVERGENT INFORMATION STREAMS BY HIPPOCAMPAL NEUROGLIAFORM CELLS

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Ece Sakalar, Thomas Klausberger, Balint Lasztoczi
Centre for Brain Research, Medical University of Vienna, Division Of Cognitive Neurobiology, Vienna, Austria

Synchronized activation of distributed neuronal assemblies is key for communication in brain circuits. In broadcasting areas synchrony emerges as gamma oscillations (30 - 150 Hz) that entrain spiking in recipient networks when information transfer is successful. In hippocampal CA1 area, temporoammonic pathway from entorhinal cortex and Schaffer collaterals from hippocampal CA3 carrying sensory and mnemonic information converge onto pyramidal cells. The information flow into and within the CA1 networks is regulated by co-existing nested electrical oscillations. We aimed to find out how cortico-hippocampal communication is regulated by local CA1 interneuron types in association with mid-frequency gamma oscillations (50-90 Hz) that occur in stratum lacunosum-moleculare, where cortical fibers terminate. We recorded electrical signals from the hippocampi of awake, head-fixed mice performing unidirectional runs along a corridor in a virtual reality environment. Using current source density analysis, we localized slow, mid-frequency and fast gamma oscillations. We simultaneously recorded the spike timing of multiple units and single GABA*ergic* neurons in CA1, using silicon probes and extracellular glass microelectrodes, respectively. The glass electrode recorded neurons were filled with neurobiotin and their cell type was identified by their axonal arborisation and protein content. We discovered that spike timing of a small population of inhibitory interneurons, which were identified as neurogliaform cells, were selectively and strongly phase-locked to mid-frequency gamma oscillations associated with cortical afferents, indicating their selective engagement. We will present data on how the neurogliaform cells regulate information transfer of converging inputs by selectively rebalancing contributions from specific pathways. (Funding: FWF P29744-B27).

[1]Instituto de Neurociencias UMH-CSIC, Cellular And Systems Neurobiology, San Juan de Alicante, Spain, [2]Istituto Superiore di Sanità, Centro Nazionale Per La Protezione Dalle Radiazioni E Fisica, Roma, Italy

The maturation of functional sensory circuits with the capacity to process information is a highly orchestrated process that takes place during postnatal stages. It involves the interplay of progressive and regressive events that will stabilize some synapses and remove others. Problems during this critical period contribute to a wide spectrum of neurological disorders in later life. The pruning of axons and dendrites is controlled by multiple factors, one of them being the activity sensed and transmitted by N-methyl-D-Aspartate receptors (NMDARs). Here we focus on a new class of NMDARs that are characterized by the presence of GluN3A subunits and play an essential role in the activity-dependent refinement of synaptic connections. In mouse primary somatosensory cortex (S1) GluN3A expression peaks around postnatal days 6-9 and declines until reaching very low adult levels, with temporal differences between cortical layers (Murillo et al., Cereb Cortex 2020). Results from our collaborators show that GluN3A-containing NMDARs participate in axonal refinement in such a way that knocking out the gene encoding GluN3A (*Grin3a*) results in an aberrant pattern of callosal innervation of S1. Therefore, in this study, we investigated the impact of GluN3A deletion on the communication between hemispheres, and analyzed the spontaneous activity and sensory processing in S1 of P20 and P40 mice. We performed multi-site bilateral recordings of spontaneous activity in S1 of awake GluN3A knockout mice (*Grin3a*-/-). Preliminary results reveal changes in the power of several frequency bands at P20. We are currently characterizing the ipsilateral responses, which are mediated by callosal inputs.

Pontine (P) or ponto-geniculo-occipital (PGO) waves are a prominent electrophysiological marker of rapid-eye-movement (REM) sleep. Although P-waves have long been recognized, they have been less studied compared to other sleep-related neural events. Recent studies in mice and macaques uncovered state-dependent functional coupling of P-waves with hippocampal oscillations including sharp wave-ripples (SWRs) during non-REM (NREM) sleep and theta oscillations during REM sleep. However, the detailed characteristics of this functional coupling remain unclear. In addition, since P-waves in mice have been reported rarely, it is also important to describe their detailed electrophysiological properties, given the importance of the animal model. Here, we address these issues by performing multiple types of electrophysiological recordings in mice. We found that while P-waves appear more frequently during REM sleep and synchronously in two hemispheres, the frequency of P-waves during REM sleep can predict REM sleep episode duration. Brainstem neural ensembles underlying P-waves consist of diverse functional classes. The duration of hippocampal SWRs was associated with the coupling with P-waves. In addition to phase coupling between P-waves and hippocampal theta oscillations during REM sleep, P-waves led to increased excitability of hippocampal populations. These results suggest that P-waves play a role in systems memory consolidation by functionally coupling with hippocampal ensembles in a state-dependent fashion.

The interplay between the medial prefrontal cortex and hippocampus during non-REM (NREM) sleep is important for the consolidation of contextual memories. To assess the role of the thalamic nucleus reuniens (Nre) in this interaction, we investigated the coupling of neuro-oscillatory activity between prelimbic cortex, Nre, and hippocampus across sleep states and their role in the consolidation of contextual memories using multi-site electrophysiological recordings and optogenetic manipulations. We showed that ripples are time-locked to the Up state of cortical slow waves, the transition to the negative slope after the Up state in thalamic slow waves, the troughs of cortical spindles, and the peaks of thalamic spindles in unperturbed baseline sleep, sleep rebound after fear conditioning. In addition, spiking activity in Nre increases before hippocampal ripples and the phase-locking of hippocampal ripples and thalamic spindles during NREM sleep was stronger after acquisition of a fear memory. We showed that optogenetic inhibition of Nre neurons reduced a clear phase-locking ripples to cortical slow waves in the ventral hippocampus while their activation altered the preferred phase of ripples to slow waves in ventral and dorsal hippocampi. However, these optogenetic manipulations of Nre during sleep after acquisition of a fear conditioning did not alter sleep-dependent memory consolidation. Collectively, these results showed that Nre is central in modulating hippocampus and cortical rhythms during NREM sleep homeostasis and congnition.

LARGE-SCALE SINGLE UNIT RECORDINGS FROM OPTOGENETICALLY IDENTIFIED NEURONS IN THE DORSAL MIDLINE THALAMUS IN FREELY BEHAVING MICE

POSTER SESSION 03 - SECTION: OSCILLATIONS IN THE BRAIN

Gergely Komlósi[1,2], László Acsády[2], György Buzsáki[1]
[1]NYU Langone Health, Neuroscience Institute, New York, United States of America, [2]Institute of Experimental Medicine, Laboratory Of Thalamus Research, BUDAPEST, Hungary

The dorsal midline thalamus (dMT) has long been implicated in behaviors associated with high arousal state, such as motivated behaviors. We recently showed that activity of calretinin (CR) containing neurons in the dMT (CR-dMT) correlates with arousal level and their selective stimulation reliably leads to behavioral arousal. Recent advances of optogenetics have helped us extend our understanding of how dMT interacts with its input-output structures at the behavioral level. However, a detailed characterization of how dMT interacts with its synaptically connected counterparts at the neuronal level is still lacking. We sought to fill this gap by performing large-scale unit recordings from optogenetically identified CR-dMT neurons during unrestrained sleep-wake behavior, while simultaneously recorded population activity from the neocortex and the ventral subiculum; two regions reciprocally connected with the dMT. To discriminate CR-dMT neurons from neighboring non-CR expressing neurons, we transduced neurons in the dMT of CR-Cre mice with Channelrhodopsin-2 and implanted optic fibers both into the somatic and into the efferent regions of the CR-dMT neurons (prelimbic cortex and ventral subiculum). Using brief optical stimulation in either structure while monitoring neuronal activity within the dMT enabled us to further discriminate CR-dMT neurons in a projection-specific manner. We analyzed the relationship between the firing characteristics of CR-dMT neurons and various patterns of cortical and subicular network activity during sleep and wakefulness. Identifying how dMT interacts with the neocortex and the subiculum at the neuronal level might help clarify its role in motivated behaviors. (P*roject was funded from EU-Horizon 2020 MSCA grant 892957.)*

CHEMOGENETIC ORBITO FRONTAL CORTEX INHIBITION AND CHEMOGENETIC AMYGDALA ACTIVATION IN HIGH COMPULSIVE RATS.

POSTER SESSION 04 - SECTION: MENTAL HEALTH, ADDICTION AND OBSESSIVE-COMPULSIVE DISORDER

Ángeles Prados-Pardo[1], Elena Martín González[1], Santiago Mora[2], Manuela Olmedo-Córdoba[1], Margarita Moreno[1]
[1]University of Almería, Psychology, Almería, Spain, [2]University of Copenhagen Panum Institute, Department Of Neuroscience, Copenhagen, Denmark

Introduction: Compulsivity is associated with the loss of inhibitory control over a broad range of behaviours that are prone to excess. Preclinical and clinical studies on compulsivity have demonstrated that fronto-limbic structures are implicated in the pathophysiology of compulsive spectrum disorders. Aims: The present study was designed to assess the effects of chemogenetic stimulation or inhibition of orbitofrontal cortex (OFC)-amygdala circuit in a preclinical model of compulsivity. Methods: male Wistar rats (approx. 300 g) were selected as either high compulsive (HD) or low (LD) drinkers according to their level acquisition of water intake (ml) on schedule-induced polydipsia (SIP, fixed time schedule of 60s) after 20 sessions. In a first experiment, we used designer receptor–mediated inhibition (hM4Di) in HD and LD rats' OFC. In a second experiment, we used designer receptor-mediated activation (hM3Dq) in HD and LD rats' amygdala. Finally, we re-exposed rats to SIP. Results: Repeated measured ANOVA revealed no significant effects nor by the chemogenetic OFC inhibition, nor by the chemogenetic amygdala activation in the water intake of HD and LD rats on SIP. Conclusions: The chemogenetic inhibition or activation of the OFC-amygdala circuit did not have effect on the compulsive behaviour observed on SIP. Future studies should explore other brain areas implicated in the inhibitory control brain circuit with chemogenetic stimulation on preclinical models of compulsivity to identify the underlying mechanisms related to obsessive-compulsive disorder. PERIORBITAL HYPERPIGMENTATION'S RELATION TO NEUROLOGY AND MENTAL HEALTH: MALADAPTIVE DAYDREAMING ACCOMPANYING PSYCHOSIS AND ITS TREATMENT METHODS

POSTER SESSION 04 - SECTION: MENTAL HEALTH, ADDICTION AND OBSESSIVE-COMPULSIVE DISORDER

Samar Khalifa
Kafrelsheikh University, Psychology, Kafr El-Sheikh, Egypt

Objective: It was observed on a 17 yo female individual experiencing Psychosis accompanying Maladaptive Daydreaming (MD) the Peri-Orbital Hyperpigmentation (POH) symptom which is characterized by the darkness and thin lids. The self diagnosed girl noticed that the POH increases after having an MD episode. it is supposed that excess amount of Oxygen resulted from over-reaction of Dopamine synthesis in Psychosis with MD, due to high activity in SN, leads to the formation of pigmented eyelids (POH). It is suggested too that the activity of DMN and SCN in the brain has a role in developing psychotic episodes which are triggered by MD. Methods: We have studied the relationship between Psychosis accompaying MD and POH to a 17 yo female individual. We established some physical exercises to strengthen the eye and the eyelid muscles and to develop and construct new dopaminergic and excitatory neurotransmitters pathways in new neural networks; to enhance the effort of the visual cortex and the primary motor cortex to see the results if they would support the hypothesis. A 22-inquiries questionnaire was conducted on 22 participants about Maladaptive daydreaming accompanying mental health issues and Peri-Orbital Hyperpigmentation. Results: In brain stimulation, POH decreased which means the individual has developed new circuits participating the visual cortex neurons in them. The muscles strength increased increasing the eyes' plasticity in addition to increasing the plasticity/action potential of the frontal cortex. 68% of the individuals said they had POH which support the hypothesis' consistency. p-value = .06. p< .10.

A PRELIMINARY INVESTIGATION ON THE EFFECT OF ACUTE TRIGEMINAL NERVE STIMULATION ON COGNITIVE FUNCTION.

POSTER SESSION 04 - SECTION: MENTAL HEALTH, ADDICTION AND OBSESSIVE-COMPULSIVE DISORDER

Beniamina Mercante[1], Paolo Enrico[1], Francesca Ginatempo[2], Nicola Loi[2], Franca Deriu[1]
[1]University of Sassari, Biomedical Sciences, Sassari, Italy, [2]University of Sassari, Biomedical Sciences, sassari, Italy

Aims: Neuromodulation techniques based on peripheral nerve stimulation are used in clinical practice as a supportive treatment for different neurologic and neuropsychiatric disorders, and in basic neuroscience research to investigate brain functions. Recent research suggests that transcutaneous trigeminal nerve stimulation (TNS) may positively affect cognitive function. However, no clear-cut evidence is available yet, since the majority of the evidence derives from clinical studies, and the few data on healthy subjects show inconsistent results. In this preliminary study we report on the effects of short-term TNS on event-related potentials (ERP) recorded during the administration of a simple visual discrimination task and a paired-click paradigm, both considered useful for studying cognitive processing functions. Methods: Thirty-two healthy subjects (15 males and 17 females; mean age 25.03±4.80 years) were assigned to two groups: real-TNS (20-min, cyclic modality 30s ON and 30s OFF, 120 Hz, 0.25ms, intensity below pain threshold) and sham-TNS. Subjects underwent EEG recording before and after sham- or real-TNS, amplitude and latency of P200 and P300 waves (visual discrimination task), and P50, N100 and P200 waves (paired-click paradigm), were analysed using repeated-measures ANOVAs. Results: TNS did not affect subjects' performance in both protocols, as shown by the non-significant differences in amplitude and latency after sham- or real-TNS interventions. Conclusions: Data demonstrate that in healthy young adults short-term TNS does not affect cognitive functions such as pre-attentional processes, early allocation of attention and immediate memory.

VENTRAL PALLIDO-SUBTHALAMIC ADAPTATIONS UNDERLYING PATHOLOGICAL DECISION MAKING IN ALCOHOL USE DISORDERS

POSTER SESSION 04 - SECTION: MENTAL HEALTH, ADDICTION AND OBSESSIVE-COMPULSIVE DISORDER

Yvan Vachez, Meaghan Creed
Washington University School of Medicine in Saint Louis, Anesthesiology Department, Saint Louis, United States of America

Alcohol use disorder is a chronic relapsing disorder characterized by impulsive and compulsive decision-making processes driven by a disinhibition of behavior control. Impaired decision-making happens during acute alcohol use, which drives a disinhibitory effect on behavior control, yet it can persist for years of abstinent people and can also actively drive relapse. The subthalamic nucleus (STN) is of particular importance for appropriate decision making, especially its ventromedial portion (vmSTN), a limbic territory involved in mood and motivated behavior. Behavioral inhibition requires burst firing of the STN while impulsivity correlates with decreased activity. The ventral Pallidum (VP), a limbic structure mainly inhibitory, projects to the STN and is theoretically the main inhibitory input of the vmSTN. VP activity reflect perceived reward, is affected by ethanol consumption and is increased in impulsive patients. We hypothesized that VP GABAergic projections to the vmSTN become persistently strengthened following alcohol intake, promoting impaired decision making and compulsivity. In a mouse model of ethanol drinking, we combined behavioral assays to highlight maladaptive decision making, tracing approaches to characterize the VP to vmSTN pathway, *ex vivo* electrophysiology patch clamp coupled with pharmacology and optogenetic modulation to elucidate how ethanol drinking alters the VP to vmSTN synapse strength, and *in vivo* optogenetic experiments to modulate the VP to vmSTN activity during decision making. Together, these results will elucidate neural substrates of inhibitory controls and how they are altered in alcohol use disorders.

Pain induces adaptations in ventral tegmental area dopamine neurons to drive anhedonia-like behavior.
The persistence of negative affect in pain leads to co-morbid symptoms such as anhedonia and depression-major health issues in the United States. The neuronal circuitry and contribution of specific cellular populations underlying these behavioral adaptations remains unknown. A common characteristic of negative affect is a decrease in motivation to initiate and complete goal-directed behavior, known as anhedonia. We report that in rodents, inflammatory pain decreased the activity of ventral tegmental area (VTA) dopamine (DA) neurons, which are critical mediators of motivational states. Pain increased rostromedial tegmental nucleus inhibitory tone onto VTA DA neurons, making them less excitable. Furthermore, the decreased activity of DA neurons was associated with reduced motivation for natural rewards, consistent with anhedonia-like behavior. Selective activation of VTA DA neurons was sufficient to restore baseline motivation and hedonic responses to natural rewards. These findings reveal pain-induced adaptations within VTA DA neurons that underlie anhedonia-like behavior.

Ventral arkypallidal neurons inhibit accumbal firing to promote reward consumption.
The nucleus accumbens shell (NAcSh) and the ventral pallidum (VP) are critical for reward processing, although the question of how coordinated activity within these nuclei orchestrates reward valuation and consumption remains unclear. Inhibition of NAcSh firing is necessary for reward consumption, but the source of this inhibition remains unknown. Here, we report that a subpopulation of VP neurons, the ventral arkypallidal (vArky) neurons, project back to the NAcSh, where they inhibit NAcSh neurons in vivo in mice. Consistent with this pathway driving reward consumption via inhibition of the NAcSh, calcium activity of vArky neurons scaled with reward palatability (which was dissociable from reward seeking) and predicted the subsequent drinking behavior during a free-access paradigm. Activation of the VP-NAcSh pathway increased ongoing reward consumption while amplifying hedonic reactions to reward. These results establish a pivotal role for vArky neurons in the promotion of reward consumption through modulation of NAcSh firing in a value-dependent manner.

Deep Brain Stimulation of the Subthalamic Nucleus Modulates Reward-Related Behavior: A Systematic Review.
Deep brain stimulation of the subthalamic nucleus (STN-DBS) is an effective treatment for the motor symptoms of movement disorders including Parkinson's Disease (PD). Despite its therapeutic benefits, STN-DBS has been associated with adverse effects on mood and cognition. Specifically, apathy, which is defined as a loss of motivation, has been reported to emerge or to worsen following STN-DBS. However, it is often challenging to disentangle the effects of STN-DBS from concurrent reduction of dopamine replacement therapy, from underlying PD pathology or from disease progression. To this end, pre-clinical models allow for the dissociation of each of these factors, and to establish neural substrates underlying the emergence of motivational symptoms following STN-DBS. Here, we performed a systematic analysis of rodent studies assessing the effects of STN-DBS on reward seeking, reward motivation and reward consumption across a variety of behavioral paradigms. We find that STN-DBS decreases reward seeking in the majority of experiments, and we outline how design of the behavioral task and DBS parameters can influence experimental outcomes. While an early hypothesis posited that DBS acts as a "functional lesion," an analysis of lesions and inhibition of the STN revealed no consistent pattern on reward-related behavior. Thus, we discuss alternative mechanisms that could contribute to the amotivational effects of STN-DBS. We also argue that optogenetic-assisted circuit dissection could yield important insight into the effects of the STN on motivated behavior in health and disease. Understanding the mechanisms underlying the effects of STN-DBS on motivated behavior-will be critical for optimizing the clinical application of STN-DBS.

Subthalamic Nucleus Stimulation Impairs Motivation: Implication for Apathy in Parkinson's Disease.
Apathy is one of the most disabling neuropsychiatric symptoms in Parkinson's disease (PD) patients and has a higher prevalence in patients under subthalamic nucleus deep brain stimulation. Indeed, despite its effectiveness for alleviating PD motor symptoms, its neuropsychiatric repercussions have not yet been fully uncovered. Because it can be alleviated by dopaminergic therapies, especially D and D dopaminergic receptor agonists, the commonest explanation proposed for apathy after subthalamic nucleus deep brain stimulation is a too-strong reduction in dopaminergic treatments. The objective of this study was to determine whether subthalamic nucleus deep brain stimulation can induce apathetic behaviors, which remains an important matter of concern. We aimed to unambiguously address this question of the motivational effects of chronic subthalamic nucleus deep brain stimulation.

Nigrostriatal Dopaminergic Denervation Does Not Promote Impulsive Choice in the Rat: Implication for Impulse Control Disorders in Parkinson's Disease.
Impulse control disorders (ICDs) are frequent behavioral complications of dopaminergic (DA) replacement therapies (DRTs) in Parkinson's disease (PD). Impulsive choice, which refers to an inability to tolerate delays to reinforcement, has been identified as a core pathophysiological process of ICDs. Although impulsive choices are exacerbated in PD patients with ICDs under DRTs, some clinical and preclinical studies suggest that the DA denervation of the dorsal striatum induced by the neurodegenerative process as well as a pre-existing high impulsivity trait, may both contribute to the emergence of ICDs in PD. We therefore investigated in a preclinical model in rats, specifically designed to study PD-related non-motor symptoms, the effect of nigrostriatal DA denervation on impulsive choice, in relation to pre-existing levels of impulsivity, measured in a Delay Discounting Task (DDT). In this procedure, rats had the choice between responding for a small sucrose reinforcer delivered immediately, or a larger sucrose reinforcer, delivered after a 0, 5, 10 or 15 s delay. In two different versions of the task, the preference for the large reinforcer decreased as the delay increased. However, and in contrast to our initial hypothesis, this discounting effect was neither exacerbated by, or related to, the extent of the substantia nigra pars compacta (SNc) DA lesion, nor it was influenced by pre-existing variability in impulsive choice. These results therefore question the potential implication of the nigrostriatal DA system in impulsive choice, as well as the DA neurodegenerative process as a factor contributing significantly to the development of ICDs in PD.

Implication of dorsostriatal D3 receptors in motivational processes: a potential target for neuropsychiatric symptoms in Parkinson's disease.
Beyond classical motor symptoms, motivational and affective deficits are frequently observed in Parkinson's disease (PD),

dramatically impairing the quality of life of patients. Using bilateral 6-hydroxydopamine (6-OHDA) lesions of the substantia nigra pars compacta (SNc) in rats, we have been able to reproduce these neuropsychiatric/non-motor impairments. The present study describes how bilateral 6-OHDA SNc lesions affect the function of the main striatal dopaminergic (DA) receptor subtypes. Autoradiography was used to measure the levels of striatal DA receptors, and operant sucrose self-administration and neuropharmacological approaches were combined to investigate the causal implication of specific DA receptors subtypes in the motivational deficits induced by a dorsostriatal DA denervation. We found that D3 receptors (DR) exclusively are down-regulated within the dorsal striatum of lesioned rats. We next showed that infusion of a DR antagonist (SB-277011A) in non-lesioned animals specifically disrupts preparatory, but not consummatory behaviors. Our findings reveal an unexpected involvement of dorsostriatal DR in motivational processes. They strongly suggest an implication of dorsostriatal DR in the neuropsychiatric symptoms observed in PD, highlighting this receptor as a potential target for pharmacological treatment.

Subthalamic deep brain stimulation differently alters striatal dopaminergic receptor levels in rats.
High-frequency stimulation (HFS) of the subthalamic nucleus (STN) is recognized as an effective treatment for the motor symptoms of Parkinson's disease (PD), but its mechanisms, particularly as concern dopaminergic transmission, remain unclear. The aim of this study was to evaluate changes in the expression of dopaminergic receptors (D1, D2, and D3 receptors) after prolonged (4 h) unilateral STN-HFS in anesthetized intact rats and rats with total dopaminergic denervation. We used [(3)H]SCH 23390, [(125)I]iodosulpride, and [(125)I]OH-PIPAT to assess the densities of D1R, D2R, and D3R, respectively, within different areas of the striatum-a major input structure of the basal ganglia-including the nucleus accumbens. We found that STN-HFS increased D1 R levels in almost all of the striatal areas examined, in both intact and denervated rats. By contrast, STN-HFS led to a large decrease in D2 R and D3R levels, limited to the nucleus accumbens and independent of the dopaminergic state of the animals. These data suggest that the influence of STN-HFS on striatal D1 R expression may contribute to its therapeutic effects on motor symptoms, whereas its impact on D2R/D3 R levels in the nucleus accumbens may account for the neuropsychiatric side effects often observed in stimulated PD patients, such as postoperative apathy.

CRF2 signaling is a novel regulator of cellular adhesion and migration in colorectal cancer cells.
Stress has been proposed to be a tumor promoting factor through the secretion of specific neuromediators, such as Urocortin2 and 3 (Ucn2/3), however its role in colorectal cancer (CRC) remains elusive. We observed that Ucn2/3 and their receptor the Corticotropin Releasing Factor receptor 2 (CRF2) were up-regulated in high grade and poorly differentiated CRC. This suggests a role for CRF2 in the loss of cellular organization and tumor progression. Using HT-29 and SW620 cells, two CRC cell lines differing in their abilities to perform cell-cell contacts, we found that CRF2 signals through Src/ERK pathway to induce the alteration of cell-cell junctions and the shuttle of p120ctn and Kaiso in the nucleus. In HT-29 cells, this signaling pathway also leads to the remodeling of cell adhesion by i) the phosphorylation of Focal Adhesion Kinase and ii) a modification of actin cytoskeleton and focal adhesion complexes. These events stimulate cell migration and invasion. In conclusion, our findings indicate that CRF2 signaling controls cellular organization and may promote metastatic potential of human CRC cells through an epithelial-mesenchymal transition like process. This contributes to the comprehension of the tumor-promoting effects of stress molecules and designates Ucn2/3-CRF2 tandem as a target to prevent CRC progression and aggressiveness.

What can rodent models tell us about apathy and associated neuropsychiatric symptoms in Parkinson's disease?
In addition to classical motor symptoms, Parkinson's disease (PD) patients display incapacitating neuropsychiatric manifestations, such as apathy, anhedonia, depression and anxiety. These hitherto generally neglected non-motor symptoms, have gained increasing interest in medical and scientific communities over the last decade because of the extent of their negative impact on PD patients' quality of life. Although recent clinical and functional imaging studies have provided useful information, the pathophysiology of apathy and associated affective impairments remains elusive. Our aim in this review is to summarize and discuss recent advances in the development of rodent models of PD-related neuropsychiatric symptoms using neurotoxin lesion-based approaches. The data collected suggest that bilateral and partial lesions of the nigrostriatal system aimed at inducing reliable neuropsychiatric-like deficits while avoiding severe motor impairments that may interfere with behavioral evaluation, is a more selective and efficient strategy than medial forebrain bundle lesions. Moreover, of all the different classes of pharmacological agents, D2/D3 receptor agonists such as pramipexole appear to be the most efficient treatment for the wide range of behavioral deficits induced by dopaminergic lesions. Lesion-based rodent models, therefore, appear to be relevant tools for studying the pathophysiology of the non-motor symptoms of PD. Data accumulated

so far confirm the causative role of dopaminergic depletion, especially in the nigrostriatal system, in the development of behavioral impairments related to apathy, depression and anxiety. They also put forward D2/D3 receptors as potential targets for the treatment of such neuropsychiatric symptoms in PD.

Introduction: Compulsivity has been considered a transdiagnostic dimension in compulsive spectrum disorders, characterized by a heterogeneous cognitive and behavioral phenotype associated with different alterations in the cortico-striatal-thalamic-cortical loop. Objective: We investigated the morphological alterations in different brain areas associated with inhibitory control deficit in a preclinical model of compulsivity. Methods: Brain volumetric differences were assessed in rats selected as high or low compulsive drinking (HD, LD), on Schedule-Induced Polydipsia (SIP), using high-resolution magnetic resonance imaging (MRI). Results: Voxel-based morphometry of segmented MRI images revealed that compulsive HD rats showed a significantly increased volume of white matter areas (Corpus Callosum and Anterior Commissure), cortical structures (Motor Cortex and dorsolateral Orbitofrontal Cortex), subcortical structures (Striatum, Preoptic Area, Amygdala, Dentate Gyrus, Subthalamic Nucleus, Periaqueductal Gray, Midbrain and Parasubiculum) and Cerebellum relative to LD animals. However, HD rats showed a decreased volume of mPFC compared to LD rats. Finally, no differences were observed between HD and LD groups in the whole brain nor in cerebrospinal fluid (CSF) volume. Conclusions: These results highlight and extend the knowledge about brain morphological differences in a compulsive phenotype of rats; pointing towards the pathogenesis of inhibitory control deficit, such as those related to goal-directed behavior, habit learning, cognitive flexibility and motor inhibition. Moreover, these findings demonstrate the importance of mapping different structural patterns to enhancing the knowledge about the vulnerability to compulsive spectrum disorders. INVESTIGATING THE MECHANISMS UNDERLYING THE BENEFICIAL EFFECTS OF EXERCISE ON COGNITIVE IMPAIRMENT ASSOCIATED WITH SCHIZOPHRENIA - FOCUS ON PARVALBUMIN INTERNEURONS AND PERINEURONAL NETS

POSTER SESSION 04 - SECTION: MENTAL HEALTH, ADDICTION AND OBSESSIVE-COMPULSIVE DISORDER

Jennifer Fletcher[1], John Gigg[2], Michael Harte[1]
[1]The University of Manchester, Division Of Pharmacy And Optometry, Manchester, United Kingdom, [2]University of Manchester, Division Of Neuroscience And Experimental Psychology, Manchester, United Kingdom

Background: NMDA receptor antagonist models have been widely used to mimic the cognitive and patholigcal deficits associated with schizophrenia. Increasing evidence indicates parvalbumin interneurons (PVI) and associated perineuronal nets (PNN) play a crucial role in cognition. In the current study we investigated changes to prefrontal PVI and PNN in the subchronic phencyclidine (scPCP) model. The second study aimed to explore PNN density changes in the model after chronic aerobic exercise, which has rescued PVI reductions in animal models and improved cognition in patients. **Methods:** 100 female lister hooded rats received vehicle or PCP (2mg/Kg, bidaily, 7 days). In study one, 60 brains were taken 8 weeks after dosing for mRNA quantification using qPCR and protein quantification using both simple western analysis and immunohistochemistry (IHC) (n = 10 per analysis and treatment). In study two vehicle and scPCP groups were subdivided into exercise and sedentary groups. Exercise involved access to a running wheel for thirty one-hour bouts over 6 weeks (n=10 per group). **Results:** Parvalbumin mRNA and protein were increased in scPCP-treated rats relative to controls; however, IHC showed reduced PVI number. There was no change to mRNA expression of PNN components, though IHC revealed reductions of total PNN density in scPCP-treated rats. After chronic exercise, PVI density increased, and PNN density decreased within treatments. **Conclusion:** These results indicate scPCP dosing results in a reduced number of dysfunctional PVI in the PFC. After exercise, decreased PNN may contribute to a more plastic PVI, increasing PVI density and improving cognitive function.

Context: Innate variability in response to reward is a striking but understudied phenomenon. This heterogeneity is most prominently seen amongst those that consume alcohol ; some drink casually while others drink in an uncontrolled manner. Dopamine dynamics are critical in encoding the reinforcing properties of rewarding and drug stimuli, yet, how these dynamics contribute to the phenotypic divergence seen in drug consumers remains unknown. Aims: Here, we aim to isolate the pre-existing neural dynamics that may explain behavioral individuation in response to natural reward and thus, future propensity to consume alcohol. Methods: Following measurement of behavioral responses to natural reward, we electrophysiologically record *in vivo* dopamine neurons' activity and their response to alcohol (i.v.) . We then utilize *in vivo* fiber photometry in freely behaving mice to record projection-specific dopamine dynamics elicited by natural rewards and investigate how voluntary alcohol drinking is predicted by these dopamine dynamics. Finally, using chemogenetics, we manipulate these activity patterns, subsequently controlling alcohol consumption in individuals. Results: We identify that innate behavioral responses to reward are mirrored by heterogeneous yet distinct dopamine firing profiles. We then establish that individual alcohol profiles are associated with pre-existing dopamine dynamics and find that individuals with a hyperdopaminergic activity profile have a lower neuronal response to alcohol and develop lower a lower preference for alcohol in the future. Conclusion: By assessing innate variability in response to rewards- natural and drug- this project will provide novel insights into the neural dynamics and mechanisms driving the phenotypic divergence we see among alcohol consumers.

Evaluation of TLR4 Inhibitor, T5342126, in Modulation of Ethanol-Drinking Behavior in Alcohol-Dependent Mice.
Several lines of evidence support a critical role of TLR4 in the neuroimmune responses associated with alcohol disorders and propose inhibitors of TLR4 signaling as potential treatments for alcoholism. In this work, we investigated the effect of T5342126 compound, a selective TLR4 inhibitor, on excessive drinking and microglial activation associated with ethanol dependence.

Different adaptations of dopamine release in Nucleus Accumbens shell and core of individual alcohol drinking groups of mice.
Alcohol use disorder (AUD) places a tremendous burden on society, with approximately two billion alcohol users in the world. While most people drink alcohol recreationally, a subpopulation (3-5%) engages in reckless and compulsive drinking, leading to the development of AUD and alcohol dependence. The Ventral Tegmental Area (VTA)-Nucleus Accumbens (NAc) circuit has been shown to encode rewarding stimuli and drive individual alcohol drinking behavior. Our previous work successfully separated C57BL/6J isogenic mice into high or low alcohol drinking subgroups after a 12-day, two-bottle choice voluntary alcohol access paradigm. Electrophysiological studies revealed that low alcohol drinking mice exhibited elevated spontaneous and burst firing properties of their VTA dopamine (DA) neurons and specifically mimicking this pattern of activity in VTA-NAc neurons in high alcohol drinking mice using optogenetics decreased their alcohol preference. It is also known

that VTA DA neurons encode the salience and rewarding properties of external stimuli while also regulating downstream dopamine concentrations. Here, as a follow-up to this study, we utilized Fast Scan Cyclic Voltammetry (FSCV) to examine dopamine release in the NAc shell and core between alcohol drinking groups. We observed dynamic changes of dopamine release in the core of high drinking mice, but failed to see widely significant differences of dopamine release in the shell of both groups, when compared with ethanol-naive controls. Overall, the present data suggest subregion-specific differences of evoked dopamine release in the NAc of low and high alcohol drinking mice, and may provide an anatomical substrate for individual alcohol drinking behavior. This article is part of the special issue on Stress, Addiction and Plasticity.

Secondary Motor Cortex Transforms Spatial Information into Planned Action during Navigation.
Fluid navigation requires constant updating of planned movements to adapt to evolving obstacles and goals. For that reason, a neural substrate for navigation demands spatial and environmental information and the ability to effect actions through efferents. The secondary motor cortex (M2) is a prime candidate for this role given its interconnectivity with association cortices that encode spatial relationships and its projection to the primary motor cortex. Here, we report that M2 neurons robustly encode both planned and current left/right turning actions across multiple turn locations in a multi-route navigational task. Comparisons within a common statistical framework reveal that M2 neurons differentiate contextual factors, including environmental position, route, action sequence, orientation, and choice availability. Despite significant modulation by environmental factors, action planning, and execution are the dominant output signals of M2 neurons. These results identify the M2 as a structure integrating spatial information toward the updating of planned movements.

Stress resilience is promoted by a Zfp189-driven transcriptional network in prefrontal cortex.
Understanding the transcriptional changes that are engaged in stress resilience may reveal novel antidepressant targets. Here we use gene co-expression analysis of RNA-sequencing data from brains of resilient mice to identify a gene network that is unique to resilience. Zfp189, which encodes a previously unstudied zinc finger protein, is the highest-ranked key driver gene in the network, and overexpression of Zfp189 in prefrontal cortical neurons preferentially activates this network and promotes behavioral resilience. The transcription factor CREB is a predicted upstream regulator of this network and binds to the Zfp189 promoter. To probe CREB-Zfp189 interactions, we employ CRISPR-mediated locus-specific transcriptional reprogramming to direct CREB or G9a (a repressive histone methyltransferase) to the Zfp189 promoter in prefrontal cortex neurons. Induction of Zfp189 with site-specific CREB is pro-resilient, whereas suppressing Zfp189 expression with G9a increases susceptibility. These findings reveal an essential role for Zfp189 and CREB-Zfp189 interactions in mediating a central transcriptional network of resilience.

α- and β-Adrenergic Receptor-Mediated Mesolimbic Homeostatic Plasticity Confers Resilience to Social Stress in Susceptible Mice.
Homeostatic plasticity in mesolimbic dopamine (DA) neurons plays an essential role in mediating resilience to social stress. Recent evidence implicates an association between stress resilience and projections from the locus coeruleus (LC) to the ventral tegmental area (VTA) (LC→VTA) DA system. However, the precise circuitry and molecular mechanisms of the homeostatic plasticity in mesolimbic DA neurons mediated by the LC→VTA circuitry, and its role in conferring resilience to social defeat stress, have not been described.

Epigenetic regulation of brain region-specific microglia clearance activity.
The rapid elimination of dying neurons and nonfunctional synapses in the brain is carried out by microglia, the resident myeloid cells of the brain. Here we show that microglia clearance activity in the adult brain is regionally regulated and depends on the rate of neuronal attrition. Cerebellar, but not striatal or cortical, microglia exhibited high levels of basal clearance activity, which correlated with an elevated degree of cerebellar neuronal attrition. Exposing forebrain microglia to apoptotic cells activated gene-expression programs supporting clearance activity. We provide evidence that the polycomb repressive complex 2 (PRC2) epigenetically restricts the expression of genes that support clearance activity in striatal and

cortical microglia. Loss of PRC2 leads to aberrant activation of a microglia clearance phenotype, which triggers changes in neuronal morphology and behavior. Our data highlight a key role of epigenetic mechanisms in preventing microglia-induced neuronal alterations that are frequently associated with neurodegenerative and psychiatric diseases.

Midbrain circuit regulation of individual alcohol drinking behaviors in mice.
Alcohol-use disorder (AUD) is the most prevalent substance-use disorder worldwide. There is substantial individual variability in alcohol drinking behaviors in the population, the neural circuit mechanisms of which remain elusive. Utilizing in vivo electrophysiological techniques, we find that low alcohol drinking (LAD) mice have dramatically higher ventral tegmental area (VTA) dopamine neuron firing and burst activity. Unexpectedly, VTA dopamine neuron activity in high alcohol drinking (HAD) mice does not differ from alcohol naive mice. Optogenetically enhancing VTA dopamine neuron burst activity in HAD mice decreases alcohol drinking behaviors. Circuit-specific recordings reveal that spontaneous activity of nucleus accumbens-projecting VTA (VTA-NAc) neurons is selectively higher in LAD mice. Specifically activating this projection is sufficient to reduce alcohol consumption in HAD mice. Furthermore, we uncover ionic and cellular mechanisms that suggest unique neuroadaptations between the alcohol drinking groups. Together, these data identify a neural circuit responsible for individual alcohol drinking behaviors.

Nicotine and alcohol: the role of midbrain dopaminergic neurons in drug reinforcement.
Nicotine and alcohol addiction are leading causes of preventable death worldwide and continue to constitute a huge socio-economic burden. Both nicotine and alcohol perturb the brain's mesocorticolimbic system. Dopamine (DA) neurons projecting from the ventral tegmental area (VTA) to multiple downstream structures, including the nucleus accumbens, prefrontal cortex, and amygdala, are highly involved in the maintenance of healthy brain function. VTA DA neurons play a crucial role in associative learning and reinforcement. Nicotine and alcohol usurp these functions, promoting reinforcement of drug taking behaviors. In this review, we will first describe how nicotine and alcohol individually affect VTA DA neurons by examining how drug exposure alters the heterogeneous VTA microcircuit and network-wide projections. We will also examine how coadministration or previous exposure to nicotine or alcohol may augment the reinforcing effects of the other. Additionally, this review briefly summarizes the role of VTA DA neurons in nicotine, alcohol, and their synergistic effects in reinforcement and also addresses the remaining questions related to the circuit-function specificity of the dopaminergic system in mediating nicotine/alcohol reinforcement and comorbidity.

EFFECTS OF TRANSCRANIAL DIRECT-CURRENT STIMULATION ON MEDIAL PREFRONTAL CORTEX IN A PRECLINICAL MODEL OF COMPULSIVITY

POSTER SESSION 04 - SECTION: MENTAL HEALTH, ADDICTION AND OBSESSIVE-COMPULSIVE DISORDER

Manuela Olmedo-Córdoba, Elena Martín González, Ángeles Prados-Pardo, Margarita Moreno
University of Almería, Psychology, Almería, Spain

Compulsivity is a failure to stop an ongoing behavior that is becoming inappropriate to the situation. Clinical research indicates that compulsive spectrum disorders often are refractory to current treatments. Transcranial direct current stimulation (tDCS), a non-invasive neurostimulation, has been proposed as a safe and effective treatment for obsessive-compulsive disorder, schizophrenia, depression and addiction. The aim of the present study has been to assess the therapeutical effectivity of anodal tDCS on a preclinical model of compulsivity. For that purpose, male Wistar rats were selected as either high (HD) or low (LD) drinkers according to their rate of drinking behavior on Schedule-Induced Polydipsia (SIP). Subsequently, an electrode was implanted by stereotaxic surgery in the left medial prefrontal cortex of HD and LD animals. After one week of recovery, animals were re-exposed to SIP. Next, HD and LD animals received anodal tDCS or sham stimulation over the medial prefrontal cortex for five consecutive days. There were four experimental groups (HD-tDCS; HD-Sham; LD-tDCS; LD-sham). One day after receiving the last stimulation, animals were re-exposed to SIP. The results will be discussed in terms of the possible effects of neurostimulation by anodal tDCS on medial prefrontal cortex to reduce compulsive behavior on SIP. Neuromodulation using anodal tDCS might induce neuroplastic changes in the inhibitory control brain circuit, pointing towards a potential treatment for compulsive spectrum disorders. MELATONIN REDUCES ALCOHOL DRINKING IN RATS WITH DISRUPTED FUNCTION OF THE SEROTONERGIC SYSTEM

POSTER SESSION 04 - SECTION: MENTAL HEALTH, ADDICTION AND OBSESSIVE-COMPULSIVE DISORDER

Ieva Pocevičiūtė[1], Rokas Buišas[2], Osvaldas Rukšėnas[3], Valentina Vengeliene[2]

The reason for the limited treatment success of substance-use-related problems may be a causal heterogeneity of this disorder, which, at least partly, is manifested as differences in substance-use motives between individuals. Aim: The aim of the present study was to assess if rats with pharmacologically induced differences in the function of the serotonergic system would respond differently to melatonin treatment compared to their control counterpart rats with respect to voluntary alcohol consumption. Method: To achieve this goal, we treated rats neonatally with the selective serotonin transporter SERT inhibitor escitalopram. This procedure has been reported to cause long-lasting sleep abnormalities in rodents. To measure the effects of neonatal escitalopram treatment on voluntary home-cage alcohol consumption rats were given intermittent access to tap water and alcohol solution. During melatonin treatment, rats had access to continuous water and alcohol solutions. Results: The study demonstrated that during adulthood, rats that had been treated with escitalopram tended to drink higher amounts of alcohol compared to control rats. Further, administration of melatonin significantly decreased alcohol intake in escitalopram-treated animals but caused only a slight, nonsignificant reduction in alcohol consumption in control rats. In conclusion, our data support the therapeutic potential of melatonin as a treatment for alcohol use disorder. However, interindividual differences between alcohol users may considerably modify the outcome of the melatonin treatment, whereby patients that manifest lower sleep quality due to disruption of serotonergic activity are more likely to benefit from this treatment.

The Anticonvulsant Lamotrigine Reduces Bout-Like Alcohol Drinking in Rats.
We used an optical lickometer system to study drinking microstructure and effect of lamotrigine in voluntary alcohol-drinking rats. We showed that, similar to humans, animals differ by their drinking microstructure where some consume alcohol exclusively in a bout-like patterns. The study suggests that anticonvulsants, such as lamotrigine, may be one treatment strategy specifically affecting this type of drinking.

In alcohol use disorders, drug memories can persist throughout abstinence, and re-exposure to the cues that signal alcohol can lead to relapse. Recent studies suggest GABAergic neurons in Lateral Hypothalamus (LH-GABA) are key players in memory processes, although the specific mechanisms through which LH-GABA encode and express memories are still understudied. In this study, we aim to describe how alcohol reward memories are encoded and expressed in LH GABA neurons. Using fibre photometry, we monitored LH-GABA calcium transients during acquisition and expression of cue-alcohol associations in rats. Then, we inhibited these neurons during acquisition of the cue-alcohol association with optogenetics. We first trained the rats on an alcohol conditioning task in which they learned to associate one conditioned stimulus (CS+) with alcohol availability in a magazine (20% EtOH in water), while a different conditioned stimulus (CS-) was presented without consequence. We then tested expression of the memory by presenting the CS+ and CS- alone. Our results show LH-GABA initially respond to all incoming stimuli regardless of their valence. This increased activity is maintained to alcohol-predictive stimuli and decreases to behaviorally irrelevant stimuli. In addition, we also found that LH-GABA activity decreases to below baseline during alcohol consumption. Moreover, in extinction, this decrease is no longer present and activity remains above baseline, potentially indicating that these neurons might be signalling reward prediction error. Finally, we also show that LH-GABA are functionally involved in the acquisition of cue-alcohol associations, as inhibiting these neurons during acquisition of such cues reduces alcohol seeking.

Alcohol Seeking Under Risk of Punishment Is Associated With Activation of Cortical and Subcortical Brain Regions.
In humans, stimuli associated with alcohol availability can provoke relapse during abstinence. In this study, we investigated the role of discriminative stimuli (DS) in the control of alcohol seeking in two types of behavioral tests. The first test examined the ability of an alcohol-associated DS to promote alcohol seeking (relapse) after punishment-imposed abstinence in the presence of a different DS. Following this, we tested whether the differentially associated DS can promote and suppress alcohol self-administration in a within-session discrimination task. During the within-session discrimination task, we also tested the rate of alcohol self-administration when two DS are presented in a compound. We first trained Long-Evans male rats (= 24) to self-administer alcohol in the presence of one DS (reward-associated discriminative stimulus, rewDS) and then punished that behavior in the presence of a different DS (punishment-associated discriminative stimulus, punDS). On the test, we found that rats tested with the rewDS showed higher alcohol seeking than rats tested with the punDS. This result shows that a single Cue DS can promote alcohol seeking in a manner comparable to contexts. Subsequently, we trained 16 of these rats in a within-session trial-based discrimination task, comprised of intervening 2-min trials of rewDS, punDS, or conflict with rewDS and punDS in compound and a reduced probability of punishment. We found that alcohol self-administration is bi-directionally regulated by the rewDS and punDS. In conflict trials, alcohol self-administration was at a rate that was intermediate between the rewDS and punDS trials. In a final test, rats were presented with one of the three trial conditions and perfused for Fos immunohistochemistry. We found Fos expression was higher in the rats tested in the conflict condition in three interconnected sub-cortical brain regions. This study demonstrated the important role that alcohol-associated DS plays an important role in promoting relapse to alcohol seeking after punishment-imposed abstinence. We also implemented a within-session discrimination task that allows for the study of alcohol seeking under motivational conflict, which may be relevant for alcohol use despite negative consequences. The results from the Fos data suggest that higher

alcohol seeking in approach-avoidance motivational conflict is associated with activation of sub-cortical regions but not cortical regions.

ALPHA7 NICOTINIC RECEPTORS IN VENTRAL, BUT NOT DORSAL, HIPPOCAMPUS REGULATE NEURONAL ACTIVATION DURING REINSTATEMENT OF HEROIN-CONDITIONED PLACE PREFERENCE

POSTER SESSION 04 - SECTION: MENTAL HEALTH, ADDICTION AND OBSESSIVE-COMPULSIVE DISORDER

Maria Giulia Coccia[1], Sue Wonnacott[2], Sharon Smith[3], David Heal[3], Chris Bailey[1]
[1]University of Bath, Pharmacy And Pharmacology, Bath, United Kingdom, [2]University of Bath, Biology And Biochemistry, Bath, United Kingdom, [3]DevelRx, Drug Abuse And Dependence, Nottingham, United Kingdom

AIMS: We previously reported the alpha7 nicotinic acetylcholine receptor (α7nAChR) antagonist, methyllycaconitine (MLA) selectively attenuated reinstatement of morphine-conditioned place preference (CPP) when injected into the ventral hippocampus (vHIP)[1]. The vHIP contributes to the processing of drug-context associations critical for promoting relapse. This study explores the role of α7nAChRs in heroin-CPP and their location and contribution to neuronal activation in vHIP. **METHODS:** Male C57BL/6J mice (7-8 weeks old) acquired heroin-induced CPP (heroin: 2mg/kg, intraperitoneal). After extinction, mice were pretreated with MLA (4mg/kg, subcutaneous) or saline and reinstatement was induced by heroin-priming (1mg/kg, intraperitoneal), followed by perfusion-fixation to detect c-Fos expression. Whole-cell patch-clamp experiments were conducted on vHIP and dHIP CA1 pyramidal neurons in brain slices from naïve male C57BL/6J mice (4 weeks old). **RESULTS:** MLA decreased heroin-primed reinstatement of heroin-CPP ($p<0.05$ Student's t-test) and post-CPP c-Fos expression in vHIP CA1 pyramidal neurons ($p<0.05$ Student's t-test), but not in dHIP. A combination of α7 positive allosteric modulator and agonist (PNU-120596 (10μM) and PNU-282987 (300nM)) induced inward currents in vHIP and dHIP ($p<0.001$ one-way ANOVA, with post-hoc Tukey's test), confirming α7nAChRs in both regions. **CONCLUSIONS:** MLA blockade of reinstatement reinforces the importance of α7nAChRs in vHIP in circuitry governing associative memories. Although α7nAChRs are expressed in CA1 pyramidal neurons in vHIP and dHIP, MLA only affected c-Fos expression after heroin CPP in vHIP. It suggests the region-specific effect of MLA to inhibit opiate CPP is due to differences in networks involving vHIP and dHIP rather than α7nAChR expression. [1]Addiction Biology 24:590–603.

Concomitant D1 and D2 dopamine receptor agonist infusion in prelimbic cortex is required to foster extinction of amphetamine-induced conditioned place preference.
Dopamine (DA) in medial prefrontal cortex is crucial in extinction of aversive or appetitive experiences. Although attention has been mostly focused on the infralimbic area of prefrontal cortex, a role of the prelimbic (PL) area has been envisaged pointing to DA transmission in the extinction of drug conditioned behavior. Evidence shows that DA exerts its action also via both D1 and D2 receptor subtypes. Here we investigated the effects of D1 and D2 receptor agonist microinfusion in the PL cortex of C57BL/6J mice on expression and extinction of amphetamine-induced conditioned place preference (CPP), in order to ascertain the effects of selective vs concomitant receptor subtypes stimulation. SKF38393 and Quinpirole were used at doses not impairing expression of amphetamine-induced CPP on the day of infusion. Acute infusion of each agonist alone did not affect extinction in subsequent days in comparison with Vehicle-treated mice, while concomitant infusion of both agonists produced a clear-cut advance of extinction of preference for the compartment previously paired with amphetamine. These results show that concomitant stimulation of D1 and D2 receptors in PL is required to foster extinction suggesting a synergic action between receptors or a heteromeric receptor involvement.

FRONTO-STRIATAL CONNECTIVITY PATTERNS ACCOUNT FOR THE IMPACT OF METHYLPHENIDATE ON CHOICE IMPULSIVITY AMONG HEALTHY ADULTS

POSTER SESSION 04 - SECTION: MENTAL HEALTH, ADDICTION AND OBSESSIVE-COMPULSIVE DISORDER

Maryana Daood[1], Leehe Peled-Avron[1], Rachel Ben-Hayun[2], Michael Nevat[1], Judith Aharon-Peretz[2], Rachel Tomer[1,3], Roee Admon[1,3]
[1]University of Haifa, School Of Psychological Sciences, Haifa, Israel, [2]Rambam Health Care Campus, The Cognitive Neurology Institute, Haifa, Israel, [3]University of Haifa, The Integrated Brain And Behavior Research Center (ibbrc), Haifa, Israel

Choice impulsivity (CI) depicts a preference towards smaller-sooner rewards over larger-delayed rewards, as revealed in delay discounting (DD) tasks. Previous research uncovered the prominent role of dopaminergic signaling within fronto-striatal circuits in mediating CI. Administration of methylphenidate (MPH), an indirect dopaminergic agonist, was shown to reduce CI in animals and pathological populations, although significant inter-individual variability in these effects was reported. Whether MPH impacts CI among healthy individuals, and whether variability in the impact of MPH is related to neural activation and connectivity patterns, has yet to be assessed. In order to address this gap, fifty-seven healthy young adults completed the DD task twice during fMRI scans, after acute administration of either MPH (20mg) or placebo, in a randomized double-blind placebo-controlled design. Acute MPH administration was found to reduce DD rates at the group level, yet substantial variability in this behavioral response was observed. MPH was also found to increase activation in the bilateral putamen and the right caudate, and to enhance functional connectivity between the left putamen and medial prefrontal cortex (mPFC), particularly during non-impulsive choices. Notably, the more putamen-mPFC functional connectivity increased during non-impulsive choices following MPH administration, the less an individual was likely to make impulsive choices. Our findings reveal, for the first time in healthy adults, that acute MPH administration is associated with reduced CI and increased striatal activation and fronto-striatal connectivity, and furthermore, that the magnitude of MPH-induced change in fronto-striatal connectivity may account for individual differences in the impact of MPH on impulsive behavior.

PREDICTING LOCAL BRAIN ACTIVITY FROM CONVERSATIONAL BEHAVIOURS: A NEW EXPERIMENTAL APPROACH TO INVESTIGATE THE NEURAL BASES OF NATURAL SOCIAL INTERACTIONS

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Thierry Chaminade[1], Youssef Hmamouche[2], Magalie Ochs[3], Laurent Prevot[4]
[1]CNRS - Aix-Marseille Université, Int, Marseille, France, [2]Mohammed VI Polytechnic University, International Center For Artificial Intelligence, Rabat, Morocco, [3]CNRS - Aix Marseille University, Lis, Marseille Cedex, France, [4]CNRS - Aix Marseille University, Lpl, Aix-en-Provence, France

Aims: “Second-person neuroscience” (Schilbach, 2013) requires new paradigms to study the neurophysiology of natural social interactions. fMRI was recorded while participants (n=24) discussed freely with a robot or a human. Acquired audio, video, eye tracking and physiological time-series synchronized with BOLD time-series (Rauchbauer, 2019) were used to identify which behavioural features are associated with brain responses across individually unique trials. Methods: Discretized local brain activity is predicted based on the behavioural recordings of each trial. Analysis included two steps, a feature extraction step to derive high-level features from raw signals, and the application of a dynamic prediction model to predict brain activity from the extracted features. 9-fold-cross-validation is performed on training data comprising eighteen participants to find the appropriate parameters of the Random Forest classifier based on the F-score, then tested on the six remaining participants. Results: We focused on a limited set of brain regions from the Brainnetome atlas (Fan, 2016) to validate the analysis, using behavioural features automatically extracted from linguistic exchanges, participants’ eye movements and conversational agents’ head and facial movements. Significantly accurate (p<0.001) predictions were found for the superior temporal sulcus, temporoparietal junction and precuneus bilaterally for Human-Human Interactions, while prediction was not significant for a white matter control region. Speech features dominated predictions for the temporal areas, while the interlocutor’s head and facial movements played an important role for prediction of the precuneus activity. Conclusions: This analysis demonstrates the possibility of associating complex combinations of behavioural features to local brain activity in unconstrained social interactions.

VISUAL SPATIAL PERCEPTION WITH DESCARTE'S THEORY IN THE VISUAL AIDS TEACHING CLASSROOM.

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Prateet Baskota
School of Education, Kathmandu University, Education, Lalitpur, Nepal

With the support of Visual-Spatial Perception with Descarte's Theory and Gardners's Visual-Spatial Intelligence Theory following narrative inquiry as to the research method, I collected the data through a series of interview sessions, casual conversations and class observations with four participants from one secondary school based on the North-eastern part of the Kathmandu Valley. I also observed their activities in the tutorial room, library, schoolroom, audio-visual laboratory, and computer test centre. For interpretation, analysis and discussion of the data, I read and reread them, searched patterns and saw the emerging themes and discussed them within the theoretical framework of Howard Gardner's 'Visual-Spatial Intelligence' theory of multiple intelligences. From the interpretation, analysis, and discussion of the data, I learned that learning a language like English through visual aids enables the learners to develop positive social skills, new techniques of reading habits in visual aids supporting the words of books, and learning constructing knowledge for life. Correspondingly, this new way of learning habits in P-Model Classroom changes the practices of students into visual literacy through technology-rich-environment scenarios in the classroom. In addition, the learning method creates a creative embellishment and fascination of students' creativity, making their classroom well-structured and engaging them in different techniques of creative works. So, this new way of learning habits supports students' efforts to understand content taught in the classroom. These findings also indicate the sturdy practice for secondary school students, which reduces the uncertain activities at the school by saving the teacher's time.

Many socio-affective behaviors, such as speech, are modulated by oxytocin. While oxytocin modulates speech perception, it is not known whether it also affects speech production. Here we investigated effects of oxytocin administration and interactions with the functional rs53576 oxytocin receptor (OXTR) polymorphism on produced speech and its underlying brain activity. During fMRI, 50 healthy male participants read sentences with either neutral or happy intonation, a covert reading condition served as a common baseline. Participants were studied once under the influence of intranasal oxytocin and in another session under placebo. Participants were grouped based on their polymorphism (AA/AG vs. GG). In carriers of the A allele, the OXTR is thought to be less effective compared to GG homozygotes. Oxytocin administration increased the second formant of produced vowels, a phonetic feature associated with speech valence. When preparing to speak, oxytocin enhanced brain activity in sensorimotor cortices of both dorsal and right ventral speech streams, as well as limbic and executive control regions. In some of these regions, oxytocin administration helped carriers of the A allele to pre-activate similar to GG homozygotes. In the remaining regions, oxytocin increased preparatory activity in all participants. Oxytocin also gated cortico-basal loops involved in the generation of happy prosody. Our findings suggest several neural processes underlying speech production are gated by oxytocin, including control of affective intonation but also of sensorimotor aspects during emotionally neutral speech.

COGNITIVE STATUS OF INDIVIDUALS WITH APHASIA- ELECTROPHYSIOLOGICAL MARKERS.

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Aneta Szymaszek, Mateusz Choinski, Elzbieta Szelag, Anna Bombinska
Nencki Institute of Experimental Biology, Polish Academy of Sciences, Laboratory Of Neuropsychology, Warsaw, Poland

Aphasia is an acquired impairment of language functions resulting from a brain lesion. It is also accompanied by deficits in non-language cognitive functions, such as working memory, executive functions and temporal resolution. Assessment of cognitive capacity in people with aphasia (PWA) with standard neuropsychological methods may be problematic due to their language difficulties. To avoid the language difficulties bias, the objective electrophysiological methods may be applied to assess the cognitive capacity of PWA. The study was aimed to verify the utility of P300 and mismatch negativity (MMN) parameters as measures of cognitive function efficiency in PWA. A total of 26 PWA after left-hemispheric stroke participated in the study. Several language and non-language cognitive functions were assessed behaviourally. Two electrophysiological procedures were applied: visual Go/No-Go task as well as auditory syllable discrimination task. Shorter P300 latencies were associated with better temporal resolution, psychomotor speed, planning ability, spatial working memory, as well as better word and sentence comprehension and verbal fluency. On the other hand, higher MMN amplitudes corresponded to better psychomotor speed, spatial working memory, phoneme hearing, word comprehension and verbal fluency. The results suggest that studied ERP components might be objective indices of non-verbal and verbal cognitive functions in PWA and can be potentially applicable to monitor cognitive status of these patients. Supported by National Science Centre, Poland, grant number: 2016/21/B/HS6/03775.

Bilingualism has raised concern about how languages are represented in the brain. Neuroimaging and electrocortical stimulation studies have shown identical cortical representations for the native (L1) and second language (L2), variable overlap or no overlap at all. Our aim was to identify and compare cortical representations for L1 and L2 within the temporal cortex considering its relation with language. We tested 5 Spanish-Basque bilingual low-grade glioma patients with left temporal tumours through intraoperative mapping and 20 healthy bilingual subjects with neuroimaging methods using a standardised multilingual picture naming test (MULTIMAP). Healthy participants showed a common system for L1 and L2, with the left middle and superior temporal areas responding differently in terms of activation. While the middle temporal gyrus showed higher activation for L1 than for L2, the superior temporal gyrus was recruited only for L1. Patients showed language specific sites for L1 in the superior temporal gyrus and for L2 in the middle temporal gyrus. Evidence combined suggests representations for both languages may involve functionally independent populations within the left temporal territory explored and underlies the importance of testing multiple languages to prevent possible deficits, moving towards individually tailored interventions.

THE EMBODIMENT OF ADJECTIVES

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Keith O`Donnell[1], Seán Commins[1], Patricia Gough[2]
[1]Maynooth University, Dept. Of Psychology, Kildare, Ireland, [2]UCD, Psychology, Dublin, Ireland

Aims: Language embodiment theories typically propose that processing language is built upon experiences of the actions, objects, and events to which the language refers (Marino et al., 2011). Generally, language embodiment experiments have tested motor responses to verbs and nouns only; therefore, knowledge of the topic is constructed upon a limited set of word categories. The current experiment used three different tasks requiring different levels of processing to test the embodiment of ***adjectives.*** **Methods:** Three behavioural experiments were conducted – a GoSignal task (*N* = 40), a lexical decision task (online) (*N* = 150), and a semantic decision task (*N* = 40). Each experiment tested the effect of adjective type (negative vs. non-negative vs. pseudo) on the expected affordance effect of noun type (i.e. quicker hand responses to hand-related vs. non-hand related nouns). **Results:** The GoSignal task revealed a significant main effect for noun type only (quicker for hand-related nouns). However, the semantic decision task revealed a main effect for noun type in the opposite direction (slower responses) and a main effect for adjective type (slower for pseudo) – but no interaction effect between adjective/noun type. The lexical decision task is ongoing. **Conclusions**: In a passive GoSignal task, there was no interaction between adjective/noun type. Similarly, there was no interaction in the semantic decision task; however, responses to adjective and noun types were significantly influenced by task demands. The lexical decision task will allow us to further test the embodiment of adjectives and the influence of task demands on embodiment.

A DEEP HIERARCHY OF PREDICTIONS ENABLES DYNAMIC ASSIGNMENT OF SEMANTIC ROLES IN SPEECH COMPREHENSION

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Yaqing Su[1], Itsaso Olasagasti[1], Anne-Lise Giraud[1,2]
[1]University of Geneva, Fundamental Neuroscience, Geneva, Switzerland, [2]Institut Pasteur, INSERM, Institut De L'audition, Paris, France

Understanding speech requires mapping fleeting and often ambiguous soundwaves to meaning. Humans are known to exploit their capacity to contextualize to facilitate this process, but how internal knowledge is used and deployed in real time remains an open question. Existing models of speech processing focus on either word recognition irrespective of meaning or interactions among abstract linguistic representations without time constraints, providing only partial insights into the dynamics of speech comprehension. Here, we present a model that incrementally extracts multiple levels of information from continuous speech signals in real time, based on the inversion of a generative model that represents the listener's internal knowledge of linguistic and non-linguistic processing levels in a nested temporal hierarchy. In each hierarchy, the model periodically incorporates bottom-up incoming evidence to update its internal representations and generate new top-down predictions. We show that a context level, beyond linguistic representations, can provide the model with semantic predictions informed by sensory inputs, crucial for the disambiguation among multiple meanings of the same word. We also show that hierarchical predictions can reduce peripheral processing effort via minimizing uncertainty and prediction error, especially when sensory precisions become degraded. With this proof-of-concept model, we demonstrate that the deployment of hierarchical predictions is a possible strategy for the brain to utilize structured knowledge dynamically for speech comprehension.

Rate and Temporal Coding of Regular and Irregular Pulse Trains in Auditory Midbrain of Normal-Hearing and Cochlear-Implanted Rabbits.
Although pitch is closely related to temporal periodicity, stimuli with a degree of temporal irregularity can evoke a pitch sensation in human listeners. However, the neural mechanisms underlying pitch perception for irregular sounds are poorly understood. Here, we recorded responses of single units in the inferior colliculus (IC) of normal hearing (NH) rabbits to acoustic pulse trains with different amounts of random jitter in the inter-pulse intervals and compared with responses to electric pulse trains delivered through a cochlear implant (CI) in a different group of rabbits. In both NH and CI animals, many IC neurons demonstrated tuning of firing rate to the average pulse rate (APR) that was robust against temporal jitter, although jitter tended to increase the firing rates for APRs ≥ 1280 Hz. Strength and limiting frequency of spike synchronization to stimulus pulses were also comparable between periodic and irregular pulse trains, although there was a slight increase in synchronization at high APRs with CI stimulation. There were clear differences between CI and NH animals in both the range of APRs over which firing rate tuning was observed and the prevalence of synchronized responses. These results suggest that the pitches of regular and irregular pulse trains are coded differently by IC neurons depending on the APR, the degree of irregularity, and the mode of stimulation. In particular, the temporal pitch produced by periodic pulse trains lacking spectral cues may be based on a rate code rather than a temporal code at higher APRs.

Robust Rate-Place Coding of Resolved Components in Harmonic and Inharmonic Complex Tones in Auditory Midbrain.
Harmonic complex tones (HCTs) commonly occurring in speech and music evoke a strong pitch at their fundamental frequency (F0), especially when they contain harmonics individually resolved by the cochlea. When all frequency components of an HCT are shifted by the same amount, the pitch of the resulting inharmonic tone (IHCT) can also shift, although the envelope repetition rate is unchanged. A rate-place code, whereby resolved harmonics are represented by local maxima in firing rates along the tonotopic axis, has been characterized in the auditory nerve and primary auditory cortex, but little is known about intermediate processing stages. We recorded single-neuron responses to HCT and IHCT with varying F0 and

sound level in the inferior colliculus (IC) of unanesthetized rabbits of both sexes. Many neurons showed peaks in firing rate when a low-numbered harmonic aligned with the neuron's characteristic frequency, demonstrating "rate-place" coding. The IC rate-place code was most prevalent for F0 > 800 Hz, was only moderately dependent on sound level over a 40 dB range, and was not sensitive to stimulus harmonicity. A spectral receptive-field model incorporating broadband inhibition better predicted the neural responses than a purely excitatory model, suggesting an enhancement of the rate-place representation by inhibition. Some IC neurons showed facilitation in response to HCT relative to pure tones, similar to cortical "harmonic template neurons" (Feng and Wang, 2017), but to a lesser degree. Our findings shed light on the transformation of rate-place coding of resolved harmonics along the auditory pathway. Harmonic complex tones are ubiquitous in speech and music and produce strong pitch percepts when they contain frequency components that are individually resolved by the cochlea. Here, we characterize a "rate-place" code for resolved harmonics in the auditory midbrain that is more robust across sound levels than the peripheral rate-place code and insensitive to the harmonic relationships among frequency components. We use a computational model to show that inhibition may play an important role in shaping the rate-place code. Our study fills a major gap in understanding the transformations in neural representations of resolved harmonics along the auditory pathway.

Pitch of harmonic complex tones: rate and temporal coding of envelope repetition rate in inferior colliculus of unanesthetized rabbits.
Harmonic complex tones (HCTs) found in speech, music, and animal vocalizations evoke strong pitch percepts at their fundamental frequencies. The strongest pitches are produced by HCTs that contain harmonics resolved by cochlear frequency analysis, but HCTs containing solely unresolved harmonics also evoke a weaker pitch at their envelope repetition rate (ERR). In the auditory periphery, neurons phase lock to the stimulus envelope, but this temporal representation of ERR degrades and gives way to rate codes along the ascending auditory pathway. To assess the role of the inferior colliculus (IC) in such transformations, we recorded IC neuron responses to HCT and sinusoidally modulated broadband noise (SAMN) with varying ERR from unanesthetized rabbits. Different interharmonic phase relationships of HCT were used to manipulate the temporal envelope without changing the power spectrum. Many IC neurons demonstrated band-pass rate tuning to ERR between 60 and 1,600 Hz for HCT and between 40 and 500 Hz for SAMN. The tuning was not related to the pure-tone best frequency of neurons but was dependent on the shape of the stimulus envelope, indicating a temporal rather than spectral origin. A phenomenological model suggests that the tuning may arise from peripheral temporal response patterns via synaptic inhibition. We also characterized temporal coding to ERR. Some IC neurons could phase lock to the stimulus envelope up to 900 Hz for either HCT or SAMN, but phase locking was weaker with SAMN. Together, the rate code and the temporal code represent a wide range of ERR, providing strong cues for the pitch of unresolved harmonics. Envelope repetition rate (ERR) provides crucial cues for pitch perception of frequency components that are not individually resolved by the cochlea, but the neural representation of ERR for stimuli containing many harmonics is poorly characterized. Here we show that the pitch of stimuli with unresolved harmonics is represented by both a rate code and a temporal code for ERR in auditory midbrain neurons and propose possible underlying neural mechanisms with a computational model.
J Neurophysiol, 2019; 122
30613198: Su Y, Delgutte B
Pitch of Harmonic Complex Tones: Rate Coding of Envelope Repetition Rate in the Auditory Midbrain.
Envelope repetition rate (ERR) is an important cue for the pitch of harmonic complex tones (HCT), especially when the tone consists entirely of unresolved harmonics. Neural synchronization to the stimulus envelope provides a prominent cue for ERR in the auditory periphery, but this temporal code becomes degraded and gives way to rate codes in higher centers. The inferior colliculus (IC) likely plays a key role in this temporal-to-rate code transformation. Here we recorded single IC neuron responses to HCT at varying fundamental frequencies ( ). ERR was manipulated by applying different inter-harmonic phase relationships. We identified a subset of neurons that showed a 'non-tonotopic' rate tuning to ERR between 160 and 1500 Hz. A comparison of neural responses to HCT and sinusoidally amplitude modulated (SAM) noise suggests that this tuning is dependent on the shape of stimulus envelope. A phenomenological model is able to reproduce the non-tonotopic tuning to ERR, and suggests it arises in the IC via synaptic inhibition.

Coordinated regulation of acid resistance in Escherichia coli.

Enteric Escherichia coli survives the highly acidic environment of the stomach through multiple acid resistance (AR) mechanisms. The most effective system, AR2, decarboxylates externally-derived glutamate to remove cytoplasmic protons and excrete GABA. The first described system, AR1, does not require an external amino acid. Its mechanism has not been determined. The regulation of the multiple AR systems and their coordination with broader cellular metabolism has not been fully explored.

READING NEGATIVE ACTION VERBS: ONE OR TWO-STEP PROCESSING IN THE PRIMARY MOTOR CORTEX?

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

William Dupont[1], Florent Lebon[2], Charalambos Papaxanthis[1], Leo Lurquin[1], Carol Madden-Lombardi[1]
[1]University of Bourgogne Franche-Comté, Inserm U1093, DIJON, France, [2]University of Bourgogne Franche-Comté, Inserm U1093, Dijon, France

Action language comprehension automatically activates distributed semantic motor representations. However, controversy persists regarding the representation of negated actions, specifically concerning the activation and inhibitory mechanisms in the motor system, and whether this occurs in one or two-steps. We conducted two experiments probing corticospinal excitability (CSE) and short intracortical inhibition (SICI) in the primary motor cortex at different timings while reading affirmative and negative action sentences. Twenty-six participants silently read manual action and non-action sentences in the affirmative or negative form (The potato is cooked, I peel / don't peel it). Using transcranial magnetic stimulation, we probed CSE in hand muscles by means of the peak-to-peak amplitude of motor-evoked potentials at rest and at several latencies (200, 300, 400, 500 and 600ms) after verb presentation. We observed a main effect of action, with greater CSE for action sentences compared to non-action sentences, regardless of verb form. In experiment two, nineteen participants silently read affirmative and negative action sentences. We measured CSE and SICI at short and long latencies after verb presentation. CSE was greater for affirmative and negative action verbs at both latencies compared to rest. SICI did not change at the short latency but increased at long ones, regardless of verb form. Our results are broadly consistent with a two-step model, as negated actions showed the same motor excitability as affirmed actions with no additional inhibition at early latencies. Neural differences between affirmative and negative verb forms in a second processing step may occur outside the primary motor cortex.

THE CONTRIBUTION OF THE SENSORY-MOTOR INTERACTIONS TO IMAGINED SPEECH

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Sophie Bouton[1,2], Thimothée Proix[3], Stephanie Martin[3], Anne-Lise Giraud[2,3]
[1]Laboratoire Dynamique du Langage, Cnrs Et Université Lyon2, Lyon, France, [2]Institut Pasteur, INSERM, Institut De L'audition, Paris, France, [3]University of Geneva, Department Of Basic Neurosciences, Geneva, Switzerland

The neural activity responsible for imagined speech has mainly been studied by comparing overt with covert speech. Although very informative, the results of these studies are limited in scope as they focus on the motor articulation of speech. However, imagined speech does not only involve the articulatory system, but also the activation of language representations. We propose here to address this issue by comparing two covert speech conditions: imagined speech and silent reading. Our hypothesis is that the coupling between the sensory-motor systems is at the origin of the activation of syllabic and phonemic representations of silent speech. We recorded magnetoencephalography data from 21 adults in two experimental conditions: the same sentence was first read silently and then imagined silently. We mapped the spatiotemporal flow of information across the cortex, characterizing the distribution and timing of evoked activity and the frequency composition of the induced activity. Temporal and motor areas show an earlier evoked response, and a stronger early information transfer in the Imagine Saying condition compared to the Silent Reading condition. Our data also show that the production of covert speech is associated with bursts of low-beta (12-15 Hz) neural oscillations in the sensory and motor areas. Finally, we observed that information propagation between motor and sensory areas relies on a phase-amplitude coupling between low-beta and low gamma.

CONTROLLING A BRAIN-COMPUTER INTERFACE TO DECODE INTERNALLY SPOKEN SYLLABLES

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Kinkini Bhadra[1], Silvia Marchesotti[1], Anne-Lise Giraud[1,2]
[1]University of Geneva, Department Of Fundamental Neurosciences, Geneva, Switzerland, [2]Institut Pasteur Center, Department Of Hearing Institute, Paris, France

Real-time decoding of covert speech from Electroencephalography (EEG) could provide non-invasive solutions for people with compromised speech, such as patients affected by aphasia. We designed an EEG-based Brain-Computer Interface (BCI) to classify two syllables having different articulatory and phonetic features. In order to investigate whether operating a BCI can be learnt, participants were trained to control the BCI daily for 5 consecutive days. We used a random forest classifier based on power spectrum density between 1-70Hz to 'train' (offline, i.e. without any feedback) and then to 'test' (online) the data with real-time visual feedback. Results show that the gamma band (30-70Hz) from the bilateral temporal electrodes largely contribute to the offline classification accuracy. Further, participants show maximum control during online BCI training on day-4, through a progressive performance improvement from day-1, followed by a decrease on day-5. Corresponding neural data showed a significant power increase on day-4 compared to day-1 in left and fronto-temporal electrodes in theta, beta, and high-gamma bands that might underpin the acquisition of BCI-control skills. EEG response related to covert speech indicate Event-Related Desynchronization and Synchronization in the frequency bands related to overt speech, namely theta, beta, and gamma bands. The location and power difference in the neural data corresponding to the two class of syllables support the classifier preference of using gamma band to distinguish between the two class of syllable. Overall, our results indicate that EEG gamma band power is effective in classifying syllable imagery and that training can improve BCI performance.

PASSIVE LEARNING OF SPEECH SOUNDS ASSOCIATED WITH MICROSTRUCTURE OF FRONTO-TEMPORO-PARIETAL BUT NOT FRONTO-STRIATAL WHITE MATTER TRACTS: POSSIBLE IMPLICATIONS FOR IMPLICIT LANGUAGE LEARNING TASKS

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Mikael Novén[1], Mikael Roll[2]
[1]Copenhagen University, Department Of Nutrition, Exercise And Sports (nexs), København, Sweden, [2]Lunds Universitet, Department Of Linguistics And Phonetics, Lund, Sweden

Language learners must become able to perceive and process new speech sounds in order to segment words and sentences. The process of obtaining these skills is, to a high degree, implicit. However, research attempting to find the neuroanatomical correlates of such an implicit learning system has mostly used artificial grammar or serial reaction time tasks that are lacking in linguistic relevance. In this study, we investigated the relationship between aptitude for implicit learning of novel speech sounds and tissue microstructure in fronto-temporo-parietal and fronto-striatal white matter tracts using the LLAMA D (phonetic memory) test and diffusion-weighted magnetic resonance imaging. We found positive correlations between phonetic memory scores and axial kurtosis in the left arcuate (AF) and superior longitudinal fasciculus (SLF) III ($r=-0.518$, $p=8.53e-05$ and $r=-0.440$, $p=0.0011$, respectively) as well as mean and radial kurtosis in the left SLF III ($r=-0.356$, $p=0.0095$ and $r=-0.378$, $p=0.0058$, respectively). Diffusion parameters in fronto-striatal tracts showed no significant association with phonetic memory score (all $p>0.05$). These results indicate that left AF and SLF III are important for passive memorisation of novel speech sounds, possibly linked to auditory-motor and sensorimotor associations involved in articulation. The lack of significant correlations in fronto-striatal tracts might be due to the absence of sequence learning in the LLAMA D test. This highlights the need for learning tasks that target more specific aspects of the neural bases of implicit learning.

Neural Dynamics And Meg, Tübingen, Germany, [4]Hearing Research Centre, Otolaryngology- Head And Neck Surgery, Medical Center, Tübingen, Germany

Human speech allows to convey information via different execution modalities. On the behavioral level, speech content is independent from production and execution modalities. However, it remains unclear whether such a content dimension can be found on the neural level and whether it is possible to dissociate it from the motor dimension. To address this, we recorded magnetoencephalography (MEG) in human subjects that performed a rule-based vocalization task. Content (one of two vowels) and production (overt or covert) were instructed separately and in random order. Applying multivariate pattern analysis (MVPA), we found robust neural information about the content and production of vocalization several seconds before vocalization behavior. Source analysis revealed neural information in speech areas of the left hemisphere. The strength of both types of neural information correlated with the degree of motor involvement. When isolated, both types of information overlapped. Later in the trial, the neural format of production information transformed depending on the content, whereas content information remained stable independent of production type. Our results provide new insights into the neural dynamics underlying basic human vocalization and open a new window for non-invasive speech research in humans.

IDENTIFICATION OF EARLY NEUROCOGNITIVE AND NEUROANATOMICAL PREDICTORS OF LANGUAGE AND LEARNING DISORDERS: SYSTEMATIC REVIEW AND META-ANALYSIS

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Maryam Alabbad[1], Muhammad Ajmal Khan[2], Nadeem Siddique[3], Shahid Bashir[4], Turki Abualait[5]
[1]Imam Abdulrahman Bin Faisal University, Physical Therapy, Dammam , Saudi Arabia, [2]Imam Abdulrahman Bin Faisal University, Deanship Of Library Affairs, Dammam, Saudi Arabia, [3]Lahore University of Management Sciences, Library Department, Lahore, Pakistan, [4]King Fahad Specialist Hospital, Neuroscience Center, Dammam, Saudi Arabia, [5]Imam Abdulrahman Bin Faisal University, Physical Therapy, Dammam, Saudi Arabia

Objective: To identify the significant early neurophysiological, neuroanatomical, and neurocognitive predictors of developmental-associated language and learning disabilities (LLDs) in children. **Data Sources:** We searched three electronic databases (PubMed, Scopus, and WOS) for studies published in English between January 2000 and November 2021. **Study Selection:** Eighty-four studies (Randomized controlled trials (RCT) n =12; non-RCT n=74) involves neurophysiological, neuroanatomical, and neurocognitive predictors of dyslexia, dyscalculia, and dysgraphia among children aged between 3–16-year-old were included. **Data Extraction:** Two reviewers independently assessed full-text articles, one reviewer extracted the data, the second reviewer checked the reliability, then narrative methods of synthesis were used, and for sufficiently similar studies, a meta-analysis of effect size was carried out (using a random-effects meta-analysis model). **Data Synthesis:** An electroencephalogram (EEG) finding revealed dyslexia-related neurophysiological predictors such as altered mismatch response, amplitude, and latency changes in event-related potentials. From functional magnetic resonance imaging (fMRI) results children with dyslexia showed decreased activity in the left parietotemporal, left occipitotemporal, left superior temporal gyrus, bilateral middle frontal gyrus, left inferior temporal gyrus, and left hemisphere prefrontal areas during reading, visual scanning, and listening tasks. Moreover, magnetoencephalography (MEG) revealed increased activity in the right inferior and superior parietal areas during arithmetic tasks in children with dyscalculia. From neurocognitive findings, a combined group of dyslexia and dysgraphia showed deficits in verbal working memory, semantic memory, quantitative reasoning, visuospatial reasoning, and phonological processing. **Conclusion:** Early predictors of neurodevelopmental-associated LLDs would be helpful as targets for specific prevention and intervention programs to be applied at very young ages.

In recent years, there have been important technological and methodological advancements in perceived and imagined speech decoding. The most advanced online decoding techniques rely heavily on the articulatory representation of syllables and words in the motor and supplementary motor cortices. However, this approach can only be applied to patients with intact motor commands. Thus, other decoding strategies that rely on the brain regions that encode speech are needed. Here, we decoded the syntactic category of perceived stimuli exploiting 29 different speech-encoding cortical areas spanning the entire brain. Using a protocol able to separate syntactic information from sound information we investigated the neural causal connections evoked by the processing of homophonous phrases, either verb phrases (VP) or noun phrases (NP). Each stimulus (a sentence) was composed of three segments where only the intermediate segment was an homophonous phrase. We used event-related causality from stereo-electroencephalographic recordings in 10 epileptic patients. We identified the different networks involved in the processing of the two syntactic operations. We extracted time-varying features on the identified significant connections and we used a Support Vector Machine to decode the syntactic content of the homophonous phrase (NP or VP) in a time-dependent fashion. The trial by trial accuracy was significantly above chance during the homophonous phrase presentation. The signals that drove the decoding were directly entangled to the syntactic representation of the stimuli rather than their articular components. A decoding strategy that relies on multiple speech-encoding cortical areas will drastically improve the performance of speech prostheses.

CEREBELLAR TDCS HAS NO EFFECT ON SEMANTIC PREDICTION

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Rastislav Rovný[1], Dominika Besterciová[1], Martin Marko[1], Igor Riečanský[1,2]
[1]Slovak Academy of Sciences, Department Of Behavioural Neuroscience, Centre Of Experimental Medicine, Bratislava, Slovak Republic, [2]Slovak Medical University in Bratislava, Department Of Psychiatry, Faculty Of Medicine, Bratislava, Slovak Republic

The cerebellum is considered to regulate behavioral output in multiple domains (motor, affective, and cognitive). While growing evidence indicates that the cerebellum supports speech and language, its exact role in language processing is yet poorly understood. It has been proposed that an important aspect of the cerebellar function is the capacity to generate predictions in perception and action. Semantic prediction importantly supports speech production and comprehension. The aim of our study was to investigate the engagement of the cerebellum in semantic prediction using transcranial direct current stimulation (tDCS). For this purpose, we administered a sentence completion task to 136 healthy adults prior and immediately after sham (n = 45), anodal (n = 45) or cathodal (n = 46) tDCS of the cerebellum (20 min, 2 mA). We found, however, that the cerebellar tDCS had no significant effect on completing predictable or unpredictable sentences. These results argue against a significant role of the cerebellum in predictive language processing. This study was supported by grants no. VEGA 2/0059/20 and APVV-19-0570.

CEREBELLAR TDCS MODULATES RETRIEVAL FROM LEXICAL-SEMANTIC MEMORY

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Dominika Besterciová[1], Rastislav Rovný[1], Martin Marko[1], Igor Riečanský[1,2]
[1]Slovak Academy of Sciences, Department Of Behavioural Neuroscience, Centre Of Experimental Medicine, Bratislava, Slovak Republic, [2]Slovak Medical University in Bratislava, Department Of Psychiatry, Faculty Of Medicine, Bratislava, Slovak Republic

Increasing evidence suggests that the cerebellum plays a role in language functions. Our study focused on lexical-semantic memory and tested the contribution of the cerebellum to automatic vs. controlled retrieval using transcranial direct current stimulation (tDCS). Our sample included 136 healthy adults, who underwent either sham (*n* = 45), anodal (*n* = 45) or cathodal tDCS (*n* = 46). The stimulating electrode (5x7 cm) was placed over the cerebellum (with its top border 1-2 cm below the inion) and the reference electrode on the right arm. Stimulation lasted for 20 minutes; the current intensity was 2 mA. Lexical-semantic retrieval was assessed prior to and after stimulation by the associative chain test (ACT), in which participants generate word chains according to specific rules (continuous retrieval of semantically related words, continuous retrieval of unrelated words or retrieval of related and unrelated words in alternation). We found that anodal tDCS facilitated continuous retrieval of semantically related words but had no effect in other retrieval conditions. Cathodal tDCS yielded no significant changes in retrieval performance. These findings indicate that the cerebellum is involved in automatic retrieval from lexical-semantic memory, rather than retrieval control. This study was supported by the project VEGA 2/0059/20 and APVV-19-0570.

EXAMINING THE ASSOCIATION BETWEEN EXECUTIVE FUNCTIONS AND DECODING IN FRENCH AND ITALIAN SCHOOL-AGED CHILDREN

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Chiara Andreola[1], Angela Pasqualotto[2,3], Grégoire Borst[1], Irene Altarelli[1]
[1]Université de Paris, Laboratoire De Psychologie Du Développement Et De L'éducation De L'enfant (lapsydÉ - Cnrs), Paris, France, [2]University of Trento, Department Of Psychology And Cognitive Science, Rovereto, Italy, [3]University of Geneva, Faculte De Psychologie Et Science De L'education, Genève, Switzerland

Executive functions (EFs) are related to reading, as regards both decoding and comprehension of print. Few studies examined in one single model the contribution of multiple EFs to decoding. The present study aims to investigate whether visual working memory (WM), verbal WM, planning, and visual attention uniquely contribute to reading speed and reading accuracy in school-aged children. It further compares those influences across orthographically opaque (French) and transparent languages (Italian). 201 French-speaking and 148 Italian-speaking 7-to-13-years-old children took part in our study. Participants performed a verbal WM task (Backward Digit Span), a visual span task (Corsi backward), a visual attentional task (barrage test) and a planning task (Tower of London). We also estimated fluid intelligence and reading (word and pseudo-words reading lists). Combining multiple regression and factor analysis, we used Structural Equation Models to test whether our theoretical model based on multiple EFs correctly describes empirical data. Results show that EFs differently contribute to reading speed and accuracy in French and Italian. Both languages show an association between verbal WM and reading accuracy and speed. However, for the French model, we report a relationship between fluid intelligence and reading accuracy, while the Italian model shows an association between visual attention and both reading speed and accuracy. Our models confirm the importance of EFs in reading and their different contribution to decoding across orthographically distinct languages, in line with previous literature.

THE ROLE OF THE POSTERIOR CEREBELLUM IN DYSFUNCTIONAL SOCIAL SEQUENCING

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Frank Van Overwalle[1], Chris Baeken[2], Kris Baetens[2]
[1]Vrije Universiteit Brussel, Psychology, Lochristi, Belgium, [2]Vrije Universiteit Brussel, Psychology, Brussel, Belgium

Aims: Recent advances in social neuroscience have highlighted the critical role of the cerebellum in social cognition, and especially the posterior cerebellum. Studies have shown that the posterior cerebellum is recruited when identifying and automatizing sequences of social actions involving mentalizing (i.e., inferring others' beliefs, intentions, traits, …), and inconsistencies in these sequences or their social implications. This supports the view that the posterior cerebellum predicts how other people's actions will unfold in an automatic and intuitive way. **Hypothesis:** We argue that the central role of the posterior cerebellum in social sequencing provides a fruitful starting point for investigating social dysfunctions in a variety of clinical pathologies, such as autism, obsessive–compulsive and bipolar disorder, depression, and addiction. Our key hypothesis is that dysfunctions of the posterior cerebellum lead to under- or overuse of inflexible social routines and lack of plasticity for learning new, more adaptive, social automatisms. **Methods & Results:** A brief review of meta-analyses shows that the posterior cerebellum is involved in most of these pathologies. Recent research applying cerebellar TMS or tDCS showed improvements in identifying social and non-social sequences, and a novel narrative training program with individuals with autism focusing on identifying social sequences in stories is currently being investigated (Van Overwalle et al, 2021). **Conclusions:** We conclude that this novel cerebellar perspective might aid to alleviate a variety of mental problems related to inflexible automatizations, by increasing posterior cerebellar plasticity using noninvasive neurostimulation or neuro-guided training programs.

SPATIAL EMBODIMENT OF TIME AND EMOTION DURING A MOVEMENT ALONG THE FRONTAL AND SAGITTAL AXIS

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Tiffanie Bernier, Michel-Ange Amorim
Université-Paris-Saclay, Ciams, Orsay Cedex, France

Aims: The literature evidencing spatial embodiment of time (Boroditsky, 2000; Flumini and Santiago 2013) or emotional valence (Bradley & Lang, 2006; Spatola et al, 2018) used push button responses without hand movements along a given axis of response. Here, we tested if hand movements would be facilitated or impaired in response to verbs, depending on whether these movements are congruent or incongruent with respect to the spatial metaphor of abstract concepts. **Methods :** Thirty-five participants indicated either the tense or the emotional of verbs using a hand movement (about 15 cm) toward a response button located along either the frontal or sagittal axis, depending on group. Each participant performed two blocks of trials: either congruent (rightward/forward: future or positive; leftward/backward: past or negative), or incongruent (rightward/forward: past or negative; leftward/backward: future or positive) with the spatial metaphor of concepts. In order to control for the fact that leftward/rightward or forward/backward movements may be asymmetric, in a preliminary control participants performed each possible movement in response to an arrow. We then subtracted these times to the reaction times in response to the verbs in order to compute a processing time (PT). **Results**: We conducted a RM-ANOVA on PTs that evidenced spatial embodiment of concepts in both group ($M_{congruent}$ = 467ms; $M_{incongruent}$ = 564ms), p = 0.016, d = 0.42, BF_{10} = 2.66 > BF_{01} = 0.38. **Conclusion:** The present study provides evidence of an influence on hand movement of abstract concepts such as time and emotional valence.

AIMS: We examined relationships between self-report cognitive and affective empathy, clinical psychopathy and brain structure in incarcerated males. **METHODS:** Perspective Taking (PT) and Empathic Concern (EC) subscales of the Interpersonal Reactivity Index were used to measure cognitive and affective empathy, respectively, and the Hare Psychopathy Checklist-Revised to measure psychopathic traits (N=550). Brain measures included FreeSurfer-derived surface area for the 68 cortical Desikan-Killiany regions following high-resolution T1-weighted MRI (N=278, all White). We also measured IQ using the WAIS-III and impulsivity using the Barratt Impulsiveness Scale. With robust multiple linear regression (P<0.05, corrected), we tested whether: brain structure relates to empathy; identified brain regions relate to psychopathic traits; psychopathy diagnosis relates to both empathy and identified brain regions. **RESULTS:** Left inferior temporal gyrus (LITG) related negatively to PT when covarying for age, IQ, psychopathic traits, crime type (non-violent/violent/homicide) and brain size. Left middle temporal gyrus (LMTG) related negatively to PT when also covarying for impulsivity. Right medial orbitofrontal cortex (RmOFC) related negatively to EC when controlling for the first five covariates. LITG and LMTG – but not RmOFC – related positively to psychopathic traits when covarying for age, IQ, crime type and brain size. Psychopathy diagnosis related to reduced PT when covarying for age, IQ and crime type as well as enlarged LITG when also covarying for brain size. **CONCLUSIONS:** Cognitive and affective empathy related negatively to the surface area of temporal and prefrontal regions, respectively. These findings provide novel insights into the brain correlates of callous-unemotional traits among antisocial

populations.

Theory of mind and psychosocial characteristics in older men.
The extent to which early-life cognitive ability shapes individuals' social functioning throughout life, in the context of later-life factors, is unknown. We investigated performance on the Faux Pas test (FP) in relation to psychosocial characteristics and childhood intelligence scores in 90 healthy older men. FP performance was associated with close social network size but not social contact, social support, or loneliness when accounting for both childhood and later-life intelligence, affect, personality, and sociodemography. We add to a growing literature on associations between theory of mind and intelligence, affect, and personality. (PsycINFO Database Record (c) 2019 APA, all rights reserved).

MUSIC ELICITS A PRIMING EFFECT IN MOTOR RELATED AREAS

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Julio Plata-Bello[1], Iván Portugués[2], Nicole Privato[2]
[1]Hospital Universitario de Canarias, Neurosurgery, La Laguna, Spain, [2]Universidad de La Laguna, Health Sciences, La Laguna, Spain

Aim To analyze the effect of listening to a popular and motivating song in brain activity at rest. *Methods* A resting-state functional magnetic resonance imaging (rs-fMRI) study was conducted. Thirty-four subjects (17 women) were included. None of the participants had received formal musical training. Two rs-fMRI runs separated by a period of four minutes where participants listened to the song “Viva la Vida” from Coldplay (2008) were performed on a 3T MRI scanner. After preprocessing, images were analyzed to identify changes in the amplitude of low frequency fluctuations (ALFF), regional homogeneity (ReHo) and functional connectivity (FC). FC analysis was performed using the seed to voxel approach. Seeds were in primary motor area (BA4), primary somatosensory area (BA1,2,3) and premotor area (BA6, including the supplementary motor area). *Results* Higher ALFF in parietal regions and cerebellum was identified in post- than pre-song listening rs-fMRI. The opposite contrast (i.e., Pre>Post) showed a higher ALFF in left frontal basal regions. Regarding ReHo changes, higher ReHo was identified in the left cerebellum (mainly in the posterior lobe) for post-song listening ReHo map. The opposite contrast (i.e., Pre>Post) showed higher ReHo in the right cerebellum, involving voxels of the occipital lobe. In the FC analysis, all selected regions of interest presented an increase in FC with the cerebellum after listening. *Conclusion* Music modulates brain’s resting-state activity. This can be interpreted as a priming effect of music that may explain (at least in part) some of the ergogenic effects of music.

SELF-RELEVANT FACES ATTENUATE THETA RHYTHMS IN OCCIPITO-TEMPORAL AND MEDIO-PREFRONTAL AREAS

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Ilona Kotlewska[1], Bartłomiej Panek[1], Anna Nowicka[2], Dariusz Asanowicz[1]
[1]Jagiellonian University, Institute Of Psychology, Krakow, Poland, [2]Nencki Institute of Experimental Biology, Laboratory Of Language Neurobiology, Warsaw, Poland

Aims Self-relevant stimuli tend to capture attention. Enhancements of own name or face processing have been hypothesized and often observed in previous studies. Recent findings suggest a pivotal role of occipital theta rhythms in visual attention, whereas medio-frontal area has been implicated in top-down control of self-reference processing. Thus, we examined the self-related effects in terms of theta-band activity (4-8 Hz), focusing on the visual processing and its functional connections with the medio-prefrontal area, in an attempt to identify a self-relevance processing network. **Methods** Twenty-five participants performed a task of simple detection of faces from four categories: own face (Self), own face from the past (Past Self), friend's face, famous face, and unknown face. **Results** Self-reference modulated theta-band power and phase in both visual and prefrontal areas. The results showed that the theta activity was smallest for own face, and was rising gradually with the diminishing self-relevance. The self-unrelated stimuli (famous, unknown) induced the strongest theta responses. In comparison, the amplitude of P3b component of the ERP was largest for the self-related stimuli, replicating previous findings. **Conclusions**
The study provided a coherent pattern of self-related modulations of face processing in theta band. Two interpretations are possible. (1) Own face processing is over-learned and automatized to such extent that it captures attention through a direct visual-prefrontal processing pathway, thus needs less local processing than other stimuli. (2) Attention-grabbing capacity of own face may be realized in part through attenuation of lower (theta-band) rate of sampling/gating of sensory information.

PHYSIOLOGICAL RESPONSE TO IMAGES OF THE THIRD PLACE ACCORDING TO THE PRESENCE OR ABSENCE OF CAMPUS LIFE EXPERIENCE BEFORE COVID-19

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Soobeen Park[1], Soojeong Kim[2]
[1]Pusan National University, Interior & Environmental Design, Busan, Korea, Republic of, [2]Pusan National university, Interior & Environmental Design, Busan, Korea, Republic of

This study quantitatively analyzed the physiological responses of subjects in order to plan a university campus lounge that will encourage user interaction after COVID-19. The subject's Prefrontal Alpha EEG Asymmetry was measured with five images and five color combination palettes. The subjects of the experiment were university students, who were divided into those who experienced campus life before COVID-19 (Group A) and who did not (Group B). The five images correspond to the representative 'Third Places': a cafe, a coworking space, a bookstore, an office, and a public rest area. Each image's color palette was converted into a 60% mosaic in a graphic program. Subjects were exposed to 10 images at an interval of 20 seconds, and their physiological preferences were compared and analyzed. Both groups showed the most positive response to the image of the café. The mean values of Group B were significantly lower than those of group A in images of coworking space, bookstore, and public rest area ($p<0.05$). Both groups also showed the most positive response in DL tones of GY, the color combination palette of bookstore. The mean values of group B were lower than those of group A ($p<0.05$), except for LGR tone of BG, color combination palette of public rest area. In conclusion, Group A and Group B responded differently to the images of 'Third Places.' Group B who did not have campus life before COVID-19 responded positively only to the image of café and showed lower sensitivity to the color scheme.

OBJECTIVE AND SUBJECTIVE FEATURES MODULATE THE AESTHETIC PERCEPTION OF INTERACTING BODY DYADS

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Andrea Orlandi, Mohammad Soleyman Nejad, Matteo Candidi
University of Rome, La Sapienza, Department Of Psychology, Rome, Italy

Dance represents an ideal framework for studies on body and action aesthetic perception and evaluation. Several investigations provided evidence for a strong link between aesthetic appreciation, previous expertise, and objective features of observed movements. Most studies on dance focused on single body stimuli and only recently on group aesthetics. Therefore, interacting body dyads stands out as a novelty in the neuroaesthetics research field; also, the possible interplay between objective and subjective features in the aesthetics of dancing dyads requires further deepening. The current project investigates aesthetic, emotional, and semantic responses to non-symbolic postures of body dyads of varying visuospatial attributes in non-expert observers. A dance-inspired training was used to create a set of virtual stimuli by digitalizing dancers' movement kinematics via motion capture. Several visuospatial features were quantified via custom MATLAB scripts and included the shared interpersonal space, distance, dyad's orientation, and symmetry. Dance allowed an ecological investigation of human action perception and avoided eventual incongruency effects due to the combination of body postures. In four studies, subjective evaluations were collected with observers' empathic and cognitive dispositional traits and preferred interpersonal distance. Our evidence indicates that the aesthetic appreciation of interacting body dyads critically depends on the level of shared interpersonal space between bodies of a dyad. Such an aesthetic experience is modulated by the observer's focus on dyads' low-level (e.g., symmetry) and high-level (e.g., emotional and semantic content) features. Crucially, the likability of body dyads is strongly linked to both observer's subjective attributes and the stimuli' visuospatial features.

Observers with autism spectrum disorders (ASDs) find it difficult to read intentions from movements. Here, we combined motion tracking, psychophysics and statistical analyses to investigate the computational bases of these difficulties. Eight- to thirteen-year-old typically developing (TD) children (n=35) and ASD children without intellectual impairment (n=35) watched a hand reaching for a bottle, either to pour or to place, and judged on the intention of the observed grasp. In a within-subjects counterbalanced order, participants watched videos of actions performed by TD and ASD children. Using a logistic regression-based model fitted to the experimental data, we analysed how TD and ASD observers read the intention information encoded in TD and ASD actions with single-subject, single-trial level resolution. By applying this approach, we were able to reveal that both TD and ASD observers read variations in movement kinematics. TD readers were better able to identify intention-informative kinematic features during observation of TD actions; conversely, ASD readers were better able to identify informative features when observing ASD actions. Crucially, while TD observers were generally able to extract the correct intention information, autistic observers were unable to do so. These findings suggest that intention reading difficulties in ASD reflect both an interaction failure in feature identification, rooted in kinematic dissimilarities between TD and ASD movements, and an individual deficit in information extraction, accompanied by an overall reduced sensitivity to kinematic variations. Initial data from a training program aimed at improving feature identification and information extraction are discussed.

Aims. Self-management of depressive symptomatology is influenced by co-morbidity, social supports, and health-related behaviors. Men are less likely to discuss depressive moods and seek healthcare. This study examines factors associated with depression among non-Hispanic Black and Hispanic men ages ≥40 years with ≥1 chronic condition in the U.S. **Methods.** Using an internet-delivered survey, data were analyzed from 1,907 non-Hispanic Black and Hispanic males with chronic conditions. A logistic regression model was fitted to assess factors associated with depressive symptomatology, identified as a Patient Health Questionnaire-2 score ≥3. The model adjusted for sociodemographics, disease characteristics, health status, social engagement and support, and lifestyle behaviors. **Results.** Twenty-four percent of participants had depressive symptomatology. Men who were Hispanic (OR=1.39, P=0.017) and took more medications daily (OR=1.10, P=0.010) were more likely to have depressive symptomatology. Men who felt socially disconnected (OR=1.65, P<0.001), relied on others to improve their health and manage problems (OR=1.04, P<0.001), and were limited from doing usual activities because of their health (OR=3.15, P<0.001) were more likely to have depressive symptomatology. Those who had barriers to self-care (OR=1.16, P<0.001), felt frustrated about their healthcare situation (OR=1.13, P<0.001), sat for longer periods each week (OR=1.01, P=0.030), and used tobacco (OR=1.56, P=0.002) were more likely to have depressive symptomatology. **Conclusion.** Findings highlight the dynamic interplay of depression, social engagement, and lifestyle behaviors among non-Hispanic Black and Hispanic men with complex disease profiles. Efforts are needed to address depressive symptomatology through self-managing conditions, strengthening supportive networks, and alleviating burdens associated with healthcare interactions.

WATCH MY MOVES AT THE SILENT DISCO: EFFECTS OF MUSIC AND SOCIAL CONTEXT ON SPONTANEOUS MOVEMENT AND INTERPERSONAL SYNCHRONY

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Félix Bigand, Giacomo Novembre
Italian Institute of Technology, Neuroscience Of Perception And Action, Rome, Italy

Spontaneous movement in response to music is a universal human behaviour that generally takes place in social and communicative contexts. Yet, studies of this phenomenon traditionally focus on individual listeners in non-interactive scenarios. The present (currently ongoing) study investigates the behavioural and neural underpinnings of music-induced movements during joint music listening. In particular, we aim to understand how specific movements are recruited during social music-listening and whether they may serve social communicative purposes. To this aim, full-body kinematics, EEG activity and eye movements are measured from pairs of listeners in a “silent disco” setting, where participants jointly listen to *groove* music through earphones. Using this novel experimental setup, we test whether neural and behavioural responses are modulated by (1) joint listening (whether participants listen to the same or different music) and (2) social context (whether participants see each other or not). Results are expected to shed light on the cognitive and neurobiological origins of the human capacity to spontaneously communicate through music and movement.

Decomposing spontaneous sign language into elementary movements: A principal component analysis-based approach.
Sign Language (SL) is a continuous and complex stream of multiple body movement features. That raises the challenging issue of providing efficient computational models for the description and analysis of these movements. In the present paper, we used Principal Component Analysis (PCA) to decompose SL motion into elementary movements called principal movements (PMs). PCA was applied to the upper-body motion capture data of six different signers freely producing discourses in French Sign Language. Common PMs were extracted from the whole dataset containing all signers, while individual PMs were extracted separately from the data of individual signers. This study provides three main findings: (1) although the data were not synchronized in time across signers and discourses, the first eight common PMs contained 94.6% of the variance of the movements; (2) the number of PMs that represented 94.6% of the variance was nearly the same for individual as for common PMs; (3) the PM subspaces were highly similar across signers. These results suggest that upper-body motion in unconstrained continuous SL discourses can be described through the dynamic combination of a reduced number of elementary movements. This opens up promising perspectives toward providing efficient automatic SL processing tools based on heavy mocap datasets, in particular for automatic recognition and generation.

34368103: Bigand F, Prigent E, Berret B, Braffort A
Machine Learning of Motion Statistics Reveals the Kinematic Signature of the Identity of a Person in Sign Language.
Sign language (SL) motion contains information about the identity of a signer, as does voice for a speaker or gait for a walker. However, how such information is encoded in the movements of a person remains unclear. In the present study, a machine learning model was trained to extract the motion features allowing for the automatic identification of signers. A motion capture (mocap) system recorded six signers during the spontaneous production of French Sign Language (LSF) discourses. A principal component analysis (PCA) was applied to time-averaged statistics of the mocap data. A linear classifier then managed to identify the signers from a reduced set of principal components (PCs). The performance of the model was not affected when information about the size and shape of the signers were normalized. Posture normalization decreased the performance of the model, which nevertheless remained over five times superior to chance level. These findings demonstrate that the identity of a signer can be characterized by specific statistics of kinematic features, beyond information related to size, shape, and posture. This is a first step toward determining the motion descriptors necessary to account for the human ability to identify signers.

INCREASED FRACTIONAL ANISOTROPY (FA) IN THE LEFT ANTERIOR CORONA RADIATA AFTER A 31-DAY WEB-BASED MINDFULNESS TRAINING

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Maria Mora Alvarez[1], Britta Hoelzel[1], Benno Bremer[1], Elena Hell[2], Ecem Tavacıoğlu[2], Kathrin Koch[1]
[1]Klinikum rechts der Isar der Technischen Universität München, Diagnostic And Interventional Neuroradiology, Munich, Germany, [2]Ludwig Maximilians Universität München, Psychology, Muenchen, Germany

Diffusion-tensor-imaging(DTI) of long-term meditators have shown increased fractional anisotropy (FA) values in major projection (i.e., corona radiata), association[i.e., cingulum and superior longitudinal fasciculus(SLF)], and commissural white matter tracts(i.e., corpus callosum)(1,2). Longitudinal studies done on naïve meditators following a short-term mindfulness training confirmed these findings as a result of a mindfulness training(2,3,4). Our aim was to investigate if a 31-day web-based mindfulness training can replicate these effects.44 right-handed normal adults(21-61 years) divided into two groups(control and experimental) were scanned twice(before and after completion of the training or completion of a control intervention) in a 3T MRI Philipps scanner using a DTI sequence for imaging of the white matter tracts. The experimental group completed an online mindfulness training course whereas the control group participated in a course on ‘everyday health’.Results of the two-way rmANOVAs showed a trend in training-associated increase in FA in the left anterior corona radiata[F(1,42)=3.281,p=0.07] of the experimental group compared to the control group. No trends were seen in the FA of the SLF, corpus callosum, and cingulum, probably due by the shortness of our training; however, increased FA values in the left corona radiata might indicate the start of neuroplasticity changes as a consequence of mindfulness practice[i.e., increased connectivity between the anterior cingulate cortex(ACC) and other brain structures]. 1.Zsadanyi et al.The Effects of Mindfulness and Meditation on the CC in the Healthy Human-Brain.*Mindfulness.*2021. 2.Tang et al.The neuroscience of mindfulness meditation.*NatRevNeurosci.*2015. 3.Kral et al.MBSR-related changes in posterior cingulate resting brain connectivity.*SocCognAffectNeurosci.*2019. 4.Yoon et al.Plastic-Changes in White-Matter Induced by Templestay.*Mindfulness.*2019.

High resolution continuous arterial spin labeling of human cerebral perfusion using a separate neck tagging RF coil.
For standard clinical applications, ASL images are typically acquired with 4-8 mm thick slices and 3-4 mm in-plane resolution. However, in this paper we demonstrate that high-resolution continuous arterial spin labeling (CASL) perfusion images can be acquired in a clinically relevant scan time using current MRI technology. CASL was implemented with a separate neck coil for labeling the arterial blood on a 4.7T MRI using standard axial 2D GE-EPI. Typical-resolution to high-resolution (voxels of 95, 60, 45, 27, or 7 mm3) images were compared for qualitative and quantitative cerebral blood flow analysis (CBF) in nine healthy volunteers (ages: 24-32 years). The highest resolution (1.5x1.5x3 = 7 mm3) CASL implementation yielded perfusion images with improved cortex depiction and increased cortical CBF measurements (53 ± 8 ml/100g/min), consistent with reduced partial volume averaging. The 7 mm3 voxel images were acquired with 6 cm brain coverage in a clinically relevant scan of 6 minutes. Improved spatial resolution facilitates CBF measurement with reduced partial volume averaging and may be valuable for the detection of perfusion deficits in small lesions and perfusion measurement in small brain regions.

INFLUENCE OF SHARED PERCEPTION ON SENSORY EVIDENCE ACCUMULATION IN THE HUMAN BRAIN

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Bahador Bahrami[1], Mustafa Yavuz[2], Jamal Esmaily[3], Ophelia Deroy[4]
[1]Ludwig Maximillian University, Department Of General Psychology And Education, Munich, Germany, [2]Istanbul University, Institute Of Health Sciences, Duzce, Turkey, [3]Ludwig Maximillian University, Department Of General Psychology And Education, München, Germany, [4]Ludwig-Maximilian-Universität, Faculty Of Philosophy, München, Germany

Audience effects show that performance can change by being observed. Yet does having shared access to the same sensory information with others, rather than just being observed, change perception? Present work aimed to investigate whether observing the same stimuli with others would change visual perception. Human participants (N=15) performed a random-dot-motion task while being watched by an observer who sat either right or left to them. There were 640 stimuli with varying levels of motion coherence that appeared either on the left or right side of the screen. The screen was separated by an opaque divider, allowing participants to see both sides, but the observer could only see stimuli presented on their own side. Thus, participants responded to stimuli that were either privately or commonly seen, while social observation was kept constant. Accuracy, reaction time (RT) and confidence were recorded. EEG data were collected using a 64-channel system. RTs were significantly slower under shared vs private conditions. Neither accuracy nor confidence were different, thus excluding a possible speed-accuracy trade-off. Consistent with previous works, a stimulus-locked (300-600 ms post-stimulus) centro-parietal positivity (CPP) was observed whose slope of rise correlated with motion coherence. Importantly, CPP slope was larger in shared vs private trials. Current results suggest that, besides social presence, dynamics of sensory evidence accumulation and corresponding behavioral reports differ when we see the same objects with others. We are currently working on an attractor network model that could explain our findings and propose a neuronal mechanism for shared vs. private perception.

EARLY LIFE ATTACHMENT IN TERM AND PRETERM BORN INFANTS.

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Lorena Jiménez-Sánchez[1,2], Lorna Ginnell[2], Sinéad O'Carroll[2], Victoria Ledsham[3], David Stoye[3], Gemma Sullivan[3], Jill Hall[3], Ann Clemens[4], James Boardman[3], Sue Fletcher-Watson[2]
[1]University of Edinburgh, Translational Neuroscience Phd Programme, Centre For Clinical Brain Sciences, Edinburgh, United Kingdom, [2]University of Edinburgh, Salvesen Mindroom Research Centre, Edinburgh, United Kingdom, [3]University of Edinburgh, Mrc Centre For Reproductive Health, Edinburgh, United Kingdom, [4]University of Edinburgh, Centre For Discovery Brain Sciences, Edinburgh, United Kingdom

Aims: Preterm birth affects infant attention, which could impact social cognition and attachment to caregivers. Therefore, we aimed to test the hypothesis that preterm birth leads to differences in infant attachment, and to identify variables that explain variance in attachment. To avoid predefined attention thresholds to categorise attachment, we used a data-driven approach on infant behaviours coded from the Still-Face Paradigm (SFP). **Methods**: 68 preterm and 68 term infants with mean (range) gestational age at birth 29.7 (22.1-32.9) and 39.6 (36.4-42.1) weeks, respectively, completed the SFP at nine months of corrected age. Attachment dimensions and categories were obtained from infant responses to the SFP using a published coding scheme, principal component (PC) and cluster analyses. Clinicodemographic and neurodevelopmental data (Vineland Adaptive Behaviour Scales) were collected at nine months and included in analyses. **Results**: Preterm and term infants did not differ in attachment dimensions (distress, fretfulness, attentiveness to caregivers/PCs; p-value > 0.07), or the distribution of attachment categories (styles/clusters, p-value > 0.28). In the whole sample, fretfulness correlated with socioeconomic deprivation (r_s = -0.23, p-value < 0.01), and attentiveness correlated with motor development (r_s = 0.24, p-value < 0.01) and birth weight (r_s = 0.17, p-value = 0.04). **Conclusion**: The data do not support differences in attachment between preterm and term infants at nine months, suggesting that atypical attention reported in preterm infants does not relate to differences in caregiver-infant attachment relationships. The data highlight putative links between socioeconomic deprivation and infant attachment, and suggest attentiveness associates with neuromotor development.

Ultrasonography-guided anterior approach for axillary nerve blockade: An anatomical study.
Combined ultrasound (US)-guided blockade of the suprascapular and axillary nerves (ANs) has been proposed as an alternative to interscalene blockade for pain control in shoulder joint pathology or postsurgical care. This technique could help avoid respiratory complications and/or almost total upper limb palsy. Nowadays, the AN blockade is mostly performed using an in-plane caudal-to-cephalic approach from the posterior surface of the shoulder, reaching the nerve immediately after it exits the neurovascular quadrangular space (part of the spatium axillare). Despite precluding most respiratory complications, this approach has not made postsurgical pain relief any better than an interscalene blockade, probably because articular branches of the AN are not blocked.Cephalic-to-caudal methylene blue injections were placed in the first segment of the AN of six Thiel-embalmed cadavers using an US-guided anterior approach in order to compare the distribution with that produced by a posterior approach to the contralateral AN in the same cadaver. Another 21 formalin-fixed cadavers were bilaterally dissected to identify the articular branches of the AN.We found a good spread of the dye on the AN and a constant relationship of this nerve with the subscapularis muscle. The dye reached the musculocutaneous nerve, which also contributes to shoulder joint innervation. We describe the anatomical landmarks for an ultrasonography-guided anterior AN blockade and hypothesize that this anterior approach will provide better pain control than the posterior approach owing to complete blocking of the joint nerve. Serotonergic innervation of the striatum in a nonhuman primate model of Parkinson's disease.
Parkinson's disease (PD) is characterized by dopaminergic neurodegeneration in the substantia nigra and dopamine depletion in the striatum. Non-dopaminergic systems are also affected, including the serotonergic system. Enhanced striatal

serotonergic innervation is a proposed compensatory mechanism for the dopaminergic deficit. Meanwhile a serotonergic deficit has been suggested as preceding the nigrostriatal dopaminergic pathology in PD. Our aim was to assess the serotonergic innervation of the striatum in a model of progressive experimental parkinsonism in macaques, from pre-symptomatic to symptomatic stages. The neurotoxin 1-methyl-4-phenyl-1,2,3,6 tetrahydropyridine (MPTP) was administered to adult macaque monkeys using a slow intoxication protocol. The intoxicated animals were classified into asymptomatic, recovered, moderate and severe parkinsonian, based on their motor behavior. The serotonergic innervation was studied by immunohistochemistry against serotonin (5-HT). In the striatum, the density of 5-HT-immunoreactive (5-HT+) axons was estimated with stereology. Images of the striatum in the immunostained sections were taken to compare the distribution patterns of the serotonergic innervation between groups. These patterns were apparently similar among the groups. Axonal density estimations showed no differences in striatal 5-HT+ innervation between the intoxicated groups and the control group. Accordingly, this study fails to find significant changes in the striatal serotonergic axonal innervation in MPTP-treated monkeys, coinciding with previous biochemical findings in our model. However, it is possible that alterations in the serotonergic system in PD could be independent of axonal density changes. Consequently, the proposed role for striatal serotonin serving as a compensatory mechanism for dopaminergic denervation merits further study. This article is part of the special issue entitled 'Serotonin Research: Crossing Scales and Boundaries'.

Associations between major psychiatric disorder polygenic risk scores and blood-based markers in UK biobank.
Major depressive disorder (MDD), schizophrenia (SCZ), and bipolar disorder (BD) have both shared and discrete genetic risk factors, and are associated with peripheral abnormalities. The relationships between such genetic architectures and blood-based markers are, however, unclear. We investigated relationships between polygenic risk scores (PRS) for these disorders and peripheral markers in the UK Biobank cohort. We calculated polygenic risk scores for n = 367,329 (MDD PRS), n = 366,465 (SCZ PRS), and n = 366,383 (BD PRS) UK Biobank cohort subjects. We then examined associations between disorder PRS and 58 inflammatory/immune, hematological, bone, cardiovascular, hormone, liver, renal and diabetes-associated blood markers using two generalized linear regression models: 'minimally adjusted' controlling for variables such as age and sex, and 'fully adjusted' including additional lifestyle covariates: BMI, alcohol and smoking status, and medication intake. There were 38/58 MDD PRS, 32/58 SCZ PRS, and 20/58 BD PRS-blood marker associations detected for our minimally adjusted model. Of these, 13/38 (MDD PRS), 14/32 (SCZ PRS), and 10/20 (BD PRS) associations remained significant after controlling for lifestyle factors. Many were disorder-specific, with 8/13 unique MDD PRS associations identified. Several disorder-specific associations for MDD and SCZ were immune-related, with mostly positive and negative associations identified for MDD and SCZ PRS respectively. This study suggests that MDD, SCZ and BD have both shared and distinct peripheral markers associated with disorder-specific genetic risk. The results also implicate inflammatory dysfunction in MDD and SCZ, albeit with differences in patterns between the two conditions, and enrich our understanding of potential underlying pathophysiological mechanisms in major psychiatric disorders.

Sex Differences in Cerebral Small Vessel Disease: A Systematic Review and Meta-Analysis.
Cerebral small vessel disease (SVD) is a common cause of stroke, mild cognitive impairment, dementia and physical impairments. Differences in SVD incidence or severity between males and females are unknown. We assessed sex differences in SVD by assessing the male-to-female ratio (M:F) of recruited participants and incidence of SVD, risk factor presence, distribution, and severity of SVD features. We assessed four recent systematic reviews on SVD and performed a supplementary search of MEDLINE to identify studies reporting M:F ratio in covert, stroke, or cognitive SVD presentations (registered protocol: CRD42020193995). We meta-analyzed differences in sex ratios across time, countries, SVD severity and presentations, age and risk factors for SVD. Amongst 123 relevant studies (= 36,910 participants) including 53 community-based, 67 hospital-based and three mixed studies published between 1989 and 2020, more males were recruited in hospital-based than in community-based studies [M:F = 1.16 (0.70) vs. M:F = 0.79 (0.35), respectively; < 0.001]. More males had moderate to severe SVD [M:F = 1.08 (0.81) vs. M:F = 0.82 (0.47) in healthy to mild SVD; < 0.001], and stroke presentations where M:F was 1.67 (0.53). M:F did not differ for recent (2015-2020) vs. pre-2015 publications, by geographical region, or age. There were insufficient sex-stratified data to explore M:F and risk factors for SVD. Our results highlight differences in male-to-female ratios in SVD severity and amongst those presenting with stroke that have important clinical and translational implications. Future SVD research should report participant demographics, risk factors and outcomes separately for males and females. [PROSPERO], identifier [CRD42020193995].

Permeable spaces between glenohumeral ligaments as potential gateways for rapid regional anesthesia of the shoulder.

Shoulder pain is a highly prevalent condition, often resulting in major life limitations, and requiring effective treatments. In this work, we explore the anatomical basis of a proposed approach to the regional anesthesia of the shoulder through a single injection under the subscapularis muscle. Bilateral experimental injections in shoulders from body donors (Radiolar ® and Methylene-Blue) under the subscapular muscle (n = 11) and cadaveric systematic dissections of other 35 shoulders from body donors were performed. Injectate spread was then qualitatively assessed. Long axis of permeable foramina in the anterior aspect of the shoulder joint capsule was measured in centimeters using a digital caliper. More than 40% of specimens had at least one permeable space (Weitbrech and/or Rouvière foramina) communicating the subscapular bursa and the articular space. We further demonstrate that an ultrasonography-guided injection under the subscapularis muscle allows the spread of the injectate through the anterior, inferior and posterodorsal walls of the articular capsule, the subacromial bursa, and the bicipital groove, as well as into the articular space for some injections. The odds of accidental intraarticular injection decrease when injecting with low volumes. This anatomical study provides a detailed description of foramina between glenohumeral ligaments. Furthermore, the data shown in this work supports, as a proof of concept, a safe alternative for rapid and specific blockade of terminal sensory branches innervating the shoulder joint capsule.

EMPATHIC REACTION FOR PAIN IN HIGH SENSORY PROCESSING SENSITIVITY PERSONS (HSP) – EEG STUDY.

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Kamila Jankowiak-Siuda, Magdalena Kozłowska, Mateusz Szpak, Anna Duszyk-Bogorodzka
SWPS University of Social Sciences and Humanities, Behavioral Neuroscience Lab, Warsaw, Warsaw, Poland

Aims. The main goal of this study was to characterize the mechanism of the empathic reaction to pain in people characterized by high sensory processing sensitivity (HSP), who show deep processing of both external and internal stimuli, with a positive and negative affect, including pain. **Methods.** The study was carried out on 31 people (16 HSP, 15 NHSP) using the EEG method of potentials associated with the ERP event. When viewing pictures presenting pain and no pain of others, the subjects were asked to imagine what others might feel. **Results.** At the level of early processing of the stimulus (N1) and late processing associated with conscious perception (P3), there were no differences in responses to the pain of others between the HSP and NHSP groups. These differences were seen in the amplitude of the mid-latency (P2, N2) waves: an empathic response to the pain of others was seen in the NHSP group, but not in the HSP group. Differences between HSP and NHSP in the amplitudes of the N1 and P3 waves, independent of the stimulus type, were observed, which may indicate the specificity of stimulus processing by HSP, and therefore should be further investigated. **Conclusions**: The results obtained initially indicate that HSP displays a higher level of emotional empathy in the empathic reaction and may give emotional significance to both painful and neutral stimuli. The HSP persons compared to NHSP persons may be characterized by different dynamics of the empathic reaction to pain.

DISSOCIATION BETWEEN OBSERVATIONAL LEARNING AND SOCIAL COMPARISON NEURAL SIGNALS

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Mathilde Lojkiewiez[1], Doris Pischedda[2], Folco Panizza[3], Jerome Sallet[4,5], Elsa Fouragnan[1], Nadège Bault[1]
[1]University of Plymouth, School Of Psychology, Plymouth, United Kingdom, [2]Charité Universitätsmedizin Berlin, Bernstein Center For Computational Neuroscience, Berlin, Germany, [3]IMT School for Advanced Studies, Momilab, Lucca, Italy, [4]Inserm, Stem Cell And Brain Research Institute, Bron, France, [5]Univeristy of Oxford, Department Of Experimental Psychology, Oxford, United Kingdom

Aims. When making decisions in the presence of our peers, several signals can shape learning. A first signal, elicited by social comparison, concerns the relative skill or welfare of an individual compared to our own and is important for learning dominance relationships. By contrast, observational learning signals enable us to learn from the successes and mistakes of others. In most studies, social comparison and observational learning signals are confounded. Our aim was to disentangle their patterns of neural activity. **Methods.** Thirty participants performed a probabilistic instrumental learning task. The learning task was designed to manipulate both the learning context - they learned either from the same or different sets of cues as their counterpart – and the outcome valence. We used a reinforcement learning model and multi-voxel pattern analysis on fMRI data to investigate latent behavioural variables estimated and their supporting neural activity. **Results**. Participants benefited more from observation in the same than in the different cues condition, suggesting an effect of observational learning. Interestingly, they also learned better from rewards than from punishments, especially in the different cues conditions and when observing a competitive, high-performing counterpart. **Conclusions.** Our results show that both observational learning and social comparison affect learning performance in our task. Further analysis will be performed to dissociate the neural basis of both processes. We expect the vmPFC, striatum and ACC to integrate information from different sources of learning (direct experience vs. observation) and the dmPFC to support social comparison. Data analysis is currently ongoing.

THE PHYSIOLOGICAL CORRELATES OF SOCIAL SPACE IN CHILDHOOD AUTISM SPECTRUM DISORDERS

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Michela Candini[1], Gianmarco Mellini[1], Simone Battaglia[1], Virginia Giuberti[2], Giuseppe Di Pellegrino[1], Francesca Frassinetti[1]
[1]University of Bologna, Department Of Psychology, Bologna, Italy, [2]AUSL Reggio Emilia, Centro Autismo - Programma Autismo, Reggio Emilia, Italy

Background Interpersonal space (IPS) is the area that individuals maintain between themselves and others and that, when it is violated, cause discomfort. The IPS's extent depends on others' behaviour, and the closeness with an unknown person increases the skin conductance response (SCR), linking between behavioral and autonomic components of IPS. **Aim** We investigate if the deficit in IPS regulation reported in children with Autism Spectrum Disorders (ASD), is associated to an altered autonomic response to social proximity. **Methods** Children with typical development (TD) and children with ASD performed two Experiments. In Experiment 1, participants stopped an unknown adult (confederate), who moved toward to or away from them, when they felt comfortable with other's distance (comfort-distancetask). In Experiment 2, participants' SCR was recorded when the confederate moved and briefly stopped at five spatial positions, simulating an approach/withdrawal movement. **Results** We found that ASD children preferred a larger IPS and exhibited higher SCR than controls. Interestingly, in TD and ASD children, the SCR increased when the confederate was closer to them, reflecting the ability to detect a possible threat around the body. However, in TD children this effect was observed in Approaching but not in Withdrawal condition, whereas in the ASD children the SCR was not modulated by the confederate's movement direction. This result can be ascribed to a deficit in ASD children in anticipating the movement direction performed by the confederate. **Conclusion** We reveal that impairment of both physiological responses and predictive mechanisms contribute to abnormal IPS regulation found in autism.

Time Interaction With Two Spatial Dimensions: From Left/Right to Near/Far.
In this study, we explored the time and space relationship according to two different spatial codings, namely, the left/right extension and the reachability of stimulus along a near/far dimension. Four experiments were carried out in which healthy participants performed the time and spatial bisection tasks in near/far space, before and after short or long tool-use training. Stimuli were prebisected horizontal lines of different temporal durations in which the midpoint was manipulated according to the Muller-Lyer illusion. The perceptual illusory effects emerged in spatial but not temporal judgments. We revealed that temporal and spatial representations dynamically change according to the action potentialities of an individual: temporal duration was perceived as shorter and the perceived line's midpoint was shifted to the left in far than in near space. Crucially, this dissociation disappeared following a but not tool-use training. Finally, we observed age-related differences in spatial attention which may be crucial in building the memory temporal standard to categorize durations.

Neural Correlates of Interpersonal Space Permeability and Flexibility in Autism Spectrum Disorder.
Previous research indicates that the size of interpersonal space at which the other is perceived as intrusive (permeability) and the ability to adapt interpersonal distance based on contextual factors (flexibility) are altered in Autism Spectrum Disorder (ASD). However, the neurophysiological basis of these alterations remains poorly understood. To fill this gap, we used fMRI and assessed interpersonal space preferences of individuals with ASD before and after engaging in cooperative and non-cooperative social interactions. Compared to matched controls, ASDs showed lower comfort in response to an approaching confederate, indicating preference for larger interpersonal space in autism (altered permeability). This preference was accompanied by reduced activity in bilateral dorsal intraparietal sulcus (dIPS) and left fusiform face area (FFA), regions previously shown to be involved in interpersonal space regulation. Furthermore, we observed differences in effective connectivity among dIPS, FFA, and amygdala in ASDs compared to controls, depending on the level of experienced comfort. No differences between groups were observed in interpersonal space regulation after an experienced social interaction (flexibility). Taken together, the present findings suggest that a dysregulation of the activity and connectivity of brain areas

involved in interpersonal space processing may contribute to avoidance of physical proximity and social impairments in ASD.
Cereb Cortex, 2021; 31

The physiological correlates of interpersonal space.
Interpersonal space (IPS) is the area around the body that individuals maintain between themselves and others during social interactions. When others violate our IPS, feeling of discomfort rise up, urging us to move farther away and reinstate an appropriate interpersonal distance. Previous studies showed that when individuals are exposed to closeness of an unknown person (a confederate), the skin conductance response (SCR) increases. However, if the SCR is modulated according to participant's preferred IPS is still an open question. To test this hypothesis, we recorded the SCR in healthy participants when a confederate stood in front of them at various distances simulating either an approach or withdrawal movement (Experiment 1). Then, the comfort-distance task was adopted to measure IPS: participants stop the confederate, who moved either toward or away from them, when they felt comfortable with other's proximity (Experiment 2). We found higher SCR when the confederate stood closer to participants simulating an IPS intrusion, compared to when the confederate moved farther away. Crucially, we provide the first evidence that SCR, acting as a warning signal, contributes to interpersonal distance preference suggesting a functional link between behavioral components of IPS regulation and the underlying physiological processes.

The plasticity of the interpersonal space in autism spectrum disorder.
In recent years, there has been a dramatic increase in research examining interpersonal space, i.e., the sector of space immediately around the body in which we interact with other people. These studies have consistently revealed impairments of interpersonal space regulation in psychopathological disorders characterized by social disability, such as autism, schizophrenia and social anxiety. The primary goal of this review is to discuss several key points that have emerged in research on interpersonal space regulation in autism spectrum disorders. Particularly, we review recent behavioral evidence revealing that individuals with autism prefer abnormally larger or shorter interpersonal distance than healthy controls, indicating a deficit in regulating the size of interpersonal space (permeability). Then, we focus on how individuals with autism fail to modify their interpersonal space following a brief cooperative interaction with an unfamiliar adult, suggesting a deficit in adapting interpersonal space to the social context (plasticity). Moreover, we discuss evidence indicating that space regulation deficits primarily affect interpersonal (i.e., social), but not peripersonal (i.e., action), space in autism. Finally, we take into consideration the variables influencing interpersonal space plasticity such as person's perspective and severity of social impairment as well as its neural underpinnings. These findings may provide a critical contribution to understanding of the functional mechanisms underlying interpersonal space regulation and its rehabilitation in autism spectrum disorders.

When social and action spaces diverge: A study in children with typical development and autism.
The space around the body has been defined as action space () and a social space (). Within the current debate about the characteristics of these spaces, here we investigated the functional properties and plasticity of action and social space in developmental age. To these aims, children with typical development and autism spectrum disorders were submitted to Reaching- and Comfort-distance tasks, to assess peripersonal and interpersonal space, respectively. Participants approached a person (confederate) or an object and stopped when they thought they could reach the stimulus (Reaching-distance task), or they felt comfortable with stimulus' proximity (Comfort-distance task). Both tasks were performed before and after a cooperative tool-use training, in which participant and confederate actively cooperated to reach tokens by using either a long (Experiment 1) or a short (Experiment 2) tool. Results showed that in both groups, peripersonal space extended following long-tool-use but not short-tool-use training. Conversely, in typical development, but not in autism spectrum disorders children, interpersonal space toward confederate reduced following the cooperative tool-use training. These findings reveal that action and social spaces are functionally dissociable both in typical and atypical development, and that action but not social space regulation is intact in children with autism.

Implicit and Explicit Routes to Recognize the Own Body: Evidence from Brain Damaged Patients.
Much research suggested that recognizing our own body-parts and attributing a body-part to our physical self-likely involve distinct processes. Accordingly, facilitation for self-body-parts was found when an implicit, but not an explicit, self-recognition was required. Here, we assess whether implicit and explicit bodily self-recognition is mediated by different cerebral networks and can be selectively impaired after brain lesion. To this aim, right- (RBD) and left- (LBD) brain damaged patients and age-matched controls were presented with rotated pictures of either self- or other-people hands. In the Implicit task participants were submitted to hand laterality judgments. In the Explicit task they had to judge whether the hand belonged, or not, to

them. In the Implicit task, controls and LBD patients, but not RBD patients, showed an advantage for self-body stimuli. In the Explicit task a disadvantage emerged for self-compared to others' body stimuli in controls as well as in patients. Moreover, when we directly compared the performance of patients and controls, we found RBD, but not LBD, patients to be impaired in both the implicit and explicit recognition of self-body-part stimuli. Conversely, no differences were found for others' body-part stimuli. Crucially, 40% RBD patients showed a selective deficit for implicit processing of self-body-part stimuli, whereas 27% of them showed a selective deficit in the explicit recognition of their own body. Additionally, we provide anatomical evidence revealing the neural basis of this dissociation. Based on both behavioral and anatomical data, we suggest that different areas of the right hemisphere underpin implicit and explicit self-body knowledge.

Personal space regulation in childhood autism: Effects of social interaction and person's perspective.
Studies in children with Typical Development (TD) and with Autism Spectrum Disorder (ASD) revealed that autism affects the personal space regulation, influencing both its size (permeability) and its changes depending on social interaction (flexibility). Here, we investigate how the nature of social interaction (Cooperative vs. Uncooperative) and the person perspective influence permeability and flexibility of interpersonal distance. Moreover, we tested whether the deficit observed in ASD children, reflects the social impairment (SI) in daily interactions. The stop-distance paradigm was used to measure the preferred distance between the participant and an unfamiliar adult (first-person perspective, Experiment 1), and between two other people (third-person perspective, Experiment 2). Interpersonal distance was measured before and after the interaction with a confederate. The Wing Subgroups Questionnaire was used to evaluate SI in everyday activities, and each ASD participant was accordingly assigned either to the lower (children with low social impairment [low-SI ASD]), or to the higher SI group (children with high social impairment [high-SI ASD]). We observed larger interpersonal distance (permeability) in both ASD groups compared to TD children. Moreover, depending on the nature of social interaction, a modulation of interpersonal distance (flexibility) was observed in TD children, both from the first- and third-person perspective. Similar findings were found in low-SI but not in high-SI ASD children, in Experiment 1. Conversely, in Experiment 2, no change was observed in both ASD groups. These findings reveal that SI severity and a person's perspective may account for the deficit observed in autism when flexibility, but not permeability, of personal space is considered. The Remapping of Time by Active Tool-Use.
Multiple, action-based space representations are each based on the extent to which action is possible toward a specific sector of space, such as near/reachable and far/unreachable. Studies on tool-use revealed how the boundaries between these representations are dynamic. Space is not only multidimensional and dynamic, but it is also known for interacting with other dimensions of magnitude, such as time. However, whether time operates on similar action-driven multiple representations and whether it can be modulated by tool-use is yet unknown. To address these issues, healthy participants performed a time bisection task in two spatial positions (near and far space) before and after an active tool-use training, which consisted of performing goal-directed actions holding a tool with their right hand (Experiment 1). Before training, perceived stimuli duration was influenced by their spatial position defined by action. Hence, a dissociation emerged between near/reachable and far/unreachable space. Strikingly, this dissociation disappeared after the active tool-use training since temporal stimuli were now perceived as nearer. The remapping was not found when a passive tool-training was executed (Experiment 2) or when the active tool-training was performed with participants' left hand (Experiment 3). Moreover, no time remapping was observed following an equivalent active hand-training but without a tool (Experiment 4). Taken together, our findings reveal that time processing is based on action-driven multiple representations. The dynamic nature of these representations is demonstrated by the remapping of time, which is action- and effector-dependent.

Who is speaking? Implicit and explicit self and other voice recognition.
In the domain of self-recognition, voice is a critical feature for self/other distinction. The aim of this study was to explore if people have an implicit and/or explicit knowledge of their voice. A group of healthy participants were submitted to an implicit and an explicit self-voice recognition task. They listened to pairs of pre-recorded auditory stimuli (words or pseudowords) pronounced by themselves, by a familiar or an unfamiliar person. Afterwards, in the "Implicit task" participants had to judge whether the pair of stimuli were pronounced by same or different speakers; in the "Explicit task" they had to identify if one of the stimuli was or not their own voice. Results showed a difference between Implicit and Explicit tasks since participants were more accurate in implicit than explicit self voice-recognition. Moreover, in the Implicit task, participants had the same level of accuracy when they had to judge stimuli pronounced with self or others' voice, whereas when an explicit voice-recognition

was required, they were less accurate with self than with others' voice.

HUMAN BRAIN RESPONSES TO CANNIBALISTIC IMAGES

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Noémie Reveyaz[1], Carsten Bogler[2], John-Dylan Haynes[2], Michael Brecht[1]
[1]Humboldt University of Berlin, Bernstein Center For Computational Neuroscience Berlin, Berlin, Germany, [2]Charité Universitätsmedizin Berlin, Bernstein Center For Computational Neuroscience Berlin, Berlin, Germany

Cannibalism is a major cultural taboo and its prevalence has been widely debated. Whether cannibalism is widespread in the animal kingdom used to be controversial, but is now firmly established, even in our closest relatives, the Chimpanzees. Anthropology faced a debate regarding presence of cannibalism in indigenous populations. Novel evidence has established cannibalism in some indigenous people and also in prehistoric populations. While it is clear that cannibalistic information evokes strong reactions in humans, little is known about how it is processed in the human brain. To address this issue, we investigate the neural processing of images showing cannibalistic material using functional Magnetic Resonance Imaging. Participants passively viewed images taken from three categories, selected in preliminary psychophysical pilot studies: “Cannibalism”, “Body Mutilation”, and “Disgust”. For each participant, 6 runs of 30 pictures were presented, each run with 10 pictures per category. Pictures were shown for 2 s followed by an 8 s break. A fixation cross was shown throughout. Preliminary data indicate that images representing “Cannibalism” evoked stronger activity in bilateral occipital and left parietal cortex than the control conditions. The “Body Mutilation” and “Disgust” signals also activated the fusiform body area and the right occipital region. The increased occipital brain activity evoked by cannibalistic stimuli might reflect increased attention. Further work is needed to understand if such differential processing of cannibalistic images reflects their cultural taboo or instead a specific biological “preparedness” to react to cannibalism.

SOCIAL TASK MANAGEMENT: SWITCHING BETWEEN HUMANIZED AND DEHUMANIZED PERCEPTION - AN EXPLORATORY EEG STUDY

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Rebecca Geiselmann[1], Sarah Crockford[2], Melissa J'Hurry[3], Anna Remington[4], Lasana Harris[3]
[1]LMU Munich, Graduate School Of Systemic Neurosciences, München, Germany, [2]Cambridge University, Theoretical And Applied Linguistics, Cambridge, United Kingdom, [3]UCL London, Experimental Psychology, London, United Kingdom, [4]UCL London, Ioe - Psychology & Human Development, London, United Kingdom

Recent behavioral and neuroimaging studies suggest that people are constantly required to transition between a humanized and dehumanized mode of perception to adapt to changing contexts and navigate their complex environment. However, the temporal dynamics underlying the controlled switch between these two perceptual and behavioral orientations towards others remain unclear. Thus, in this paper we examined the switch between humanized and dehumanized perception using EEG. We recorded EEG activity from 19 (30.24 ± 11.98 years; 8 men) neurotypical participants who were presented with 80 color-images of individuals. To operationalize humanized and dehumanized perception, participants were asked to perform a social (warmth) and a financial (competence) decision task respectively, based on the images. The social and non-social task were presented in form of 'stay' or 'switch' trials. In the ‚switch' condition trials alternated between the two tasks, in the ‚stay' condition participants repeated the same task. As hypothesized, N170 amplitudes were larger to the social compared to the financial task. However, unexpectedly, P300 amplitudes did not differ between stay and switch trials. Supporting prior social cognition research, differences in N170 amplitudes indicate that a dehumanized mode of perception begins when early, exogenous, perceptual processes are employed. However, contradicting prior task-switching studies, findings related to P300 amplitudes suggest that task switching in social contexts is not implemented by endogenous, cognitive processes but by an alternative, yet unexplored, control mechanism. Thus, overall, we assume the control of social cognition to be distinct to the control of other previously researched cognitive systems.

STRATEGIES THAT ACTIVATE THE SOOTHING AND THREAT SYSTEM DURING A BODY IMAGE STRESSOR ARE ASSOCIATED WITH INTENTIONS TO ENGAGE IN DISORDERED EATING BEHAVIOUR AMONG WOMEN

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Kheana Barbeau-Julien[1], Kayla Boileau[2], Luc Pelletier[2]
[1]University of Ottawa, Psychology, ottawa, Canada, [2]University of Ottawa, Psychology, Ottawa, Canada

Aims: Self-compassion encompasses being kind to oneself with non-judgemental acceptance and awareness, while acknowledging that others may face similar circumstances. Self-compassion is thought to deactivate the stress system by activating the soothing system, mitigating stress reactivity. For those with high eating disorder symptoms, threats to body image, such as mirror exposure, elicits a stress response and compensatory behaviours (i.e., disordered eating). It has yet to be investigated whether the link between stress responses and disordered eating is mediated by strategies that activate the self-soothing system, the threat system or attentional-emotional interoceptive regulation. This study examined whether self-compassion, attention and emotion regulation, and appearance fixing mediate the relationship between eating disorder symptoms and intent for disordered eating after a body image stressor. Methods: 55 undergraduate women spoke about their bodies while exposed to a mirror in the presence of female confederates. Trait eating disorder symptoms were measured prior to the task. Self-compassion, attention and emotion regulation, appearance fixing, and intentions to engage in disordered eating were measured following the task. Results: Self-compassion and one individual component of self-compassion, self-kindness, and appearance fixing significantly mediated the relationship between eating disorder symptoms and intentions for disordered eating. Neither attention nor emotion regulation were mediators in the relationship between eating disorder symptoms and intentions for disordered eating. Conclusions: Activating the self-soothing system by being self-compassionate may reduce compensatory eating behaviour in those with higher eating disorder symptoms, whereas fixating on appearance may increase compensatory behaviours by activating the threat response system during a stressor.

Family members and peers' negative and positive body talk: How they relate to adolescent girls' body talk and eating disorder attitudes.
Research examining the interpersonal correlates of body talk has primarily focused on the negative consequences of perceiving fat talk on women's own body talk and eating behaviours; however, little is known about the correlates and effects of positive body talk. This study examined the associations between perceived family and peer negative and positive body talk and adolescent girls' body talk and eating disorder attitudes, and the mediating role of adolescents' fear of negative evaluation and self-compassion in these relationships. Influences of family members and peers were compared to examine the uniformity of these interpersonal processes. Adolescent girls (N = 331, M age = 15.7, SD = 1.0) completed a survey. Path analysis models suggested that in the peer and family models, perceived negative body talk was associated with more self-related negative talk through fear of negative evaluation and lower self-compassion, whereas perceived positive body talk was associated with more self-related positive talk through self-compassion. Additionally, adolescents' fear of negative evaluation and self-related negative talk were mediators between perceived negative body talk and eating disorder attitudes. Results suggest that negative and positive body talk are cultivated interpersonally by increasing evaluative concerns and decreasing self-compassion.

Self-Compassion as a Mediator of the Relationship between Adult Women's Attachment and Intuitive Eating.
Despite growing interest in intuitive eating-a non-dieting approach to eating that is based on feeding the body in accordance with physiological and satiety cues-research on its determinants is scarce. The present study aimed to examine the associations between dimensions of adult attachment (i.e., anxiety and avoidance) and intuitive eating, and the mediating role of self-compassion in these relationships. The sample comprised 201 French-Canadian young adult women (M = 25.1, SD = 4.6). Participants completed self-report questionnaires through an online survey. Results of the structural equation model demonstrated that attachment-related anxiety and avoidance were negatively associated with intuitive eating, and

these relationships were at least partially mediated by self-compassion. Findings suggest that women who have high levels of attachment anxiety or avoidance engage in less intuitive eating partly because they are less self-compassionate. Results highlight the importance of self-compassion in facilitating adaptive eating behaviors in adult women, especially if they have an insecure attachment style to romantic partners.

Environmental enrichment and its influence on rodent offspring and maternal behaviours, a scoping style review of indices of depression and anxiety.
Environmental enrichment is a widely used experimental manipulation that consistently shows measurable effects on rodent behaviour across the lifespan. This scoping review assesses and thematically summarizes the literature of the past decade concerning the effects of environmental enrichment applied during sensitive developmental periods in rodent mothers and offspring. Maternal behaviours as well as maternal and offspring anxiety- and depressive-like behaviours are considered. Relevant terms were searched across five databases (Embase, MEDLINE, PsycINFO, PubMed, Web of Science) and articles were screened with inclusion and exclusion criteria. The remaining articles were thematically analysed. Our results suggest that a greater number of articles reviewed the impacts of environmental enrichment on offspring anxiety-like behaviour (n = 23) rather than on depressive-like behaviour (n = 11) or maternal caregiving behaviour (n = 12). Maternal anxiety- (n = 4) or depressive-like (n = 2) behaviours are not often evaluated for in enrichment studies. The main behavioural tests of anxiety that were reviewed include the elevated plus-maze, the open field test, and the light-dark box whereas those for depression included the forced swim test and the sucrose preference test. Our results yielded mixed findings and significant variation in behavioural responses across all tests. In mothers, trends of increased maternal care behaviours and decreased maternal depressive-like behaviours in enriched mothers were appreciated. Enrichment during the gestational period was identified as pivotal to creating behavioural change in mother subjects. In enriched offspring rodents, a trend towards decreased anxiety-like behaviours was observed most often. Potential confounds inherent in enrichment paradigms and relevant theories of enrichment and their relation to rodent behavioural tests are discussed.

Development of a consensus statement on the role of the family in the physical activity, sedentary, and sleep behaviours of children and youth.
Children and youth who meet the physical activity, sedentary, and sleep behaviour recommendations in the Canadian 24-Hour Movement Guidelines are more likely to have desirable physical and psychosocial health outcomes. Yet, few children and youth actually meet the recommendations. The family is a key source of influence that can affect lifestyle behaviours. The purpose of this paper is to describe the process used to develop the Consensus Statement on the Role of the Family in the Physical Activity, Sedentary, and Sleep Behaviours of Children and Youth (0-17 years) and present, explain, substantiate, and discuss the final Consensus Statement.

Ethnic differences in diurnal cortisol profiles in healthy adults: A meta-analysis.
Cortisol is a well-known biomarker of the physiological stress system; atypical cortisol patterns have been linked to many psychological and physiological illnesses. Previous studies have found vast health disparities among ethnic groups; however, studies examining the relationship between cortisol and ethnicity have found mixed results. This meta-analysis investigated whether there are differences in diurnal cortisol outcomes among ethnic groups, while considering the moderating roles of various individual factors and methodological approaches.

Examining fat talk and self-compassion as distinct motivational processes in women's eating regulation: A self-determination theory perspective.
This study examined whether pursuing intrinsic versus extrinsic goals was associated with distinct motivational processes in eating regulation and with healthy versus unhealthy eating. Path analysis demonstrated that appearance goals were associated with fat talk, whereas health goals were associated with self-compassion. Fat talk was positively associated with non-self-determined motivation and unhealthy eating, whereas self-compassion was positively associated with self-determined motivation and healthy eating, and negatively associated with unhealthy eating. Findings emphasize the negative effects of pursuing appearance goals and engaging in fat talk and the benefits of pursuing health goals and being self-compassionate.

Why do women engage in fat talk? Examining fat talk using Self-Determination Theory as an explanatory framework.
This study used Self-Determination Theory to examine the motivational processes involved in individuals' engagement in fat talk and its association with unhealthy eating behaviors. Female undergraduate students (N=453) completed an online questionnaire, which assessed general and contextual motivation, importance placed on goals, fat talk, and unhealthy eating behaviors. Structural equation modeling revealed that being generally non-self-determined and placing more importance on extrinsic goals, such as thinness, was associated with fat talk. Fat talk was further associated with non-self-determined motivation for eating regulation, which in turn was associated with unhealthy eating. General self-determination and placing more importance on intrinsic goals, such as health, were not associated with fat talk, but instead, were associated with more adaptive forms of eating regulation and diet quality. Findings further current knowledge on the respective roles of motivation and goals on the engagement in fat talk, and its consequences on eating regulation and behavior.

VOICE DISCRIMINATION IN MARMOSET MONKEYS USING BEHAVIORAL TESTING

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Manon Obliger, Régis Trapeau, Bruno Nazarian, Xavier Degiovanni, Sabrina Ravel, Pascal Belin
CNRS-AMU, Institut Des Neurosciences De La Timone Umr 7289, Marseille, France

Marmosets can perform vocalization labeling tasks or identity discrimination using playbacks. In this study, we wanted to train marmosets in an operant sound discrimination task and determine the acoustic parameters involved in sound discrimination. We adapted an in-cage automated test system, allowing ad libitum access and individualized learning. The first task is a Same/Different task, the purpose is to train monkeys to differentiate between two calls and indicate whether they are equal or different. To do this, the subject hears two successive sounds and then touches the touch screen on the left if the sounds are equal or on the right if they are different. The second task is a Go/Nogo like task, the goal is to train the monkeys to discriminate between two calls from different individuals. The monkey successively hears a random number of Nogo stimuli (the same sound) before a Go stimulus (different sound). The monkey succeeds if it touches the touch screen when the go stimulus is played. The results obtained in the first task show that even if 12 marmosets, out of 14 tested, understood the sound-touch-reward association, most of them were unable to perform the full task and discriminate the difference in the sounds. For the second task, the preliminary results indicate that the task is more suitable for marmosets to discriminate sounds. Ultimately, this task will allow us to test the discrimination among voice parameters and compare the performance in comparable tasks in other primates.

ELECTROPHYSIOLOGICAL INVESTIGATION OF FMRI-IDENTIFIED VOICE PATCHES IN THE MACAQUE TEMPORAL CORTEX

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Margherita Giamundo[1], Régis Trapeau[2], Xavier Degiovanni[3], Pascal Belin[4]
[1]Aix-Marseille University, Institut De Neurosciences De La Timone, Marseille, France, [2]Aix-Marseille Université, Institute Of Neuroscience Of La Timone, Marseille, France, [3]CNRS-AMU, Institut Des Neurosciences De La Timone Umr 7289, Marseille, France, [4]Institut de Neurosciences de la Timone, Université Aix-marseille, Marseille, France

The ability to process voice information is a crucial aspect of our social life. Neuroimaging studies have shown the existence of temporal and frontal cortical regions selective for conspecific vocalizations in both humans and non-human primates, supporting the hypothesis of a homology on the voice processing between humans and their closest relatives. But how the voice information is treated at the neuronal level in these areas is still not clear. To tackle this issue, we implanted two macaque monkeys with multiple high density multi-electrode arrays in fMRI-localized voice patches of the superior temporal gyrus. The neuronal activity was recorded during an auditory stimulation task in which a large set of stimuli from different categories (human voices, macaque vocalizations, marmoset vocalizations, non-vocal sounds) was presented. A total of 1550 single and multi-units was recorded from 5 arrays in the 2 monkeys. Preliminary results showed complex and heterogeneous patterns of neural response among stimulus categories. At the population level, the activity was dynamically modulated along the stimulus presentation time, representing different aspects of voice information. Moreover, decoding analysis shows that anterior patches were able to better discriminate between different call types of conspecific (macaque) vocalizations than more posterior patches. These results are bringing new knowledge on the neural substrates of voice information processing in fMRI-localized voice patches, probing for the first time spatial and temporal specificities of activation.

MULTIMODAL SENSORY INTEGRATION FOR FLY SEXUAL BEHAVIOUR

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Dana Galili[1], Istvan Taisz[1], Daniel Münch[2], Erika Donà[1], Shanice Bailey[3], William Morris[3], Kimberly Meechan[3], Irene Varela[3], Carlos Ribeiro[2], Gregory Jefferis[1,3]
[1]MRC Laboratory of Molecular Biology, Neurobiology Division, Cambridge, United Kingdom, [2]Champalimaud Foundation, Champalimaud Research, Lisbon, Portugal, [3]University of Cambridge, Drosophila Connectomics, Zoology, Cambridge, United Kingdom

Aims: The brain integrates sensory streams to create a coherent representation of external events. During courtship, a female fly receives multiple male-specific sensory inputs, including olfactory, visual, auditory, tactile and others. We study how separate streams are combined in the female brain to evaluate the male, and decide whether to accept him. **Methods**: we used a combination of connectomics, optogenetic activation of neuronal populations during social interaction, and functional imaging in the *Drosophila* female brain, to study sensory pathways responding to male-specific signals. **Results:** We identified sensory pathways responding to male taste or pheromone smell (cis-Vaccenyl acetate, cVA). Optogenetic activation of either pathway alone has no effect on female sexual receptivity, but simultaneous activation of both pathways increased female receptivity. Using the female connectome, we identified a third order neuronal population that receives synaptic input from both sensory streams, the aSP-g neurons. Manipulating aSP-g neurons during behaviour bi-directionally modulate female receptivity. We additionally identified lvPN neurons, a novel, parallel cVA-responsive pathway, which bi-directionally modulate female receptivity, and signal pheromone information to a central receptivity hub, pC1 neurons. In a behavioural epistasis experiment, we found that aSP-g neurons are able to partially restore female receptivity when pC1 neurons are ablated. **Conclusions:** We describe parallel pheromone-responsive channels; both control female receptivity but with distinct logic. While the lvPN->pC1 channel directly regulates receptivity, multisensory integration of taste and smell at aSP-g dendrites is required for that pathway to promote receptivity. Thus two separate pathways with overlapping sensory information cooperate to regulate female receptivity.

NEURAL CORRELATES OF THIRD-PARTY PUNISHMENT: EEG STUDY

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Oksana Zinchenko, Anush Revazyan, Victoria Moiseeva, Vasily Klucharev
HSE, Institute For Cognitive Neuroscience, Moscow, Russian Federation

Aims: Current study focused on the role of the neural salience network in third-party punishment of violation of the distribution norm. The recent study showed that the medial frontal negativity (MFN), that is generated by the salience network, is implicated into the altruistic tendencies (Sun et al., 2015). But this study failed to find a link between the MFC and third-party punishment behavior. We aimed to further investigate the relationship between third-party behavior and MFN. Methods: Seventeen right-handed adults were instructed to play the third-party dictator game. We analyzed EEG the time window when third-parties observed the distribution of 40 monetary units (MU) between the dictator and the recipient (-200 to 1000 ms). We analyzed the MFN (200-230 ms) at Fz and Cz electrodes using the permutation test with FDR correction. For behavioral data, we calculated the *fairness sensitivity* index as a ratio of MUs invested in third-party punishment of the nearly fair splits (25:15) and MUs invested in third-party punishment of unfair splits (30:10, 35:5, 40:0): MU(unfair splits)+MU(nearly fair splits)/MU(unfair splits)-MU(nearly fair splits). Results: Similar to Sun and colleagues (2015), we observed the MFN evoked by the unfair splits in comparison to fair splits. But in contrast to Sun and colleagues (2015), we found a significant correlation between *fairness sensitivity* index and MFN amplitude: r = -0,516; p = 0,034. Conclusions: Our findings suggest that people with the larger MFN evoked by unfair dictators' behavior also imposed stronger altruistic punishments of norm violations.

ROBUST INFERENCE AND MODELING OF SOCIAL EFFECTS ON MICE LEARNING IN INTELLICAGES

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Michał Lenarczyk[1], Bartosz Jura[1], Zofia Harda[2], Magdalena Ziemiańska[2], Łukasz Szumiec[2], Jan Rodriguez Parkitna[2], Daniel Wójcik[1,3]
[1]Jagiellonian University, Faculty Of Management And Social Communication, Kraków, Poland, [2]Maj Institute of Pharmacology Polish Academy of Sciences, Department Of Molecular Neuropharmacology, Kraków, Poland, [3]Nencki Institute of Experimental Biology, Polish Academy of Sciences, Laboratory Of Neuroinformatics, Warszawa, Poland

Learning by imitating others in a group allows to acquire and reuse knowledge learned by peers. It is beneficial to the group as a whole as it allows to predict expected consequences of decisions without experiencing them.
Here, we attempt to measure the ability to learn from others in mice using Intellicages, a system that tracks access to drinking bottles of animals housed in a group. In our proposed paradigm, reward (access to sweetened water) is offered conditionally depending on random assignment of each animal to either “majority” or “minority” group. The two groups are assigned different reward locations. To assess the effect of mutual influence we developed a formalism and a model-based approach to analysis of Intellicage data. The proposed methods combine point process techniques known from spike train analysis with reinforcement learning and are validated with simulated data. Using data from Intellicage experiments with different expected social effects and different reward protocols we show a range of analytical approaches and present their effectiveness. Our results show that the proposed stochastic models capture the mice behaviour well and can be used to estimate the social effects of learning in different situations, adding extra information for quantitative description of different strains or modified animals. Corresponding generative models can be useful for prediction of group behaviour, for example, at early planning stages of experiments in which Intellicages are employed.

ON THE ENVIRONMENTAL AND BEHAVIOURAL VARIABLES THAT INFLUENCE EMPATHY AND PROSOCIAL BEHAVIOUR IN MICE

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Charitha Omprakash[1], Ada Braun[1], Pavol Bauer[2], Sanja Mikulovic[1]
[1]Leibniz Institute for Neurobiology Magdeburg, Cognition And Emtion Research Group, Magdeburg, Germany, [2]Leibniz Institute für Neurobiologie, Cognition And Emotion Research Group, MAGDEBURG, Germany

Increasing research evidence convincingly demonstrates the presence of empathy and prosocial behaviours in rodents, and the modulation of these behaviours is based on social experiences. However, these experiments have been conducted mostly on rodents housed in pairs, in laboratory conditions, and monitored only during the experimental period. This leaves us with limited knowledge of the effect of the environment and behavioural variables on empathy and prosocial behaviours. To get a better understanding of the personality traits and the effect of different environments on these behaviours, we created ‘Social Cities’. In these ‘Social Cities’, groups of mice can comfortably live together for extended periods of time. After they were habituated in the cities, we established a helping behaviour experiment during which one individual was in need. Our main question was to investigate the social relationship between the “helpers” and the “victim”. Analysing the video data recorded from multiple cameras on several days, we first determined single animal identities and their body poses using a computer vision approach. We then extracted a large set of behavioural features and performed regression analysis to determine which variables affect the outcome of the helping behaviour experiment. For further work, we seek to modify environmental variables of the experiment and determine how they modify the social dynamics and the willingness to help during the behavioural paradigm.

ENCODING SOCIAL EXPLORATION IN THE AMYGDALA

POSTER SESSION 04 - SECTION: NEURAL CORRELATES OF SOCIAL INTERACTIONS

Maria Sol Fustiñana[1], Yael Bitterman[1], Tobias Eichlisberger[1], Tewis Bouwmeester[2], Andreas Lüthi[1]
[1]Friedrich Miescher Institute for Biomedical Research, Neuroscience, Basel, Switzerland, [2]Novartis Institutes for Biomedical Research, Developmental Molecular Pathways, Basel, Switzerland

An animal's behavior is determined by metabolic, emotional and social factors. Depending on its state, an animal will focus on avoiding threats, foraging for food or on social interactions, and will display the appropriate behavioral repertoire. Moreover, survival and reproduction depend on the ability to adapt to changes in the environment by prioritizing the appropriate state. Although these states are thought to be associated with particular functional configurations of large-brain systems, the underlying principles are poorly understood. Using deep-brain calcium imaging of mice engaged in spatial or social exploration, we investigate the basolateral amygdala (BLA), a region that integrates emotional, social and metabolic information. We demonstrate that the BLA encodes animals' engagement in exploratory behavior by means of two large, functionally anticorrelated ensembles exhibiting slow dynamics. These findings reveal that the basolateral amygdala acts as a low-dimensional, but context-dependent, hierarchical classifier that encodes state-dependent behavioral repertoires. This computational function may have a fundamental role in the regulation of internal states in health and disease.

OBJECT DECODING WITH SPATIAL ATTENTION IN THE HUMAN LATERAL OCCIPITAL COMPLEX

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Jesus Garcia Ramirez[1], Michaël Vanhoyland[1], Thomas Decramer[1], Anais Van Hoylandt[1], Johan Van Loon[1,2], Wim Van Paesschen[3], Thomas Serre[4], Peter Janssen[5,6], Tom Theys[1,2]
[1]KU Leuven, Research Group Experimental Neurosurgery And Neuroanatomy, Leuven, Belgium, [2]University Hospital Leuven, Neurosurgery, Leuven, Belgium, [3]Ku Leuven, Neurology, Leuven, Belgium, [4]Brown University, Carney Institute For Brain Science, Providence, United States of America, [5]KU Leuven, Research Group Neuro- And Psychophysiology, Leuven, Belgium, [6]KU Leuven, Leuven Brain Institute, Leuven, Belgium

Spatial attention can selectively enhance responses of sensory neurons. According to invasive electrophysiological studies performed in non-human primates (NHPs), the main effect of spatial attention is to resolve competition between objects in the same image in such a way that the neural population response to the object at the attended location resembles the response to the same object when presented in isolation. Until now, this hypothesis remained untested at the single unit activity level in human visual cortex. We had the unique opportunity to record intracortical neuronal activity (96-electrodes Utah arrays) from the lateral occipital complex (LOC) in 2 epilepsy surgery patients during a spatial attention task. In this task, we presented two objects at a time, and cued subjects to covertly attend to a particular location in the visual field to detect a specific object. We then decoded information related to the identity of each of the objects present in the image from the recorded population using linear classifiers. The results show that we could only decode the object at the cued position above chance level, suggesting that spatial attention works similarly in NHPs and human visual cortex. Finally, we studied the dynamics of spatial attention by decoding object identity every 50 ms. The amount of information related the identity of the object at the cued location became significant at 125 ms after stimulus onset but increased markedly after this initial visual response. This indicates that spatial attention not only biases bottom-up processing but may also involve recurrent computations.

TASK-INDEPENDENT ENCODING OF ABSTRACT BEHAVIORAL CATEGORIES IN FERRET PREMOTOR CORTEX

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Jeffrey Boucher[1], Shihab Shamma[1,2], Yves Boubenec[1]
[1]Ecole Normale Superieure, PSL University, CNRS, Lsp, Paris, France, [2]University of Maryland, Neural Systems Laboratory, College Park, United States of America

Multiple regions of frontal cortex have been shown to encode a variety of task-related signals, including task-relevant sensory features and stimulus behavioral categories, possibly with major inter-species differences (Mante et al, 2013, Rogers & DeWeese 2014, Siegel et al, 2015, Fritz et al 2010, Lui et al 2020, Reinert et al 2021). To date, there are conflicting results about the extent to which specific frontal regions preserve low-level sensory information, or are restricted to high-level behavioral categories. To tackle this question, we trained ferrets on a Go/NoGo auditory task, alternating in blocks requiring flexible attention to different acoustic dimensions. Using the burgeoning technology of functional Ultrasound Imaging (fUS), we recorded hemodynamic responses of multiple functional areas of ferret frontal cortex while the animals performed the alternating task, with sub-millimeter spatial resolution, up to 6 mm below the cortical surface. We have observed stimulus-evoked responses sparsely throughout this cortex, but have additionally observed robust differences in the response to Go and NoGo sounds during behavior in contained regions including lateral premotor cortex (lPMC) and the paraorbital gyrus (pOBG), as well as motor and sensorimotor cortex. In each case, these contrasts are independent of the sensory dimension the ferret attended to, suggesting that at this stage in processing and at this spatial resolution, the evoked responses no longer strongly encode specific stimulus identity. This result is not dependent on choice, as Go/NoGo differences are similar in these locations whether the ferret correctly rejects the NoGo or if they mistakenly lick.

CATEGORY-DEPENDENT TASK-LOAD EFFECTS AT CATEGORY-SELECTIVE AREAS

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Yul-Wan Sung, Seiji Ogawa
Tohoku Fukushi University, Kansei Fukushi Research Institute, Sendai, Japan

Brain imaging studies by functional MRI (fMRI) revealed primary and high cognitive functional areas. For visual stimuli, categorically selective brain areas were found consistently in relation with visual object processing. However, effects of other tasks not related with stimulus attributes on fMRI responses at those stimulus-selective areas are unclear yet. In this study we examined the dependency of the functional specificity to visual stimuli on a load task at face and visual language processing areas. We examined whether the category selective areas at ventral region selectively respond to task-load levels or not. Face and characters images were used as visual stimulation for fMRI experiments. The load levels were two of simple discrimination and complex. One was simple discrimination task and the other was an associative task with stimuli. 3T MRI scanner with 12 channel head matrix coil was used for fMRI experiments. Four-teen subjects participated in the study. The study was approved by the Institutional Review Board of Tohoku Fukushi University. Stimulus-selective areas were identified by localization scans for face and visual language areas. Responses in the areas were compared. We found that the task-load level affected on the fMRI response selectively to its preferred stimulation at each categorically specific area, that is, non-preferred stimulus was not affected by the task-load level. This indicates that the effects of applied task on category-selective areas were from top-down modulation or associative interaction with stimulus processing. Further study will elucidate the mechanism.

EFFECTS OF ACUTE EXERCISE ON INHIBITORY CONTROL AND FRONTAL THETA OSCILLATIONS IN PREADOLESCENT CHILDREN

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Shu-Shih Hsieh[1], Shih-Chun Kao[2], Lauren Raine[3], Katherine Mcdonald[4], Charles Hillman[5]
[1]Kingston University, Department Of Psychology, Kingston upon Thames, United Kingdom, [2]Purdue University, Department Of Health And Kinesiology, West Lafayette, United States of America, [3]Northeastern University, Department Of Physical Therapy, Movement, And Rehabilitation Sciences, Boston, United States of America, [4]Northeastern University, Department Of Psychology, Boston, United States of America, [5]Northeastern University, Department Of Psychology & Department Of Physical Therapy, Movement, And Rehabilitation Sciences, Boston, United States of America

Aims: To determine the neural underpinnings of acute exercise-induced changes in inhibitory control, this study investigated the acute effects of aerobic exercise on neural oscillations during an inhibitory control task in preadolescent children. **Methods:** Thirty-three preadolescent children between 8-11 years old were recruited into this randomized, within-subjects, crossover study. Participants engaged in an aerobic exercise condition (20 minutes of moderate intensity treadmill walking; heart rate during exercise = 61 ± 4% of pre-determined maximal heart rate) and a 20-minute seated rest condition in a counterbalanced order. After both experimental conditions, participants completed a modified Eriksen flanker task to assess inhibitory control, with concurrent electroencephalography (EEG) data collection. **Results:** Our data indicated that, during incongruent trials requiring greater amounts of inhibitory control, participants had higher response accuracy following aerobic exercise relative to seated rest. There was also a congruency effect on response accuracy, wherein higher accuracy was observed during congruent trials relative to incongruent trials, only following seated rest; an effect not found following aerobic exercise. Neuroelectric analyses revealed a similar congruency effect on task-related frontal theta synchronization following seated rest, wherein theta synchronization was larger during congruent relative to incongruent trials. Lastly, during incongruent trials, there was a trend (p = .07) for theta synchronization, wherein greater theta synchronization was found following aerobic exercise relative to seated rest. **Conclusions:** Acute exercise may transiently enhance performance on tasks requiring greater inhibitory control in preadolescent children, which are accompanied by flexible modulation of top-down cortical control signified by frontal theta oscillations.

EFFECT OF THE VOCAL AND EMOTIONAL PROSODIC CONTENT ON THE NEURAL ADAPTATION TO SOUNDS.

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Annabelle Merchie[1], Sylvie Roux[1], Frédérique Bonnet-Brilhault[1], Carles Escera[2,3,4], Marie Gomot[1]
[1]Inserm, Umr 1253, Ibrain, Université De Tours, Tours, France, [2]University of Barcelona, Brainlab Cognitive Neuroscience Research Group, Department Of Clinical Psychology And Psychobiology, Barcelona, Spain, [3]University of Barcelona, Institute Of Neurosciences, Barcelona, Spain, [4]Institut de Recerca Sant Joan de Déu, Irsjd, Esplugues del Llobregat (Barcelona), Spain

Adaptation to sensory information is essential to detect, anticipate and respond to changes in the environment, especially for the adaptation of behavior in response to others' voices and emotions. Whether social content and emotional prosody impact the process of neural adaptation to sounds remains to be investigated. At the brain level, adaptation is characterized by a decrease of the response amplitude to a repeated stimulus. This phenomenon is referred to as Repetition Suppression (RS) and is measured using ERPs through the modulation of P1 at about 100ms in response to sounds. We compared RS and P1 between vocal and non-vocal as well as emotional and non-emotional sounds by recording auditory evoked potentials in a group of adults. Results showed that in a changing context (roving paradigm), regularity encoding is possible for both vocal and non-vocal sounds, but with different dynamics according to the nature of the sounds. In fact, fewer repetitions are required for the stabilization of the P1 amplitude to non-vocal sounds compared to vocal ones. Moreover, results suggest that participants adapt more rapidly to sounds involving emotional prosody than to neutral sounds, consistently with the social and empathetic nature of human beings. The presence of Repetition Positivity (RP) in all conditions indicates that adaptation operates for sounds of different nature. However, the number of repetitions required to reach regularity encoding depends on the vocal and emotional content of the sounds.

40HZ-TRANSCRANIAL ALTERNATING CURRENT STIMULATION (TACS) MODULATES ILLUSORY PERCEPTION: SHEDDING LIGHT ON PAREIDOLIA

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Annalisa Palmisano[1], Giulio Chiarantoni[1], Francesco Bossi[2], Alessio Conti[1], Vitiana D'Elia[1], Serena Tagliente[1], Davide Rivolta[1]
[1]University of Bari Aldo Moro, Department Of Education, Psychology, Communication, Bari, Italy, [2]IMT School for Advanced Studies Lucca, Imt, Lucca, Italy

Aims: The study aims to investigate the physiological substrate of face Pareidolia, that is the perception of faces in non-existent entities. Transcranial Alternating Current Stimulation (tACS) at gamma (γ) frequency was adopted to modulate face Pareidolia phenomena.

Methods: 40Hz-tACS was delivered over the right lateral occipito-temporal cortex of 75 participants during or after the administration of 5 tasks for illusory perception, including the 'Toast test' for faces, and a 'Mooney task' (Faces and Objects) with both validated and ad-hoc generated stimuli. Participants were divided into three groups receiving 35 minutes of either Sham, Online, or Offline stimulation.

Results: Results from the Toast Test showed significant effects on RTs: Pareidolia responses (erroneous face detections) were significantly slower than non-Pareidolia detections in the Sham ($p < .0001$) and Online ($p < .001$) groups, but not in the Offline one. Results from the Mooney (Faces) task showed Pareidolia responses' accuracy in the Offline group was significantly lower than in the Sham ($p < .01$) and Online ($p < .05$) ones. A similar but weaker pattern emerged for Objects.

Conclusions: This is the first study investigating face Pareidolia via a tACS protocol. Our study showed an aftereffect of 40Hz-tACS over the right lateral occipito-temporal cortex on visual perception, which was modulated toward a higher proneness to Pareidolia (i.e., change in RTs and a higher rate of illusory face detections). It sheds some light on γ-tACS potential to modulate brain plasticity for future clinical applications in abnormal visual perception.

LATERALIZED OCCIPITAL TMS ELICITS DIFFERENTIAL PHOSPHENE EEG ACTIVITY BETWEEN LEFT AND RIGHT HEMISPHERES

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Davide Bonfanti, Chiara Mazzi, Alessandra Tafuro, Silvia Savazzi
University of Verona, Physiology And Psychology, Verona, Italy

Aims: This study aims to shed light on the neural dynamics leading to visual perception, looking for differences between the hemispheres. To do so, we used TMS over left and right primary visual cortex to trigger phosphenes while recording EEG signal, to detect hemispheric differences in conscious and unconscious visual processing. **Methods:** Eighteen participants were tested. Firstly, we determined an individual stimulation intensity at which participants could perceive a phosphene on 50% of trials, per each stimulation site (i.e. electrodes O1 and O2). We then administered single-pulse TMS and participants reported the presence or absence of a phosphene by pressing respectively two keyboard keys. Participants received 360 TMS pulses per stimulation site, which were counterbalanced. **Results:** A significant effect of stimulated hemisphere and phosphene awareness was found on recorded TEPs. The interaction was also significant: analysis of positive and negative answers separately for the two sites revealed that stimulating O1 determined early differential activity located over occipital and right frontal electrodes, while O2 stimulation elicited later activations on centro-parietal electrodes as a function of awareness. **Conclusions:** Phosphene perception seems to elicit differential activity depending on the stimulated hemisphere, with earlier activations occurring after left stimulation compared to right stimulation. These differential patterns may suggest a different role for the two hemispheres in processing visual information.

Competing theories of consciousness stress the importance of reverberating activity in sensory areas, of integrated information in the posterior cortex, or of global broadcasting of information through frontoparietal (FP) networks. Here, we recorded neural activity from 727 intracranial contacts in 13 patients with drug-resistant epilepsy, while they detected near-threshold peripheral targets preceded by supra-threshold, non-predictive exogenous cues. Valid cues increased the number of seen targets. K-means clustering grouped electrode activities according to their temporal trajectories across experimental conditions. Three patterns emerged: 1) validly cued seen targets elicited stronger neural activity than invalidly cued ones; after fast transient target-related visual activity, there was sustained activity in FP and temporal regions, followed by late accumulation activity in bilateral PFC. 2) Invalidly cued seen targets elicited early, sustained activity in the right hemisphere temporoparietal junction / inferior frontal gyrus (reorienting network). 3) Seen, but not unseen, targets elicited late sustained activity in the left dorsolateral PFC, independent of attention. White matter tractography showed that the superior longitudinal fasciculus (SLF) II/III connected the FP network with sustained activity; SLF I/III connected the FP network with late accumulation activity; SLF III connected the reorienting network. Simulation of the task with recurrent neural networks supported the causal contribution of these FP networks to conscious perception. Our evidence from direct brain activity recording, white matter tractography, and computational modeling specifies the different roles of FP networks in conscious processing, resulting from orienting and reorienting of spatial attention. Left dorsolateral PFC activity can instead reflect post-orienting perceptual decisions.

TWO INDEPENDENT MOVEMENT STATE RELATED INFLUENCES ON SENSORY PROCESSING

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Xinyu Chen[1], Liyu Cao[1,2], Barbara Haendel[1,3]
[1]Julius-Maximilians-Universität Würzburg, Department Of Psychology (iii), Wuerzburg, Germany, [2]Zhejiang University, Department Of Psychology And Behavioral Science, Zhe Jiang, China, [3]University Hospital Wuerzburg, Neurology Department, Wuerzburg, Germany

Walking influences visual processing related neural responses, however, the underlying mechanism remains underexplored. Based on previous findings, we hypothesised that walking leads to a processing change that can be predicted by a movement state related decrease in alpha power. The influence of the state dependent alpha power on sensory processing and the resulting neural activity should therefore be only minorly affected by the stimulus type. In the current study, we investigated the neural nature of those walking-induced changes (ERP and alpha power) and behavioural performance in a discrimination task while participants were standing or freely walking. Mobile EEG was combined with AR glasses for mobile visual stimulation. The results showed enhanced early N1 and decreased P3 responses to stimulus onset during walking. This amplitude modulation was correlated with pre-stimulus alpha power, and alpha power was reduced during walking. As predicted further, the walking-induced N1/P3 amplitude modulation was independent of the exact stimulus nature, such as eccentricity, hemifield and distractor presence. Stimulus-induced alpha power on the other hand showed a modulation by movement state specifically for certain stimulus feature, namely a reduction during walking for eccentricity of 1 degree without distractor. These findings indicate two movement-related influences on sensory processing. One is based on an ongoing reduction in alpha power due to walking which will increase early responses to sensory input such as N1. The second influence is specific for the central visual field and when no distracting input is present, indicating attention modulation at the central visual field during walking.

Differential effects of walking across visual cortical processing stages.
Perceptual processes are almost exclusively investigated and understood under marked movement restriction, while natural behaviour includes pronounced movements. Recent human studies have indicated a profound influence of body movement on early visual responses (e.g., evoked components around 100 msec in EEG, electroencephalogram). However, very little is known about the influence of free walking on later visual responses (e.g., responses related to visual selective attention in a later time window than the stimulus evoked N1 component). In the current study, we measured neural signals (EEG) and behavioural performance in a visual selective attention task while participants were standing or freely walking. The results showed that walking was associated with an amplification of early sensory-evoked potential as indicated by the N1 component. Interestingly, neural indexes of the succeeding processing stages of stimulus discrimination and identification, namely the N2pc component and alpha oscillations, and the eventual behavioural measures were comparable between standing and walking. Additionally, in both standing and walking conditions, an overall advantage in target processing for the right visual field was observed. Our work provides evidence that the early sensory processing is enhanced during locomotion while the succeeding processing steps in a later time window are not modulated by locomotion. We conclude that walking has differential effects across visual cortical processing stages.

Overground Walking Decreases Alpha Activity and Entrains Eye Movements in Humans.
Experiments in animal models have shown that running increases neuronal activity in early visual areas in light as well as in darkness. This suggests that visual processing is influenced by locomotion independent of visual input. Combining mobile electroencephalography, motion- and eye-tracking, we investigated the influence of overground free walking on cortical alpha activity (~10 Hz) and eye movements in healthy humans. Alpha activity has been considered a valuable marker of inhibition of sensory processing and shown to negatively correlate with neuronal firing rates. We found that walking led to a decrease in alpha activity over occipital cortex compared to standing. This decrease was present during walking in darkness as well as

during light. Importantly, eye movements could not explain the change in alpha activity. Nevertheless, we found that walking and eye related movements were linked. While the blink rate increased with increasing walking speed independent of light or darkness, saccade rate was only significantly linked to walking speed in the light. Pupil size, on the other hand, was larger during darkness than during light, but only showed a modulation by walking in darkness. Analyzing the effect of walking with respect to the stride cycle, we further found that blinks and saccades preferentially occurred during the double support phase of walking. Alpha power, as shown previously, was lower during the swing phase than during the double support phase. We however could exclude the possibility that the alpha modulation was introduced by a walking movement induced change in electrode impedance. Overall, our work indicates that the human visual system is influenced by the current locomotion state of the body. This influence affects eye movement pattern as well as neuronal activity in sensory areas and might form part of an implicit strategy to optimally extract sensory information during locomotion.

The effects of idealism and relativism on the moral judgement of social vs. environmental issues, and their relation to self-reported pro-environmental behaviours.
Many studies have demonstrated that moral philosophies, such as idealism and relativism, could be used as robust predictors of judgements and behaviours related to common moral issues, such as business ethics, unethical beliefs, workplace deviance, marketing practices, gambling, etc. However, little consideration has been given to using moral philosophies to predict environmentally (un)friendly attitudes and behaviours, which could also be classified as moral. In this study, we have assessed the impact of idealism and relativism using the Ethics Position Theory. We have tested its capacity to predict moral identity, moral judgement of social vs. environmental issues, and self-reported pro-environmental behaviours. The results from an online MTurk study of 432 US participants revealed that idealism had a significant impact on all the tested variables, but the case was different with relativism. Consistently with the findings of previous studies, we found relativism to be a strong predictor of moral identity and moral judgement of social issues. In contrast, relativism only weakly interacted with making moral judgements of environmental issues, and had no effects in predicting pro-environmental behaviours. These findings suggest that Ethics Position Theory could have a strong potential for defining moral differences between environmental attitudes and behaviours, capturing the moral drivers of an attitude-behaviour gap, which continuously stands as a barrier in motivating people to become more pro-environmental.

Application of 3D Printing in the Construction of Burr Hole Ring for Deep Brain Stimulation Implants.
3D printing has been widely applied in the medical field since the 1980s, especially in surgery, such as preoperative simulation, anatomical learning and surgical training. This raises the possibility of using 3D printing to construct a neurosurgical implant. Our previous works took the construction of the burr hole ring as an example, described the process of using softwares like computer aided design (CAD), Pro/Engineer (Pro/E) and 3D printer to construct physical products. That is, a total of three steps are required, the drawing of 2D-image, the construction of 3D-image of burr hole ring, and using a 3D printer to print the physical model of burr hole ring. This protocol shows that the burr hole ring made of carbon fiber can be rapidly and accurately molded by 3D printing. It indicated that both CAD and Pro/E softwares can be used to construct the burr hole ring via integrating with the clinical imaging data and further applied 3D printing to make the individual consumables.

PLEASE DON'T STOP THE MUSIC: AUDITORY SPATIAL CUEING REDUCES NEGLECT AFTER RIGHT-HEMISPHERIC STROKE - A PROOF OF CONCEPT STUDY

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Brigitte Kaufmann[1,2,3], Paolo Bartolomeo[2], Julia Frey[1], Tobias Pflugshaupt[1], Samuel Knobel[4], Tobais Nef[4], René Müri[3,4], Thomas Nyffeler[1,3,4]
[1]Neurocenter, Luzerner Kantonsspital, Luzern, Switzerland, [2]Sorbonne Université, Institut Du Cerveau - Paris Brain Institute - Icm, Paris, France, [3]Perception and Eye Movement Laboratory, Department Of Clinical Research And Department Of Neurology, Bern, Switzerland, [4]ARTORG Center for Biomedical Engineering Research, University Of Bern, Bern, Switzerland

Neglect after stroke is a supramodal syndrome affecting not only the visual but also auditory modality. Preliminary studies used this audio-visual cross-modal effect to show short-lasting effects on attention towards the neglected space. Here we aimed to investigate the therapeutic potential of auditory stimulation combining the unspecific effect of music (i.e. listen to preferred music) with the effects of auditory spatial cueing (i.e. dynamic presentation of music as moving from right to left). The effect of this technique was investigated in two proof-of-concept experiments using repeated-measures, cross-over designs in 21 patients with visual neglect after right-hemispheric stroke. In experiment I (n=9), patients showed a significant larger improvement in Letter Cancellation after listening to preferred music *with* than *without* auditory spatial cueing. After granting its feasibility, the long-term effects of this technique were investigated in experiment II (n=12), using video-oculography, a sensitive tool to assess spatial attention over time. Listening to music *with* auditory spatial cueing –compared to *without*– significantly improved neglect in terms of free visual exploration behaviour for up to 3h. Hence, the positive effects of auditory stimulation with preferred music can be significantly enhanced and prolonged when combined with a spatial cueing component. Additional Voxel-based-lesion-symptom-mapping analysis revealed that the response variability of this effect is determined by the integrity of the IPL with its intra-and inter-hesmipheric connections (SLF_II, parieto-parietal Callosum). Finally, the patients experienced listening to music with auditory spatial cueing as pleasant. Thus, supporting the potential of this technique as an add-on in neurorehabilitative neglect therapy.

NEURAL DYNAMICS OF TASK-SWITCHING IN SENSORIMOTOR DECISION-MAKING

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Tobias Ludwig[1,2,3,4], Florian Sandhaeger[1,2,4], Anna-Antonia Pape[1,2,4], Markus Siegel[1,2,4]
[1]Centre for Integrative Neuroscience, University Of Tübingen, Tübingen, Germany, [2]MEG Center, University Of Tübingen, Tübingen, Germany, [3]Max Planck Institute for Biological Cybernetics, Computational Neuroscience, Tübingen, Germany, [4]Hertie Institute for Clinical Brain Research, Dept. Neural Dynamics And Meg, Tübingen, Germany

The ability to flexibly switch between tasks or rules is crucial for intelligent behaviour. Psychological studies show lower accuracy and longer reaction times after switching from one task to another, yet the source of these switch costs and the neural switch mechanisms remain poorly understood. We used magnetoencephalography (MEG) to resolve the neural dynamics of task-switching in human perceptual decision-making. In a visuomotor decision-making task (Pape & Siegel 2016), two task features randomly alternated or repeated from trial to trial: the order of the visual stimulus and choice-response cue ("order"), as well as the choice-response mapping itself ("mapping"). Using multivariate pattern analysis (MVPA), we found weaker neural order and mapping information after a switch. Furthermore, we found switch-specific neural signals for both types of task-switches, independent of the switch direction, about half a second after presentation of the corresponding switch cue. There was little cross-information between the different types of switches, suggesting that the switch signals are domain-dependent. Our results provide new insights into the large-scale neural dynamics underlying different types of task-switching in human sensorimotor decision-making. **References**: Pape AA and Siegel M (2016) Motor cortex activity predicts response alternation during sensorimotor decisions. ANALYSIS OF INFORMATION CODING AND EXCHANGE IN THE MULTIPLE DEMAND NETWORK USING FMRI-MEG FUSION

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Hamid Karimi-Rouzbahani[1], Anina Rich[2], Alexandra Woolgar[1]
[1]University of Cambridge, Mrc Cognition And Brain Sciences Unit, Cambridge, United Kingdom, [2]Macquarie University, School Of Psychological Sciences, Sydney, Australia

The multiple-demand network (MDN) encodes information across a variety of cognitive tasks. It is hypothesised to select and integrate information from across neural systems (Duncan et al. 2020) but evidence for the timing and potential exchange of information across the MDN is lacking. To fill this gap, we fused the time courses of information coding (from MEG) to the information contained in different MDN regions (from fMRI) using Representational Similarity Analysis. We then developed a novel fusion-based connectivity analysis to evaluate information exchange across the MDN. On each trial, one of four visual stimuli appeared (white squares on grey background; two in top-right and two in top-left hemi-fields), and participants (MEG: n=24; fMRI: n=30) had to press one of four buttons. They learned two orthogonal stimulus-button mappings (rules; indicated by fixation colour) in a training phase. We fused four aspects of information: coarse stimulus (left vs. right stimuli), fine stimulus (inner vs. outer stimuli), rule and response information. Both coarse and fine stimulus information appeared first in posterior followed by anterior regions of the MDN. Rule information appeared in the same order. Parietal MDN showed the response information immediately before the response. Connectivity analysis showed information transfer from occipital to MDN and its circulation within the MDN most dominantly for the fine stimulus information. These results provide evidence for differential timing of information processing across nodes of the MDN. The new connectivity method opens new opportunities for accurate study of information exchange with high spatial and temporal resolution.

THE INFLUENCE OF RETINAL AND REAL-WORLD SPEEDS ON SPEED PERCEPTION FOR MOTION IN DEPTH

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Yusei Yoshimura[1], Tomohiro Kizuka[2], Seiji Ono[2]
[1]University of Tsukuba, Doctoral Program In Physical Education, Health And Sport Sciences, Tsukuba, Japan, [2]University of Tsukuba, Faculty Of Health And Sport Sciences, Tsukuba, Japan

For motion in depth, retinal motion accelerates as the target approaches the observer when the target moves at a constant speed in the world. The purpose of this study was to determine whether the difference between retinal and real-world speeds affects speed perception for motion in depth. Therefore, we used a two-alternative forced-choice paradigm and implemented two experimental tasks (retinal constant and world constant tasks) to measure psychometric functions for speed discrimination. For the retinal constant task, a visual stimulus moved at a constant speed on the retina and randomly moved 4 to 8 deg (far condition), 8 to 12 deg (middle condition), and 12 to 16 deg (near condition) as vergence angle. For the world constant task, a visual stimulus moved at a constant speed in the real-world and randomly moved 80 to 60 cm (far condition), 60 to 40 cm (middle condition), and 40 to 20 cm (near condition) from the observer. The results of the retinal constant task showed that the stimulus speed was perceived faster in the order of the far, middle, and near conditions. In contrast, the results of the world constant task represented that the stimulus speed was perceived faster for the near condition than for the middle and far conditions. Therefore, our results suggest that target speed moving far to near is not always perceived depending on the retinal speed. It is also suggested that the retinal speed of motion influences the speed perception when the target position is close to the observer.

OSCILLATORY BRAIN ACTIVITY IN INFANTS DURING VISUAL ATTENTION TO DYNAMIC FACES AND OBJECTS AT THE AGE OF 11 MONTHS.

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Tanaya Batabyal[1], Anna Korczak[2], Anna Anzulewicz[1], Przemyslaw Tomalski[2]
[1]University of Warsaw, Psychology, Warsaw, Poland, [2]Institute of Psychology PAN, Psychology, Warsaw, Poland

Infants learn a lot about their social world from observing faces. Previous studies have demonstrated, attenuation of the alpha power spectral density (PSD) in the frontal, central and posterior electrodes, during sustained visual attention(Orekhova, 2001; Stroganova, 1999). Additionally, children with better inhibitory control and more mature attention shifting abilities, had higher gamma power density (PSD) functions (Benasich, 2008).Thus, this study aimed to test, replicability of these results while an infant is watching dynamic social stimuli involving rhyming faces and rotating toys on the screen. 51 typically developing infant's EEG data of 11 months-old were assessed for changes in power in the Alpha (6 to 9 Hz), Lower Gamma (21 to 30Hz) and Upper Gamma (31 to 44Hz) bands. Results showed that infants had lower alpha PSD in frontal, central and left temperoparietal electrodes ($t(50)=-3.080, p<.003, t(50)=-2.535$ $p<.014$, $t(50)=-3.862$ $p<.000$) and lower PSD in lower and upper gamma frequencies in central,occipital, left temperoparietal and right temperoparietal electrodes ($t(50)=-1.888, p<.065, t(50)=-3.175, p<.003, t(50)=-2.760. p<.008, t(50)=-2.178, p<.034$ $t(50)=-2.242$, $p=.029$, $t(50)=-3.282, p=.002$, $t(50)=-2.920, p=.005, t(50)= -2.351, p=.023$) during viewing of the dynamic actress in comparison to dynamic toys. The results imply that infants find dynamic facial movement more engaging and exhibit better attentional control to moving toys stimuli.

Our continuous visual experience in daily life is frequently interrupted by rapid changes of visual dynamics and semantics of unfolding events. Research on neural responses to change in naturalistic stimuli has focused on the individual effects of visual movement and event boundaries in film. Here we investigate the relative importance of neural responses in human intracranial recordings to rapid visual change caused by motion, scene cuts, event boundaries and eye movements. We analyzed intracranial recordings from a total of 6328 electrodes, as well as eyetracking data, from 26 patients who passively watched up to 50 minutes of videos. We extracted high-frequency broadband activity (BHA, 70-150Hz) neural responses to optic flow, saccades, and scene cuts using a system identification approach. Responses to optic flow were much weaker than responses to saccades or scene cuts and mostly localized to the occipital lobe. Responses to both saccades and scene cuts are distributed widely across the brain, beyond traditional visual processing areas. While responses to saccades are rapid (~200ms), responses to scene cuts last up to 1000 ms. Scene cuts associated with semantic event boundaries elicit stronger responses as compared to other cuts with matched low-level visual properties. They also elicited more selective responses in higher level cortical areas. In summary, we suggest that novelty in the visual input is the dominant driver of immediate neural responses, with increasing reach and duration for semantically complex novelty.

Functional connectivity of EEG is subject-specific, associated with phenotype, and different from fMRI.
A variety of psychiatric, behavioral and cognitive phenotypes have been linked to brain "functional connectivity" -- the pattern of correlation observed between different brain regions. Most commonly assessed using functional magnetic resonance imaging (fMRI), here, we investigate the connectivity-phenotype associations with functional connectivity measured with electroencephalography (EEG), using phase-coupling. We analyzed data from the publicly available Healthy Brain Network Biobank. This database compiles a growing sample of children and adolescents, currently encompassing 1657 individuals. Among a variety of assessment instruments we focus on ten phenotypic and additional demographic measures that capture most of the variance in this sample. The largest effect sizes are found for age and sex for both fMRI and EEG. We replicate previous findings of an association of Intelligence Quotient (IQ) and Attention Deficit Hyperactivity Disorder (ADHD) with the pattern of fMRI functional connectivity. We also find an association with socioeconomic status, anxiety and the Child Behavior Checklist Score. For EEG we find a significant connectivity-phenotype relationship with IQ. The actual spatial patterns of functional connectivity are quite different between fMRI and source-space EEG. However, within EEG we observe clusters of functional connectivity that are consistent across frequency bands. Additionally we analyzed reproducibility of functional connectivity. We compare connectivity obtained with different tasks, including resting state, a video and a visual flicker task. For both EEG and fMRI the variation between tasks was smaller than the variability observed between subjects. We also found an increase of reliability with increasing frequency of the EEG, and increased sampling duration. We conclude that, while the patterns of functional connectivity are distinct between fMRI and phase-coupling of EEG, they are nonetheless similar in their robustness to the task, and similar in that idiosyncratic patterns of connectivity predict individual phenotypes. THE NEXT TRIAL WILL BE CONFLICTING! EEG SIGNATURES OF PROACTIVE CONTROL IN THE FLANKER TASK.

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Dariusz Asanowicz, Ilona Kotlewska, Bartłomiej Panek
Jagiellonian University, Institute Of Psychology, Krakow, Poland

Aims. The study was set to investigate the neural basis of proactive adjustments of executive control, and their modulatory effects on online processing of response conflict. **Methods.** In two experiments, participants (N 59) performed the flanker task in with conflict trials were signaled by predictive cues. The electroencephalogram (EEG) was recorded in both experiments. **Results and Conclusions.** The following questions were addressed: *Does conflict-cueing improve performance?* We observed improved behavioral performance in the predictive condition, suggesting that participants proactively utilized the cues to prepare for the upcoming demands. *How is conflict processing affected by predictive cueing?* Conflict-related modulations of midfrontal N2, theta power, and theta phase synchrony were smaller in the predictive than in the neutral condition. This suggests that proactive control suppressed the impact of incongruent flankers, so that the conflict was reduced, and so was the online control involvement. *Is proactive control implemented through pre-activation of online control?* Conflict-cueing also increased midfrontal theta power and connectivity before target onset, suggesting pre-activation of the control processes beforehand. *Do proactive and reactive control depend on common or unique processes?* Unlike the online control, the proactive control triggered a burst of theta power in the right hemisphere's dorsal and ventral lateral prefrontal cortices. In other words, two separate components of frontal theta power were observed during the proactive adjustments of control. This indicates that the two modes of control involve partially unique neural processes.

THE PROBABILISTIC INTEGRATION OF SOMATOSENSORY INFORMATION INTO THE MOTOR RESPONSE USING EEG AS BIOMARKER IN PSYCHOSIS

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Anaelle Alouit[1], Anton Iftimovici[1,2], Macarena Cuenca[1,3], Céline Ramdani[4], Martine Gavaret[1,2], Marie-Odile Krebs[1,2], Pâvel Lindberg[1], Lucile Dupin[1]
[1]INSERM U1266 - Université de Paris, Institute Of Psychiatry And Neuroscience Of Paris, Paris, France, [2]GHU Paris Psychiatrie & Neurosciences, Hôpital Sainte-anne, Paris, France, [3]Centre de Recherche Clinique, Hôpital Sainte-anne, Paris, France, [4]Service de Santé des Armées, Institut De Recherche Biomédicale Des Armées, Brétigny-sur-Orge, France

People with a first episode of psychosis may show cognitive deficits, sensorimotor impairments, and neurological soft signs. In schizophrenia, an imbalance in cortical excitation / inhibition has been shown to be related to sensorimotor and attentional deficits. Since motor actions are facilitated by somatosensory information and attention, we hypothesized that altered motor response in psychosis could be due to impaired processing and integration of somatosensory information. The overall goal of this study is to identify brain biomarkers of psychosis, in order to provide early predictive markers on the risk of developing psychiatric pathology, such as schizophrenia. Specifically, we aim to study (i) the modulation of cortical excitability and inhibition, (ii) the temporal and spatial dynamics of sensorimotor integration, and (iii) to correlate the cortical processing to the prodromal clinical symptoms. To do so, we developed a visuo-haptic attentional task where the participant is instructed to press one key or another with left or right hand, based on a visual signal preceded by a spatially congruent or incongruent tactile cue, in order to modulate spatial attention in a varying probabilistic context. Our method utilizes 64-channel electroencephalography, and is based on the recording and analysis of the somatosensory evoked potentials. This technique allows us to measure primary somatosensory cortex activity, related alpha and beta oscillations known to quantify cortical excitability and attentional adaptation. The preliminary data indicate that our protocol can measure spatial attention modulation, and shows how the integration of somatosensation, as an attentional cue, influences behavioral and neurophysiological measures.

AIMS: Body recognition is a fundamental survival skill for many social animals. Several body-selective regions have already been identified in both humans and nonhuman primates. However, there is no comprehensive comparison of the species selectivity or of the network organization of those body patches. The present 7T fMRI study investigated the neural correlates of dynamic human and monkey bodies and faces in human participants. METHODS: The study used a block design with videos of dynamic faces, bodies, and objects from both monkey and human recording. Scramble stimuli were created for systematic control of low-level features. Univariate analysis and ICA-based network analysis were conducted in parallel to find body/species modulations at both voxel and network levels. RESULTS: Widely distributed body patches were found by univariate analysis including extrastriate body area (EBA), superior temporal sulcus (STS), medial frontal gyrus (MFG), temporoparietal junction (TPJ), amygdala, etc. Among the body patches, the highest species-selectivity was found in MFG and amygdala. Two networks, with major involvement of lateral occipital cortex and right STS respectively, were found sensitive to human bodies. The rSTS network showed higher species selectivity for bodies than for faces, and within the network, significant human-body-induced connectivity was found around EBA, TPJ, and inferior frontal gyrus (IFG). CONCLUSION: By using dynamic stimuli and multiple analysis methodologies, we found widely distributed body patches covered by two large-scale cortical networks. Furthermore, the results suggested that the network connectivity of EBA, TPJ, and IFG may play an important role in human body perception.

SPATIAL AND FEATURE-SELECTIVE ATTENTION INTERACT MULTIPLICATIVELY IN MULTIPLE-DEMAND NETWORK

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Nadene Dermody[1], Romy Lorenz[1,2], Alexandra Woolgar[1]
[1]University of Cambridge, Mrc Cognition And Brain Sciences Unit, Cambridge, United Kingdom, [2]Max Planck Institute for Human Cognitive and Brain Sciences, Department Of Neurophysics, Leipzig, Germany

Aim: Distinct neural effects are associated with attention deployed to a location (spatial attention) or to a particular object feature (feature attention), but it is less clear how these types of attention interact to affect information processing. To examine this, we compared the effects of spatial and feature attention on stimulus representations within a frontoparietal "multiple-demand" (MD) network posited to play a critical role in attentional control. **Method:** Participants (N=30, 16 female, 14 male, mean age=27.2) underwent fMRI while they covertly attended to one of two objects, presented left and right of a fixation cross (spatial attention manipulation), and reported the attended object's colour ("red" or "green") or shape ("X-shaped" or "flat") (feature attention manipulation) via button press (Fig1, Panel A). We used multivariate pattern analysis to measure coding of attended and unattended stimulus information. **Results:** We found a significant multiplicative interaction between spatial and feature attention in MD ($F_{(1,30)}$=69.924, p<.001) and visual cortices ($F_{(1,30)}$=17.304, p<.001). Moreover, stimulus decoding was only above chance for the attended feature of the attended object (BF_{10}>100)(Fig1, Panel B). We additionally found these task-relevant representations were organised along two major dimensions, reflecting physical stimulus properties and task
difficulty.

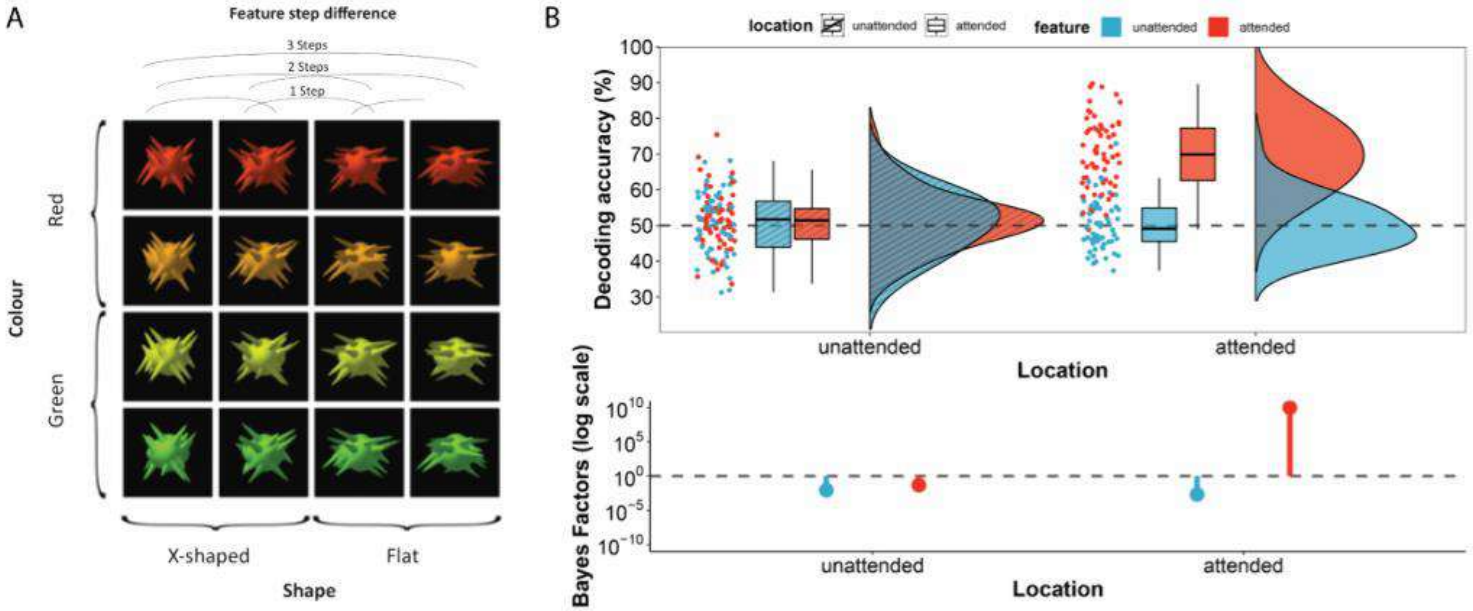

Fig 1. **Panel A:** Visual stimuli used in the experiment, adapted from Goddard et al (*J Cog Neurosci*, 2022) . Each object varied across two dimensions, colour and shape. In the colour task, participants categorised the attended object as either "red" or "green". In the shape task, participants categorised the attended object as either "X-shaped" or "flat", based on the orientations of the object's spikes. For each colour and shape, objects were either close or far from the decision boundary (e.g., "weakly red" and "strongly red", respectively) making some discriminations easier than others. Feature step size difference for decoding is shown for shape, with those one step apart reflecting a "small" discrimination, two steps "medium", and three steps "large". **Panel B:** Average decoding accuracy for unattended and attended feature information for the object at the attended or unattended location, averaged across MD ROIs. Decoding accuracy here reflects average accuracy in decoding colour or shape information in the object that was in the attended (solid colour) or unattended (lined colour) location, when the feature in question was attended (red) or unattended (blue). Scatter at left depicts decoding accuracy for each participant for the given condition. Boxplots indicate median decoding accuracy, first and third quartiles, and largest and smallest decoding accuracy value. Half violin plots indicate data distribution. The strength of evidence for above chance (H1) or at chance (H0) decoding was tested using Bayesian t-tests and is shown here as Bayes Factors for each of these conditions on a logarithmic scale.

Conclusion: Our results suggest spatial and feature attention interact multiplicatively, selectively enhancing coding of the attended feature of the attended object. Rather than boosting processing of whole objects or relevant features across space, selective attention in the MD system – at least in this difficult perceptual task – appears to reflect all-or-nothing tuning to behaviourally relevant information.

ANODAL TRANSCRANIAL DIRECT CURRENT STIMULATION TARGETING TEMPOROPARIETAL JUNCTION INCREASES SUSTAINED ATTENTION AND VISUOMOTOR ABILITIES VIA EMBODIMENT MODULATION.

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Valentina Cesari, Danilo Menicucci, Sergio Frumento, Graziella Orrù, Angelo Gemignani
University of Pisa, Department Of Surgical, Medical And Molecular Pathology And Critical Care Medicine, Pisa, Italy

AIMS The sense of embodiment allows to experience non-bodily objects as part of the body (ownership), to feel the author of observed actions (agency), and to know the positioning of the body in space (location). The aim of this study was to investigate the effect of the modulation of the embodiment on cognitive performance, as previous works scarcely investigated the relationship between them. **METHODS** We modulated the sense of embodiment during a sustained attention driving task in virtual reality *via* anodal transcranial direct current stimulation (tDCS) targeting temporo-parietal junction (a pivotal area in bodily self-processing) using within-subject design with sham-controlled stimulation. Twenty-four healthy volunteers underwent two randomized and balanced sessions. Changes in sustained attentional performance were evaluated by studying the series of visuomotor adjustments during the task; the components of the embodiment were assessed using psychometric questionnaires. Also, correlations between variations from active to sham of task indices with those of the embodiment were computed. **RESULTS** After anodal tDCS, participants showed greater accuracy, less attentional lapses, and higher long-range correlations of the series of visuomotor adjustments during task, and these results paralleled with greater sense of agency, location, and total embodiment. Correlations between variations in task indices and changes in embodiment indices showed that greater agency and total embodiment were associated with less attentional lapses. **CONCLUSIONS** Embodiment might positively affect attentional and dexterous performance; this relationship might be explained by greater confidence toward the non-bodily objects that could facilitate the attentional and visuomotor control over the task.

DECODING THE NEURAL CORRELATES OF MUSICAL PREDICTIONS WITH DEEP LEARNING

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Mathieu Pham Van Cang, Keith Doelling, Luc Arnal
Institut de l'Audition, Institut Pasteur, Paris, France

Our acoustic environment is full of statistical regularities. According to the predictive coding (PC) theory, the human brain uses such predictable features to generate expectations about future stimuli to optimize perception. Music is a complex naturalistic stimulus containing rhythmic and harmonic regularities and constitutes an ideal framework for studying the neural underpinnings of PC. To study neural correlates of temporal predictions in music listening, we capitalize on deep learning models to extract relevant features of predictive processing. We collected magnetoencephalography (MEG) data on 27 normal-hearing subjects listening to piano performances repeated throughout the experiment. We then assessed the same musical pieces in terms of continuous predictive features, namely surprisal and entropy. Those mathematical quantities were estimated by a recurrent neural network originally designed to generate piano performances. This model is particularly promising as compared with methods commonly used in the field: (i) it relies on minimal prior musical knowledge and (ii) it efficiently works on polyphonic music. Validating this approach on behavioral data confirms that this model efficiently predicts continuous human surprisal ratings to the same music. Using a temporal response function – a linear model mapping the continuous stimulus features to the MEG data – we quantify the relative influence of exogenous (stimulus driven) and endogenous (prediction driven) neural signals underlying processing of musical sequences. Finally, comparing the signatures of ongoing (probabilistic) versus memory-based (experiential) expectations, we distinguish two categories of commonly confounded priors to further delineate the spatial and spectrotemporal architecture of predictive processing in the human brain.

LET'S FACE IT: LATERALIZATION OF THE FACE PERCEPTION NETWORK IS CHARACTERIZED BY LARGE INTERINDIVIDUAL VARIABILITY AND NOT BY A CLEAR RIGHT HEMISPHERIC DOMINANCE

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Ina Thome[1], Jannika Volk[1], José García Alanis[2], Christoph Vogelbacher[1], Olaf Streinsträter[1], Andreas Jansen[1]
[1]University of Marburg, Psychiatry, Marburg, Germany, [2]Johannes-Gutenberg University Mainz, Psychology, Mainz, Germany

Aims: In face perception research, the dominant role is almost unanimously attributed to the right hemisphere. However, large scale functional magnetic resonance imaging (fMRI) studies that systematically assess hemispheric lateralization in the core system of face perception are missing. Thus, we aimed to thoroughly investigate hemispheric lateralization in the core system in a large cohort, decribing the distribution of lateralization results across subjects and analyzing effects of area, handedness, and sex. **Methods:** 108 healthy subjects (23 left-handers) were included in an fMRI study. Lateralization was assessed with a lateralization index (LI) that compares the brain activation strength between homologous brain areas in the left and right hemisphere. Effects of brain area, handedness, and sex were tested with a generalized linear mixed effects regression model. **Results:** We found no main effect of area, sex, or handedness and no significant interactions. In contrast to our expectations, there was no clear right-hemispheric dominance, neither on the single subject level nor on the group-level. On the contrary, our results clearly show substantial variability between subjects. LIs ranged from strong left to strong right dominance. Only approximately 50% of subjects could be classified as right dominant. **Conclusion:** Strictly speaking, we do not question the dominance of the right hemisphere per se. However – based on fMRI activations patterns – it might be more suitable to describe the face perception network as "bilateral with a slight tendency towards right-dominance at the group level and a large interindividual variability".

Developmental changes within the extended face processing network: A cross-sectional functional magnetic resonance imaging study.
In the field of face processing, the so-called "core network" has been intensively researched. Its neural activity can be reliably detected in children and adults using functional magnetic resonance imaging (fMRI). However, the core network's counterpart, the so-called "extended network," has been less researched. In the present study, we compared children's and adults' brain activity in the extended system, in particular in the amygdala, the insula, and the inferior frontal gyrus (IFG). Using fMRI, we compared the brain activation pattern between children aged 7-9 years and adults during an emotional face processing task. On the one hand, children showed increased activity in the extended face processing system in relation to adults, particularly in the left amygdala, the right insula, and the left IFG. On the other hand, lateralization indices revealed a "leftward bias" in children's IFG compared to adults. These results suggest that brain activity associated with face processing is characterized by a developmental decrease in activity. They further show that the development is associated with a rightward migration of face-related IFG activation, possibly due to the competition for neural space between several developing brain functions ("developmental competition hypothesis").

"I Spy with my Little Eye, Something that is a Face…": A Brain Network for Illusory Face Detection.
The most basic aspect of face perception is simply detecting the presence of a face, which requires the extraction of features that it has in common with other faces. Putatively, it is caused by matching high-dimensional sensory input with internal face templates, achieved through a top-down mediated coupling between prefrontal regions and brain areas in the occipito-temporal cortex ("core system of face perception"). Illusory face detection tasks can be used to study these top-down influences. In the present functional magnetic resonance imaging study, we showed that illusory face perception activated just as real faces the core system, albeit with atypical left-lateralization of the occipital face area. The core system was coupled with two distinct brain regions in the lateral prefrontal (inferior frontal gyrus, IFG) and orbitofrontal cortex (OFC). A dynamic causal modeling (DCM) analysis revealed that activity in the core system during illusory face detection was upregulated by a modulatory face-specific influence of the IFG, not as previously assumed by the OFC. Based on these

findings, we were able to develop the most comprehensive neuroanatomical framework of illusory face detection until now.

The Trajectory of Hemispheric Lateralization in the Core System of Face Processing: A Cross-Sectional Functional Magnetic Resonance Imaging Pilot Study.
Face processing is mediated by a distributed neural network commonly divided into a "core system" and an "extended system." The core system consists of several, typically right-lateralized brain regions in the occipito-temporal cortex, including the occipital face area (OFA), the fusiform face area (FFA) and the posterior superior temporal sulcus (pSTS). It was recently proposed that the face processing network is initially bilateral and becomes right-specialized in the course of the development of reading abilities due to the competition between language-related regions in the left occipito-temporal cortex (e.g., the visual word form area, VWFA) and the FFA for common neural resources. In the present pilot study, we assessed the neural face processing network in 12 children (aged 7-9 years) and 10 adults with functional magnetic resonance imaging (fMRI). The hemispheric lateralization of the core face regions was compared between both groups. The study had two goals: First, we aimed to establish an fMRI paradigm suitable for assessing activation in the core system of face processing in young children at the single subject level. Second, we planned to collect data for a power analysis to calculate the necessary group size for a large-scale cross-sectional imaging study assessing the ontogenetic development of the lateralization of the face processing network, with focus on the FFA. It was possible to detect brain activity in the core system of 75% of children at the single subject level. The average scan-to-scan motion of the included children was comparable to adults, ruling out that potential activation differences between groups are caused by unequal motion artifacts. Hemispheric lateralization of the FFA was 0.07 ± 0.48 in children (indicating bilateral activation) and -0.32 ± 0.52 in adults (indicating right-hemispheric dominance). These results thus showed, as expected, a trend for increased lateralization in adults. The estimated effect size for the FFA lateralization difference was = 0.78 (indicating medium to large effects). An adequately powered follow-up study (sensitivity 0.8) testing developmental changes of FFA lateralization would therefore require the inclusion of 18 children and 26 adults.

Neoplastic Cells are the Major Source of MT-MMPs in -Mutant Glioma, Thus Enhancing Tumor-Cell Intrinsic Brain Infiltration.
Tumor-cell infiltration is a major obstacle to successful therapy for brain tumors. Membrane-type matrix metalloproteinases (MT-MMPs), a metzincin subfamily of six proteases, are important mediators of infiltration. The cellular source of MT-MMPs and their role in glioma biology, however, remain controversial. Thus, we comprehensively analyzed the expression of MT-MMPs in primary brain tumors. All MT-MMPs were differentially expressed in primary brain tumors. In diffuse gliomas, MT-MMP1, -3, and -4 were predominantly expressed by IDH1 tumor cells, while macrophages/microglia contributed significantly less to MT-MMP expression. For functional analyses, individual MT-MMPs were expressed in primary mouse p53 astrocytes. Invasion and migration potential of MT-MMP-transduced astrocytes was determined via scratch, matrigel invasion, and novel organotypic porcine spinal slice migration (OPoSSM) and invasion assays. Overall, MT-MMP-transduced astrocytes showed enhanced migration compared to controls. MMP14 was the strongest mediator of migration in scratch assays. However, in the OPoSSM assays, the glycosylphosphatidylinositol (GPI)-anchored MT-MMPs MMP17 and MMP25, not MMP14, mediated the highest infiltration rates of astrocytes. Our data unequivocally demonstrate for the first time that glioma cells, not microglia, are the predominant producers of MT-MMPs in glioma and can act as potent mediators of tumor-cell infiltration into CNS tissue. These proteases are therefore promising targets for therapeutic interventions.

Illusory face detection in pure noise images: The role of interindividual variability in fMRI activation patterns.
Illusory face detection tasks can be used to study the neural correlates of top-down influences on face perception. In a typical functional magnetic resonance imaging (fMRI) study design, subjects are presented with pure noise images, but are told that half of the stimuli contain a face. The illusory face perception network is assessed by comparing blood oxygenation level dependent (BOLD) responses to images in which a face has been detected against BOLD activity related to images in which no face has been detected. In the present study, we highlight the existence of strong interindividual differences of BOLD activation patterns associated with illusory face perception. In the core system of face perception, 4 of 9 subjects had highly significant ($p<0.05$, corrected for multiple comparisons) activity in the bilateral occipital face area (OFA) and fusiform face area (FFA). In contrast, 5 of 9 subjects did not show any activity in these regions, even at statistical thresholds as liberal as $p = 0.05$, uncorrected. At the group level, this variability is reflected by non-significant activity in all regions of the core system. We argue that these differences might be related to individual differences in task execution: only some participants really detected faces in the noise images, while the other subjects simply responded in the desired way. This has several

implications for future studies on illusory face detection. First, future studies should not only analyze results at the group level, but also for single subjects. Second, subjects should be explicitly queried after the fMRI experiment about whether they really detected faces or not. Third, if possible, not only the overt response of the subject, but also additional parameters that might indicate the perception of a noise stimulus as face should be collected (e.g., behavioral classification images).

ALPHA POWER IS COUPLED TO THE INFRA-SLOW GASTRIC RHYTHM IN DIFFERENT VISUAL TASKS

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Janina Hüer[1,2], Nicolai Wolpert[1], Catherine Tallon-Baudry[1]
[1]Laboratoire de Neurosciences Cognitives et Computationelles, Inserm, Ecole Normale Supérieure, Université Psl, Paris, France, [2]Ernst Strüngmann Institute (ESI) for Neuroscience, In Cooperation With Max Planck Society, Frankfurt, Germany

Rhythmic bodily signals influence cortical activity as well as perception in animals and humans. In addition to influences from cardiac and respiration cycles, the infra-slow gastric rhythm (0.05 Hz) has recently been shown to be coupled to brain activity in humans. Alpha power in occipitoparietal areas and the insula, as well as BOLD activity in a large network cutting across classical resting-state networks, are coupled to the phase of the gastric rhythm. So far, the coupling has only been investigated during resting-state. Does gastric-brain coupling also occur when participants are engaged in a task? Here, we address this issue in two experiments where participants were either passively presented with different natural images or were performing a visual perceptual task at threshold. We measured the gastric basal rhythm using electrogastrography and brain activity with magnetoencephalography and analyzed gastric-alpha coupling during fixation. We find that alpha rhythm power was significantly coupled to the phase of the gastric rhythm in both experiments. Source analysis and parcellation into resting state networks revealed that coupling consistently occurred within the default and visual network, while differences between the experiments appeared for the somatomotor network. Our results show that alpha power is coupled to the gastric rhythm while participants are engaged in a more active behaviour, which opens the possibility that gastric-alpha coupling plays a functional role.

EFFORT AND ATTENTION MEASUREMENT IN NATURAL SPEECH PERCEPTION USING EEG AND PUPILLOMETRY

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Ivan Iotzov, Lucas Parra
City College of New York, Biomedical Engineering, New York, United States of America

Aims: This study aims to demonstrate a novel paradigm for measuring speech intelligibility for subjects in adverse listening conditions. Additionally, we use a combination of EEG and pupillometry to measure the subject's attention and effort levels in various listening conditions. These are compared among conditions in order to show a contrast between effort and attention in naturalistic listening tasks. **Methods**: Subjects are asked to listen to narrative speech in a variety of noisy listening conditions while responding with button presses if certain target words are heard. This method allows for granular measurement of behavioral performance which is then compared with biometric signals. Inter-subject correlation (ISC) of brain signals and pupillometry provide objective measures of subject effort and attention. **Results**: We find that performance on the behavioral task is linked with ISC of both pupil and neural signals. Surprisingly, we find that most subjects showed overall pupillary contraction in more adverse listening conditions. Additionally, we find a pupillary dilation present when target words are detected that is mirrored in EEG responses, but not present when the subject does not recognize the target. **Conclusions**: We show a relationship between effort and attention during a naturalistic listening task using pupillometric and EEG signals. Both of these signals are predictive of subject performance on a word-identification listening task. We also demonstrate cases in various listening conditions where effort and attention are modulated differently from one another.

IS THERE A LINK BETWEEN RHYTHMIC AND ATTENTIONAL ABILITIES?

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Anaïs Desbernats[1], Mélodie Matrat[1,2], Mélanie Jucla[2], Jessica Tallet[1]
[1]ToNIC, Toulouse NeuroImaging Center, Université de Toulouse, Inserm, Ups, Toulouse, France, [2]Laboratoire de NeuroPsychoLinguistique, EA 4156 (LNPL), Université de Toulouse, Ut2j, Toulouse, France

Aims. Sensorimotor synchronization (SMS) is a natural healthy human skill and is particularly accurate and stable with auditory or audio-visual compared to visual rhythmic stimuli. However, inter-individual differences exist in rhythmic abilities, probably due to the intervention of cognitive functions such as attention. In the present study, we aimed to test the link between attentional capacities of participants and their rhythmic abilities measured by SMS to rhythmic auditory, visual and audio-visual stimuli. **Methods.** To date, sixteen right-handed participants (age 23,8 ± 2 years) performed a SMS task by tapping on a button with their right thumb in synchrony with stimuli delivered in 4 Modalities (Congruent Audio-Visual CAV, Auditory A, Visual V, Incongruent Audio-Visual IAV) presented in a pseudo-random order. Using circular analyses, we computed the mean angle (θ) and length (L) of the resultant vector for each Modality. We also collected the median reaction time and its standard deviation during auditory, visual and audio-visual attentional tasks. Correlations will be performed between each variable of the SMS and attentional tasks for each Modality. Significance level will be corrected for multiple comparisons. **Results.** We expect that SMS to rhythmic A, V and CAV stimuli will be respectively correlated with auditory, visual and audio-visual attentional variables. Results are being processed to verify these assumptions. **Conclusion.** Results will provide a better understanding of the modality-specific link between rhythmic and attentional abilities. Behavioral results will be completed by electroencephalographic analyses related to attentional level during SMS (alpha frequency band over parietal regions).

SYNCHRONIZATION OF PUPIL SIZE DURING AUDITORY NARRATIVES PREDICTS MEMORY

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Jens Madsen, Lucas Parra
City College of New York, Biomedical Engineering, New York, United States of America

The pupil of the eye is said to be the window into the human mind. Yet a great number of factors influence the size of the pupil. The luminance changes in our field of view, sudden changes in our environment or cognitive effort during task solving among others. In past research we have found the pupil size to synchronize between people when they watch short audiovisual stimuli. However to which extent this is cognitive processing of the stimuli or simply the luminance fluctuations in the video that is causing this synchronization is largely unknown. In this study we show that pupil size synchronizes between people when they listen to auditory narratives. This intersubject correlation (ISC) is modulated by attention on a time scale of 5-10 seconds and it is predictive of memory performance across subjects. One might expect that the modulation by attention is due to a change in the brain-pupil coupling, however we don't find the coupling between EEG and pupils to depend on attentional state. We therefore investigate which features of the auditory narratives are predictive of the pupil size. Surprisingly we find pupil size is correlated with the envelope of the speech signal at slow time scales, and the strength of that correlation depends on whether subjects are paying attention. We show that the pupil is responsive to word onset and semantic novelty in auditory narratives. This work opens up the possibility to track attention to speech and its semantics just by looking at the eyes.

ANATOMICAL CHARACTERIZATION OF THE FRONTAL VOICE AREAS BASED ON THE INDIVIDUAL SULCAL ANATOMY

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Melina Cordeau[1], Ihsane Bichoutar[1], David Meunier[1], Guillaume Auzias[1], Olivier Coulon[1,2], Isaure Michaud[1], Kep-Kee Loh[1,2], Pascal Belin[1,2]

In communication, two aspects are very important to maintain a conversation: voice production and voice perception. In voice perception, vocal stimuli carry a wealth of information on the interlocutor: age, gender, identity, mood, etc. The existence of a specialized voice processing cortical network has been well established in humans using fMRI: in particular, the “Temporal Voice Areas” (TVAs, Belin et al., 2000; Pernet et al., 2015) are organized bilaterally in three clusters arranged along the anterior, middle and posterior parts of the superior temporal sulcus and gyrus (STS/STG). More recently, voice selective regions have also been found in the frontal lobe (Aglieri et al., 2018). A group analysis led to the characterization of three bilateral clusters in the frontal lobe: the anterior, middle and posterior "Frontal Voice Areas" (a, m and pFVAs). Here we perform an anatomo-functional characterization of the FVAs based on individual sulcal anatomy: voice-selective regions were identified as those showing a significantly greater activity for vocal versus non-vocal sounds. For each subject, functional peaks were identified in volume space, and then visualised on the cortical surface mesh, in order to characterize their individual anatomical locations, and to compare them across individuals. We found that FVAs at the individual level could be identified bilaterally in a large proportion of individuals, although with a variable number of peaks. Importantly, despite substantial variations in their cortical locations across participants, the closest sulci to the six FVAs remained largely consistent across individuals, revealing critical sulci-function links for FVAs localisations in the human brain.

FMRI ATTENTION-BASED NEUROFEEDBACK CORRELATES WITH SPECIFIC CHANGES IN ATTENTIONAL BEHAVIOURAL PERFORMANCE AND ATTENTIONAL BRAIN FUNCTIONS

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Célia Loriette[1], Souhir Dali[1], Carine De Sousa Ferreira[1], Franck Lamberton[2], Danielle Ibarrola[2], Suliann Ben Hamed[1]
[1]UMR5229 Institut des sciences cognitives Marc Jeannerod, Neural Bases Of Spatial Cognition And Action, BRON CEDEX, France, [2]CERMEP, Imagerie Du Vivant, Bron, France

Neurofeedback aims at training targeted brain functions, by converting ongoing brain activity in selected brain regions into a sensory feedback to help subjects learn regulate their brain activity. Although neurofeedback is emerging as an important cognitive training tool offering a non-pharmacological solution to brain disorders, this effort has still not translated into clear advances in clinical brain-based attention training protocols. In this study, we deploy a functional magnetic resonance imaging (fMRI) real-time neurofeedback protocol to enhance covert spatial attention in healthy participants by directly showing them, on every trial, how informative was their brain signal in response to a cued instruction. We show that neurofeedback triggers participant dependent behavioral changes as well as specific changes in the spatial attentional cortical network. The reported behavioral effects are not specifically linked to the task used during the neurofeedback but also reflect onto a range of other attentional tasks, indicating a potential for generalization. Brain changes in the main task manifest as an enhanced fronto-parietal top-down attentional control associated with a functional reorganization of the occipital cortex. Mirroring this effect, we identify, after cognitive training, in resting state data, specific brain plasticity changes characterized by a perduring functional disconnection between the fronto-parietal and the visual network. Overall, these results indicate that neurofeedback re-organizes the balance between top-down and bottom-up attentional control and can thus become an efficient non-invasive tool to enhance spatial attention and mitigate specific attention deficits such as observed in Attention Deficit and Hyperactivity Disorder patients.

Nencki Institute of Experimental Biology, Polish Academy of Sciences, Laboratory Of Neuropsychology, Warsaw, Poland

Abstract Temporal Information Processing (TIP) constitutes an essential component of human cognition because many cognitive functions like language, attention, memory, motor control, planning, etc. are characterized by the specific temporal dynamics. Because the *theta* band activity has been suggested to be involved in processes of cognitive control, we tested if it is also related to individual differences in TIP. The main goal of this study was to find electrophysiological markers of TIP efficiency in resting EEG. Thirty seven young healthy participants (M_{age} = 25 years) completed: (1) Temporal-Order Judgement task (TOJ) which measured the efficiency of TIP on the millisecond level, and (2) EEG resting state procedure. The Fast Fourier Transform was used for assessment of frontal and central *theta* spectral amplitudes from 2-s epochs. To analyse the relationship between resting *theta* activity and TOJ efficiency, Pearson's correlation analyses were performed. These analyses showed positive moderate significant correlations between the indices of TOJ and resting *theta* both frontal ($r = .345$, $p = .037$), and central activity ($r = .332$, $p = .039$). These results showed that more efficient millisecound timing is associated with lower both frontal and central *theta* power. This suggests that the *theta* rhythm may be a good electrophysiological marker of TIP efficiency. Such new knowledge may provide more insights into the dynamic flow of information in our brains, as well as to relationship '*time-cognition'*. IMPLICIT AND EXPLICIT TIMING – DO THEY SHARE A REPRESENTATION OF TIME?

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Sophie Herbst[1], Jonas Obleser[2,3], Virginie Van Wassenhove[1]
[1]NeuroSpin Center, CEA/DRF/Joliot, Université Paris-Saclay, Inserm Cognitive Neuroimaging Unit, Gif sur Yvette, France, [2]University of Lübeck, Department Of Psychology, Lübeck, Germany, [3]University of Lübeck, Center Of Brain, Behavior, And Metabolism, Lübeck, Germany

Human observers efficiently extract temporal regularities from sensory environments to form implicit temporal predictions. Also, time provides the structure to our conscious experience, for instance as the perceived duration between two events. Thus, time is implicit and essential for cognition, but also explicit, i.e. consciously represented. Here, we asked whether implicit and explicit timing rely on shared vs. separate mechanisms, using an auditory foreperiod paradigm in a magnetoencephalography experiment. Implicit temporal predictability was induced by a manipulation of the foreperiod. Participants received two consecutive task instructions: discriminate pitch (indirect measure of implicit timing) or duration (direct measure of explicit timing). The results show that the human brain uses the implicit temporal statistics of sensory environments, to enhance the behavioral and neural responses to auditory stimuli. Surprisingly however, temporal predictability did not improve explicit timing. In both tasks, attentional orienting in time during predictive foreperiods was indexed by an increase in alpha power over visual and parietal areas. Furthermore, pre-target induced beta power in sensorimotor and parietal areas increased during implicit compared to explicit timing, in line with the suggested role for beta oscillations in temporal prediction. Yet, no distinct neural dynamics emerged when participants explicitly paid attention to time. In conclusion, these results show that implicit timing automatically shapes behavior and sensory processing, and is reflected in oscillatory responses, but does not necessarily translate to explicit duration judgements.

DOES TEMPORAL PREDICTABILITY ENHANCE AUDITORY TEMPORAL RESOLUTION ? BEHAVIORAL RESULTS FROM A GAP DETECTION PARADIGM

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Valentine Mandin, Virginie Van Wassenhove, Sophie Herbst
Cognitive Neuroimaging Unit, Inserm, Cea, Cnrs, Université Paris-saclay, Neurospin Center, Gif-sur-Yvette, France

Perception takes advantage of the dynamic structure of our sensory environment. Temporal predictions of "when" an event will occur are built from temporal regularities, and used to orient attention in time. These temporal predictions improve motor responses to, and perceptual processing of, predicted inputs. Here, we studied whether the perceptual benefits from temporal predictions can be explained by an enhanced temporal resolution of the sensory system. Studies in the visual modality indeed showed that temporal resolution was improved by non-rhythmic temporal predictions, constructed from a predictive time interval separating two discrete events. To extend this finding to the auditory literature, we built a behavioral experiment where we coupled a gap detection task, assessing temporal resolution, and a foreperiod paradigm, inducing non-rhythmic temporal predictions. 26 healthy adult human participants were behaviorally tested on a 2-alternative-forced-choice version of the gap detection task. We measured performance for varying gap durations by means of psychometric curves. To induce temporal predictability, we kept the foreperiod intervals between the onset of the stimulus and the gap constant in half of the blocks. In the other blocks, the foreperiod intervals were randomly assigned. Our analyses showed that temporal predictions did not improve the performance in the gap detection task. However, response time improvements did indicate the use of temporal predictions, and suggested a possible decrease of decision times by temporal predictability. Hence, non-rhythmic temporal predictions did not benefit auditory temporal resolution as we operationalized it. Further research is needed to assess the generality of these findings.

SELECTIVE ATTENTION AND ADAPTATION IN AN AUDIO-VISUAL TEMPORAL ORDER JUDGMENT TASK

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Harish Gunasekaran, Virginie Van Wassenhove
Cognitive Neuroimaging Unit, INSERM, CEA, CNRS, Université Paris-Saclay, Neurospin Center, Gif-sur-Yvette, France

The encoding of event timing in the brain is crucial to build a coherent and unified representation of the external world. While audio-visual events can be perceived as 'one' coherent event, differences in the speeds of light and sound, local transduction and coding circuitry delays, and selective attention contribute to temporal delays that can be captured by asking participants to estimate the temporal order of sensory events. We know that the repeated exposures of a participant to a pair of desynchronized audio-visual stimuli shift individuals' simultaneity towards the exposed delay e.g. adaptation with a sound followed by a visual event will shift perceived simultaneity towards the sound. In this study, we asked whether such temporal recalibration is valid if the exposed delay is re-referenced to the individual's subjective simultaneity. Second, we tested whether selective attention impacted the direction of the shift. We conducted a behavioral experiment (N = 32) using temporal order judgment and lag-adaptation paradigms. Results did not replicate the literature and an additional experiment will be reported.

NEUROCOGNITIVE EVIDENCE OF ENHANCED IMPLICIT TEMPORAL PROCESSING IN VIDEO GAME PLAYERS

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Francois Foerster[1], Matthieu Chidharom[2], Anne Bonnefond[1], Anne Giersch[1]
[1]INSERM U1114, Psychiatry Hospital Of Strasbourg, Strasbourg, France, [2]Lehigh University, Psychology Department, Bethlehem, United States of America

Winning in action video games requires to predict timed events in order to react fast enough. In these games, the temporal structure of events is repetitive enough to develop implicit (automatic) preparation mechanisms. We compared action video game players (VGPs) and non-VGPs in a reaction time task involving both implicit time preparations and explicit (conscious) temporal attention cues. Participants were immersed in virtual reality and instructed to respond to a visual target appearing at variable delays after a warning signal (WS). In half of the trials, an explicit cue indicated when the target would occur after the WS. Behavioral, oculomotor and EEG data consistently indicate that, compared with NVGPs, VGPs better prepare in time using implicit mechanisms. This sheds light on the neglected role of implicit timing in VGPs and related electrophysiological mechanisms. The results further suggest that game-based interventions may help remediate timing alterations found in psychiatric populations.

PREFRONTAL THETA OSCILLATIONS SHAPE V4 GAMMA MODULATION AND INTERAREAL COHERENCE DURING SPATIAL ATTENTION

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Sofia Paneri[1,2], Panagiotis Sapountzis[2], Georgia Gregoriou[1,2]
[1]University of Crete, Faculty Of Medicine, Heraklion, Greece, [2]Foundation for Research and Technology-Hellas (FORTH), Institute Of Applied And Computational Mahematics, Heraklion, Greece

The Frontal Eye Field is considered a source of spatial attention signals to visual areas but little is known about how other prefrontal regions contribute to this process. To examine the role of ventrolateral prefrontal cortex (vlPFC) in spatial attention, we performed simultaneous extracellular recordings from vlPFC and V4 in two macaques engaged in a covert spatial attention task. Attention modulated spiking activity in both areas but attention effects emerged significantly earlier in vlPFC compared to V4. Within V4, LFP power and spike-LFP coherence were significantly enhanced by spatial attention in gamma frequencies (>30Hz) and they were reduced in low frequencies (4-30Hz). Within vlPFC, theta power and coherence (4-8Hz) were significantly enhanced with attention. Across the two areas, phase coupling was found both in the theta and gamma bands with attention. Results from spike-LFP coherence between V4 and vlPFC and a Granger causality analysis between LFPs indicated a vlPFC origin for theta interactions and a V4 origin for gamma interactions. Notably, attentional effects in theta and gamma V4-vlPFC coherence showed a significant positive correlation indicating a theta–gamma band interdependence and PFC theta phase modulated V4 gamma amplitude and V4-vlPFC gamma coherence. Effects in theta band coherence emerged significantly earlier compared to gamma band coherence. These results indicate that vlPFC theta provides a possible mechanism for the attentional modulation of gamma synchrony in V4. Work was co-financed by Greece and the European Union (European Regional Development Fund) through the Operational Programme “Competitiveness Entrepreneurship Innovation 2014-2020” (MIS 5070462).

Distinct roles of prefrontal and parietal areas in the encoding of attentional priority.
When searching for an object in a crowded scene, information about the similarity of stimuli to the target object is thought to be encoded in spatial priority maps, which are subsequently used to guide shifts of attention and gaze to likely targets. Two key cortical areas that have been described as holding priority maps are the frontal eye field (FEF) and the lateral intraparietal area (LIP). However, little is known about their distinct contributions in priority encoding. Here, we compared neuronal responses in FEF and LIP during free-viewing visual search. Although saccade selection signals emerged earlier in FEF, information about the target emerged at similar latencies in distinct populations within the two areas. Notably, however, effects in FEF were more pronounced. Moreover, LIP neurons encoded the similarity of stimuli to the target independent of saccade selection, whereas in FEF, encoding of target similarity was strongly modulated by saccade selection. Taken together, our findings suggest hierarchical processing of saccade selection signals and parallel processing of feature-based attention signals within the parietofrontal network with FEF having a more prominent role in priority encoding. Furthermore, they suggest discrete roles of FEF and LIP in the construction of priority maps.

Top-Down Control of Visual Attention by the Prefrontal Cortex. Functional Specialization and Long-Range Interactions.
The ability to select information that is relevant to current behavioral goals is the hallmark of voluntary attention and an essential part of our cognition. Attention tasks are a prime example to study at the neuronal level, how task related information can be selectively processed in the brain while irrelevant information is filtered out. Whereas, numerous studies have focused on elucidating the mechanisms of visual attention at the single neuron and population level in the visual cortices, considerably less work has been devoted to deciphering the distinct contribution of higher-order brain areas, which are known to be critical for the employment of attention. Among these areas, the prefrontal cortex (PFC) has long been considered a source of top-down signals that bias selection in early visual areas in favor of the attended features. Here, we review recent experimental data that support the role of PFC in attention. We examine the existing evidence for functional

specialization within PFC and we discuss how long-range interactions between PFC subregions and posterior visual areas may be implemented in the brain and contribute to the attentional modulation of different measures of neural activity in visual cortices.

Oscillatory synchrony as a mechanism of attentional processing.
The question of how the brain selects which stimuli in our visual field will be given priority to enter into perception, to guide our actions and to form our memories has been a matter of intense research in studies of visual attention. Work in humans and animal models has revealed an extended network of areas involved in the control and maintenance of attention. For many years, imaging studies in humans constituted the main source of a systems level approach, while electrophysiological recordings in non-human primates provided insight into the cellular mechanisms of visual attention. Recent technological advances and the development of sophisticated analytical tools have allowed us to bridge the gap between the two approaches and assess how neuronal ensembles across a distributed network of areas interact in visual attention tasks. A growing body of evidence suggests that oscillatory synchrony plays a crucial role in the selective communication of neuronal populations that encode the attended stimuli. Here, we discuss data from theoretical and electrophysiological studies, with more emphasis on findings from humans and non-human primates that point to the relevance of oscillatory activity and synchrony for attentional processing and behavior. These findings suggest that oscillatory synchrony in specific frequencies reflects the biophysical properties of specific cell types and local circuits and allows the brain to dynamically switch between different spatio-temporal patterns of activity to achieve flexible integration and selective routing of information along selected neuronal populations according to behavioral demands. This article is part of a Special Issue entitled SI: Prediction and Attention.

LATENCY PEAK OF EARLY VISUAL EVOKED POTENTIAL IS MODIFIED BY AGE AND NOVELTY DURING VISUAL MEMORY TASK

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Marie Pieron, Elsie Moukarzel, Valentin Ritou, Cendra Agulhon
CNRS, Umr8002 Incc, Paris, France

Encoding of a sensory stimulus is believed to be the first step in perceptual learning. Detection of novel events is strongly related to memory, as it requires a comparison between incoming events and memory representations. In the mouse model, the plasticity dynamic measured by the visual evoked potential (VEP) latency modulation has not yet been studied during a visual memory task. To understand visual maturation, we recorded VEP in non-anaesthetized mice *in vivo* at two developmental stages during a visual memory task. We also examined if a novel stimulus has an impact on the speed of sensory processing, as indicated by latency modulations of early visual ERP components. N1 and N2 peak latencies are shorter for adult than for juvenile mice. The repetition of the familiar stimuli for 6 days led to a reduction of latency with the acquisition of the familiarity only for the juvenile group. Moreover, for juvenile mice, shorter peak latencies for N2 and P2 were observed in response to a novel *versus* a familiar stimulus but also an increase of latency variability. Our results indicate developmental differences in processing the acquisition of the familiarity of a visual stimulus. As age affects N1 and N2 latency values during the visual recognition memory task, they could be a potential measure of cortical maturation. In the juvenile group, the novelty effect on the latency of earlier peak (N2, P2) could result from a pre-attentional phenomenon. New stimuli capture better attention than a familiar one.

THE STRUCTURE OF NEURONAL INFORMATION MULTIPLEXING IN THE FRONTAL EYE FIELD ACCOUNTS FOR BOTH NEURONAL AND BEHAVIORAL VARIABILITY.

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Julian Amengual[1], Fabio Di Bello[1], Sameh Ben Hadj Hassen[1], Suliann Ben Hamed[1,2]
[1]UMR5229 Institut des sciences cognitives Marc Jeannerod, Neural Bases Of Spatial Cognition And Action, BRON CEDEX, France, [2]CNRS, Institut Des Sciences Cognitives, Bron Cedex, France

The frontal eye field (FEF) is a cortical area classically associated with spatial attention, perception and oculomotor functions. However, in any given task, these different functions do not account for all the observed neuronal variability. This “unaccounted for” neuronal variability can be considered as noise or associated to covert functions. Here, we show that the major part of FEF neuronal non-attention related variability is associated with specific task-and behavior-related sources that predict the structure of neuronal information multiplexing in the FEF. To do so, we trained two macaques to perform a visual attention task while recording FEF neuronal activity using multi-contact electrodes. As previously described, the neural population encoded the position of the attentional locus. Concurrently, FEF neurons encoded task-related (time in trial; CTOA) and behavior-related (reaction time, RT; focus of attention, TA) parameters prior to target onset. Using demixed principal component analysis, we characterized the functional relationship between the neural populations associated with each of these parameters and we investigated how this functional relationship predicts behavior. All parameters were encoded in the FEF by orthogonal components by pairs, except for CTOA and RT and CTOA and TA. This overlap correlated with the behavioral interaction between these two pairs of parameters. We thus present evidence that different sources of information can be extracted simultaneously from the FEF, and we describe how FEF neurons mix this information accounting for behavioral variability. This has major implications for the understanding of prefrontal cortex functional organization and for the real-time access to cognitive information.

DISTINCT NEURONAL STATES ENCODE TASK IDENTITY IN FRONTAL EYE FIELD AND INTERACT WITH ITS CORE SPATIAL PROPERTIES

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Axel Mouille[1], Corentin Gaillard[2], Elaine Astrand[3], Claire Wardak[4], Julian Amengual[5], Suliann Ben Hamed[1]
[1]Institut des Sciences Cognitive Marc Jeannerod, Neuroscience Cognitive, bron, France, [2]Otto-von-Guericke university Magdeburg, Sensorische Physiologie, Magdeburg, Germany, [3]Malardalen University, Division Of Intelligent Future Technologies, Västerås, Sweden, [4]Université de Tours, Umr 1253, Ibrain, Inserm, Tours, France, [5]UMR5229 Institut des sciences cognitives Marc Jeannerod, Neural Bases Of Spatial Cognition And Action, BRON CEDEX, France

Human cognition relies on the coordinated activity of multiple neuronal populations dynamically interacting together and shaping our behavior. Interestingly, single-neuron activity in the prefrontal cortex displays mixed selectivity, showing simultaneous tuning to different task-related processes. For example, prefrontal populations can jointly represent the position of a visual spatial information, spatial attention and working memory content. This feature is a hallmark of high-dimensionality, which provides the ability to encode different types of information simultaneously. In this context, the question we tackle is whether the prefrontal cortex population also represents task identity and how this impacts on its core specific functional computations. We trained two monkeys to perform three different task: a memory guided saccade task and two cued target detection tasks: peripherally cued (cue at expected target location, exogenous) and centrally cued (central cue, endogenous). During their performance, multi-unit activity (MUA) was recorded in both Frontal eye fields (FEF). Using demixed Principal Component Analysis, we found a two-dimensional neural states that fully characterized each of these tasks. This result indicates a task-related neural state in the recorded population. Furthermore, we observed that encoding of the spatial information was task-dependent. Such interaction between task and position coding indicates that task and spatial information are non-linearly mixed which is considered as a signature of a high-dimensional neuronal representation. Overall, this indicates that the FEF encodes ongoing task-identity in an identifiable neuronal dimension that interacts with its core spatial computations.

COVERT SPATIAL ATTENTION-BASED NEUROFEEDBACK CHANGES THE NEURONAL POPULATION CODE OF THE FRONTAL EYE FIELDS IN AN OSCILLATORY MANNER: A NON-HUMAN PRIMATE STUDY

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Fardin Afdideh[1], Julian Amengual[1], Corentin Gaillard[2], Elaine Astrand[3], Suliann Ben Hamed[1]
[1]Institut des Sciences Cognitives Marc Jeannerod, Cnrs Umr 5229, Bron, France, [2]Institute of Biology, Otto-von-Guericke-Universitaet, Department Of Sensory Physiology, Magdeburg, Germany, [3]Malardalen University, Division Of Intelligent Future Technologies, Västerås, Sweden

A brain-computer interface (BCI) system is a synthetic interface with the brain allowing direct communication between the subject's neuronal activity and the external world. In the context of cognitive BCIs, the goal is to enhance or restore behavior through changes in the neural code. However, little is known about how cognitive BCIs impact the neural code. To improve attention, we thus conceived a closed-loop, invasive, adaptive, cognitive, and synchronous BCI system based on neurofeedback (NF). Two 24-contact electrodes were implanted in each Frontal Eye Field to record multiunit activity (MUA) from two macaques during a cued visuospatial attentional task. The position of the attentional spotlight (AS) was decoded in real-time. Its location relative to the expected target was indicated as auditory feedback. Subjects were rewarded for keeping decoded AS in the cued quadrant. To investigate the impact of NF on the spatial attention neuronal population code over time, cross-temporal decoding maps (CTDM) were computed either within or across pre-NF and post-NF neuronal data. When computing the CTDM using pre-NF and post-NF trials as training and test sets, after NF, the prefrontal population spatial code for attention changed dynamically during the cue-to-target interval in an oscillatory manner, but not within the pre-NF nor the post-NF CTDM. This indicates an alternation between a new code generated by the NF and the pre-existent pre-NF code, at two distinct non-harmonic frequencies: 4.5Hz and 7.6Hz (average estimates). These changes in neural code are correlated with complex rhythmic changes in behavioural performance.

INFORMATION ROUTING BETWEEN CORTICAL LAYERS IN MACAQUE AREA V1 DEPENDS ON THE PHASE-RELATION BETWEEN THEIR GAMMA-OSCILLATIONS

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Eric Drebitz, Lukas-Paul Rausch, Esperanza Domingo Gil, Andreas Kreiter
University of Bremen, Brain Research Institute, Bremen, Germany

Local neuronal populations cannot process concurrently arriving information in parallel. Selective attention resolves this conflict, resulting in preferential processing of vital information. An explanatory approach for this preferential processing is "Routing-by-synchronization". Its driving concept is that receiving neurons should selectively synchronize their oscillatory activity with those subsets of inputs delivering the vital information. The synchronization allows sender neurons to provide information at the most effective period of the receiving neurons' oscillatory cycle. However, selective attention might also influence oscillatory activity on the input side to facilitate the synchronization with upstream neurons. To test this hypothesis, we investigate 1.) if information transmission depends on phase-specific synchronization and 2.) whether attention modulates this phase-specific synchronization. Therefore, we recorded with multi-contact-probes in area V1 of two monkeys (*Macaca mulatta*) performing a demanding shape-tracking task. The visual stimuli randomly and quickly changed their luminance. This task-irrelevant flicker allowed the ongoing estimation of stimulus-specific representation by calculating the spectral coherence between neuronal signals and the flicker signal. We found that the level of stimulus-specific information arriving in superficial layers depended on the phase difference between the oscillatory activity in granular- and supragranular layers. Furthermore, the phase-difference promoting most information to superficial V1 occurred more frequently when animals attended the respective stimulus. These results show: (1) that phase-relations between neurons of different layers have an optimal mode for routing information and (2) that dynamic adjustments of phase-relations between neurons located in different layers of V1 support preferential routing and processing of the behaviorally relevant information.

Optimizing the Yield of Multi-Unit Activity by Including the Entire Spiking Activity.
Neurophysiological data acquisition using multi-electrode arrays and/or (semi-) chronic recordings frequently has to deal with low signal-to-noise ratio (SNR) of neuronal responses and potential failure of detecting evoked responses within random background fluctuations. Conventional methods to extract action potentials (spikes) from background noise often apply thresholds to the recorded signal, usually allowing reliable detection of spikes when data exhibit a good SNR, but often failing when SNR is poor. We here investigate a threshold-independent, fast, and automated procedure for analysis of low SNR data, based on fullwave-rectification and low-pass filtering the signal as a measure of the entire spiking activity (ESA). We investigate the sensitivity and reliability of the ESA-signal for detecting evoked responses by applying an automated receptive field (RF) mapping procedure to semi-chronically recorded data from primary visual cortex (V1) of five macaque monkeys. For recording sites with low SNR, the usage of ESA improved the detection rate of RFs by a factor of 2.5 in comparison to MUA-based detection. For recording sites with medium and high SNR, ESA delivered 30% more RFs than MUA. This significantly higher yield of ESA-based RF-detection still hold true when using an iterative procedure for determining the optimal spike threshold for each MUA individually. Moreover, selectivity measures for ESA-based RFs were quite compatible with MUA-based RFs. Regarding RF size, ESA delivered larger RFs than thresholded MUA, but size difference was consistent over all SNR fractions. Regarding orientation selectivity, ESA delivered more sites with significant orientation-dependent responses but with somewhat lower orientation indexes than MUA. However, preferred orientations were similar for both signal types. The results suggest that ESA is a powerful signal for applications requiring automated, fast, and reliable response detection, as e.g., brain-computer interfaces and neuroprosthetics, due to its high sensitivity and its independence from user-dependent intervention. Because the full information of the spiking activity is preserved, ESA also constitutes a valuable alternative for offline analysis of data with limited SNR.

Attention Configures Synchronization Within Local Neuronal Networks for Processing of the Behaviorally Relevant Stimulus.

The need for fast and dynamic processing of relevant information imposes high demands onto the flexibility and efficiency of the nervous system. A good example for such flexibility is the attention-dependent selection of relevant sensory information. Studies investigating attentional modulations of neuronal responses to simultaneously arriving input showed that neurons respond, as if only the attended stimulus would be present within their receptive fields (RF). However, attention also improves neuronal representation and behavioral performance, when only one stimulus is present. Thus, attention serves for selecting relevant input and changes the neuronal processing of signals representing selected stimuli, ultimately leading to a more efficient behavioral performance. Here, we tested the hypothesis that attention configures the strength of functional coupling between a local neuronal network's neurons specifically for effective processing of signals representing attended stimuli. This coupling is measured as the strength of γ-synchronization between these neurons. The hypothesis predicts that the pattern of synchronization in local networks should depend on which stimulus is attended. Furthermore, we expect this pattern to be similar for the attended stimulus presented alone or together with irrelevant stimuli in the RF. To test these predictions, we recorded spiking-activity and local field potentials (LFP) with closely spaced electrodes in area V4 of monkeys performing a demanding attention task. Our results show that the γ-band phase coherence (γ-PhC) between spiking-activity and the LFP, as well as the spiking-activity of two groups of neurons, strongly depended on which of the two stimuli in the RF was attended. The γ-PhC was almost identical for the attended stimulus presented either alone or together with a distractor. The functional relevance of dynamic γ-band synchronization is further supported by the observation of strongly degraded γ-PhC before behavioral errors, while firing rates were barely affected. These qualitatively different results point toward a failure of attention-dependent top-down mechanisms to correctly synchronize the local neuronal network in V4, even though this network receives the correctly selected input. These findings support the idea of a flexible, demand-dependent dynamic configuration of local neuronal networks, for performing different functions, even on the same sensory input.

A novel approach for removing micro-stimulation artifacts and reconstruction of broad-band neuronal signals.
Electrical stimulation is a widely used method in the neurosciences with a variety of application fields. However, stimulation frequently induces large and long-lasting artifacts, which superimpose on the actual neuronal signal. Existing methods were developed for analyzing fast events such as spikes, but are not well suited for the restoration of LFP signals.

Biochemical characterization of trans-sialidase TS1 variants from Trypanosoma congolense.
Animal African trypanosomiasis, sleeping sickness in humans and Nagana in cattle, is a resurgent disease in Africa caused by Trypanosoma parasites. Trans-sialidases expressed by trypanosomes play an important role in the infection cycle of insects and mammals. Whereas trans-sialidases of other trypanosomes like the American T. cruzi are well investigated, relatively little research has been done on these enzymes of T. congolense.

IMPACT OF TASK-IRRELEVANT AUDITORY INFORMATION ON A VISUAL RATE CATEGORIZATION TASK

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Mattia Zanzi, Davide Zoccolan
SISSA, Cognitive Neuroscience, Trieste, Italy

Successful discrimination of sensory information often depends on the ability to integrate inputs across sensory modalities. In the brain, recent evidence demonstrated that primary sensory regions, traditionally considered unisensory, participate in multisensory processing. For instance, mouse V1 neurons were shown to encode the temporal congruency of audiovisual stimuli. Yet, the perceptual role of multisensory interactions in the sensory cortex remains unexplored at the behavioral level. We thus designed an audiovisual task and trained rats to make a decision based on the temporal frequency (TF) of outward-moving circular gratings, paired with a fixed-amplitude sound. To explore the impact of auditory information on visual perception, we then introduced amplitude modulation to the sounds, delivering both temporally congruent and incongruent audiovisual stimuli. Although rats were not explicitly trained to judge the rate of the acoustic feature, the psychometric curves revealed higher sensitivity to the TF of the visual stimuli when paired with rate-changing sounds, compared to fixed-amplitude sounds. Surprisingly, this sharpening was independent of the temporal coherence of the visual and the auditory features. By contrast, rats reacted faster when visual stimuli were paired with fixed-amplitude compared to temporally-modulated sounds. Our data suggest that information about task-irrelevant but behaviorally-salient sounds are reflexively routed to early visual areas, where it spontaneously facilitates the detection of visual events. Our experimental approach can thus pave the way to the investigation of the functional impact of auditory inputs over visual cortical representations, mediated by well-established cortico-cortical connections.

ROLE OF THE ANTERIOR AND POSTERIOR PARAVENTRICULAR NUCLEUS OF THE THALAMUS ON SIGN-TRACKING IN INBRED C57BL/6J AND DBA/2J MICE

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Valeria Tarmati[1], Cristina Orsini[1], Simona Cabib[2]
[1]Sapienza, Psychology, Rome, Italy, [2]IRCCS Fondazione Santa Lucia, Department Of Experimental Nuerosciences, Roma, Italy

Aims: Sign-tracking (ST) behavior is a model of overwhelming attraction to rewards-associated stimuli due to incentive salience attribution as measured by the Pavlovian Conditioned Approach (PCA) paradigm. Previous studies suggested different strain-specific neurobiological substrates underlying ST behavior. This study was aimed at investigating the genotype-dependent networks mediating ST phenotype in C57BL/6J (C57) and DBA/2J (DBA) mice. **Methods**: In experiment 1 quantification of the c-fos protein was a marker of neural activation of strain-specific circuits during expression of ST behavior. After training, Paired (CS-food presentation) and Unpaired (random CS and food presentation) mice underwent a short exposure only to the lever-CS and then sacrificed for the immunohistochemistry. According to the results, in experiment 2 an excitotoxic lesion by NMDA infusion within the anterior and posterior Paraventricular Nucleus of the Thalamus (PVT) was performed before PCA training. **Results**: PVT was the only area expressing c-fos immunostaining in both strains though with opposite direction. Indeed, when compared to the respective Unpaired mice, c-fos expression was increased in C57 Paired and decreased in DBA Paired mice. Moreover, while the aPVT showed to be more involved in ST expression for DBA mice, any antero-posterior gradient was found relative to the activation for C57 mice. However, lesion of the aPVT selectively reduced ST behavior in DBA mice, while the pPVT lesion selectively reduced ST behavior in C57 mice. **Conclusions**: This strain-dependent functional role of the PVT and its anatomical division confirm the hypothesis that ST phenotype may be mediated by different networks in these strains.

Repetitive and Inflexible Active Coping and Addiction-like Neuroplasticity in Stressed Mice of a Helplessness-Resistant Inbred Strain.
Dysfunctional coping styles are involved in the development, persistence, and relapse of psychiatric diseases. Passive coping with stress challenges (helplessness) is most commonly used in animal models of dysfunctional coping, although active coping strategies are associated with generalized anxiety disorder, social anxiety disorder, panic, and phobias as well as obsessive-compulsive and post-traumatic stress disorder. This paper analyzes the development of dysfunctional active coping strategies of mice of the helplessness-resistant DBA/2J (D2) inbred strain, submitted to temporary reduction in food availability in an uncontrollable and unavoidable condition. The results indicate that food-restricted D2 mice developed a stereotyped form of food anticipatory activity and dysfunctional reactive coping in novel aversive contexts and acquired inflexible and perseverant escape strategies in novel stressful situations. The evaluation of FosB/DeltaFosB immunostaining in different brain areas of food-restricted D2 mice revealed a pattern of expression typically associated with behavioral sensitization to addictive drugs and compulsivity. These results support the conclusion that an active coping style represents an endophenotype of mental disturbances characterized by perseverant and inflexible behavior.

Opposite genotype-specific effects of serotoninergic treatments on Pavlovian Conditioned Approach in mice of two inbred strains C57 BL/6J and DBA/2J.
Individual variability in the response to pharmacological therapies is a major problem in the treatment of psychiatric disorders. Comparative studies of phenotypes expressed by mice of the C57BL/6J (C57) and DBA/2J (DBA) inbred strains can help identify neurobiological determinants of this variability at preclinical levels. We have recently demonstrated that whereas young adult mice of both strains develop sign-tracking in a Pavlovian Conditioned Approach (PCA), a trait associated with dysfunctional behavior in rat models, in full adult C57 mice acquisition of this phenotype is inhibited by pre-frontal cortical (PFC) serotonin (5HT) transmission. These findings suggest a different role of 5HT transmission on sign-tracking

development in mice of the two genotypes. In the present experiments, we tested the effects of the 5-HT synthesis booster 5-hydroxytryptophan (5-HTP) and of the selective 5HT reuptake inhibitor (SSRI) fluoxetine on the development and expression of sign-tracking in young adult mice from both inbred strains. In mice of the C57 strain, administration of 5-HTP before each training session blocked the training-induced shift to positive PCA scores which indicates the development of sign-tracking, whereas the same treatment was ineffective in mice of DBA strain. On the other hand, a single administration of fluoxetine was ineffective in unhandled saline- and 5-HTP-treated C57 mice, whereas it enhanced the expression of positive PCA scores by mice of DBA strain treated with 5-HTP during training. These findings confirm the strain-specific inhibitory role of PFC 5-HT transmission on sign-tracking development by mice of the C57 strain and support the hypothesis that different genotype-specific neurobiological substrates of dysfunctional phenotypes contribute to variable effects of pharmacotherapies.

TEMPORAL SURPRISE REDUCES AROUSAL AND THE CONTINGENT NEGATIVE VARIATION

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Dominika Drazyk, Marcus Missal
Université Catholique de Louvain, Institute Of Neuroscience (ions), Bruxelles, Belgium

Temporal expectation builds up before predicted sensory stimuli. However, events do not always occur at the predicted time, potentially creating temporal surprise. Psychological theory suggests that stimulus-bound surprise could alter subjective expectation and affect levels of arousal. First, we hypothesised that low temporal predictability could decrease arousal-related oculomotor responses. Secondly, we tested the influence of temporal surprise on the contingent negative variation (CNV) that reflects subjective expectation. Finally, we assumed that lowered temporal expectation could prolong the saccadic reaction times. Eye movements and EEG were recorded in 42 subjects performing a simple variable foreperiod task. A central target was briefly presented on a display followed by an eccentric one after a variable delay (or foreperiod). The task was to gaze at the central target and wait for the eccentric one to make a saccadic eye movement. In different blocks of trials, the variance of the FP distribution (μ = 1600 ms or 2400 ms) was either 5 ms or 120 ms. Pupil size and centrally located CNV preceding the visually-guided saccade were reduced in the high surprise condition. The maximum velocity of visually-guided saccades decreased with increasing temporal surprise but their latency was only minimally affected by stimulus predictability. Results suggest that temporal surprise decreased arousal and expectation. This effect could be mediated by a reduced CNV.

RESEARCH OF THE READING FATIGUE AND THE SIGNIFICANCE OF THIS PARAMETER FOR ASSESSING THE COGNITIVE STATE OF A READER

POSTER SESSION 04 - SECTION: ATTENTION AND PERCEPTION

Victor Anisimov, Ksenia Babanova, Andrey Pikunov, Sergey Zuev, Alexandra Latyshkova, Konstantin Chernozatonskiy
Oken Technologies Inc, NY, United States of America

For many years fatigue has been a topic of scientific and applied research, especially in relation to evaluating a person's cognitive state in occupations settings such as factory work, client services, education and other areas where a work routine tends to lead to fatigue. Reading and education are also topics of great scientific interest in their broader sense. A person who is tired is hardly capable of perceiving new information; tiredness reduces cognitive abilities including attention, concentration and a capacity for work. A reader becomes distracted when fatigue develops.

According to the available literature, fatigue is associated with physiological parameters that reflect the human body's functional state. Eye movements are great indicators of mental state and cognitive processes that are represented in the brain at that moment. The eyes develop ontogenetically from telencephalon, and highly reflect the processes of human's exploration and search behavior. While these statements seem at first glance to be purely theoretical, they are nevertheless directly related to almost every psychological process, activity or mental state.

In this study the authors developed algorithms for estimating fatigue during reading based on eye tracking data collected from modern smartphone or tablet PC. The described method could prove useful for evaluating reading and comprehension effectiveness in order to make predictions about the state of a person's cognitive capabilities.

MODULATION OF MOTOR SEQUENCE LEARNING WITH TDCS AT 4MA

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Gavin Hsu[1], A. Duke Shereen[2], Lucas Parra[1]
[1]City College of New York, Biomedical Engineering, New York, United States of America, [2]The Graduate Center, City University of New York, Advanced Science Research Center, New York, United States of America

In vivo human trials of transcranial direct current stimulation (tDCS) on motor learning have seen mixed results in the literature at the typical intensities of up to 2mA. We hypothesize that, provided sufficiently high field intensity is delivered to the motor cortex, tDCS can have a reliable behavioral effect on motor sequence learning. In a single-blind design, 72 healthy right-handed adult participants received anodal (N = 36) HD-tDCS while they performed a sequential finger tapping task (FTT) using their non-dominant hand for 12 minutes. A cathodal (N = 36) group served as an active control for sensation and an additional bllinded sham control group (N = 36) was used to establish baseline levels of learning. Functional magnetic resonance imaging (fMRI) of healthy participants (N = 10) was used in a current flow model to formulate a generalized 4+4 focal high-definition tDCS (HD-tDCS) electrode montage with 4 anterior and 4 parietal electrodes each drawing 1mA, targeting the hand knob on the contralateral primary motor cortex (M1). We find a significant gain in task performance in in anodal stimulation over cathodal stimulation (Cohen's d = 0.7), as well as over no stimulation. This effect persisted for at least one hour and carried over to the untrained hand as well as an untrained sequence. Sensation levels of 4mA tDCS were similar in both active groups and did not exceed moderate levels of discomfort. These results demonstrate that 4mA HD-tDCS distributed over a 4+4 montage yields a reliable boost of motor sequence learning and is well tolerated.

OPTIMIZING THE MONTAGE FOR CEREBELLAR TRANSCRANIAL ALTERNATING CURRENT STIMULATION (TACS): A COMBINED COMPUTATIONAL AND EXPERIMENTAL STUDY

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Fatemeh Sadeghi Hassanabadi[1], Jonas Misselhorn[2], Simone Zittel-Dirks[1], Christian Gerloff[1]
[1]University Medical Center Hamburg-Eppendorf (UKE), Neurology, Hamburg, Germany, [2]University Medical Center Hamburg-Eppendorf (UKE), Department Of Neurophysiology And Pathophysiology, Hamburg, Germany

Objective. The application of cerebellar transcranial alternating current stimulation (tACS) is limited by the absence of commonly agreed montages and also the presence of unpleasant side effects. We aimed to find the most effective cerebellar tACS montage with minimum side effects (skin sensations and phosphenes). *Approach.* We first simulated cerebellar tACS with four montages (return electrode on forehead, buccinator, jaw, and neck positions) to compare induced cerebellar current, then stimulated healthy participants and evaluated side effects for each montage and different stimulation frequencies. *Main results.* The simulation revealed a descending order of current density in the cerebellum from forehead to buccinator, jaw, and neck respectively. Montages inducing higher current intensity in the eyeballs during the simulation resulted in stronger and broader phosphenes during tACS sessions. Strong co-stimulation of the brainstem was observed for the neck. Skin sensations did not differ between montages or frequencies. We propose the jaw montage as an optimal choice for maximizing cerebellar stimulation while minimizing unwanted side effects. *Significance.* These findings contribute to adopting a standard cerebellar tACS protocol. The combination of computational modelling and experimental data offers improved experimental control, safety, effectiveness, and reproducibility to all brain stimulation practices.

6 Hz transcranial alternating current stimulation of mPFC improves sustained attention and modulates alpha phase synchronization and power in dorsal attention network.
Transcranial alternating current stimulation (tACS) is a noninvasive brain stimulation tool appropriate to modulate cortical oscillations and activity via the application of weak currents. The major goal of this study was to investigate the effects of medial Prefrontal Cortex (mPFC) stimulation on sustained attention task performance measured by Rapid Visual Information Processing (RVIP) task and the brain networks assumed to be critical to sustained attention. mPFC has been shown to be involved in sustained attention performance and as a main hub in default mode network (DMN). mPFC activity modulation via theta tACS was implemented in this study. This was a single blind study with 21 participants receiving active and sham stimulation with the electrodes on FPz and the Inion. tACS was able to impact different RVIP measures (total hits, A' (sensitivity to target), total correct rejection, etc.). Relative power spectrum density (PSD) analysis yielded significant increases in theta frequency mostly in the fronto-central regions after active tACS and current source density (CSD) analysis yielded significant power modulations in theta frequency band in post-central gyrus. Furthermore, phase locking value (PLV) analysis showed that there were significant changes in cortical connections in the Dorsal Attention Network (DAN) in alpha frequency band. This study showed that theta frequency tACS over mPFC, was able to produce significant modulations in an RVIP task and its associated brain networks in healthy participants.

Current deep brain stimulation electrodes have a very limited spatial resolution which highly limits their application for targeted single neuron stimulation. To overcome this limitation, we propose a living biohybrid electrode in which we exploit real neurons as relays to transmit information from a stretchable microelectrode array (MEA[1]) to a neuronal target structure. To achieve this goal we are establishing a PDMS microstructure based *in vitro* co-culture system mounted on conventional glass MEAs in which we can seed embryonic rat retinal and thalamus spheroids at defined locations within the PDMS microstructure and guide the axons unidirectionally[2] across electrodes[3] through few µm sized channels towards the target. We optimize the design for reliable unidirectional multichannel stimulation of the target tissue. We show that retinal neurons grow several mm long axons within the PDMS guidance structures to innervate the thalamic target spheroids. We compare how different structural elements enhance unidirectional axon merging, growth speed, channel crosstalk and efficiency to stimulate thalamic target structures. *References* 1. 1 Renz, A. et al. Regulation of Cerebral Cortex Folding by Controlling Neuronal Migration via FLRT Adhesion Molecules.
The folding of the mammalian cerebral cortex into sulci and gyri is thought to be favored by the amplification of basal progenitor cells and their tangential migration. Here, we provide a molecular mechanism for the role of migration in this process by showing that changes in intercellular adhesion of migrating cortical neurons result in cortical folding. Mice with deletions of FLRT1 and FLRT3 adhesion molecules develop macroscopic sulci with preserved layered organization and radial glial morphology. Cortex folding in these mutants does not require progenitor cell amplification but is dependent on changes in neuron migration. Analyses and simulations suggest that sulcus formation in the absence of FLRT1/3 results from reduced intercellular adhesion, increased neuron migration, and clustering in the cortical plate. Notably, FLRT1/3 expression is low in the human cortex and in future sulcus areas of ferrets, suggesting that intercellular adhesion is a key regulator of cortical folding across species.

FLRT structure: balancing repulsion and cell adhesion in cortical and vascular development.
FLRTs are broadly expressed proteins with the unique property of acting as homophilic cell adhesion molecules and as heterophilic repulsive ligands of Unc5/Netrin receptors. How these functions direct cell behavior and the molecular mechanisms involved remain largely unclear. Here we use X-ray crystallography to reveal the distinct structural bases for FLRT-mediated cell adhesion and repulsion in neurons. We apply this knowledge to elucidate FLRT functions during cortical development. We show that FLRTs regulate both the radial migration of pyramidal neurons, as well as their tangential spread. Mechanistically, radial migration is controlled by repulsive FLRT2-Unc5D interactions, while spatial organization in the tangential axis involves adhesive FLRT-FLRT interactions. Further, we show that the fundamental mechanisms of FLRT adhesion and repulsion are conserved between neurons and vascular endothelial cells. Our results reveal FLRTs as powerful

guidance factors with structurally encoded repulsive and adhesive surfaces.

Structural Basis of Teneurin-Latrophilin Interaction in Repulsive Guidance of Migrating Neurons.
Teneurins are ancient metazoan cell adhesion receptors that control brain development and neuronal wiring in higher animals. The extracellular C terminus binds the adhesion GPCR Latrophilin, forming a trans-cellular complex with synaptogenic functions. However, Teneurins, Latrophilins, and FLRT proteins are also expressed during murine cortical cell migration at earlier developmental stages. Here, we present crystal structures of Teneurin-Latrophilin complexes that reveal how the lectin and olfactomedin domains of Latrophilin bind across a spiraling beta-barrel domain of Teneurin, the YD shell. We couple structure-based protein engineering to biophysical analysis, cell migration assays, and in utero electroporation experiments to probe the importance of the interaction in cortical neuron migration. We show that binding of Latrophilins to Teneurins and FLRTs directs the migration of neurons using a contact repulsion-dependent mechanism. The effect is observed with cell bodies and small neurites rather than their processes. The results exemplify how a structure-encoded synaptogenic protein complex is also used for repulsive cell guidance.

Soft Electronics Based on Stretchable and Conductive Nanocomposites for Biomedical Applications.
Research on the field of implantable electronic devices that can be directly applied in the body with various functionalities is increasingly intensifying due to its great potential for various therapeutic applications. While conventional implantable electronics generally include rigid and hard conductive materials, their surrounding biological objects are soft and dynamic. The mechanical mismatch between implanted devices and biological environments induces damages in the body especially for long-term applications. Stretchable electronics with outstanding mechanical compliance with biological objects effectively improve such limitations of existing rigid implantable electronics. In this article, the recent progress of implantable soft electronics based on various conductive nanocomposites is systematically described. In particular, representative fabrication approaches of conductive and stretchable nanocomposites for implantable soft electronics and various in vivo applications of implantable soft electronics are focused on. To conclude, challenges and perspectives of current implantable soft electronics that should be considered for further advances are discussed.

An experimental paradigm to investigate stimulation dependent activity in topologically constrained neuronal networks.
We present a stimulate and record paradigm to examine the behavior of multiple neuronal networks with controlled topology in vitro. Our approach enabled us to electrically induce and record neuronal activity from 60 independent networks in parallel over multiple weeks. We investigated the network performance of neuronal networks of primary hippocampal neurons until 29 days in vitro. We introduced a systematic stimulate and record protocol during which well-defined 4-node neural networks were stimulated electrically 4 times per second (4Hz) and their response was recorded over many days. We found that the network response pattern to a stimulus remained fairly stable for at least 12 h. Moreover, continuous stimulation over multiple weeks did not cause a significant change in the stimulation-induced mean spiking frequency of a circuit. We investigated the effect of stimulation amplitude and stimulation timing on the detailed network response. Finally, we could show that our setup can apply complex stimulation protocols with 125 different stimulation patterns. We used these patterns to perform basic addition tasks with the network, revealing the highly non-linear nature of biological networks' responses to complex stimuli.

FLRT3 Marks Direction-Selective Retinal Ganglion Cells That Project to the Medial Terminal Nucleus.
The mammalian retina extracts a multitude of diverse features from the visual scene such as color, contrast, and direction of motion. These features are transmitted separately to the brain by more than 40 different retinal ganglion cell (RGC) subtypes. However, so far only a few genetic markers exist to fully characterize the different RGC subtypes. Here, we present a novel genetic Flrt3-CreERT2 knock-in mouse that labels a small subpopulation of RGCs. Using single-cell injection of fluorescent dyes in Flrt3 positive RGCs, we distinguished four morphological RGC subtypes. Anterograde tracings using a fluorescent Cre-dependent Adeno-associated virus (AAV) revealed that a subgroup of Flrt3 positive RGCs specifically project to the medial terminal nucleus (MTN), which is part of the accessory optic system (AOS) and is essential in driving reflex eye movements for retinal image stabilization. Functional characterization using patch-clamp recordings showed that the MTN-projecting Flrt3 RGCs preferentially respond to downward motion in an ON-fashion. These neurons distribute in a regular pattern and most of them are bistratified at the level of the ON and OFF bands of cholinergic starburst amacrine cells where they express the known ON-OFF direction-selective RGC marker CART. Together, our results indicate that MTN-projecting

Flrt3 RGCs represent a new functionally homogeneous AOS projecting direction-selective RGC subpopulation. Front Mol Neurosci, 2021; 14

CLOSED-LOOP NEUROMODULATION OF SPINAL CIRCUITS FOR THE TREATMENT OF GAIT DEFICITS IN ANIMAL MODELS OF PARKINSON'S DISEASE.

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Elisa Lilly Garulli, Burçe Kabaoglu, Christoph Harms, Nikolaus Wenger
Charité – Universitätsmedizin Berlin, Experimental Neurology, Berlin, Germany

Around one-third of parkinsonian patients suffer from gait impairments. Given the poor response to dopaminergic medication and standard DBS therapies, this poses an unmet clinical need. Our project focuses on establishing a closed-loop, epidural electrical stimulation system to treat gait disorder in Parkinson's disease, specifically freezing of gait (FOG) episodes. Using a rat model of Parkinson's disease (6-OHDA unilateral injection in the Medial Forebrain Bundle), we are characterizing neural biomarkers of movement and pathological episodes. During motor tasks we record from the cortex using ECoG screws and from the Subthalamic Nucleus using bipolar electrodes. Simultaneously, we record kinematic data using a marker-based video capturing system.
We established analysis pipelines that allow us to explore the power spectrum at the time of voluntary initiation of movement, as well as during gait cycles. This sets the basis for the detection of neural biomarkers of involuntary, pathological movement interruptions.
Following a comprehensive characterization of the neural correlates of movement, we will close the loop by monitoring changes in supraspinal motor networks in real-time and adjusting the stimulation parameters accordingly.
Detecting pathological patterns will allow us to deliver timely epidural stimulation in the spinal cord, aimed at preventing FOG episodes, or, in the best-case scenario, avoid them altogether.

Gait impairments in Parkinson's disease (PD) are a scientific and therapeutic challenge as freezing of gait (FOG) shows a limited response to dopamine replacement and standard STN-DBS therapies. Recently, epidural electrical stimulation (EES) of the spinal cord was proposed as an alternative treatment for gait impairments in PD. However, due to limited understanding of the underlying neurobiology of FOG, the efficacy of EES for gait recovery remains an open question. Animal models of PD offer us the opportunity to unravel the mechanisms of gait network disorders. To this extent, we will investigate the specificity of EES, then characterize the effect of stimulation parameters on pathological oscillations in the locomotor network; finally, we will test an EES paradigm to retune the pathological oscillations and improve the motor deficits that accompany them.
To achieve this healthy rats will be implanted with EES electrodes over the cervical, thoracic and lumbar segments of the spinal cord and the response will be recorded in the supraspinal motor network. Then, the neural activity will be recorded in synchrony with refined movement tracking, to identify biomarkers to predict FOG. Finally, we will combine the gathered knowledge to implant neural electrodes, EES implants, and electromyography probes in PD model rats to assess the effects of segment-specific EES on gait deficit amelioration and retuning of pathological network oscillations. Our approach will be benchmarked against dopamine replacement therapy.
This project will help evaluate the impact of segment-specific EES on network modulation, to treat motor deficits in animal models of PD.

Aims Brain excitability can be defined as the ability of the cortex to produce a response following a brief direct stimulation. According to standard systems theory, the best way to infer the state of a system is to record and characterize its impulse response to a brief event, producing much more informative data than simply recording spontaneous brain activity. This unique technique allows to infer brain connectivity and dynamics which can be altered in several neurological disorders such as Parkinson's disease (PD). **Methods** During the first step of this project, we have been able to transfer a technology used in clinic, based on brain excitability, to the preclinical stage. This methodological approach was developed in freely moving rodents. A proof-of-concept study was realized in naive animals. In a second step, we applied this technique in an animal model of PD, the unilateral 6-OHDA lesioned rat, to identify a specific EEG signature. We focused our effort on PD because of its well-known altered connectivity within the cortico-basal ganglia-thalamo-cortical circuits. **Results** We successfully transferred this methodology to naïve rats and obtained highly reproducible responses with site-specificities. By comparing evoked responses between 6-OHDA and control groups, we identified a specific electroencephalographic signature. **Conclusions** In this study, we demonstrated that inferring brain excitability using electrical stimulation could be a relevant tool to discover new signatures in PD and could be extended to other pathologies involving excitability dysfunctions (e.g: Alzheimer, Multiple Sclerosis). Such unique methodological approach would play a key role in drug development process.

ELECTRIC-DIPOLE INTERACTIONS EXPLAIN THE EFFECTS OF ENDOGENOUS AND EXOGENOUS ELECTRIC FIELDS

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Joana Covelo[1], Jaume Colom Hernandez[1,2], Alain Destexhe[2], Maria V. Sanchez-Vives[1,3]
[1]Institut d'Investigacions Biomediques August Pi i Sunyer, Systems Neuroscience Group, Barcelona, Spain, [2]CNRS, Paris-Saclay University, Neuropsi, Saclay, France, [3]ICREA, Catalan Institution For Research And Advanced Studies, Barcelona, Spain

Cortical activity can be modulated by endogenous and exogenous electric fields (EF). In a previous study (Rebollo *et al.*, 2021), experimental and computational data suggested that endogenous EF-mediated effects are compatible with electric dipoles, which contribute to the synchronization of neighbouring cortical columns. Moreover, tDCS models have shown that the orientation of the current flow determines the effect of the intervention (Rawji *et al.*, 2019). In the current study, we investigated the rotation of exogenous EFs to assess the hypothesis that electric dipoles aligned with the cortical columns are responsible for the impact of EF direction on cortical modulation. In cortical slices expressing spontaneous slow oscillations (ca. 0.3 Hz), we applied constant exogenous EFs (-/+ 3 V/m) with different orientations (0º, 45º and 90º between the cortical surface and the DC electrodes). While DC fields orthogonal to the brain surface had a maximum modulatory effect, the effectivity decreased with the rotation of the EF, having a null effect when parallel to the cortical surface. These results were successfully reproduced in a computational model with interacting dipoles. The mean-field model suggested that the membrane potential shift created by an external EF is proportional to the cosine of the EF angle being applied and to the coefficient of ephaptic coupling. Therefore, we present experimental and computational data supporting the role of electric dipoles on the impact of both endogenous and exogenous electric fields in the cerebral cortex. WIRELESS CONTROL OF INSECT-MACHINE HYBRID

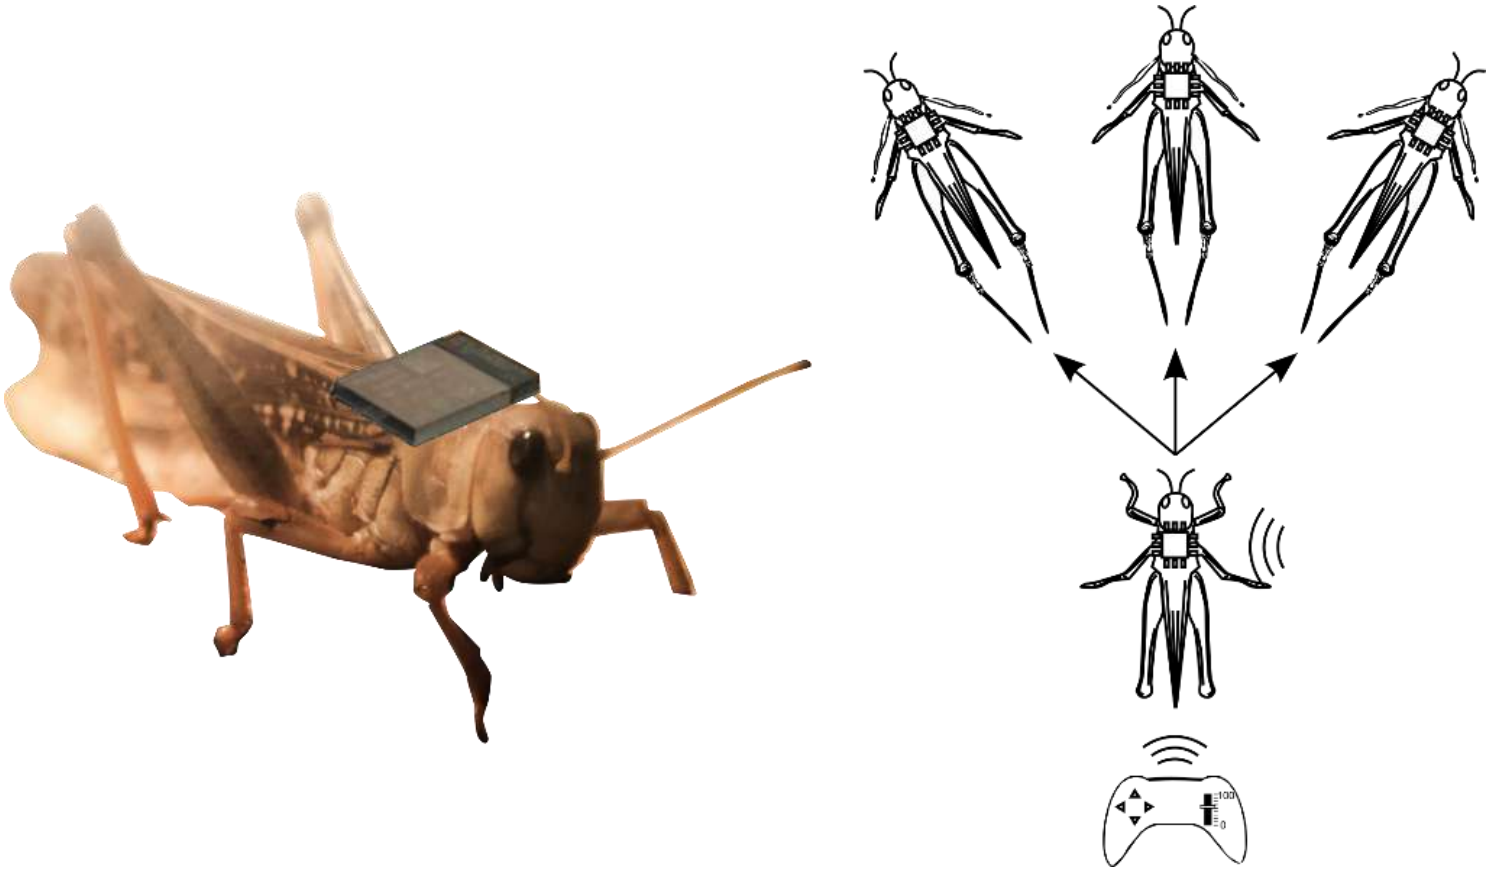
POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Francisco Zurita, Lukas Hiendlmeier, Bernhard Wolfrum
Technical University of Munich, Munich Institute Of Biomedical Engineering, Garching bei München, Germany



Insects are powerful animal models for neuroscience research. Normally, studies involving them are conducted in tissue preparations or fixed positions of the animal. However, more insight can be obtained from studies in freely moving animals. The aim of this work is to trigger the jumping mechanism of the locust artificially and wirelessly, to better understand the underlying neurophysiological mechanisms involved in an untethered subject. Both legs of the locust are interfaced at the muscle and motor nerves. Self-folding electrodes are implanted into the chest of the animal to interface with the extensor nerve fibers, and Ag wire is used to interface with the flexor muscle of the locust. Finally, these electrodes are connected to a microcontroller, which is set on the back of the insect. The microcontroller triggers the jumping, by stimulating nerve and muscles with frequency-modulated pulse trains. We successfully interfaced the extensor nerve and flexor muscle to elicit controlled extension and flexion movements of the legs after the surgery. Furthermore, we mounted the microcontroller on the back of the animal and observed that it does not prevent it from performing its regular activities. The work shows how to use electrical stimulation to modulate the jump of the locust in an untethered way. We expect to be able to modulate the length and direction of the jump with the stimulation signal's frequency and dephasing.

HIPPOCAMPAL SYNAPTIC PLASTICITY MEDIATES VAGUS NERVE STIMULATION INDUCED COGNITIVE ENHANCEMENT IN HEALTHY MALE RATS

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Laura Olsen[1], Raquel Moore[1], Naomi Bechmann[1], Victoria Ethridge[2], Nathan Gargas[2], Sylvia Cunningham[1], Zhanpeng Kuang[1], Joshua Whicker[1], Joyce Rohan[2], Candice Hatcher-Solis[1]

Aims Vagus nerve stimulation (VNS) improves cognition in humans and rodents, but the underlying mechanisms of this enhancement are not understood. Behavioral performance and hippocampal (HC) electrophysiology/neurotrophin expression were measured in healthy adult rats after VNS paired training to investigate changes in cognition and synaptic plasticity. **Methods** All animal activities were approved under an IACUC protocol. Platinum/iridium electrodes were surgically implanted around the left VN of anesthetized male Sprague-Dawley rats (N=47). VNS (100 μs biphasic pulses, 30 Hz, 0.8 mA) paired Novel Object Recognition (NOR)/Passive Avoidance Task (PAT) were assessed 24 h after training and post-mortem tissue was collected 48 h after VNS (N=28). Electrophysiology recordings were collected using a microelectrode array system to assess function effects on HC slices 90 min after VNS (N=19). Sham received the same treatment without VNS and experimenters were blinded. **Results** Stimulated rats exhibited improved performance in NOR ($p<0.05$, n=12) and PAT ($p<0.05$, n=14). VNS enhanced long-term potentiation ($p<0.05$, n=7-12) and spike amplitude ($p<0.05$, n=7-12), while reducing paired pulse facilitation ($p<0.05$, n=7-12) in the CA1. Immunohistochemical analysis found increased brain derived neurotrophic factor expression in the CA1 ($p<0.05$, n=8-9) and CA2 ($p<0.01$, n=7-8). **Conclusions** These findings suggest that our VNS parameters promote synaptic plasticity and target the CA1, which may mediate the positive cognitive effects of VNS. This study significantly contributes to a better understanding of VNS mediated HC synaptic plasticity, which may improve clinical utilization of VNS for cognitive enhancement.

A role for viral infections in Parkinson's etiology?
Despite over 200 years since its first description by James Parkinson, the cause(s) of most cases of Parkinson's disease (PD) are yet to be elucidated. The disparity between the current understanding of PD symptomology and pathology has led to numerous symptomatic therapies, but no strategy for prevention or disease cure. An association between certain viral infections and neurodegenerative diseases has been recognized, but largely ignored or dismissed as controversial, for decades. Recent epidemiological studies have renewed scientific interest in investigating microbial interactions with the central nervous system (CNS). This review examines past and current clinical findings and overviews the potential molecular implications of viruses in PD pathology.

Viral mimetic priming enhances α-synuclein-induced degeneration: Implications for Parkinson's disease.
Evidence is accumulating to suggest that viral infections and consequent viral-mediated neuroinflammation may contribute to the etiology of idiopathic Parkinson's disease. Moreover, viruses have been shown to influence α-synuclein oligomerization as well as the autophagic clearance of abnormal intra-cellular proteins aggregations, both of which are key neuropathological events in Parkinson's disease pathogenesis. To further investigate the interaction between viral-mediated neuroinflammation and α-synuclein aggregation in the context of Parkinson's disease, this study sought to determine the impact of viral neuroinflammatory priming on α-synuclein aggregate-induced neuroinflammation and neurotoxicity in the rat nigrostriatal pathway. To do so, male Sprague-Dawley rats were intra-nigrally injected with a synthetic mimetic of viral dsRNA (poly I:C) followed two weeks later by a peptidomimetic small molecule which accelerates α-synuclein fibril formation (FN075). The impact of the viral priming on α-synuclein aggregation-induced neuroinflammation, neurodegeneration and motor dysfunction was assessed. We found that prior administration of the viral mimetic poly I:C significantly exacerbated or precipitated the α-synuclein aggregate induced neuropathological and behavioral effects. Specifically, sequential exposure to the two

challenges caused a significant increase in nigral microgliosis ($p < 0.001$) and astrocytosis ($p < 0.01$); precipitated a significant degeneration of the nigrostriatal cell bodies ($p < 0.05$); and precipitated a significant impairment in forelimb kinesis ($p < 0.01$) and sensorimotor integration ($p < 0.01$). The enhanced sensitivity of the nigrostriatal neurons to pathological α-synuclein aggregation after viral neuroinflammatory priming further suggests that viral infections may contribute to the etiology and pathogenesis of Parkinson's disease.

THE NEURAL CIRCUIT DYNAMICS EVOKED BY TEMPORAL INTERFERENCE (TI) ELECTRICAL NEUROSTIMULATION IN VIVO

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Patrycja Dzialecka, Nir Grossman
UK Dementia Research Institute, Imperial College London, Department Of Brain Sciences, London, United Kingdom

Temporal interference (TI) is a novel electrical brain stimulation technique that can target deep brain structures noninvasively. It is based on the simultaneous application of two kHz electric fields, which generate a field with an amplitude-modulation (AM) oscillating at the difference frequency where the applied fields overlap. Previous work suggested that the TI stimulation area corresponds to the area of maximum AM. However, there has been no experimental evidence up to date to confirm this hypothesis. Herein, we set to examine for the first time the direct response of large-scale neural circuits to TI stimulation *in vivo*. We used widefield calcium imaging to track the activity of large cortical populations of Thy1-GCaMP6s mice undergoing TI and control (i.e., traditional AC) stimulation. We found that TI stimulation reliably evoked neuronal oscillations at the difference frequency of the applied fields. The strength of the evoked response was inversely proportional to the carrier frequency used. The locus of the oscillatory response was located between the stimulating electrodes, as was predicted by our FEM modelling of the TI fields. This is the first demonstration of the direct effects of TI on neural circuits *in vivo*, which is an essential step in uncovering the mechanism of action and facilitating the translation of the technique.

Vagus nerve signals from the gut to brain are disrupted by consuming large amounts of high-calorie foods, neccessitating greater food intake to elicit a similar neural response. Non-invasive vagus nerve stimulation (nVNS) via a branch innervating the ear is a candidate treatment for obesity. We aimed to test the optimal ear position(s) for nVNS and explore the effects of nVNS during hungry and full states. In a within-subject design, each participant received nVNS in four different locations (cymba conchae, tragus, lobe, or tragus AND cymba conchae (CT)) on separate days. In each session, participants were asked to drink a chocolate flavored milk. rMSSD (measure of heart-rate variability) was measured for 15 minutes before and at least 35 minutes after consumption. We observed a significant effect of time ($F[1,13] = 8.157$, $p=.014$), such that rMSSD decreases after drink consumption. We also observed an interaction between location and time ($F[3,39] = 3.845$, $p=.017$). There was no main effect of location. The pre-drink effect of cymba nVNS was to lower rMSSD compared to CT (post-hoc $p_{corr}=0.03$), and unlike nVNS in the other locations, cymba does not decrease in rMSSD post drink consumption. Before drink consumption, rMSSD is lower with nVNS in cymba conchae, which remains similarly low after drink consumption. rMSSD decreases for all other conditions after drink consumption. These results suggest that nVNS in the cymba conchae in a hungry state has a similar acute effect on vagal tone as food consumption: to decrease heart rate variability. NON-INVASIVE VAGUS NERVE STIMULATION REDUCES WANTING OF A PALATABLE CHOCOLATE DRINK

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Berçem Yar[1], Ilkim Buyukguduk[2], Zeynep Altınkaya[3], Dilan Koyuncu[3], Uğur Dal[3], Lina Öztürk[4], Hüseyin Yanık[5], Evren Değirmenci[5], Maria Veldhuizen[6]
[1]Mersin University, Psychology, Mersin, Turkey, [2]Mersin University, Experimental Psychology, Mersin, Turkey, [3]Mersin University, Faculty Of Medicine, Physiology, Mersin, Turkey, [4]Mersin University, Faculty Of Medicine, Mersin, Turkey, [5]Institute of Science, Electrical And Electronics Engineering, Mersin, Turkey, [6]Mersin University, Faculty Of Medicine, Anatomy, Mersin, Turkey

The vagus nerve plays an important role in the regulation of food intake. Non-invasive vagus nerve stimulation via the branch innervating the ear (nVNS) is considered as an alternative approach to treatment of obesity. The aim of this study was to determine the optimal ear position(s) for nVNS is the outer ear as well as to explore the effect of nVNS on hedonic and perceptual response to food. In a within-subject design (10 women, on average 29.4 +/- 6.7 years old), with 4 sessions per subject, each on separate days. In a session participants were asked to arrive fasted, then they received 15 minutes of stimulation (4 different locations: lobe (control), cymba conchae, tragus, or tragus and cymba conchae). Then they sample and rated a palatable chocolate drink (10% fat, 10% sugar, w/v). The drink was rated for liking, wanting ('how much do you want to consume this drink?'), intensity, sweetness, sourness, fattiness, creaminess, calorie-richness, healthiness, and familiarity on visual analog scales. Wanting after tVNS in cymba conchae is lower (main effect of location $F[3,33]=3.721$, $p=0.021$) compared to the other locations. There was a trend for liking to be decreased after tVNS in cymba conchae too (main effect of location $F(3,33)=2.689$, $p = 0.062$). Other ratings did not show an effect of stimulation location. We conclude that only nVNS in cymba conchae location affects motivation to consume foods, in line with recent reports of an increased drive to work for rewards in tVNS. BIOPHYSICAL INVESTIGATION OF TEMPORAL INTERFERENCE STIMULATION MECHANISM

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Charlotte Luff[1,2], Robert Peach[1,2,3], Nir Grossman[1,2]
[1]Imperial College London, Uk Dementia Research Institute, London, United Kingdom, [2]Imperial College London, Brain Sciences, London, United Kingdom, [3]University Hospital Würzburg, Neurology, Würzburg, Germany

Temporal Interference (TI) stimulation is a non-invasive deep brain stimulation technique. During TI, two electric fields are applied to the brain at kHz frequencies that differ in frequency by a small amount. The two fields overlap at the target brain location to drive neural activity at the difference frequency of the applied fields. The mechanism by which TI stimulation drives activity at the difference frequency, despite no (or minute) depolarisation at the applied kHz frequencies, is unknown. Herein we report the discovery that TI stimulation is mediated by a nonlinear frequency mixing phenomenon at the neural cell membrane. We show, using *ex-vivo* whole-cell patch-clamp recordings and extracellular stimulation, that subthreshold transmembrane depolarisation at two different frequencies reliably evokes polarisation at their difference frequency, across a broad range of frequencies, spanning endogenous to kHz frequencies. The frequency mixing product at the difference frequency is sustained under synaptic input block, but attenuated under voltage-gated ion channel block, indicating a cell membrane origin involving voltage-gated ion channels. The strength of the nonlinear frequency mixing process, and thus the strength of TI stimulation, is dependent on the applied frequency but not on the difference frequency. Overall, our work demonstrates how nonlinear biophysical properties of the cell membrane support novel electrical neurostimulation paradigms such as TI. Additionally, this insight into the mechanism of action, and parameter space, of TI may aid in the development and clinical adoption of the technique.

STIMULATION OF VAGAL AFFERENTS IN DIFFERENT EAR LOCATIONS DOES NOT INFLUENCE EFFERENT METABOLISM PRE- OR POST CONSUMPTION OF A PALATABLE DRINK

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Maria Veldhuizen[1], Ilkim Buyukguduk[2], Berçem Yar[3], Lina Öztürk[4], Zeynep Altınkaya[5], Dilan Koyuncu[5], Hüseyin Yanık[6], Evren Değirmenci[6], Uğur Dal[5]
[1]Mersin University, Faculty Of Medicine, Anatomy, Mersin, Turkey, [2]Mersin University, Experimental Psychology, Mersin, Turkey, [3]Mersin University, Psychology, Mersin, Turkey, [4]Mersin University, Faculty Of Medicine, Mersin, Turkey, [5]Mersin University, Faculty Of Medicine, Physiology, Mersin, Turkey, [6]Institute of Science, Electrical And Electronics Engineering, Mersin, Turkey

The vagus nerve forms a connection between nutrient-sensing cells in the gut and the brain. Stimulation of vagal cell bodies in the nodose ganglion is capable of conditioning flavor preferences and releasing dopamine in the dorsal striatum. This makes the vagus nerve an interesting stimulation target for modulating responses to food reward in humans. Non-invasive vagus nerve stimulation via the auricular branch in the ear has successfully been used to influence processes related to vagus nerve activity. There is disagreement on the optimal ear location for nVNS. The aim of this study was to compare the effect of nVNS in four different locations of the ear on efferent metabolism before and after consumption of a palatable chocolate drink (10% fat, 10% sugar, w/v). In a randomized cross-over design with 14 participants (10 women, on average 29.4 +/- 6.7 years old), we applied transcutaneous VNS in earlobe (control), cymba conchae, tragus and cymba concha + tragus and measured gastric frequency (GF) and diet-induced thermogenesis (DIT). We observed no differential effect of nVNS location on GF or DIT (p's >.182). We did observe an effect of time on DIT, such that DIT always increased post-drink consumption, regardless of ear location ($F[1,13] = 96.026$, $p<.001$). We conclude that efferent metabolism as reflected in GF and DIT is not sensitive to acute shifts in vagal tone pre- or post-consumption of a palatable drink. Funded by TÜBİTAK project no 118C299

INVASIVE AND NON-INVASIVE TEMPORARY INTERFERING ELECTRIC FIELDS STIMULATION (TIEF) OF THE RAT BRAIN: A C-FOS IMMUNOCYTOCHEMICAL QUANTITATIVE ANALYSIS

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Venezia Carmona[1], Inés Fernández Del Campo[1], Jose M. Delgado-García[2], Ignacio Plaza[1], José Antonio Santos[2], Iván Díaz[1], Miguel Merchan[1]
[1]University of Salamanca, Instituto De Neurociencias De Castilla Y Leon, Salamanca, Spain, [2]Pablo de Olavide University, Division Of Neurosciences, Sevilla, Spain

We reported here the effects of TIEF in the rat brain using both transcranial and epidural approaches for stimulation. For non-invasive stimulation, a 0.015 mm silver wires were placed inside two 0.2 mm polyamide tubes filled with saline solution and glued on the skull surface along with two 1 cm autoadhesive electrodes placed on the chest. Dorsal electrodes were paired with ventral ones and activated at 2000 Hz and 2010 Hz, with an intensity of 0.12 mA, in a 30-min single session. For epidural stimulation protocol, we implanted four 1 mm silver ball electrodes on the left surface of the skull fixed in specific stereotaxic coordinates. Paired electrodes were activated by 2000 Hz and 2005 Hz, 0.60 mA, in 30 min sessions in four consecutive days. In both experimental groups, 40 min after the end of the stimulation protocol, animals were perfused and processes for C-fos (activation maps) and GFAP (tissular damage) immunocytochemistry. Three serial sections per case at specific coordinates were analyzed densitometrical- and morphometrically after density thresholding segmentation (ImageJ). MATLAB full section maps performed after codification of the collected data from ImageJ analysis allowed to compare changes in number, size, and optical density distribution of immunoreactive neurons. These types of analysis allowed us to define the activated brain areas in the different experimental groups. Present results support the presence of cortical, instead of deep brain activation areas, by the two types of interfering fields stimulation protocols. REMOTE DEEP BRAIN STIMULATION BY TRANSGENE-FREE MAGNETOMECHANICAL APPROACH

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Chao-Chun Cheng, Chih-Lun Su, Ping-Hsiang Yen, Po-Han Chiang
National Yang Ming Chiao Tung University, Institute Of Biomedical Engineering, Hsinchu City, Taiwan

Deep brain stimulation (DBS) has been used to treat neurological diseases, especially related to movement disorders like Parkinson's disease, essential tremor and other diseases. However, the conventional DBS treatment is an invasive treatment method that requires electrodes implanted in the deep brain area. Although other minimally invasive treatment methods have been developed, including optical, acoustic, and electromagnetic for neuronal manipulation. Only the magnetic field can penetrate the brain without absorption or scattering. Wireless DBS with magnetogenetics were developed rapidly in the last decade. However, overexpression of exogenous ion channels and gene delivery with viral vectors might raise the concern of potential side effects. Here, we used a low-frequency and weak alternating magnetic field driving the magnetic nanodiscs to generate mechanical force for activating the transgene-free neurons. In our study, iron oxide magnetic nanodiscs were synthesized with diameter at ~270 nm. The torque of magnetic nanodiscs generated by applying alternative magnetic field in low frequency could repeatedly induce neuronal activity. Moreover, we revealed that the intrinsic mechanosensitive ion channel transient receptor potential canonical (TRPC), which were widely expressed in the brain, played crucial roles in this magnetomechanical stimulation. Finally, we injected the magnetic nanodiscs into the subthalamic nucleus and applied the magnetic stimulation in awake mice after recovery. The magnetomechanical force triggered neuronal activities in the target and downstream areas. Therefore, we developed a wireless DBS without transgene or hardware implantations by using magnetomechanical approach.

THE EFFICACY OF NON-INVASIVE BRAIN STIMULATION TECHNIQUES ON CHRONIC PRIMARY PAIN DISORDERS: A SYSTEMATIC REVIEW AND META-ANALYSIS

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Alessandra Telesca[1], Alessia Gallucci[1], Alessandra Vergallito[2], Leonor Romero Lauro[2]
[1]University of Milano-Bicocca, Medicine And Surgery, Milano, Italy, [2]University of Milano-Bicocca, Psychology, Milano, Italy

Background: Chronic Primary Pain (CPP) is characterized by an intense pain, not explained by lesions/damage to the nervous system, lasting for more than three months. Not all CPP patients benefit from standard pharmacological therapies nor are suitable for invasive neurosurgery treatments. Non-invasive brain stimulation (NIBS) uses cortical stimulation to reduce pain by directly altering brain activity, and its effects in treating CPP is still unclear. **Objectives:** We aimed at evaluating NIBS effects on CPP patients. **Methods:** A PRISMA systematic review was performed in PubMed, Embase, Scopus and Web of Science in May 2021. English-written, original studies measuring the effects of NIBS on pain perception were considered. The quality of studies was assessed with the Cochrane Risk of Bias and the Robins-I. The meta-analysis was conducted considering the pain intensity measured through visual or numerical rating scales as outcome of interest. **Results:** 134 studies were included, comprising 2444 patients and 13 different Primary Pain conditions. The meta-analysis was run on a preliminary cohort of 39 studies. When compared to sham effects, real NIBS induced a significant decrease of pain intensity (SMD −0.58 [CI: −0.83, −0.32];$p < 0.001$). **Conclusions:** Our findings showed a reduction of the perceived pain following real vs. sham stimulation, suggesting that NIBS can be used as an alternative or as a combined approach in CPP treatment.

Cognitive reserve is associated with altered clinical expression in amyotrophic lateral sclerosis.
: Long-term life experiences, such as education, occupational attainment, leisure activities, and bilingualism, have been considered proxies of cognitive reserve (CR). In neurodegenerative disease, CR is considered as a modulator of a more favorable cognitive trajectory and motor functions. Our study investigated the role of CR on cognitive and motor involvement in a large cohort of incident patients with amyotrophic lateral sclerosis (ALS). : Cognition assessment and clinical and demographic information were obtained in 101 incident ALS patients. CR was measured based on years of education, occupational attainment, amount of leisure activities, and bilingualism. Correlation and regression analyses were performed to test the association between CR and the clinical expression of ALS. : We found that all proxies of CR were positively associated with executive functions, verbal fluency, and memory domains. Motor impairment was inversely related to educational level and occupational attainment. Regression analysis documented the association between CR and cognitive performances in all patients and the predictive role of CR in modulating motor functional disability in patients with bulbar-onset. : Our findings showed that CR mediates the extent of cognitive decline and that of functional bulbar impairment, suggesting that the concept of reserve applied to ALS should encompass cognitive and motor domains.

BRAIN DERIVED NEUROTROPHIC FACTOR NEGATIVELY RESPONDED TO TRANSCRANIAL DIRECT CURRENT STIMULATION: RANDOMIZED CONTROLLED TRAIL

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Hussein Youssef[1], Nema Abd El-Hameed Mohamed[2], Mohamed Hamdy[3]
[1]Koç University, Neuroscience, Istanbul, Turkey, [2]Alexandria University, Department Of Zoology, Alexandria, Egypt, [3]Alexandria University, Neuropsychiatry, Alexandria, Egypt

Background Brain-derived neurotrophic factor (BDNF) levels could objectively indicate synaptic plasticity, it has also been suggested that modulation of BDNF might be a part of mechanisms involved in transcranial direct current stimulation tDCS effects on synaptic connectivity. The aim of this study is to investigate associated change within BDNF level in response to tDCS in subacute stroke patients. The trial registration in the clinical trial ID is NCT04770363.

Methods 36 sub-acute ischemic stroke survivors participated, randomly assigned to one of three groups receiving tDCS, bihemispheric (Anodal over affected M1, and cathodal over healthy M1) or unihemispheric (Anodal over affected M1, and cathodal stimulation over supraorbital bone) or sham (No current). ActivaDose tDCS (USA) used, consisted of 20 minutes of 2 mA intensity; in each session for 12 sessions three sessions per week. A 3ml blood sample was withdrawn. First sample was withdrawn in first session and second sample by last session. BDNF were determined using commercially available ELISA kits.

Results there was a statistically significant difference (Negative change) within groups for bihemispheric (P-value = .011), and unihemispheric stimulation (P-value = .003). For sham group, no significant difference (P-value = .492). Significant difference between groups (P-value = .005). Post-hoc test by pairwise revealed both bihemispheric & unihemispheric stimulation significantly decreased BDNF levels more than sham (P = .001), (P = .021), respectively and with no significant difference between both experimental groups (P = .217).
Conclusion BDNF has showed significant decrease after tDCS in stroke patients, even motor measures positively improved.

DOSE DEPENDENT EFFECTS OF TMS ON THE MODULATION OF FRONTO-STRIATAL CONNECTIVITY. A 18F-DMFP PET STUDY.

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Usman Jawed Shaikh[1], Antonello Pellicano[1], Andre Schueppen[1], Oliver Winz[2], Alexander Heinzel[2], Felix Mottaghy[2], Ferdinand Binkofski[1]

Introduction: Transcranial Magnetic Stimulation (TMS) can modulate fronto-striatal connectivity in the human brain. Positron Emission Tomography (PET) and TMS were combined to investigate the fronto-striatal connectivity in the human brain. We employed ^{18}F-DesmethoxyFallypride (DMFP) - a high affinity Dopamine receptor-antagonist - to measure the release of endogenous dopamine in the striatum in response to repeated blocks of excitatory, intermittent theta burst stimulation (iTBS) of the Prefrontal Cortex (PFC). **Methods:** 23 healthy subjects participated in two PET sessions, each one with four blocks of iTBS separated by 30 minutes: *sham* (control) and *verum* (90% of individual resting motor threshold). Binding Potentials (BPs) were collected for sham and verum sessions across 28 time frames (about 130 minutes) in striatal regions (Nucleus Caudate and Putamen). **Results:** Verum iTBS increased the dopamine release in striatal regions, as compared to sham iTBS. Dopamine levels in the verum session increased progressively across the time frames within about 75 minutes (after three blocks of iTBS) and then eventually remained stable until the end of the session. **Conclusion:** Results suggest that the short iTBS protocol performed in repeated blocks can effectively induce a dose dependent increase in dopaminergic fronto-striatal connectivity. This scheme could present an alternative to painful, long stimulation protocols in experimental and theurapeutic settings. Specifically, it was demonstrated that three repeated iTBS, spaced by short intervals, achieve larger effects than one single stimulation. This finding has implications for the planning of therapeutic interventions, for example, treatment of major

depression.

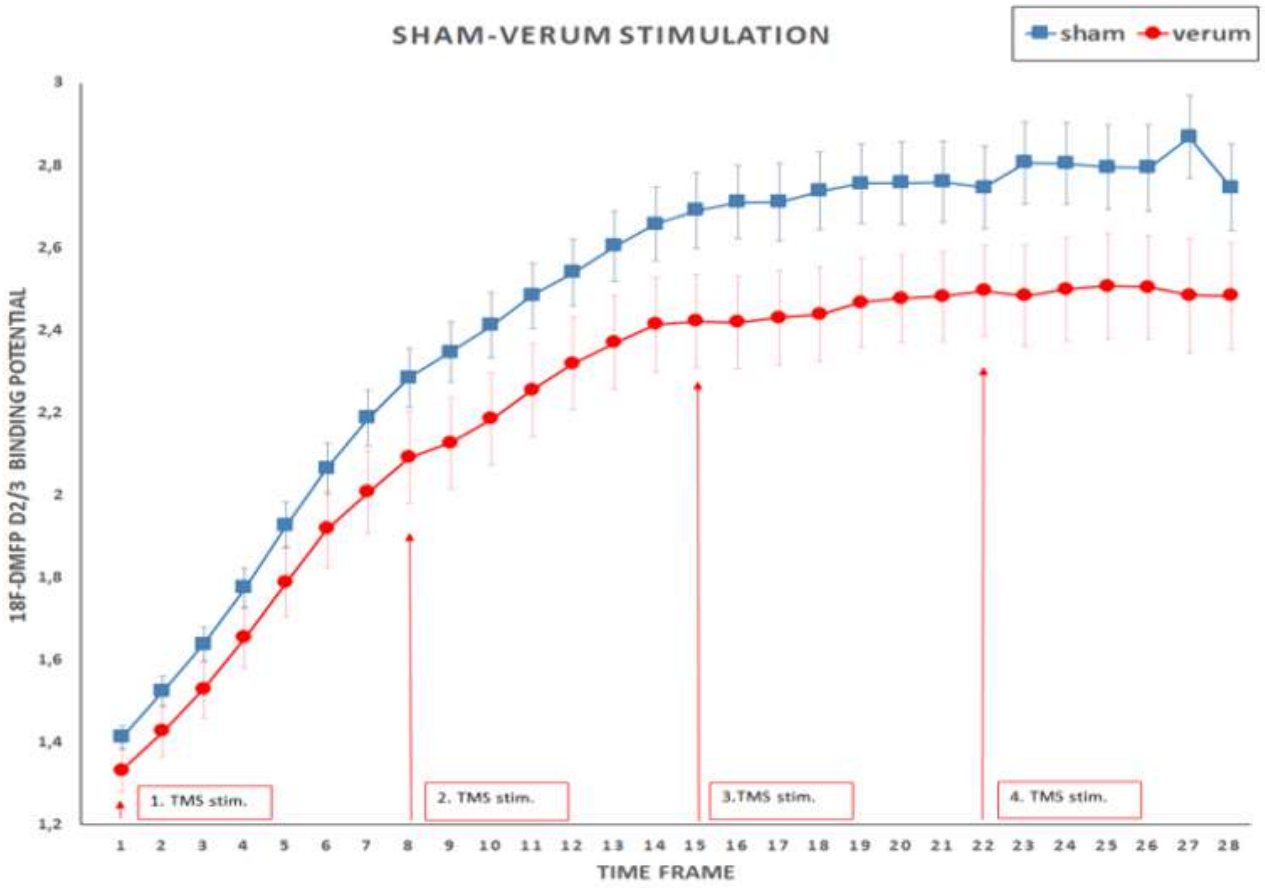

Figure 1: Mean Binding Potentials (BPs) at sham and verum TMSs across 28 time frames. We observed lower BPs in the verum stimulation compared to sham stimulation. Moreover, BPs in the verum condition showed a progressive decrease from time frame 1 to time frame 19 (about 75 mins) and then essentially stabilized until the end of the session, frame 28.

REPEATED ANODAL TRANSCRANIAL DIRECT CURRENT STIMULATION (RA-TDCS) INCREASES HIPPOCAMPAL CELL PROLIFERATION IN YOUNG-ADULT MICE

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Stéphanie Dumontoy[1], Bahrie Ramadan[1], Pierre-Yves Risold[1], Solène Pedron[2], Christophe Houdayer[1], Adeline Etiévant[1], Lidia Cabeza[1], Emmanuel Haffen[1], Yvan Peterschmitt[1], Vincent Van Waes[1]

Repeated anodal transcranial direct current stimulation (RA-tDCS) is a neuromodulatory technique consisting in stimulating the cerebral cortex with a weak constant electric current in a non-invasive manner. RA-tDCS has antidepressant-like properties and improves memory both in human and laboratory animals. However, the mechanisms of action of RA-tDCS remain poorly understood. Since adult hippocampal neurogenesis is involved in the pathophysiology of depression and in cognitive processes, our aim was to study the impact of RA-tDCS on hippocampal neurogenesis levels in mice. RA-tDCS was applied 20 minutes per day for five consecutive days over the frontal cortex of 2-month-old and 10-month-old female mice (young-adults and adults, respectively). Then, animals received 3 intraperitoneal injections of bromodeoxyuridine (BrdU) and the brains were collected 1 or 21 days later. Cell proliferation, survival and differentiation were evaluated using simple or double staining immunohistochemistry. RA-tDCS increased cell proliferation specifically in young-adult animals, preferentially in the dorsal part of the dentate gyrus. Whatever the age, RA-tDCS had no significant effect on cell survival or differentiation. We conclude that the behavioural effects of RA-tDCS in mice previously described by our team (antidepressant and pro-cognitive properties) might be independent of an effect of RA-tDCS on neurogenesis levels in hippocampus.

RETEST-RELIABILITY OF REPETITIVE TRANSCRANIAL MAGNETIC STIMULATION OVER THE HEALTHY HUMAN MOTOR CORTEX: A SYSTEMATIC REVIEW

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Carolina Kanig[1,2], Mirja Osnabruegge[1,2], Wolfgang Mack[2], Stefan Schoisswohl[1,2], Martin Schecklmann[1]
[1]University Regensburg, Psychiatry And Psychotherapy, Regensburg, Germany, [2]Universität der Bundeswehr München, Human Sciences, Neubiberg, Germany

Background: Repetitive transcranial magnetic stimulation (rTMS) is a standard tool to investigate neuronal plasticity. Yet, underlying mechanisms are not fully understood and heuristics about inhibitory and facilitatory cortical changes lack of evidence. Hence, identifying reliable protocols is necessary to derive validity of rTMS induced plastic changes. **Aims:** The present work systematically reviews studies on healthy subjects to extract and compare retest-reliability of rTMS effects, assessed by single-pulse TMS measures of the human primary motor cortex, i.e. motor evoked potentials of hand muscles. By structured methodological quality assessment, we wanted to ensure comparability of these experiments. **Methods:** Out of 742 database entries published until January 2022 in PubMed, fourteen articles were judged as eligible from two independent authors according to PRISMA guidelines. Inclusion criteria were English language and repeated application of rTMS on primary motor cortex of healthy subjects. Retest-reliability measures were compared. Two independent authors rated the quality of experiments with a standardized assessment tool and calculated sum scores. For inter-rater reliability we conducted Cohen's Kappa. **Results:** More recent protocols like paired associative stimulation (PAS) and theta burst stimulation (TBS) reveal moderate values of reliability whereas standard continuous rTMS procedures, for example 1 Hz, 10 Hz or 20 Hz, were less reliable. Methodological quality was similar and Cohen's Kappas strong to almost perfect. **Conclusions:** Some repetitive transcranial magnetic stimulation protocols are repeatable over time. Still, results are heterogeneous and depict existing inconsistencies across the field of TMS. Continuous improvements in quality of recent studies reveal promising outlooks to future research.

Aims Ischemic stroke consists of a rapid loss of cerebral function as consequence of the obstruction of a brain vessel, followed by subsequent damage to neighbouring tissue. Cerebral tissue quickly becomes irreversibly damaged in the vicinity of the closed vessel, but this tissue is potentially salvageable towards the periphery of the lesion during the initial phases after stroke, a region called the ischemic penumbra. This study is an in-vitro approach to understand the effect of Extreme Low Frequency Electromagnetic Stimulation (ELF-EMS) on oxygen-glucose deprivation (OGD) induced neuronal cell death in vitro. Methods Primary neuronal cultures derived from cerebral cortex of embryonic E18 pups were subjected to OGD in the presence of an inhibitor of glycolysis, iodoacetic acid (IAA 20 µM or 50 µM). After OGD, neurons were magnetically stimulated in a solenoid designed and characterized with SIM4LIFE (ZMT Zurich MedTech AG) to generate a homogenous magnetic field (MF) on the cell plate. Neuronal death was measured 24h after OGD using fluormetry and calcein-AM as the survival dye. Results We tested different protocols of magnetic stimulation (f=10-100 Hz and B=300 µT -10 mT). None of the protocols applied for 24 h induce any affect in neuronal survival under basal conditions (without OGD). Importantly, magnetic stimulation significantly reduced neuronal cell death secondary to OGD. Conclusions This preliminary study shows the potential use of MF in the ELF band for decreasing neuronal cell death after OGD and points to MF as a possible therapeutic strategy to reduce ischemic penumbra damage.

NEURAL NONLINEARITIES REVEAL ONLINE EFFECTS OF TACS

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Nima Noury[1,2,3], Markus Siegel[1,2,3], Fabio Damiani[1,2,3]
[1]MEG Center, University Of Tübingen, Tübingen, Germany, [2]Centre for Integrative Neuroscience, University Of Tübingen, Tübingen, Germany, [3]Hertie Institute for Clinical Brain Research, Neural Dynamics And Meg, Tübingen, Germany

Despite the widespread use of transcranial alternating current stimulation (tACS) as a non-invasive brain stimulation technique, it remains challenging to study online neural effects of tACS due to stimulation artifacts. Here, we exploitneural nonlinearities to account for artifacts and reveal online neural effects of tACS. We first provide a linear model that predicts brain response to tACS. Then, we show that magnetoencephalography (MEG) measurements during tACS deviate from the predictions of this model. More specifically, we measured brain activity in human subjects either during 10 Hz visual flicker stimulation, during 10 Hz tACS, or during simultaneous visual stimulation and tACS. We found that brain activity during the simultaneous condition deviated from the linear combination of responses to theseparate stimulation conditions. Furthermore, this interaction depended on the relative phase of visual stimulation and tACS. Our work provides a new approach to study online neural effects of tACS, and adds novel evidence for aninteraction between tACS and ongoing neural activity.

RELIABILITY OF MOTOR EVOKED POTENTIALS IN HAND MUSCLES OF HEALTHY INDIVIDUALS: A SYSTEMATIC REVIEW

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Mirja Osnabruegge[1,2], Carolina Kanig[1,2], Wolfgang Mack[2], Martin Schecklmann[1], Stefan Schoisswohl[1,2]
[1]University Regensburg, Psychiatry And Psychotherapy, Regensburg, Germany, [2]Universität der Bundeswehr München, Human Sciences, Neubiberg, Germany

Aims: Motor evoked potentials elicited by transcranial magnetic stimulation over the primary motor cortex are used as a neurophysiological marker of cortical excitability in daily clinical and scientific practice. Tough, the reliability of this outcome parameter has not been clarified. Using a systematic approach, the present work reviews and critically appraises studies on the reliability of motor evoked potential amplitudes and input-output curves derived from hand muscles of healthy subjects. **Methods**: A systematic literature research was performed in PubMed, according to the PRISMA guidelines. Articles published up to July 2021 were included. Two authors conducted the search independently and rated the articles in terms of eligibility and methodical criteria with standardized instruments. Reliability parameters were extracted and summarized in a structured way. Included studies had to be written in English, conducted repeated measures on the hand muscles of healthy individuals and reported statistical reliability parameter. **Results**: Twenty-eight articles testing short- and long-term reliability fulfilled the inclusion requirements. Critical appraisal of the studies reveals methodological heterogeneity and partly contradictory results regarding the reliability of the outcome parameters. Reliability is influenced by the number of applied stimuli, muscle target, stimulation intensity, inter-pulse interval and waveform. **Conclusion**: The methodology of transcranial magnetic studies is still subject to heterogeneity, which could contribute to the partly contradictory results. According to the current knowledge status, the reliability of the outcome parameters can be increased by adjusting the experimental setup.

CONTINUOUS THETA BURST STIMULATION DECREASES STRIATAL DOPAMINE RELEASE ACUTELY BUT NOT CHRONICALLY: AN IN VIVO AND POSTMORTEM STUDY

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Lucero Aceves-Serrano[1], Jason Neva[2], Jonathan Munro[3], Martin Parent[3], Lara Boyd[4], Doris Doudet[1]
[1]University of British Columbia, Medicine, Vancouver, Canada, [2]Université de Montréal, Faculté De Médecine, Montreal, Canada, [3]CERVO Brain Research Center, Department Of Psychiatry And Neuroscience, Quebec, Canada, [4]University of British Columbia, Physical Therapy, Vancouver, Canada

Aim: To evaluate the immediate and chronic effects of theta burst stimulation (TBS) on the dopaminergic system. **Method:** Using healthy non-human primates and positron emission tomography (PET), we scanned animals with [^{11}C]raclopride (a $D_{2/3}$ receptor antagonist) before and immediately after the first session and 24hrs after a 3-week course of daily TBS delivery to the awake animals. Subjects received either sham, continuous (cTBS) or intermittent TBS (iTBS). The animals were then euthanized, and immunofluorescence staining was carried out with antibodies targeting the D_2 receptor to further evaluate chronic TBS effects. **Results:** CTBS (an inhibitory form of rTMS) over the left primary motor cortex acutely decreased dopamine release bilaterally in the putamen as shown by an increase in [^{11}C]raclopride binding. No significant changes in tracer binding were noted after chronic stimulation. ITBS (an excitatory form of rTMS) produced mixed results (both increase and decrease in tracer binding) leading to non-significant effects on dopamine release, acutely or chronically. Similarly, sham stimulation produced no effects. Post-mortem evaluation showed no significant difference in D_2 receptor immunoreactivity between active TBS and sham stimulation. **Conclusions:** In healthy brains, acute cTBS had a more consistent effect on DA release than iTBS but both seemed to induce a transient effect with no long-term changes in D_2 receptors as measured in vivo and post-mortem. Taken together this suggests that the DA system may not be directly responsible for long-term TBS clinical therapeutic efficacy or that compensatory homeostatic responses in a healthy brain obscures the possible effects in disease conditions.

EFFECTIVENESS OF INTERMITTENT THETA BURST STIMULATION OVER THE MEDIAL PREFRONTAL CORTEX COMBINED WITH ATTENTION MODIFICATION TRAINING ON EMOTION REGULATION

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Maria Sikki[1], Katerina Konikkou[1], Kostas Fanti[1], Nikos Konstantinou[2]
[1]University of Cyprus, Psychology, Nicosia, Cyprus, [2]Cyprus University of Technology, Department Of Rehabilitation Sciences, Limassol, Cyprus

Literature supports the critical role of medial prefrontal cortex (mPFC) in facilitating and managing emotions. Aim of the current study was the development of a treatment program to enhance emotion regulation. The treatment included intermittent Theta Burst Stimulation (iTBS) over the mPFC combined with Attention Modification Training (AMT). Eighty-seven participants (Mage = 21.02, SD = 1.89, males 50,6%) were recruited from a community sample in Cyprus. The duration of the treatment was 8 sessions and participants were randomized in three groups: iTBS - AMT, iTBS - control AMT, and sham iTBS - AMT. Prefrontal hemoglobin activation during emotional scripts (fear, sad and happy) was recorded prior and after the treatment using functional near-infrared spectroscopy. Repeated measures ANOVA was conducted for the average hemoglobin concentration in mPFC to examine the effectiveness of the treatment. As expected higher mPFC hemoglobin activation was observed during sad scripts and results shown a significant interaction between the types of emotional stimuli and the treatment. The two groups who received iTBS – AMT and sham iTBS - AMT shown decreased mPFC hemoglobin activation after treatment in all emotions. The group that received iTBS - control AMT shown increased mPFC hemoglobin activation in sad and happy scripts, but the opposite was found for fearful scripts. The goal of AMT was to direct attention to empathetic cues and current findings suggest that by stimulating prefrontal areas associated with emotion regulation, iTBS improved the effectiveness of AMT compared to sham stimulation on reducing mPFC hemoglobin activation.

Triarchic dimensions of psychopathy in young adulthood: Associations with clinical and physiological measures after accounting for adolescent psychopathic traits.
This study examined associations of psychopathy facets of boldness, meanness, and disinhibition with clinically relevant variables and physiological reactivity to affective stimuli. These associations were examined after accounting for developmental associations with adolescent psychopathic traits, namely callous-unemotional traits, narcissism, and impulsivity. Psychopathic traits were assessed during adolescence using the Antisocial Process Screening Device and the Inventory of Callous Unemotional traits and during young adulthood via the Triarchic Psychopathy Measure. Clinical variables (N = 99, Mage = 15.91, 53% female), as well as affective and physiological responses (heart rate, skin conductance, startle modulation) to violent and erotic videos (N = 88, Mage = 19.92, 50% female) were also assessed during adulthood. After accounting for adolescent psychopathic traits, boldness was associated with high cognitive reappraisal and low anxiety, fear, and hostility, and meanness was related to callous-unemotional traits, hostility, less sympathy to victims, and less use of cognitive reappraisal. Disinhibition, by contrast, was associated with impulsivity, increased anxiety, and hostile and aggressive tendencies, as well as conduct disorder, antisocial personality disorder symptoms, and cognitive suppression. In addition, evidence was found for different physiological measures operating as biological indicators of these distinctive dimensions, with reduced resting heart rate and cardiac reactivity to violent stimuli indicative of boldness, above and beyond adolescent psychopathic traits, and low startle potentiation for violent stimuli indicative of callous-unemotional traits and meanness. These findings provide evidence for the value of a multidomain approach for clarifying neurobiological mechanisms of psychopathic tendencies that can inform prevention and treatment efforts. Stability and change in callous-unemotional traits: Longitudinal associations with potential individual and contextual risk and protective factors.
This longitudinal study examines developmental heterogeneity in callous-unemotional (CU) traits in a large sample of school-age children in Cyprus. Latent Class Growth Analysis revealed 4 trajectory groups of CU traits across 3 time points: stable

high, increasing, decreasing, and low. Findings suggested that children in the stable high CU trajectory were more likely to (a) exhibit high and stable levels of conduct problems, attention-deficit/hyperactivity disorder symptoms, impulsivity and narcissism, (b) experience low parental involvement and high parental distress, (c) report low peer support and school connectedness, and (d) score lower on academic performance, executive functioning, social competence, and self-regulation compared to children with low, decreasing, and increasing CU traits. These findings were verified by both parent and child reports. Repeated analysis of variance suggested that increases and decreases in CU traits were associated with similar changes in conduct problems, narcissism, impulsivity, and maternal involvement. Further, children in the decreasing trajectory group were not differentiated from children in the low risk group on measures of executive functioning, academic performance, school connectedness, and peer social support at the last wave of measurement. These findings provide evidence for the importance of taking longitudinal change into account for understanding developmental heterogeneity in CU traits and the association of these traits with possible protective (e.g., stable high maternal involvement) and risk (e.g., decreases in maternal involvement and increases in conduct problems, impulsivity and narcissism) variables. THE EFFECTS OF PREFRONTAL VS PARIETAL CORTEX TRANSCRANIAL DIRECT CURRENT STIMULATION (TDCS) ON INHIBITION AND MEASURES OF SELF-ESTEEM

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Milos Ljubisavljevic[1], Jonida Basha[1], Fatima Ismail[2]
[1]CMHS UAE University, Physiology/neuroscience, Al Ain, United Arab Emirates, [2]CMHS UAE University, Pediatrics Department, Al Ain, United Arab Emirates

We examined the effects of transcranial direct current stimulation (tDCS), dorsolateral prefrontal cortex (DLPFC), and inferior parietal lobule (IPL) on inhibition and subjective psychological aspects like general body image and self-esteem state and trait. tDCS was administered at 1.5 mA for five days, 20 min each day (two rounds of 10 min divided by a 10 min break during which subjects engaged in mindfulness task) to DLPFC, IPL, or as SHAM stimulation. To decompose immediate and cumulative effects, we measured inhibition through the Go/no-go task together with self-esteem trait and state and body appreciation through a battery of questionnaires on days 1 and 5. We found that false alarm errors decreased in the DLPFC group, increased in IPL, and remained the same in the SHAM group. Correct hits and reaction time to Go signals were not altered. Only at day 5, there was a trend for DLPFC stimulation to increase the false alarms between pre and post-stimulation, possibly mirroring immediate and cumulative effects. Self-esteem and body perception were not affected by stimulation. Instead, there was a significant improvement in self-esteem trait over time in all groups, possibly due to the mindfulness exercise. These preliminary results indicate that tDCS modulates inhibition in fronto-parietal areas with opposite effects, enhancing it in DLPFC and impairing it in IPL. Judgments of self and body seem to be not affected by neuromodulation but may rely on broader regions as more complex constructs.

ENHANCING STANDARD ADDICTION TREATMENT PROTOCOLS EFFICACY THROUGH NON-INVASIVE BRAIN STIMULATION: A TDCS STUDY

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Lilia Del Mauro, Albert Matoshi, Susana Vicente, Nicoletta Piccitto, Andrea Silva, Laura Cappelletti, Pietro Farneti, Leonor Romero Lauro
University of Milano-Bicocca, Psychology, Milan, Italy

Aims: Substance abuse stands as a major health concern, severely affecting the well-being of addicted individuals. However, a gold standard treatment able to successfully reduce the high rate of relapses typically associated with this pathology has not been identified yet. Neuroimaging investigations highlighted diffuse brain alterations involving the dorsolateral prefrontal cortex (DLPFC). In this randomized sham-controlled study we tested whether transcranial direct current stimulation (tDCS) applied over the DLPFC could improve the recovery of addiction. Methods: 60 patients enrolled in a residential (n=39) or outpatient (n=21) intensive rehab program received either 6 active (n=34) bilateral (2 mA for 20 min) or sham (n=26) tDCS over the DLPFC (anodal right/cathodal left) over a period of two weeks. During stimulation drugs or alcohol related cues were presented to increase the desire of consumption. Measures of craving, depression, impulsiveness, general psychopathology and quality of life were collected before and after the treatment. A 3- and 6-months follow-ups were also included. Results: For each measure of outcome a mixed model was run, showing significant improvements in craving scores, impulsiveness, depression, psychopathology and overall perception of quality of life over time. No statistically significant differences between active and sham stimulation emerged. Conclusions: Our results, although still preliminary, suggest the feasibility of successfully applying tDCS within clinical settings to boost standard addiction rehabilitation protocols. Once collected the entire sample and follow-ups, this study will provide powerful insight on the therapeutic role of tDCS in the recovery of addiction.

Abstract Background Transcranial Pulse Stimulation (TPS) is a recent development of Non-invasive Brain Stimulation (NIBS) that has been proven effective to significantly improve Alzheimer patients' cognition, memory and execution function. There is no trial evaluating the efficacy of TPS on Major Depressive Disorder (MDD) nationwide. We aimed to evaluate the efficacy of TPS on young adults with MDD in Hong Kong. **Methods** In this single-blinded, randomized controlled trial, participants received a 2-week TPS treatment comprised six 30-min TPS sessions. Thirty participants were recruited and randomized into either the TPS group or the Waitlist Control (WC) group. Randomization was stratified by gender and age by an independent statistician on a 1: 1 ratio. Our primary outcome was determined by whether participants' depressive symptom severity demonstrated significant reduction, compared with the WC group, using Hamilton Depression Rating Scale-17 ($HDRS_{17}$). Clin.Trials.gov, number NCT05006365. **Findings** We recruited 30 participants aged between 18-54 years and were predominantly female (73%), ethnic Chinese from 1 August – 31 Oct 2021. There was a significant group x time interaction ($F(1, 28) = 18.8$, $p < .001$)[y1] . Compared with the WC group, there was a significant reduction in the depressive symptom severity in the TPS group (mean difference = -6.60, $p = 0.02$, Cohen's $d = -0.93$). Results showed a significant intervention effect and the effect was large. **Interpretation** TPS is safe and effective to reduce depressive symptoms among young individuals with MDD in this trial. **Funding** DGRF, the Hong Kong Polytechnic University, Hong Kong SAR, China

To develop a minimally invasive way to electrically stimulate the brain in order to preserve neurons in brain regions involved in memory by means of epicranial electrical stimulation (ECS), we implanted two adult rhesus monkeys with two platinum stimulation electrodes on the temporal skull on both sides. Animals were trained in a non-navigational spatial memory task. We observed a significant memory improvement (percent correct) with ECS at 40 Hz and 3 mA, but stimulation at 10 Hz induced a significant decrease in performance. We measured the changes in neuronal activity in the upper bank of the lateral sulcus in the same animal. Overall, 16 out of 25 cells recorded showed significant changes. When comparing pre and post stimulation spike rate, 10 Hz stimulation caused a significant decrease in spike rate when considering a 500 ms interval post stimulation, while 40 Hz stimulation increased the spike rate around 450 ms above the level before stimulation. To chart the effects of ECS at the network level, we performed functional Magnetic Resonance Imaging (fMRI) during ECS in one monkey, while we alternated stimulation blocks with no-stimulation blocks. ECS at 40 Hz and at 3 mA resulted in significant activation of the hippocampus bilaterally, and of lateral temporal cortex on one side underneath the electrode. Interestingly, ECS at 10 Hz and at 3 mA showed no significant activations in the hippocampus and only weak activations in lateral temporal cortex. Our results suggest a promising role for ECS for improving cognition and activating deeper brain regions.

Stroke remains a leading cause of long-term disability in developed countries and the second leading cause of death worldwide. Recent decades have witnessed substantial progress in understanding the pathophysiology of ischemic stroke and the treatment of stroke-related motor deficit. However, current therapies fail to offer patients satisfactory improvements. Therefore, a more effective approach for treating stroke-related motor deficit is still needed. Here we investigated the effect of electrical stimulation of the subthalamic nucleus (ES-STN) on motor deficit induced by photothrombotic lesion in the motor cortex (MC). We hypothesized that ES-STN can reduce motor deficit in stroke rats. First, 1 Sprague-Dawley rat was included in this pilot study. He was trained with the single pellet reaching task (SFPRT) and determined the baseline performance. We then induced a photothrombotic ischemic lesion in the forelimb region of the MC. After stroke induction we implanted a stimulation electrode into the STN. 4 days after stroke we performed ES-STN while evaluating SFPRT performance. We performed 100 Hz stimulation where rat showed improved performance during stimulation. At 130 Hz rat showed even more improvement. We then performed histology to confirm that the stimulation electrode was in the STN. Our pilot study indicates that ES-STN may be a promising approach for treating cortical stroke-related motor deficit. A larger scale study with more subjects is necessary to further investigate the effect of ES-STN on the motor deficit after cortical stroke.

A NOVEL TDCS RAT MODEL TO STUDY LEARNING & MEMORY

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Luuk Van Boekholdt, Silke Kerstens, Myles Mclaughlin
KU Leuven, Department Of Neurosciences, Leuven, Belgium

Transcranial direct current stimulation (tDCS) is a popular non-invasive neuromodulation method that passes a weak current through two electrodes on the scalp. It is currently assumed that the technique's underlying modulatory mechanisms involve the direct (de)polarization of brain regions, but evidence is scarce. Recent research even suggests a potential role for peripheral nerve activation in mediating tDCS's modulatory effects. In order to understand tDCS's working mechanism, it is important to study the effects of the technique's cerebral and peripheral electric fields at a behavioral and neurophysiological level. To this end, we developed an awake rat model in which DC electric fields can be generated respectively in brain regions or the skin. For cerebral stimulation, this model uses multiple skull electrodes, while peripheral stimulation is achieved with subcutaneous carbon electrodes. These electrodes do not immobilize the animal and allow for isolated stimulation of the cerebrum and skin in the freely moving rat. We investigated whether DC stimulation over the skull (over the hippocampus) or skin (around the occipital nerve) could effectively enhance learning. Preliminary results indicate that 30 minutes of stimulation (0.25 mA) of the skull, but not of the skin, can enhance passive avoidance learning in this rat model. Future experiments are necessary to clarify amplitude thresholds at which learning can be enhanced through the skull and skin. By determining the applied electric field strengths in brain regions and skin, we obtain an estimate of the tDCS electrode configuration and amplitude required in humans to achieve similar modulatory effects.

INVESTIGATE TDCS NEUROPHYSIOLOGICAL MECHANISMS IN HEALTHY VOLUNTEERS USING A NOVEL TDCS CONDITION

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Silke Kerstens[1], Jean-Jacques Orban De Xivry[2], Myles Mc Laughlin[1]
[1]KU Leuven, Department Of Neurosciences, Leuven Brain Institute, Leuven, Belgium, [2]KU Leuven, Department Of Movement Sciences, Leuven Brain Institute, Leuven, Belgium

Transcranial direct current stimulation (tDCS) is a noninvasive neuromodulation method that can increase cortical excitability by applying direct current over stimulation electrodes on the scalp. Until recently, it was accepted tDCS causes neuromodulation via direct polarization of cortical neurons. However, recent studies show the electric field in the brain is relatively weak and suggest that the stronger field in the scalp may directly stimulate cranial nerves. Interestingly, direct stimulation of cranial nerves can also affect cortical excitability and plasticity. In a healthy volunteer study, we are investigating the neurophysiological mechanism behind tDCS: are observed effects caused by direct polarization of cortical neurons, or by indirect cranial nerve stimulation or a combination of both? We developed a novel tDCS stimulation condition in which the peripheral input is blocked by applying topical anesthetics on the scalp underneath the stimulation electrodes, referred to as transcranial-only tDCS. We will compare the effects of tDCS on motor sequence learning to this novel stimulation condition and standard sham stimulation in a double blinded study including 99 healthy volunteers, pre-registered at the Open Science Framework platform. Data collection is ongoing. After data collection and analysis, if our results indicate tDCS significantly improves motor sequence learning compared to sham but the effect disappears for transcranial-only tDCS, we could conclude the observed learning effect are mainly caused by co-stimulation of peripheral nerves in the scalp. If not, we could conclude the effects are caused by cortical polarization.

USING A PUPIL DILATION METRIC TO CHARACTERIZE THE EFFECT OF TRIGEMINAL NERVE STIMULATION

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Nina Seminck[1], Ahmad Khatoum[1], Myles Mc Laughlin[2]
[1]KU Leuven, Neurosciences, Leuven, Belgium, [2]KU Leuven, Exp Orl, Department Of Neuroscience, Leuven Brain Institute, Leuven, Belgium

External stimulation of the trigeminal nerve is thought to activate certain nuclei in the brainstem, such as the locus coeruleus (LC), providing a means to indirectly stimulate noradrenergic pathways in the central nervous system. Trigeminal nerve stimulation (TNS) is already used in multiple clinical settings, however healthy volunteer studies are limited and the working mechanism underlying TNS effects are poorly understood. Studies showed that LC activity correlated positively with norepinephrine (NE) concentrations in the brain and that pupil size increases when LC increases. Taken together, the LC-NE system might play a role in TNS effects. In the current study, the effect of TNS on pupil dilation was investigated in healthy volunteers. Participants (n=4, data collection ongoing) underwent three different stimulation conditions (TNS, sham and median nerve stimulation - MNS) while pupil diameter was recorded. In addition to sham stimulation, MNS was applied as a control condition as it is thought to not activate the LC. TNS, sham and MNS were applied alternatingly with 4000 ms between each stimulation condition. The results showed that TNS elicited a pupil response approximately 1.5 ms after stimulation onset, while sham elicited small to no pupil responses. MNS also elicited a pupil response, however compared to TNS, pupil responses were smaller with MNS stimulation. The preliminary results suggest that the LC-NE system might contribute to the working mechanisms underpinning TNS effects. However, more participants need to be included to confirm these results.

TOLERABILITY AND BLINDING EFFICACY OF PERSONALIZED THETA-MODULATED TRANSCRANIAL ELECTRICAL CURRENT STIMULATION

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Marija Stanković[1], Marko Živanović[2], Uroš Konstantinović[1], Dunja Paunovic[1], Katarina Vulić[1], Jovana Bjekić[1], Saša Filipović[1]
[1]University of Belgrade, Institute for Medical Research, Human Neuroscience Group, Belgrade, Serbia, [2]University of Belgrade, Faculty of Philosophy, Department Of Psychology, Institute Of Psychology And Laboratory For Research Of Individual Differences, Belgrade, Serbia

Transcranial electrical stimulation (tES) is widely used in neuromodulation research. Numerous studies show that the conventional type of tES – transcranial direct current stimulation (tDCS) is a safe and well-tolerated technique. An increasingly popular line of research focuses on implementing alternative tES protocols aimed at the entrainment of brain oscillations. Thus, there is a need for a detailed assessment of the side effects profile and blinding efficacy of such protocols. Here we evaluate the tolerability and blinding efficacy of two personalized oscillatory tES protocols: Transcranial alternating current stimulation (tACS) and oscillatory tDCS (otDCS), applied in individual theta frequency for each participant (4-8Hz). Forty-two young, healthy individuals took part in a within-subject experiment in which they went through four stimulation conditions in a counterbalanced order: TACS (2mA peak-to-peak), otDCS (1.5mA±0.5mA), constant tDCS (1.5mA), and sham. The participants rated discomfort level at four timepoints during the 20-minute stimulation. Before and after each stimulation condition, they completed the standardized side effects questionnaire. The successfulness of blinding was assessed with the end-of-study guess of the sham condition. Overall, the reported discomfort level was low and comparable across all stimulation conditions, with otDCS being slightly more unpleasant than sham. Mild tingling and itching sensations were the most common side effects. No serious side effects were detected. Participant blinding was successful, and sham-guessing was not related to the reported discomfort in any of the stimulation conditions. The data has shown that personalized theta otDCS and tACS are well-tolerated and safe, with adequate blinding success.

DESIGN AND IMPLEMENTATION OF AN AT-HOME EEG-NEUROFEEDBACK PROTOCOL FOR DECREASING VISUAL MOTION SENSITIVITY

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Ódinn Rúnarsson, Tobias Wibble
Karolinska Institutet, Mbc/department Of Clinical Neuroscience, Stockholm, Sweden

Aims Patients who suffer from motion-sickness, vertigo and other conditions relating to visually induced dizziness (VID) will often feel dizzy when exposed to intense visual stimuli. This study aims to show how a visual neurofeedback system may be used for treating motion-sickness and VID. **Methods** We constructed a neurofeedback system, synchronizing a virtual spinning maze-like pattern where the velocity was proportional to theta wave activity as recorded by a wearable EEG (Muse 2). Eight participants (5M and 3F, aged 28.6 ± 8.6) had their balance, EEG, eye-movements and overall neurofeedback proficiency measured, after which they were issued a 7-day neurofeedback training regimen before repeating the trials. **Results** One subject was excluded due to achieving the highest level of neurofeedback-control at baseline. A 19.3% drop in theta wave activity was seen from the first day of training to last ($n = 7$, $p < 0.001$). Mean theta wave activity during in-lab testing dropped by 9.4% ± 0.9% ($p = 0.048$), eye-tracking showed that torsional slow-phase velocities dropped by 18.5% ± 3.9% ($p = 0.005$) while balance was unaffected. **Conclusions** The neurofeedback regimen was successful in allowing participants to lower their levels of attention, as shown by both EEG data as well as the decreased eye movement response, both reflecting attentional levels. While the training had no effect on balance in healthy participants, it may be interesting to repeat the procedure on VID patients. This study suggests that neurofeedback training may serve a clinical function in decreasing participants' sensitivity to visual motion.

CHANGES IN INTEROCEPTIVE ABILTIES FOLLOWING HDTDCS

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Sandra Mai-Lippold[1], Lorena Desdentado[2], Beate Herbert[3], Olga Pollatos[1]
[1]Ulm University, Institute of Psychology and Education, Clinical And Health Psychology, Ulm, Germany, [2]Universidad de Valencia, Facultad De Psicología, Instituto Polibienestar / Dpto. Personalidad, Evaluación Y Tratamientos Psicológicos, Valencia, Spain, [3]Eberhard Karls University of Tübingen, Psychology, Tübingen, Germany

Interoception characterizes the processing of ongoing bodily changes as well as their perception and is usually subdivided into different facets such as interoceptive accuracy (IAcc), sensibility (IS) or emotional interoceptive evaluation (IE). Interoceptive abilities are related to various psychological phenomena (emotions, psychopathology), playing a crucial role in many theories of emotional processing. Changing interoceptive abilities by the use of neurostimulation is an innovative way to examine its importance and to find new methods to implement in therapeutic interventions. In a pilot study we used high-definition transcranial direct current stimulation (HD-tDCS) to improve interoceptive abilities targeting underlying neural networks. 52 participants were included in two conditions (stimulating protocol, sham) in randomized order and different interoceptive facets (IAcc, IS, IE) were examined during the experimental conditions. In addition, subjective report and questionnaire data were assessed. Main results revealed that using the HD-tDCS protocol targeting interoceptive network structures such as the anterior insula did not significantly improve interoceptive accuracy as measured by a heartbeat perception task or respiratory resistance task, while first findings referred to effects for other interoceptive dimensions. Our study suggests that stimulating the interoceptive network using HD-tDCS could benefit from a more intense or repetitive protocol or the combination to other methods known to be efficient in a short-term interval application. Further research is needed to better exploit this promising research avenue.

THE EFFECTS OF MAGNETOELECTRIC DEEP BRAIN STIMULATION ON THE MONOAMINERGIC SYSTEMS IN MICE

POSTER SESSION 04 - SECTION: NEUROSTIMULATION AND NEUROFEEDBACK

Faisal Alosaimi[1], Rick Knoben[1], David Dominguez-Paredes[1], Faris Almasabi[1], Sarah Hescham[1], Kristen Kozielski[2], Yasin Temel[1], Ali Jahanshahi[1]

Aim: Deep brain stimulation (DBS) is used to alleviate motor disabilities in neurological disorders. However, the current approach requires invasive brain surgery. Recently, we have shown that injectable magnetoelectric nanoelectrodes may offer an alternative approach to conventional DBS. However, this method is in its infancy, and research is required to characterize its mechanisms of action. Herein, we aimed to investigate the effect of magnetoelectric stimulation on main neurotransmitter systems that have implications for DBS and movement disorders. Methods: Mice were injected with either magnetoelectric nanoparticles (MENPs) or magnetostrictive nanoparticles (MSNPs) in the subthalamic nucleus (STN). Mice underwent magnetic stimulation, and their motor behavior was assessed. In addition, post-mortem brains were processed for immunohistochemistry (IHC) to assess the co-expression of c-Fos with either tyrosine hydroxylase (TH), or tryptophan hydroxylase-2 (TPH2). *Results*: The stimulated animals exhibited an increased distance traveled in the open field test. In IHC we found a significant increase in c-Fos expression in the motor cortex (MC) and paraventricular region of the thalamus (PV-thalamus) after magnetic stimulation. Stimulated animals showed fewer TPH2/c-Fos double-labeled cells in the dorsal raphe nucleus (DRN), as well as TH/c-Fos double-labeled cells in the ventral tegmental area (VTA). *Conclusion:* These findings suggest that magnetic stimulation of MENPs in mice enables selective modulation of the deep brain areas and animal behavior. The measured behavioral responses are associated with changes in relevant neurotransmitter systems. These changes are somewhat similar to those that have been observed in conventional DBS, suggesting that magnetic DBS could replace electrical DBS.

FLEXIBLE POLYMER-BASED NEURAL PROBES DEVELOPED FOR LAMINAR RECORDINGS FROM THE HUMAN NEOCORTEX

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Richárd Fiáth[1,2], Borbála Árkossy[2], Eric Klein[3], Patrick Ruther[3,4], István Ulbert[1,2]
[1]Research Centre for Natural Sciences, Institute Of Cognitive Neuroscience And Psychology, Budapest, Hungary, [2]Pázmány Péter Catholic University, Faculty Of Information Technology And Bionics, Budapest, Hungary, [3]University of Freiburg, Department Of Microsystems Engineering (imtek), Freiburg, Germany, [4]University of Freiburg, Cluster Of Excellence, Brainlinks-braintools, Freiburg, Germany

In this study, we developed and validated a single-shank polymer-based neural probe designed for human intracortical laminar recordings. The flexible probe has a 3.9-mm-long, 75 to 300-µm-wide and 10-µm-thick tapered, implantable shank which contains 24 linearly placed gold microelectrodes with a diameter of 20 µm and center-to-center distance of 150 µm. Two probe variants with two different connector types were developed to compare their electrophysiological performance as well as their usability under different experimental conditions. To test the probes, first we performed impedance spectroscopy *in vitro*, in physiological saline solution. The impedance magnitude of recording sites was 221 ± 130 kΩ at 1 kHz (mean ± s.d. of 117 sites). Electrophysiological performance of the probes was validated in *in vivo* experiments by acute implantations into neocortical and hippocampal areas of anesthetized rats and mice. We recorded good-quality local field potentials, single- and multi-unit activity from the investigated brain regions. We were able to monitor cortical slow waves as well as hippocampal gamma activity with the implant. Furthermore, we could detect spike amplitudes over 100 µV and record the activity of multiple well-isolated single units simultaneously. Our future plans are to chronically implant the flexible probes in rodents to evaluate their long-term electrophysiological performance as well as the brain tissue response in the vicinity of the probe shank. Our long-term goal is to test the devices in human cortical tissue, for example, by implanting them into the brain of drug-resistant epileptic patients who are potential candidates for brain surgery.

Dataset of cortical activity recorded with high spatial resolution from anesthetized rats.
Publicly available neural recordings obtained with high spatial resolution are scarce. Here, we present an electrophysiological dataset recorded from the neocortex of twenty rats anesthetized with ketamine/xylazine. The wideband, spontaneous recordings were acquired with a single-shank silicon-based probe having 128 densely-packed recording sites arranged in a 32 × 4 array. The dataset contains the activity of a total of 7126 sorted single units extracted from all layers of the cortex. Here, we share raw neural recordings, as well as spike times, extracellular spike waveforms and several properties of units packaged in a standardized electrophysiological data format. For technical validation of our dataset, we provide the distributions of derived single unit properties along with various spike sorting quality metrics. This large collection of in vivo data enables the investigation of the high-resolution electrical footprint of cortical neurons which in turn may aid their electrophysiology-based classification. Furthermore, the dataset might be used to study the laminar-specific neuronal activity during slow oscillation, a brain rhythm strongly involved in neural mechanisms underlying memory consolidation and sleep.

Recording site placement on planar silicon-based probes affects signal quality in acute neuronal recordings.
Multisite, silicon-based probes are widely used tools to record the electrical activity of neuronal populations. Several physical features of these devices are designed to improve their recording performance. Here, our goal was to investigate whether the position of recording sites on the silicon shank might affect the quality of the recorded neural signal in acute experiments. Neural recordings obtained with five different types of high-density, single-shank, planar silicon probes from anesthetized rats were analyzed. Wideband data were filtered to extract spiking activity, then the amplitude distribution of samples and quantitative properties of the recorded brain activity (single unit yield, spike amplitude and isolation distance) were compared between sites located at different positions of the silicon shank, focusing particularly on edge and center sites. Edge sites outperformed center sites: for all five probe types there was a significant difference in the signal power computed from the

amplitude distributions, and edge sites recorded significantly more large amplitude samples both in the positive and negative range. Although the single unit yield was similar between site positions, the difference in spike amplitudes was noticeable in the range corresponding to high-amplitude spikes. Furthermore, the advantage of edge sites slightly decreased with decreasing shank width. Our results might aid the design of novel neural implants in enhancing their recording performance by identifying more efficient recording site placements.

A community-based transcriptomics classification and nomenclature of neocortical cell types.
To understand the function of cortical circuits, it is necessary to catalog their cellular diversity. Past attempts to do so using anatomical, physiological or molecular features of cortical cells have not resulted in a unified taxonomy of neuronal or glial cell types, partly due to limited data. Single-cell transcriptomics is enabling, for the first time, systematic high-throughput measurements of cortical cells and generation of datasets that hold the promise of being complete, accurate and permanent. Statistical analyses of these data reveal clusters that often correspond to cell types previously defined by morphological or physiological criteria and that appear conserved across cortical areas and species. To capitalize on these new methods, we propose the adoption of a transcriptome-based taxonomy of cell types for mammalian neocortex. This classification should be hierarchical and use a standardized nomenclature. It should be based on a probabilistic definition of a cell type and incorporate data from different approaches, developmental stages and species. A community-based classification and data aggregation model, such as a knowledge graph, could provide a common foundation for the study of cortical circuits. This community-based classification, nomenclature and data aggregation could serve as an example for cell type atlases in other parts of the body.

Slow insertion of silicon probes improves the quality of acute neuronal recordings.
Neural probes designed for extracellular recording of brain electrical activity are traditionally implanted with an insertion speed between 1 μm/s and 1 mm/s into the brain tissue. Although the physical effects of insertion speed on the tissue are well studied, there is a lack of research investigating how the quality of the acquired electrophysiological signal depends on the speed of probe insertion. In this study, we used four different insertion speeds (0.002 mm/s, 0.02 mm/s, 0.1 mm/s, 1 mm/s) to implant high-density silicon probes into deep layers of the somatosensory cortex of ketamine/xylazine anesthetized rats. After implantation, various qualitative and quantitative properties of the recorded cortical activity were compared across different speeds in an acute manner. Our results demonstrate that after the slowest insertion both the signal-to-noise ratio and the number of separable single units were significantly higher compared with those measured after inserting probes at faster speeds. Furthermore, the amplitude of recorded spikes as well as the quality of single unit clusters showed similar speed-dependent differences. Post hoc quantification of the neuronal density around the probe track showed a significantly higher number of NeuN-labelled cells after the slowest insertion compared with the fastest insertion. Our findings suggest that advancing rigid probes slowly (~1 μm/s) into the brain tissue might result in less tissue damage, and thus in neuronal recordings of improved quality compared with measurements obtained after inserting probes with higher speeds.

Fine-scale mapping of cortical laminar activity during sleep slow oscillations using high-density linear silicon probes.
The cortical slow (~1 Hz) oscillation (SO), which is thought to play an active role in the consolidation of memories, is a brain rhythm characteristic of slow-wave sleep, with alternating periods of neuronal activity and silence. Although the laminar distribution of cortical activity during SO is well-studied by using linear neural probes, traditional devices have a relatively low (20-100 μm) spatial resolution along cortical layers.

Long-term recording performance and biocompatibility of chronically implanted cylindrically-shaped, polymer-based neural interfaces.
Stereo-electroencephalography depth electrodes, regularly implanted into drug-resistant patients with focal epilepsy to

localize the epileptic focus, have a low channel count (6-12 macro- or microelectrodes), limited spatial resolution (0.5-1 cm) and large contact area of the recording sites (~mm2). Thus, they are not suited for high-density local field potential and multiunit recordings. In this paper, we evaluated the long-term electrophysiological recording performance and histocompatibility of a neural interface consisting of 32 microelectrodes providing a physical shape similar to clinical devices. The cylindrically-shaped depth probes made of polyimide (PI) were chronically implanted for 13 weeks into the brain of rats, while cortical or thalamic activity (local field potentials, single-unit and multi-unit activity) was recorded regularly to monitor the temporal change of several features of the electrophysiological performance. To examine the tissue reaction around the probe, neuron-selective and astroglia-selective immunostaining methods were applied. Stable single-unit and multi-unit activity were recorded for several weeks with the implanted depth probes and a weak or moderate tissue reaction was found around the probe track. Our data on biocompatibility presented here and in vivo experiments in non-human primates provide a strong indication that this type of neural probe can be applied in stereo-electroencephalography recordings of up to 2 weeks in humans targeting the localization of epileptic foci providing an increased spatial resolution and the ability to monitor local field potentials and neuronal spiking activity.

A silicon-based neural probe with densely-packed low-impedance titanium nitride microelectrodes for ultrahigh-resolution in vivo recordings.
In this study, we developed and validated a single-shank silicon-based neural probe with 128 closely-packed microelectrodes suitable for high-resolution extracellular recordings. The 8-mm-long, 100-µm-wide and 50-µm-thick implantable shank of the probe fabricated using a 0.13-µm complementary metal-oxide-semiconductor (CMOS) metallization technology contains square-shaped (20 × 20 µm), low-impedance (~ 50 kΩ at 1 kHz) recording sites made of rough and porous titanium nitride which are arranged in a 32 × 4 dense array with an inter-electrode pitch of 22.5 µm. The electrophysiological performance of the probe was tested in in vivo experiments by implanting it acutely into neocortical areas of anesthetized animals (rats, mice and cats). We recorded local field potentials, single- and multi-unit activity with superior quality from all layers of the neocortex of the three animal models, even after reusing the probe in multiple (> 10) experiments. The low-impedance electrodes monitored spiking activity with high signal-to-noise ratio; the peak-to-peak amplitude of extracellularly recorded action potentials of well-separable neurons ranged from 0.1 mV up to 1.1 mV. The high spatial sampling of neuronal activity made it possible to detect action potentials of the same neuron on multiple, adjacent recording sites, allowing a more reliable single unit isolation and the investigation of the spatiotemporal dynamics of extracellular action potential waveforms in greater detail. Moreover, the probe was developed with the specific goal to use it as a tool for the validation of electrophysiological data recorded with high-channel-count, high-density neural probes comprising integrated CMOS circuitry.

Large-scale recording of thalamocortical circuits: in vivo electrophysiology with the two-dimensional electronic depth control silicon probe.
Recording simultaneous activity of a large number of neurons in distributed neuronal networks is crucial to understand higher order brain functions. We demonstrate the in vivo performance of a recently developed electrophysiological recording system comprising a two-dimensional, multi-shank, high-density silicon probe with integrated complementary metal-oxide semiconductor electronics. The system implements the concept of electronic depth control (EDC), which enables the electronic selection of a limited number of recording sites on each of the probe shafts. This innovative feature of the system permits simultaneous recording of local field potentials (LFP) and single- and multiple-unit activity (SUA and MUA, respectively) from multiple brain sites with high quality and without the actual physical movement of the probe. To evaluate the in vivo recording capabilities of the EDC probe, we recorded LFP, MUA, and SUA in acute experiments from cortical and thalamic brain areas of anesthetized rats and mice. The advantages of large-scale recording with the EDC probe are illustrated by investigating the spatiotemporal dynamics of pharmacologically induced thalamocortical slow-wave activity in rats and by the two-dimensional tonotopic mapping of the auditory thalamus. In mice, spatial distribution of thalamic responses to optogenetic stimulation of the neocortex was examined. Utilizing the benefits of the EDC system may result in a higher yield of useful data from a single experiment compared with traditional passive multielectrode arrays, and thus in the reduction of animals needed for a research study.

Laminar analysis of the slow wave activity in the somatosensory cortex of anesthetized rats.
Rhythmic slow waves characterize brain electrical activity during natural deep sleep and under anesthesia, reflecting the synchronous membrane potential fluctuations of neurons in the thalamocortical network. Strong evidence indicates that the neocortex plays an important role in the generation of slow wave activity (SWA), however, contributions of individual cortical

layers to the SWA generation are still unclear. The anatomically correct laminar profiles of SWA were revealed under ketamine/xylazine anesthesia, with combined local field potential recordings, multiple-unit activity (MUA), current source density (CSD) and time-frequency analyses precisely co-registered with histology. The up-state related negative field potential wave showed the largest amplitude in layer IV, the CSD was largest in layers I and III, whereas MUA was maximal in layer V, suggesting spatially dissociated firing and synaptic/transmembrane processes in the rat somatosensory cortex. Up-state related firing could start in virtually any layers (III-VI) of the cortex, but were most frequently initiated in layer V. However, in a subset of experiments, layer IV was considerably active in initiating up-state related MUA even in the absence of somatosensory stimulation. Somatosensory stimulation further strengthened up-state initiation in layer IV. Our results confirm that cortical layer V firing may have a major contribution to the up-state generation of ketamine/xylazine-induced SWA, however, thalamic influence through the thalamorecipient layer IV can also play an initiating role, even in the absence of sensory stimulation.

Time Multiplexed Active Neural Probe with 1356 Parallel Recording Sites.
We present a high electrode density and high channel count CMOS (complementary metal-oxide-semiconductor) active neural probe containing 1344 neuron sized recording pixels (20 µm × 20 µm) and 12 reference pixels (20 µm × 80 µm), densely packed on a 50 µm thick, 100 µm wide, and 8 mm long shank. The active electrodes or pixels consist of dedicated in-situ circuits for signal source amplification, which are directly located under each electrode. The probe supports the simultaneous recording of all 1356 electrodes with sufficient signal to noise ratio for typical neuroscience applications. For enhanced performance, further noise reduction can be achieved while using half of the electrodes (678). Both of these numbers considerably surpass the state-of-the art active neural probes in both electrode count and number of recording channels. The measured input referred noise in the action potential band is 12.4 µVrms, while using 678 electrodes, with just 3 µW power dissipation per pixel and 45 µW per read-out channel (including data transmission).

PLASTICITY AND MICROORGANIZATION OF SYNAPTIC TRANSMISSION IN THE HUMAN CORTEX

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Andrea Santuy[1], Thomas Wuttke[1], Angel Merchan Perez[2], Henner Koch[3]
[1]Hertie Institute for Clincal Brain Research, Dept. Of Neurology And Epileptology, Tuebingen, Germany, [2]Universidad Politécnica de Madrid, Laboratorio Cajal De Circuitos Corticales, Madrid, Spain, [3]Aachen University, Universitätsklinikum Aachen, Aachen, Germany

Aims: Homeostatic plasticity is an intrinsic property of neurons that keeps synaptic transmission between a physiological range, and therefore it is of great relevance for the functional activity and survival of neurons, however, so far has only been described in rodents. This project focuses on the characterization of homeostatic plasticity in the human brain. Methods: Human organotypic cortical slice cultures enable the investigation of dynamic properties of human neurons over a long time period, allowing to implement protocols to investigate long term changes on human neuronal networks that developed physiologically. After extracting brain tissue from the temporal pole and culturing it, we silence synaptic transmission via tetrodotoxin administration and wash out the drug after 48h. We then record the electrophysiological changes suffered by the network via Multielectrode Array Recordings. Finally, with confocal and volumetric electron microscopy we image that same tissue and reconstruct the spines and synapses, correlating the changes in synaptic activity with the morphological alterations that those same synapses show. Results and Conclusions: With this ongoing project we will determine whether homeostatic plasticity takes place in the human brain. Finding out how it acts is of great relevance for the development of new drugs to treat diseases that seem to arise as a consequence of the misfunction of some of the proteins involved in this regulation, such as schizophrenia, autism spectrum disorder o depression.

Glutamatergic Dysfunction and Synaptic Ultrastructural Alterations in Schizophrenia and Autism Spectrum Disorder: Evidence from Human and Rodent Studies.
The correlation between dysfunction in the glutamatergic system and neuropsychiatric disorders, including schizophrenia and autism spectrum disorder, is undisputed. Both disorders are associated with molecular and ultrastructural alterations that affect synaptic plasticity and thus the molecular and physiological basis of learning and memory. Altered synaptic plasticity, accompanied by changes in protein synthesis and trafficking of postsynaptic proteins, as well as structural modifications of excitatory synapses, are critically involved in the postnatal development of the mammalian nervous system. In this review, we summarize glutamatergic alterations and ultrastructural changes in synapses in schizophrenia and autism spectrum disorder of genetic or drug-related origin, and briefly comment on the possible reversibility of these neuropsychiatric disorders in the light of findings in regular synaptic physiology.

Estimation of the number of synapses in the hippocampus and brain-wide by volume electron microscopy and genetic labeling.
Determining the number of synapses that are present in different brain regions is crucial to understand brain connectivity as a whole. Membrane-associated guanylate kinases (MAGUKs) are a family of scaffolding proteins that are expressed in excitatory glutamatergic synapses. We used genetic labeling of two of these proteins (PSD95 and SAP102), and Spinning Disc confocal Microscopy (SDM), to estimate the number of fluorescent puncta in the CA1 area of the hippocampus. We also used FIB-SEM, a three-dimensional electron microscopy technique, to calculate the actual numbers of synapses in the same area. We then estimated the ratio between the three-dimensional densities obtained with FIB-SEM (synapses/µm) and the bi-dimensional densities obtained with SDM (puncta/100 µm). Given that it is impractical to use FIB-SEM brain-wide, we used previously available SDM data from other brain regions and we applied this ratio as a conversion factor to estimate the minimum density of synapses in those regions. We found the highest densities of synapses in the isocortex, olfactory areas, hippocampal formation and cortical subplate. Low densities were found in the pallidum, hypothalamus, brainstem and

cerebellum. Finally, the striatum and thalamus showed a wide range of synapse densities.

Area-Specific Synapse Structure in Branched Posterior Nucleus Axons Reveals a New Level of Complexity in Thalamocortical Networks.
Thalamocortical posterior nucleus (Po) axons innervating the vibrissal somatosensory (S1) and motor (MC) cortices are key links in the brain neuronal network that allows rodents to explore the environment whisking with their motile snout vibrissae. Here, using fine-scale high-end 3D electron microscopy, we demonstrate in adult male C57BL/6 wild-type mice marked differences between MC versus S1 Po synapses in (1) bouton and active zone size, (2) neurotransmitter vesicle pool size, (3) distribution of mitochondria around synapses, and (4) proportion of synapses established on dendritic spines and dendritic shafts. These differences are as large, or even more pronounced, than those between Po and ventro-posterior thalamic nucleus synapses in S1. Moreover, using single-axon transfection labeling, we demonstrate that the above differences actually occur on the MC versus the S1 branches of individual Po cell axons that innervate both areas. Along with recently-discovered divergences in efficacy and plasticity, the synaptic structure differences reported here thus reveal a new subcellular level of complexity. This is a finding that upends current models of thalamocortical circuitry, and that might as well illuminate the functional logic of other branched projection axon systems. Many long-distance brain connections depend on neurons whose branched axons target separate regions. Using 3D electron microscopy and single-cell transfection, we investigated the mouse Posterior thalamic nucleus (Po) cell axons that simultaneously innervate motor and sensory areas of the cerebral cortex involved in whisker movement control. We demonstrate significant differences in the size of the boutons made in each area by individual Po axons, as well as in functionally-relevant parameters in the composition of their synapses. In addition, we found similarly large differences between the synapses of Po versus ventral posteromedial thalamic nucleus axons in the whisker sensory cortex. Area-specific synapse structure in individual axons implies a new, unsuspected level of complexity in long-distance brain connections.

Size, Shape, and Distribution of Multivesicular Bodies in the Juvenile Rat Somatosensory Cortex: A 3D Electron Microscopy Study.
Multivesicular bodies (MVBs) are membrane-bound organelles that belong to the endosomal pathway. They participate in the transport, sorting, storage, recycling, degradation, and release of multiple substances. They interchange cargo with other organelles and participate in their renovation and degradation. We have used focused ion beam milling and scanning electron microscopy (FIB-SEM) to obtain stacks of serial sections from the neuropil of the somatosensory cortex of the juvenile rat. Using dedicated software, we have 3D-reconstructed 1618 MVBs. The mean density of MVBs was 0.21 per cubic micron. They were unequally distributed between dendrites (39.14%), axons (18.16%), and nonsynaptic cell processes (42.70%). About one out of five MVBs (18.16%) were docked on mitochondria, representing the process by which the endosomal pathway participates in mitochondrial maintenance. Other features of MVBs, such as the presence of tubular protrusions (6.66%) or clathrin coats (19.74%) can also be interpreted in functional terms, since both are typical of early endosomes. The sizes of MVBs follow a lognormal distribution, with differences across cortical layers and cellular compartments. The mean volume of dendritic MVBs is more than twice as large as the volume of axonic MVBs. In layer I, they are smaller, on average, than in the other layers.

A Quantitative Study on the Distribution of Mitochondria in the Neuropil of the Juvenile Rat Somatosensory Cortex.
Mitochondria play a key role in energy production and calcium buffering, among many other functions. They provide most of the energy required by neurons, and they are transported along axons and dendrites to the regions of higher energy demands. We have used focused ion beam milling and scanning electron microscopy (FIB/SEM) to obtain stacks of serial sections from the somatosensory cortex of the juvenile rat. We have estimated the volume fraction occupied by mitochondria and their distribution between dendritic, axonal, and nonsynaptic processes. The volume fraction of mitochondria increased from layer I (4.59%) to reach its maximum in layer IV (7.74%) and decreased to its minimum in layer VI (4.03%). On average, 44% of mitochondrial volume was located in dendrites, 15% in axons and 41% in nonsynaptic elements. Given that dendrites, axons, and nonsynaptic elements occupied 38%, 23%, and 39% of the neuropil, respectively, it can be concluded that dendrites are proportionally richer in mitochondria with respect to axons, supporting the notion that most energy consumption takes place at the postsynaptic side. We also found a positive correlation between the volume fraction of mitochondria located in neuronal processes and the density of synapses.

Study of the Size and Shape of Synapses in the Juvenile Rat Somatosensory Cortex with 3D Electron Microscopy.
Changes in the size of the synaptic junction are thought to have significant functional consequences. We used focused ion beam milling and scanning electron microscopy (FIB/SEM) to obtain stacks of serial sections from the six layers of the rat somatosensory cortex. We have segmented in 3D a large number of synapses (= 6891) to analyze the size and shape of excitatory (asymmetric) and inhibitory (symmetric) synapses, using dedicated software. This study provided three main findings. Firstly, the mean synaptic sizes were smaller for asymmetric than for symmetric synapses in all cortical layers. In all cases, synaptic junction sizes followed a log-normal distribution. Secondly, most cortical synapses had disc-shaped postsynaptic densities (PSDs; 93%). A few were perforated (4.5%), while a smaller proportion (2.5%) showed a tortuous horseshoe-shaped perimeter. Thirdly, the curvature was larger for symmetric than for asymmetric synapses in all layers. However, there was no correlation between synaptic area and curvature.

Quantitative 3D Ultrastructure of Thalamocortical Synapses from the "Lemniscal" Ventral Posteromedial Nucleus in Mouse Barrel Cortex.
Thalamocortical synapses from "lemniscal" neurons of the dorsomedial portion of the rodent ventral posteromedial nucleus (VPMdm) are able to induce with remarkable efficacy, despite their relative low numbers, the firing of primary somatosensory cortex (S1) layer 4 (L4) neurons. To which extent this high efficacy depends on structural synaptic features remains unclear. Using both serial transmission (TEM) and focused ion beam milling scanning electron microscopy (FIB/SEM), we 3D-reconstructed and quantitatively analyzed anterogradely labeled VPMdm axons in L4 of adult mouse S1. All VPMdm synapses are asymmetric. Virtually all are established by axonal boutons, 53% of which contact multiple (2-4) elements (overall synapse/bouton ratio = 1.6). Most boutons are large (mean 0.47 µm3), and contain 1-3 mitochondria. Vesicle pools and postsynaptic density (PSD) surface areas are large compared to others in rodent cortex. Most PSDs are complex. Most synapses (83%) are established on dendritic spine heads. Furthermore, 15% of the postsynaptic spines receive a second, symmetric synapse. In addition, 13% of the spine heads have a large protrusion inserted into a membrane pouch of the VPMdm bouton. The unusual combination of structural features in VPMdm synapses is likely to contribute significantly to the high efficacy, strength, and plasticity of these thalamocortical synapses.

Volume electron microscopy of the distribution of synapses in the neuropil of the juvenile rat somatosensory cortex.
Knowing the proportions of asymmetric (excitatory) and symmetric (inhibitory) synapses in the neuropil is critical for understanding the design of cortical circuits. We used focused ion beam milling and scanning electron microscopy (FIB/SEM) to obtain stacks of serial sections from the six layers of the juvenile rat (postnatal day 14) somatosensory cortex (hindlimb representation). We segmented in three-dimensions 6184 synaptic junctions and determined whether they were established on dendritic spines or dendritic shafts. Of all these synapses, 87-94% were asymmetric and 6-13% were symmetric. Asymmetric synapses were preferentially located on dendritic spines in all layers (80-91%) while symmetric synapses were mainly located on dendritic shafts (62-86%). Furthermore, we found that less than 6% of the dendritic spines establish more than one synapse. The vast majority of axospinous synapses were established on the spine head. Synapses on the spine neck were scarce, although they were more common when the dendritic spine established multiple synapses. This study provides a new large quantitative dataset that may contribute not only to the knowledge of the ultrastructure of the cortex, but also towards defining the connectivity patterns through all cortical layers.

Haptically assisted connection procedure for the reconstruction of dendritic spines.
Dendritic spines are thin protrusions that cover the dendritic surface of numerous neurons in the brain and whose function seems to play a key role in neural circuits. The correct segmentation of those structures is difficult due to their small size and the resulting spines can appear incomplete. This paper presents a four-step procedure for the complete reconstruction of dendritic spines. The haptically driven procedure is intended to work as an image processing stage before the automatic segmentation step giving the final representation of the dendritic spines. The procedure is designed to allow both the navigation and the volume image editing to be carried out using a haptic device. A use case employing our procedure together with a commercial software package for the segmentation stage is illustrated. Finally, the haptic editing is evaluated in two experiments; the first experiment concerns the benefits of the force feedback and the second checks the suitability of the use of a haptic device as input. In both cases, the results shows that the procedure improves the editing accuracy.

LOW-AMPLITUDE ELECTRICAL MICROSTIMULATION OF A CORTICAL COLUMN IN RAT BARREL CORTEX WITH HIGH-DENSITY SILICON PROBES

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Paweł Jurgielewicz[1], Małgorzata Szypulska[1], Piotr Wiącek[1], Andrzej Skoczeń[1], Tomasz Fiutowski[1], Władysław Dąbrowski[1], Bartosz Mindur[1], Ewa Kublik[2], Paweł Hottowy[1]

Aims We tested the efficiency of the newly developed 512-channel stimulation/recording system in evoking neuronal responses within a barrel column of a rat. Methods The system is based on a custom-designed 64-channel CMOS chip that provides independent microstimulation and recording in every channel. It can control up to four probes with a total of 512 electrodes. For the tests, we used gold-plated Neuronexus and Masmanidis lab probes (0.1-0.2 MΩ). Probes were inserted into the barrel cortex of an adult, anaesthetized rat. Stimulation pulses with amplitudes of 1-4 μA were applied simultaneously to clusters of 1-5 electrodes in up to 80 locations in the barrel column. Results In response to the microstimulation, we recorded action potentials (AP) and electrically evoked local field potentials (EEP). APs with latencies as low as 1 ms characterized individual activated neurons. Slow EEPs waves, similar in shape to the LFP evoked by tactile whisker stimulation, were visible on multiple shanks of the stimulating probe. Their amplitude scaled with the intensity of the applied current. Stimulation in lower cortical layers induced high-frequency oscillations typical for strong multi-whisker responses. Conclusions Using a custom-built 512-channel system and standard commercial silicon probes for patterned low-amplitude stimulation in the rat barrel cortex, we successfully evoked subcomponents of natural sensory responses. **Funding: This work was supported by the Polish National Science Centre grant DEC-2013/10/M/NZ4/00268 (PH). Modular Data Acquisition System for Recording Activity and Electrical Stimulation of Brain Tissue Using Dedicated Electronics.
In this paper, we present a modular Data Acquisition (DAQ) system for simultaneous electrical stimulation and recording of brain activity. The DAQ system is designed to work with custom-designed Application Specific Integrated Circuit (ASIC) called Neurostim-3 and a variety of commercially available Multi-Electrode Arrays (MEAs). The system can control simultaneously up to 512 independent bidirectional i.e., input-output channels. We present in-depth insight into both hardware and software architectures and discuss relationships between cooperating parts of that system. The particular focus of this study was the exploration of efficient software design so that it could perform all its tasks in real-time using a standard Personal Computer (PC) without the need for data precomputation even for the most demanding experiment scenarios. Not only do we show bare performance metrics, but we also used this software to characterise signal processing capabilities of Neurostim-3 (e.g., gain linearity, transmission band) so that to obtain information on how well it can handle neural signals in real-world applications. The results indicate that each Neurostim-3 channel exhibits signal gain linearity in a wide range of input signal amplitudes. Moreover, their high-pass cut-off frequency gets close to 0.6Hz making it suitable for recording both Local Field Potential (LFP) and spiking brain activity signals. Additionally, the current stimulation circuitry was checked in terms of the ability to reproduce complex patterns. Finally, we present data acquired using our system from the experiments on a living rat's brain, which proved we obtained physiological data from non-stimulated and stimulated tissue. The presented results lead us to conclude that our hardware and software can work efficiently and effectively in tandem giving valuable insights into how information is being processed by the brain.

The fundamental mechanisms of information processing in the brain are still poorly understood. Despite the vast amount of technical possibilities, we still have very little understanding about basic neuroscience concepts such as memory formation and learning. Due to the high complexity of the brain a functional isolation of single circuits is not possible *in vivo*. Thus, further progress in neuroscience requires a fundamentally new approach in which we can employ intelligent circuit design to test fundamental neural network hypotheses. We aim to tackle this challenge using the bottom-up neuroscience approach, in which we engineer biological neuronal networks *in vitro* with precise architectures and connectivity using polydimethylsiloxane (PDMS) microstructures. Such a system enables the analysis of neuronal information processing at a much more simplified level with only a few neurons[1,2]. We have developed methods to ahere PDMS microstructures to complementary metal-oxide-semiconductor (CMOS) microelectrode arrays, that provide up to 26'400 microelectrodes[3]. These platforms allow to study engineered neuronal networks with unprecedented spatial resolution. We show that we can reliably adhere PDMS microstructures to CMOS MEAs and guide axonal growth with high precision. We demonstrate that we can maintain viable rat primary neuron cultures for several weeks and obtain signals with high signal-to-noise ratio across the whole microstructure[4]. **References**:

MAXLAB LIVE AXONTRACKING ASSAY: LABEL-FREE IDENTIFICATION AND FUNCTIONAL CHARACTERIZATION OF AXONS IN NEURONAL NETWORKS AT HIGH-THROUGHPUT

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Zhuoliang Li[1], David Jäckel[1], Blandine Clément[2], Anaïs Thammavongsa[1], Marie Obien[1]
[1]MaxWell Biosystems, Maxwell Biosystems, Zurich, Switzerland, [2]ETH Zürich, Institute For Biomedical Engineering, Zurich, Switzerland

Axons enable neuronal communication by propagating electrical signals within neuronal networks. Its dysfunction plays a central role in deliberating pathologies such as Parkinson's Disease and Amyotrophic Lateral Sclerosis. Therefore, access to axonal physiology is crucial for studying information processing within neuronal networks and accelerating drug development for neurological disorders. High-density microelectrode array (HD-MEA) technology enables chronic label-free *in-vitro* extracellular recordings of axonal action potentials in neurons. MaxOne (single-) and MaxTwo (multi-well) HD-MEA Systems (MaxWell Biosystems, Switzerland) simultaneously capture fast propagating action potentials along multiple axons. Here, we present the MaxLab Live AxonTracking Assay, a software which automatically detects and functionally characterizes axonal signals across hundreds of neurons within a network. We reliably identified and measured from axonal arbors in primary neuronal cultures as well as human iPSC-derived glutamatergic and motor neurons over multiple weeks. We tracked the signal propagation to deduce the conduction velocity, axonal length, and number of axonal branches. We found that the neuronal and branch propagation velocity significantly increased between DIV 13 and 20, corresponding to the maturation of the neuronal network. In conclusion, MaxLab Live AxonTracking Assay combined with HD-MEA technology enables reliable access to electrophysiological recordings of axons, providing a novel functional phenotype for neurological disease modelling and drug screening studies.

THIN FLEXIBLE ARRAYS FOR LONG-TERM MULTI-ELECTRODE RECORDINGS IN MACAQUE PRIMARY VISUAL CORTEX

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Lara Merken[1], Maarten Schelles[2], Frederik Ceyssens[2], Peter Janssen[1]
[1]KU Leuven, Neurosciences, Leuven, Belgium, [2]KU Leuven, Electrical Engineering (esat), Leuven, Belgium

The need for large-scale invasive recordings has increased with the increasing interest in brain-machine interfaces (BMI). Chronically implanted multi-electrode arrays (MEAs) are used because hundreds of neurons can be recorded for a long period of time. However, most MEAs are made from rigid materials, which are less compliant with the brain tissue, with short shafts and containing only 1 electrode, making it impossible to reach deeper cortical areas and increase the spatial resolution of the recordings. Here, we developed and tested thin (typically 20 by 80 microns diameter) flexible MEAs with one to three electrodes per shaft, inserted in the primary visual cortex of 2 macaque monkeys (92 in monkey 1 and 103 electrodes in monkey 2). To allow manual insertion of the floating arrays, we temporarily strengthened the shafts with a bio-degradable polylactic-co-glycolic acid (PLGA) coating. A high-resolution Magnetic Resonance Imaging (MRI) scan demonstrated the MRI compatibility of the arrays. We observed clear single-unit activity on 40% of the electrodes, and multi-unit activity (MUA) on 60-100% of the electrodes. Even after 5 months, we measured significant MUA responses on 60-90% of the electrodes, with highly stable receptive fields. Histological analysis 3 months after implantation in monkey 1 showed minimal scar tissue formation around the implantation site. In conclusion, we achieved long-term recordings of neural responses with thin, MRI compatible, flexible arrays that can reach deeper cortical areas. These new implants offer essential advantages for future BMIs in terms of reduced scar tissue formation, high scalability and large brain coverage.

TRANSCRANIAL DIRECT CURRENT STIMULATION EFFECTS ACROSS MOTOR CORTEX LAYERS IN AWAKE MICE

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Carlos Andres Sanchez Leon, Michael Nitsche, Christoph Van Thriel
Leibniz Research Centre for Working Environment and Human Factors, Psychology And Neuroscience, Dortmund, Germany

Previous studies have demonstrated the clinical value of transcranial direct current stimulation (tDCS) for modulating sensory, motor, and cognitive functions, nevertheless, knowledge about how external electric fields affect different components of neuronal networks is still not completely clear, and in vivo animal models are not fully developed. For this reason, we aimed to establish a mouse model of M1-tDCS that replicates acute-effects and after-effects of stimulation observed in humans. To evaluate the impact of tDCS, we recorded electrical activity in M1 of alert mice during and after M1-tDCS. Neuronal activity was recorded from layers 2-3, 5 and 6, evoked by stimulation of the ventral-lateral-nucleus of the thalamus (VAL). M1-tDCS was applied at 50,100,200 and 300 µA for 5s to test the acute-effects on neuronal excitability, and during 15min to analyze after-effects. Acute M1-tDCS increased and decreased the amplitude of the VAL-evoked-potentials in a polarity- and intensity-dependent manner. We observed an increase of evoked-potentials for anodal stimulation and a decrease for cathodal stimulation. For 15min of anodal or cathodal tDCS, there was a similar polarity- and intensity-dependent modulation of the VAL-evoked-potential amplitude during the 15-min of stimulation for all intensities tested, but when tDCS was switched off, only protocols with higher intensities induced a robust after-effect during one hour after stimulation. The current study demonstrates the feasibility of a mouse model of M1-tDCS to accomplish similar modulatory effects of tDCS as observed in human experiments. A proper adjustment of tDCS parameters is required to obtain these translational effects.

Altered Cerebellar Response to Somatosensory Stimuli in the Mouse Model of Autism.
Atypical sensory processing is currently included within the diagnostic criteria of autism. The cerebellum is known to integrate sensory inputs of different modalities through its connectivity to the cerebral cortex. Interestingly, cerebellar malformations are among the most replicated features found in postmortem brain of individuals with autism. We studied sensory processing in the cerebellum in a mouse model of autism, knock-out (KO) for the gene. is widely expressed in Purkinje cells (PCs) and has been recently reported to regulate their morphology. Further, individuals with mutations display cerebellar malformations and CNTNAP2 antibodies are associated with a mild form of cerebellar ataxia. Previous studies in the mouse model show an altered cerebellar sensory learning. However, a physiological analysis of cerebellar function has not been performed yet. We studied sensory evoked potentials in cerebellar Crus I/II region on electrical stimulation of the whisker pad in alert mice and found striking differences between wild-type and KO mice. In addition, single-cell recordings identified alterations in both sensory-evoked and spontaneous firing patterns of PCs. These changes were accompanied by altered intrinsic properties and morphologic features of these neurons. Together, these results indicate that the mouse model could provide novel insight into the pathophysiological mechanisms of autism core sensory deficits.

Impact of chronic transcranial random noise stimulation (tRNS) on GABAergic and glutamatergic activity markers in the prefrontal cortex of juvenile mice.
Transcranial random noise stimulation (tRNS), a non-invasive neuromodulatory technique capable of altering cortical activity, has been proposed to improve the signal-to-noise ratio at the neuronal level and the sensitivity of the neurons following an inverted U-function. The aim of this study was to examine the effects of tRNS on vGLUT1 and GAD 65-67 and its safety in terms of pathological changes. For that, juvenile mice were randomly distributed in three different groups: "tRNS 1×" receiving tRNS at the density current used in humans (0.3A/m, 20min), "tRNS 100×" receiving tRNS at two orders of magnitude higher (30.0A/m, 20min) and "sham" (0.3A/m, 15s). Nine tRNS sessions during 5 weeks were administered to the prefrontal cortex of awake animals. No detectable tissue macroscopic lesions were observed after tRNS sessions. Post-stimulation immunohistochemical analysis of GAD 65-67 and vGLUT1 immunoreactivity showed reduced GAD 65-67

immunoreactivity levels in the region directly beneath the electrode for tRNS 1× group with no significant effects in the tRNS 100× nor sham group. The observed results suggest an excitatory effect associated with a decrease in GABA levels in absence of major histopathological alterations providing a novel mechanistic explanation for tRNS effects.

Immediate and after effects of transcranial direct-current stimulation in the mouse primary somatosensory cortex.
Transcranial direct-current stimulation (tDCS) is a non-invasive brain stimulation technique consisting in the application of weak electric currents on the scalp. Although previous studies have demonstrated the clinical value of tDCS for modulating sensory, motor, and cognitive functions, there are still huge gaps in the knowledge of the underlying physiological mechanisms. To define the immediate impact as well as the after effects of tDCS on sensory processing, we first performed electrophysiological recordings in primary somatosensory cortex (S1) of alert mice during and after administration of S1-tDCS, and followed up with immunohistochemical analysis of the stimulated brain regions. During the application of cathodal and anodal transcranial currents we observed polarity-specific bidirectional changes in the N1 component of the sensory-evoked potentials (SEPs) and associated gamma oscillations. On the other hand, 20 min of cathodal stimulation produced significant after-effects including a decreased SEP amplitude for up to 30 min, a power reduction in the 20-80 Hz range and a decrease in gamma event related synchronization (ERS). In contrast, no significant changes in SEP amplitude or power analysis were observed after anodal stimulation except for a significant increase in gamma ERS after tDCS cessation. The polarity-specific differences of these after effects were corroborated by immunohistochemical analysis, which revealed an unbalance of GAD 65-67 immunoreactivity between the stimulated versus non-stimulated S1 region only after cathodal tDCS. These results highlight the differences between immediate and after effects of tDCS, as well as the asymmetric after effects induced by anodal and cathodal stimulation.

Exploring new transcranial electrical stimulation strategies to modulate brain function in animal models.
Transcranial electrical stimulation (tES) refers to a group of non-invasive brain stimulation techniques to induce changes in the excitability of cortical neurons in humans. In recent years, studies in animal models have been shown to be essential for disentangling the neuromodulatory effects of tES, defining safety limits, and exploring potential therapeutic applications in neurological and neuropsychiatric disorders. Testing in animal models is valuable for the development of new unconventional protocols intended to improve tES administration and optimize the desired effects by increasing its focality and enabling deep-brain stimulation. Successful and controlled application of tES in humans relies on the knowledge acquired from studies meticulously performed in animal models.

Using animal models to improve the design and application of transcranial electrical stimulation in humans.
Transcranial electrical stimulation (tES) is a non-invasive stimulation technique used for modulating brain function in humans. To help tES reach its full therapeutic potential, it is necessary to address a number of critical gaps in our knowledge. Here, we review studies that have taken advantage of animal models to provide invaluable insight about the basic science behind tES.

Multiple clinical and experimental studies have reported concurrent cortical seizures and spreading depolarisation (SD). Nonetheless, the relationship between these phenomena remains enigmatic. During epileptic paroxysms, SD-induced activity suppression has been observed to result in seizure termination. However, other studies have observed an increase in epileptiform discharges immediately following SD. To dissect interactions between ictal discharges, seizures and SD waves, we developed a method to characterise the spatial propagation and interaction of these events in the cortex of awake mice. We expressed GCaMP7f bilaterally, and recorded the propagation of picrotoxin-induced seizures and SDs through different cortical regions using widefield imaging. Moreover, we simultaneously recorded from novel multisite graphene solution-gated field effect transistor (gSGFET) arrays; which allowed recording of full-bandwidth electrophysiological signals. To examine the temporal relationship between seizures and SD, we developed an automated analysis pipeline to characterize events based on origin and propagation. For each event, we extracted multiple properties and performed unbiased analysis. We resolve the full-bandwidth gSGFET recordings into physiological frequency bands and investigate the power of each during different events. This allowed correlation of cortical oscillations with activity throughout both hemispheres. Using these methods, we were able to perform high-throughput event analyses to examine the diversity of ictal-associated DC-events. The methodology presented in this study provides a novel approach to investigate the relationship between SD and seizures. We envision that combined calcium imaging and gSGFET recordings will provide unparalleled insight into seizure initiation and termination; and will facilitate the development of novel therapeutic avenues and technology.

Characterization of optogenetically-induced cortical spreading depression in awake mice using graphene micro-transistor arrays.
The development of experimental methodology utilizing graphene micro-transistor arrays to facilitate and advance translational research into cortical spreading depression (CSD) in the awake brain.CSDs were reliably induced in awake nontransgenic mice using optogenetic methods. High-fidelity DC-coupled electrophysiological mapping of propagating CSDs was obtained using flexible arrays of graphene soultion-gated field-effect transistors (gSGFETs).Viral vectors targetted channelrhopsin expression in neurons of the motor cortex resulting in a transduction volume ⩾1 mm. 5-10 s of continous blue light stimulation induced CSD that propagated across the cortex at a velocity of 3.0 ± 0.1 mm min. Graphene micro-transistor arrays enabled high-density mapping of infraslow activity correlated with neuronal activity suppression across multiple frequency bands during both CSD initiation and propagation. Localized differences in the CSD waveform could be detected and categorized into distinct clusters demonstrating the spatial resolution advantages of DC-coupled recordings. We exploited the reliable and repeatable induction of CSDs using this preparation to perform proof-of-principle pharmacological interrogation studies using NMDA antagonists. MK801 (3 mg kg) suppressed CSD induction and propagation, an effect mirrored, albeit transiently, by ketamine (15 mg kg), thus demonstrating this models' applicability as a preclinical drug

screening platform. Finally, we report that CSDs could be detected through the skull using graphene micro-transistors, highlighting additional advantages and future applications of this technology.CSD is thought to contribute to the pathophysiology of several neurological diseases. CSD research will benefit from technological advances that permit high density electrophysiological mapping of the CSD waveform and propagation across the cortex. We report anassay that permits minimally invasive optogenetic induction, combined with multichannel DC-coupled recordings enabled by gSGFETs in the awake brain. Adoption of this technological approach could facilitate and transform preclinical investigations of CSD in disease relevant models.

Full-bandwidth electrophysiology of seizures and epileptiform activity enabled by flexible graphene microtransistor depth neural probes.
Mapping the entire frequency bandwidth of brain electrophysiological signals is of paramount importance for understanding physiological and pathological states. The ability to record simultaneously DC-shifts, infraslow oscillations (<0.1 Hz), typical local field potentials (0.1-80 Hz) and higher frequencies (80-600 Hz) using the same recording site would particularly benefit preclinical epilepsy research and could provide clinical biomarkers for improved seizure onset zone delineation. However, commonly used metal microelectrode technology suffers from instabilities that hamper the high fidelity of DC-coupled recordings, which are needed to access signals of very low frequency. In this study we used flexible graphene depth neural probes (gDNPs), consisting of a linear array of graphene microtransistors, to concurrently record DC-shifts and high-frequency neuronal activity in awake rodents. We show here that gDNPs can reliably record and map with high spatial resolution seizures, pre-ictal DC-shifts and seizure-associated spreading depolarizations together with higher frequencies through the cortical laminae to the hippocampus in a mouse model of chemically induced seizures. Moreover, we demonstrate the functionality of chronically implanted devices over 10 weeks by recording with high fidelity spontaneous spike-wave discharges and associated infraslow oscillations in a rat model of absence epilepsy. Altogether, our work highlights the suitability of this technology for in vivo electrophysiology research, and in particular epilepsy research, by allowing stable and chronic DC-coupled recordings.

A NOVEL MULTIMODAL APPROACH FOR PROBING SYNAPTIC CONNECTIVITY AND FUNCTION

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Xiaohan Xue, Alessio Buccino, Sreedhar Saseendran Kumar, Andreas Hierlemann, Julian Bartram
ETH Zürich, Department Of Biosystems Science And Engineering, Basel, Switzerland

Numerous synaptic processes, such as long-term synaptic plasticity and short-term modulations of transmission efficacy, can depend on the spiking patterns of the corresponding pre- and postsynaptic cells. Some progress has been made towards revealing the underlying principles of such regulations by identifying and monitoring monosynaptic connectivity. However, existing techniques do not provide both the precise spiking sequence of the presynaptic cell and additional information on structural (e.g., accurate location of the synapse, synapse size) or functional properties (e.g., transmission) of the synapse. Here, we introduce a novel multimodal approach to overcome this limitation by combining high-resolution dendritic spine Ca^{2+} imaging with simultaneous large-scale recording of extracellular spiking by means of high-density microelectrode arrays (HD-MEAs). Primary rat cortical neurons, sparsely expressing jGCaMP7b, were plated on a CMOS-based HD-MEA that features 26’400 electrodes at 17.5 µm pitch and allows for simultaneous recording from up to 1’024 electrodes. A spinning-disc upright confocal microscope was employed to perform simultaneous Ca^{2+} imaging from target dendritic spines of the postsynaptic cell. We developed an open-source analysis pipeline to identify the presynaptic unit of a specific dendritic spine based on correlation of pre- and postsynaptic activity. Moreover, we introduce a surrogate-based statistical test to identify only trustworthy connections. Finally, we used data-driven simulations to validate and optimize this approach and demonstrate that it can successfully infer connections in *in vitro* recordings. The presented method represents a versatile tool to characterize synaptic properties and processes, including activity-dependent synaptic development, spatial synaptic organization, and synaptic interactions.

Aims: Combination of functional and optical analysis becomes increasingly important in neuroscience. Here, we present an approach for fabrication of reproducible, chemically and mechanically robust functionalized multi-electrode array (MEA) based on indium tin oxide (ITO) and magnesium fluoride (MgF_2) thin films on thin glass substrates. These new MEAs are especially suited for combination with a new super-resolution microscopy (SRM) technique also shown here. **Methods:** The MgF_2 layers were deposited using electron beam evaporation. The ITO layers using sputtering. The structuring of films was performed by photolithography and ion beam etching. The film properties of these MEAs were analysed by atomic-force microscopy, scanning-electron microscopy, X-ray diffraction, electrical 4-point- and spectral transmission measurements. Finally, we tested the functionalization of the MgF_2 layer by using an immunostaining of 10 µm brain slices for direct stochastic optical reconstruction microscopy (*d*STORM) recording. **Results:** We found that the transmittance of the coated substrates is adjustable by the layer thickness. Brain slices were adherent to the MgF2 layers. By analysis of synaptic structures with *d*STORM we found similar localization properties compared to regularly coated cover slips. The conductivity measurements showed no isolating defects or leakage currents for the 110 nm MgF_2 layer. **Conclusions:** In summary, this approach may serve as a basis for further developments with respect to the simultaneous use of optical and electrophysiological *in-vitro* experiments. The possibility to correlate microscopy with electrophysiology is an important step towards understanding the molecular mechanisms of neuronal and synaptic function and of molecular pathophysiology in neurological diseases.

Astrocytes regulate neuronal network maturation and function and control neuronal electrochemical activity by secreting and circulating excitatory and inhibitory transmitters. Therefore, astrocyte dysfunctions and resulting abnormal neuronal function and homeostasis can be linked to diseases such as epilepsy. We studied the regulatory effects of astrocytes in drug-induced epileptic-like activity. We cultured rat cortical neuron-astrocyte co-cultures with different neuron-astrocyte ratios on microelectrode arrays. The cell ratios ranged from 'pure' neuronal cultures without separately added astrocytes up to 50/50 percent of neuron/astrocyte co-cultures. Neuronal activity was recorded weekly, and cultures were stimulated with gamma-aminobutyric acid type A receptor ($GABA_AR$) blocker gabazine at 28 days *in vitro*. Astrocytes enhanced neuronal maturation during the first weeks *in vitro* and significantly affected neuronal connectivity and drug efficacy depending on the astrocyte numbers in the culture. The drug showed its efficacy later in time with the increasing ratio of astrocytes in the culture; the 50/50 co-culture presented a delay of drug action of about 200s. Furthermore, the effect size of the drug on the connectivity weights appeared higher for co-cultures with higher numbers of astrocytes. Different neuron/astrocyte ratios could model different brain areas and, as our results suggest, different seizure susceptibilities in the brain. The diverse responses to drug-induced hyper-synchronization in the co-cultures elucidates the importance of considering the different proportions of astrocytes in *in vitro* epilepsy models. Acknowledgment: The project has received funding from the European Union's Horizon 2020 research and innovation programme, grant agreement No. 824164.

A 3D-PRINTED NEURAL IMPLANT FOR EXTRACELLULAR RECORDINGS

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Dorian Röders[1], Celil Sevincik[2], Jonas Rose[1]
[1]Ruhr University Bochum, Faculty Of Psychology, Neural Basis Of Learning, Bochum, Germany, [2]Ruhr University Bochum, Psychology, Biopsychology, Bochum, Germany

The main factors for a successful electrode implantation and a successful electrophysiological recording are the precise positioning of the electrode, the stability of the implant and a fast operation procedure. Here we introduce a novel 3D-printed modular implant. The implant consists of a base that is individually designed using an MRI of the subject to achieve exact fit to the skull. This base can contain multiple sites where electrodes, connectors or reference screws can be attached. All components can be placed before, during or after the initial implantation to allow flexible change of recording site or electrode after the initial operation. Our approach also allows the minimally invasive replacement or repositioning of electrodes. Breaking up complicated procedures into multiple shorter procedures can also be a feasible way to reduce duration of anesthesia. Our new design also offers an easy system to securely attach wired and wireless headstages. All in all, this novel approach can reduce the duration of surgeries by bringing fully assembled implants to the OR and it allows adjustments in minimally invasive procedures including the partial explantation between experiments. Keywords: Implant, 3D printing, extracellular recording, operation

NOVEL MULTI-SENSOR ORIGAMI PLATFORM FOR IN-VITRO BRAIN MODELS

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Noam Rahav[1], Uri Ashery[1,2], Ben Maoz[2,3]
[1]Tel Aviv University, Neurobiology, Tel Aviv, Israel, [2]Tel Aviv University, Sagol School Of Neuroscience, Tel Aviv, Israel, [3]Tel Aviv University, Biomedical Engineering, Tel Aviv, Israel

Advances in the field of tissue engineering enables better emulation of the human body by creating multi-cellular 3D in-vitro models. To better understand brain functionality and find therapeutic solutions, the neuro-vascular-unit (NVU) is being investigated worldwide. While complex 3D brain structures are fabricated by bio-printing and other methods; the monitoring of these models is very challenging and there is a lack of sensing solutions. To address this need we developed a multi-sensory platform that could be customized for each brain model. In our platform we combine flexible chip structure, a permeability sensor: trans-endothelial electrical resistance (TEER) and electrical activity sensors: 3D multi electrode array (MEA); all to advance brain research. To establish this platform we designed and fabricated an assembled chip which its hinges facilitates the folding of the structure around the printed NVU, like origami. This design allows minimum harm to the tissue. The placing of the electrodes is designed in advance in a complementary way to the biological structure, enabling exact location in relation to the blood vessel and the parenchymal tissue. The platform is easy to handle with common tissue culture equipment and the model is visually accessible via microscope. To make the platform more useful and meaningful for the scientific community the 3D electrical sensing electrodes are connected to a commercial MEA system. By giving access to the molecular brain this platform could advance basic physiological research, disease investigation as well as drug testing.

Because of their low invasiveness and high spatiotemporal resolution, high-density epidural multielectrode arrays (hd-EMAs) constitute a key technology for future clinical applications. In combination with cortical stimulation, monitoring ongoing brain activity with chronically implanted arrays can serve to manipulate pathological brain states in targeted manner. We here introduce a new multielectrode array with eighteen electrode contacts on a small polyimide patch with 3 mm diameter, arranged around a central opening for an optical fibre for combining chronic epidural recordings with optogenetic stimulation in the mouse model. The hd-EMA was fabricated on top of a 100 mm oxidized silicon wafer by applying a thin layer of the polyimide U-Varnish S (UBE Europe GmbH, Germany) onto the wafer's surface, followed by sputtering a 300 nm gold layer on top of it. Electrode thickness was increased by 2.7 µm via electroplating, resulting in a total thickness of 3 µm. After structuring the design of the connector tracks, a quick oxygen plasma treatment via reactive ion etching (RIE) served to improve the adhesion between both polyimide layers. Finally, a layer of polyimide U-Varnish S was applied and structured, resulting in a flexible, polyimide-encapsulated multielectrode array. Each electrode has a diameter of 280 µm. Electrodes are arranged around a central opening of 300 µm diameter for the optical fibre and have an inter-electrode, center-to-center spacing of 565 – 1390 µm. We coated half of all electrodes with the electrically conductive polymer PEDOT:PSS to further analyze its influence on signal quality. Supported by DFG WE 5469/3-1.

MICROPORED ELECTRODES FOR IMPROVED BIOCOMPATIBILITY AND NEURONAL ATTACHMENT IN IMPLANTABLE BRAIN ELECTRODE ARRAYS

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Fulvia Del Duca[1,2], Tetsuhiko Teshima[1,2], Francisco Zurita[1,2], Simon Jacob[3], Bernhard Wolfrum[1,2]
[1]Technical University of Munich, Munich Institute Of Biomedical Engineering, Garching bei München, Germany, [2]NTT Research Incorporated, Medical & Health Informatics Laboratories, Sunnyvale, United States of America, [3]Technical University of Munich, Department Of Neurosurgery, Klinikum Rechts Der Isar, Munich, Germany

Thin-film flexible microelectrode arrays gained attention in neurophysiology for their minimal tissue displacement and their high compliance compared to silicon probes, which minimize subsequent tissue inflammation. However, their flat structure disrupts the 3D distribution of cells and hinders transport of molecules. In this work, we design and fabricate flexible multielectrode arrays with micropored torus-shaped electrodes, with the aim of allowing interpenetration and adhesion of neurons inside the pored electrode. Further, we aim to promote the natural diffusion of important molecules and signaling species through the pores, improving biocompatibility. The fabrication of these electrodes involves chemical vapor deposition of parylene-C, photolithographic patterning of gold, and dry etching to open the through-hole in the active sites. The pored electrodes are further galvanized into a torus shape to increase surface area. As a proof of principle, we test the devices for biocompatibility both with cardiomyocyte-like cells in-vitro and in locusts in-vivo. The resulting device is 8 µm thin and compliant with neural tissue. The electrode openings are through-hole circular gold structures with an inner diameter of 15 µm, comparable to neuronal cells. In-vitro, cardiomyocyte-like cells adhere to the electrode surface and inside the gold torus pores. We further demonstrate successful in-vivo, long-term implantation of the probes in locusts' neural tissue. In conclusion, the micropored electrodes allow interpenetration of cells and diffusion of molecules. Micropore-patterning of the electrode's substrate will further yield a mesh-like structure, which we expect will integrate seamlessly with the brain tissue.

ON-DEMAND OPTOGENETIC-INDUCTION OF SEIZURES AND ITS CHARACTERISATION IN A MOUSE MODEL OF FOCAL CONDITIONAL KNOCKOUT OF KIR4.1 CHANNELS

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Neela Codadu[1], Andrea Bonaccini Calia[2], Eduard Masvidal-Codina[3], Yunan Gao[1], Anton Guimera-Brunet[3], Rob Wykes[4]

Kir4.1 inwardly-rectifying potassium channels play a key role in maintaining physiological levels of extracellular potassium ions in the brain and are exclusively expressed in glial cells in CNS. Kir4.1 channel levels are reduced in TLE patients and loss-of-function mutations in Kir4.1 encoding *KCNJ10* gene were reported to cause EAST/SeSAME epileptic disorders. Global knockout of Kir4.1 in mice were shown to be lethal with lifespan of only 3-4 post-natal weeks. This hampers our ability to understand the activity and properties of an epileptic network lacking Kir4.1. Furthermore, the shorter lifespan restricts the ability to record and modulate multiple seizures. To overcome the above problems, we have investigated targeted regional knockout in hippocampus of adult *kcnj10*-floxed mice. 24x7 telemetry recordings indicate that these animals develop spontaneous seizures 7-14 days after injection of cre-expressing viral constructs under astrocyte-specific promoters. To examine the Kir4.1 knockout effects on ultraslow potential shifts associated with seizures, i.e., active DC-shifts and post-ictal spreading depolarisation, we used an awake head-fixed setup, with graphene transistors capable of wideband recordings. Recorded spontaneous and optogenetically-evoked seizures and epileptiform activity. Optogenetic-activation of pyramidal neurons induced seizures in a stimulation frequency- and duration-dependent manner. Furthermore, almost all seizures induced were observed to be associated with large ultraslow potential shifts and their metrics were analysed. Here, we report a novel method to record spontaneous seizures and optogenetically induce seizures on-demand in a focal conditional Kir4.1 knockout mouse model that will provide insights into the role Kir4.1 plays in seizure and seizure and spreading depolarisation susceptibility.

Medial septal GABAergic neurons reduce seizure duration upon optogenetic closed-loop stimulation.
Seizures can emerge from multiple or large foci in temporal lobe epilepsy, complicating focally targeted strategies such as surgical resection or the modulation of the activity of specific hippocampal neuronal populations through genetic or optogenetic techniques. Here, we evaluate a strategy in which optogenetic activation of medial septal GABAergic neurons, which provide extensive projections throughout the hippocampus, is used to control seizures. We utilized the chronic intrahippocampal kainate mouse model of temporal lobe epilepsy, which results in spontaneous seizures and as is often the case in human patients, presents with hippocampal sclerosis. Medial septal GABAergic neuron populations were immunohistochemically labelled and were not reduced in epileptic conditions. Genetic labelling with mRuby of medial septal GABAergic neuron synaptic puncta and imaging across the rostral to caudal extent of the hippocampus, also indicated an unchanged number of putative synapses in epilepsy. Furthermore, optogenetic stimulation of medial septal GABAergic neurons consistently modulated oscillations across multiple hippocampal locations in control and epileptic conditions. Finally, wireless optogenetic stimulation of medial septal GABAergic neurons, upon electrographic detection of spontaneous hippocampal seizures, resulted in reduced seizure durations. We propose medial septal GABAergic neurons as a novel target for optogenetic control of seizures in temporal lobe epilepsy.

Divergent paths to seizure-like events.
Much debate exists about how the brain transitions into an epileptic seizure. One source of confusion is that there are likely to be critical differences between experimental seizure models. To address this, we have compared the evolving activity patterns in two widely used in vitro models of epileptic discharges. Brain slices from young adult mice were prepared in the same way and bathed either in 0 Mg or 100 µmol/L 4AP artificial cerebrospinal fluid. We have found that while local field

potential recordings of epileptiform discharges in the two models appear broadly similar, patch-clamp analysis reveals an important difference in the relative degree of glutamatergic involvement. 4AP affects parvalbumin-expressing interneurons more than other cortical populations, destabilizing their resting state and inducing spontaneous bursting behavior. Consequently, the most prominent pattern of transient discharge ("interictal event") in this model is almost purely GABAergic, although the transition to seizure-like events (SLEs) involves pyramidal recruitment. In contrast, interictal discharges in 0 Mg are only maintained by a very large glutamatergic component that also involves transient discharges of the interneurons. Seizure-like events in 0 Mg have significantly higher power in the high gamma frequency band (60-120Hz) than these events do in 4AP, and are greatly delayed in onset by diazepam, unlike 4AP events. We, therefore, conclude that the 0 Mg and 4AP models display fundamentally different levels of glutamatergic drive, demonstrating how ostensibly similar pathological discharges can arise from different sources. We contend that similar interpretative issues will also be relevant to clinical practice.

Excitatory GABAergic signalling is associated with benzodiazepine resistance in status epilepticus.
Status epilepticus is defined as a state of unrelenting seizure activity. Generalized convulsive status epilepticus is associated with a rapidly rising mortality rate, and thus constitutes a medical emergency. Benzodiazepines, which act as positive modulators of chloride (Cl-) permeable GABAA receptors, are indicated as first-line treatment, but this is ineffective in many cases. We found that 48% of children presenting with status epilepticus were unresponsive to benzodiazepine treatment, and critically, that the duration of status epilepticus at the time of treatment is an important predictor of non-responsiveness. We therefore investigated the cellular mechanisms that underlie acquired benzodiazepine resistance, using rodent organotypic and acute brain slices. Removing Mg2+ ions leads to an evolving pattern of epileptiform activity, and eventually to a persistent state of repetitive discharges that strongly resembles clinical EEG recordings of status epilepticus. We found that diazepam loses its antiseizure efficacy and conversely exacerbates epileptiform activity during this stage of status epilepticus-like activity. Interestingly, a low concentration of the barbiturate phenobarbital had a similar exacerbating effect on status epilepticus-like activity, while a high concentration of phenobarbital was effective at reducing or preventing epileptiform discharges. We then show that the persistent status epilepticus-like activity is associated with a reduction in GABAA receptor conductance and Cl- extrusion capability. We explored the effect on intraneuronal Cl- using both gramicidin, perforated-patch clamp recordings and Cl- imaging. This showed that during status epilepticus-like activity, reduced Cl- extrusion capacity was further exacerbated by activity-dependent Cl- loading, resulting in a persistently high intraneuronal Cl-. Consistent with these results, we found that optogenetic stimulation of GABAergic interneurons in the status epilepticus-like state, actually enhanced epileptiform activity in a GABAAR dependent manner. Together our findings describe a novel potential mechanism underlying benzodiazepine-resistant status epilepticus, with relevance to how this life-threatening condition should be managed in the clinic.

Differential contribution of pyramidal cells and interneurons to activity-dependent gene transcription changes.
The type of neuronal activity determines the outcome of gene expression. Hence, the characterization of underlying mechanisms in transcriptome alterations may serve as a biomarker and provide new intervention methods for the treatment of pathologic conditions. Parrish et al. (Parrish RR, Codadu NK, Racca C, Trevelyan AJ. 120: 2358-2367, 2018) show that the changes in interneuronal gene transcription are correlated with the type of the activated neuronal population and that the initiation route of Ras/ERK MAPK pathway determines the polarity of the gene expression.

Feedforward inhibition ahead of ictal wavefronts is provided by both parvalbumin- and somatostatin-expressing interneurons. There is a rapid interneuronal response to focal activity in cortex, which restrains laterally propagating activity, including spreading epileptiform activity. The interneuronal response involves intense activation of both parvalbumin- and somatostatin-expressing interneurons. Interneuronal bursting is time-locked to glutamatergic barrages in the pre-ictal period. Ca imaging using conditional expression of GCaMP6f provides an accurate readout of the evolving firing patterns in both types of interneuron. The activation profiles of the two interneuronal classes are temporally offset, with the parvalbumin population being activated first, and typically, at higher rates.

Region-specific differences and areal interactions underlying transitions in epileptiform activity.
Local neocortical and hippocampal territories show different and sterotypical patterns of acutely evolving, epileptiform activity.

Neocortical and entorhinal networks show tonic-clonic-like events, but the main hippocampal territories do not, unless it is relayed from the other areas. Transitions in the pattern of locally recorded epileptiform activity can be indicative of a shift in the source of pathological activity, and may spread through both synaptic and non-synaptic means. Hippocampal epileptiform activity is promoted by 4-aminopyridine and inhibited by GABA receptor agonists, and appears far more sensitive to these drugs than neocortical activity. These signature features of local epileptiform activity can provide useful insight into the primary source of ictal activity, aiding both experimental and clinical investigation.

Graphical user interface for simultaneous profiling of activity patterns in multiple neuronal subclasses.
We provide notes on how to use a graphical user interface (GUI), implemented with MATLAB, for aligning imaging datasets of biological tissue. The original use was for matching two imaging data sets, where one set was taken of the living preparation and another was taken post-fixation and following immunohistochemical processing. This technique is described in detail in an accompanying paper (Parrish et al., [1], where we also include information about the experimental procedures, and examples of the usage of the GUI.

Pyramidal cell activity levels affect the polarity of activity-induced gene transcription changes in interneurons.
Changes in gene expression are an important mechanism by which activity levels are regulated in the nervous system. It is not known, however, how network activity influences gene expression in interneurons; since they themselves provide negative feedback in the form of synaptic inhibition, there exists a potential conflict between their cellular homeostatic tendencies and those of the network. We present a means of examining this issue, utilizing simple in vitro models showing different patterns of intense network activity. We found that the degree of concurrent pyramidal activation changed the polarity of the induced gene transcription. When pyramidal cells were quiescent, interneuronal activation led to an upregulation of glutamate decarboxylase 1 (GAD1) and parvalbumin (Pvalb) gene transcriptions, mediated by activation of the Ras/extracellular signal-related kinase mitogen-activated protein kinase (Ras/ERK MAPK) pathway. In contrast, coactivation of pyramidal cells led to an ionotropic glutamate receptor N-methyl-d-aspartate 2B-dependent decrease in transcription. Our results demonstrate a hitherto unrecognized complexity in how activity-dependent gene expression changes are manifest in cortical networks. NEW & NOTEWORTHY We demonstrate a novel feedback mechanism in cortical networks, by which glutamatergic drive, mediated through the Ras/ERK MAPK pathway, regulates gene transcription in interneurons. Using a unique feature of certain in vitro epilepsy models, we show that without this glutamatergic feedback, intense activation of interneurons causes parvalbumin and glutamate decarboxylase 1 mRNA expression to increase. If, on the other hand, pyramidal cells are coactivated with interneurons, this leads to a downregulation of these genes.

Simultaneous profiling of activity patterns in multiple neuronal subclasses.
Neuronal networks typically comprise heterogeneous populations of neurons. A core objective when seeking to understand such networks, therefore, is to identify what roles these different neuronal classes play. Acquiring single cell electrophysiology data for multiple cell classes can prove to be a large and daunting task. Alternatively, Ca network imaging provides activity profiles of large numbers of neurons simultaneously, but without distinguishing between cell classes.

Astrocyte-Mediated Neuronal Synchronization Properties Revealed by False Gliotransmitter Release.
Astrocytes spontaneously release glutamate (Glut) as a gliotransmitter (GT), resulting in the generation of extrasynaptic NMDAR-mediated slow inward currents (SICs) in neighboring neurons, which can increase local neuronal excitability. However, there is a deficit in our knowledge of the factors that control spontaneous astrocyte GT release and the extent of its influence. We found that, in rat brain slices, increasing the supply of the physiological transmitter Glut increased the frequency and signaling charge of SICs over an extended period. This phenomenon was replicated by exogenous preexposure to the amino acid D-aspartate (D-Asp). Using D-Asp as a "false" GT, we determined the extent of local neuron excitation by GT release in ventrobasal thalamus, CA1 hippocampus, and somatosensory cortex. By analyzing synchronized neuronal NMDAR-mediated excitation, we found that the properties of the excitation were conserved in different brain areas. In the three areas, astrocyte-derived GT release synchronized groups of neurons at distances of >;200 μm. Individual neurons participated in more than one synchronized population, indicating that individual neurons can be excited by more than one astrocyte and that individual astrocytes may determine a neuron's synchronized network. The results confirm that astrocytes can act as excitatory nodes that can influence neurons over a significant range in a number of brain regions. Our findings further suggest that chronic elevation of ambient Glut levels can lead to increased GT Glut release, which may be

relevant in some pathological states. Astrocytes spontaneously release glutamate (Glut) and other gliotransmitters (GTs) that can modify neuronal activity. Exposing brain slices to Glut and D-aspartate (D-Asp) before recording resulted in an increase in frequency of GT-mediated astrocyte-neuron signaling. Using D-Asp, it was possible to investigate the effects of specific GT release at neuronal NMDARs. Calcium imaging showed synchronized activity in groups of neurons in cortex, hippocampus, and thalamus. The size of these populations was similar in all areas and some neurons were involved in more than one synchronous group. The findings show that GT release is supply dependent and that the properties of the signaling and activated networks are largely conserved between different brain areas.

LARGE-SCALE RECORDINGS IN THE FOREBRAIN-BASAL-GANGLIA CIRCUIT OF SINGING ZEBRA FINCHES USING CHRONICALLY IMPLANTED NEUROPIXELS

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Corinna Lorenz[1,2], Ezequiel Arneodo[3], Richard Hahnloser[2], Nicolas Giret[1]

Songbirds have evolved with a network of brain areas dedicated to one specific task – learning and producing complex song. This close link between structure and behavior is a rare trait in the animal kingdom, thus presenting them as an excellent model for the study of neural motor learning and control. Research in this field, however, still lags behind technical advances of high-yield electrophysiology because songbirds are particularly small and sensitive to the weight of a chronic implant. We designed and implemented a lightweight and reusable tool that allows for chronic Neuropixels recordings in freely moving zebra finches (*Taeniopygia guttata*). We tested the implant targeting both the cortical premotor region LMAN and the basal-ganglia-like striatal area including Area X and recorded neural activity during singing from eight animals. Our preliminary data show that the birds were able to cope with the weight of the implant (1.7g) and returned to a singing rate of up to several hundreds of motif renditions per hour within a few days after the implantation surgery. Furthermore, the device enabled us to acquire a large data set with several hundred spiking units after spike sorting and manual curation, including dozens of units from LMAN and Area X. As such, our device provides the opportunity for large-scale recordings that have become a critical tool to gain insight into neural population dynamics.

Undirected singing rate as a non-invasive tool for welfare monitoring in isolated male zebra finches.
Research on the songbird zebra finch (Taeniopygia guttata) has advanced our behavioral, hormonal, neuronal, and genetic understanding of vocal learning. However, little is known about the impact of typical experimental manipulations on the welfare of these birds. Here we explore whether the undirected singing rate can be used as an indicator of welfare. We tested this idea by performing a post hoc analysis of singing behavior in isolated male zebra finches subjected to interactive white noise, to surgery, or to tethering. We find that the latter two experimental manipulations transiently but reliably decreased singing rates. By contraposition, we infer that a high-sustained singing rate is suggestive of successful coping or improved welfare in these experiments. Our analysis across more than 300 days of song data suggests that a singing rate above a threshold of several hundred song motifs per day implies an absence of an acute stressor or a successful coping with stress. Because singing rate can be measured in a completely automatic fashion, its observation can help to reduce experimenter bias in welfare monitoring. Because singing rate measurements are non-invasive, we expect this study to contribute to the refinement of the current welfare monitoring tools in zebra finches.

Serotonin Decreases the Gain of Visual Responses in Awake Macaque V1.
Serotonin, an important neuromodulator in the brain, is implicated in affective and cognitive functions. However, its role even for basic cortical processes is controversial. For example, in the mammalian primary visual cortex (V1), heterogenous serotonergic modulation has been observed in anesthetized animals. Here, we combined extracellular single-unit recordings with iontophoresis in awake animals. We examined the role of serotonin on well-defined tuning properties (orientation, spatial frequency, contrast, and size) in V1 of two male macaque monkeys. We find that in the awake macaque the modulatory effect of serotonin is surprisingly uniform: it causes a mainly multiplicative decrease of the visual responses and a slight increase in the stimulus-selective response latency. Moreover, serotonin neither systematically changes the selectivity or variability of the response, nor the interneuronal correlation unexplained by the stimulus ("noise-correlation"). The modulation by serotonin has qualitative similarities with that for a decrease in stimulus contrast, but differs quantitatively from decreasing contrast. It can be captured by a simple additive change to a threshold-linear spiking nonlinearity. Together, our results show that

serotonin is well suited to control the response gain of neurons in V1 depending on the animal's behavioral or motivational context, complementing other known state-dependent gain-control mechanisms. Serotonin is an important neuromodulator in the brain and a major target for drugs used to treat psychiatric disorders. Nonetheless, surprisingly little is known about how it shapes information processing in sensory areas. Here we examined the serotonergic modulation of visual processing in the primary visual cortex of awake behaving macaque monkeys. We found that serotonin mainly decreased the gain of the visual responses, without systematically changing their selectivity, variability, or covariability. This identifies a simple computational function of serotonin for state-dependent sensory processing, depending on the animal's affective or motivational state.

Rubber hand illusion affects joint angle perception.
The Rubber Hand Illusion (RHI) is a well-established experimental paradigm. It has been shown that the RHI can affect hand location estimates, arm and hand motion towards goals, the subjective visual appearance of the own hand, and the feeling of body ownership. Several studies also indicate that the peri-hand space is partially remapped around the rubber hand. Nonetheless, the question remains if and to what extent the RHI can affect the perception of other body parts. In this study we ask if the RHI can alter the perception of the elbow joint. Participants had to adjust an angular representation on a screen according to their proprioceptive perception of their own elbow joint angle. The results show that the RHI does indeed alter the elbow joint estimation, increasing the agreement with the position and orientation of the artificial hand. Thus, the results show that the brain does not only adjust the perception of the hand in body-relative space, but it also modifies the perception of other body parts. In conclusion, we propose that the brain continuously strives to maintain a consistent internal body image and that this image can be influenced by the available sensory information sources, which are mediated and mapped onto each other by means of a postural, kinematic body model.

Amyotrophic Lateral Sclerosis (ALS) is a neurodegenerative disorder that causes progressive paralysis and death on average within three years of symptom onset. There is currently no effective treatment, and the discovery of novel therapies is hindered by the lack of early disease progression biomarkers. Transcranial magnetic stimulation (TMS) combined with single-channel EMG has demonstrated that cortical-spinal hyperexcitability is an early pathogenic mechanism preceding irreversible muscular atrophy in ALS. However, it is still unclear how well different TMS parameters of abnormal cortico-spinal excitability track disease progression. This study piloted the novel combination of TMS with the 64-channel high-density surface EMG (HDSEMG) for the first time. Established TMS protocols probing cortical inhibition through the duration of the cortical silent period (CSP), the magnitude of short interval intracortical inhibition (SICI) and intracortical facilitation (ICF), were measured during simultaneous HDSEMG registration from the first dorsal interosseous (FDI) muscle of the dominant hand in 15 healthy volunteers (9 males, 6 females, mean age 69.3). This study indicated high data quality and the methodological validity of our novel approach, which allowed for the characterisation of CSP, SICI and ICF with better spatial resolution into a 3D anatomical map of the FDI firing. The application of these findings has the potential to improve our understanding of the topographical distribution of disinhibition or excess facilitation that has been postulated to underlie cortical hyperexcitability in ALS. Precisely determining how excitability abnormalities evolve over time may help the progression of a detailed anatomical map of disease trajectory in ALS.

[Aims] Neuropixels probes have dramatically increased the number of neurons that can be acquired in a single experiment. With chronic recordings, these neurons can be tracked across days, but this typically requires the experimenter to permanently cement the probe to the skull. There is thus substantial interest in developing chronic implants that are recoverable while being light enough to be used in mice. [Methods] Here, we present the "Apollo Implant", a device for reversible chronic implantation of Neuropixels 2.0 probes. The implant comprises two modules which are combined before implantation. The payload module accommodates two probes, for a maximum of 8 shanks in the brain, and is recoverable (~€8). The docking module is cemented to the skull during implantation and is not recoverable (~€2). The implant is made of Formlabs Rigid Resin and weighs ~2.0 g with two probes. Its design is open source and can be readily adjusted to change the angle of insertion or the distance between the probes. [Results] We used the Apollo Implant to insert the same probes across at least 4 mice with no noticeable reduction in recording quality. We successfully tracked the same neurons across weeks, allowing us to explore changes of sensory responses and correlation patterns over time, and during a behavioural task. [Conclusions] Thus, the Apollo Implant provides a cheap, lightweight, and flexible solution for chronic recordings in head-fixed mice. We are currently developing versions of the implant optimised for Neuropixels 1.0 probes and freely moving animals.

Here we show, that based on parallel multichannel extracellular and single-channel intracellular potential recordings, it is possible to reconstruct the spatio-temporal distribution of membrane potential with the spatial resolution of the extracellular recordings in a single neuron. Moreover, we show, that reconstruction of intracellular membrane potential made possible the distinction between two components of the current source density (CSD): the resistive and the capacitive currents. This distinction would provide a clue to the proper interpretation of the CSD distribution, as the resistive component corresponds to the active channel currents, both synaptic and voltage-sensitive channel membrane currents, while capacitive current corresponds to the passive counter currents. The importance of this distinction is further emphasized by different features of the resistive membrane current distribution compared to the CSD. As the CSD is a net membrane current, the sum of the CSD along a whole intact cell should be zero at each time moment, according to the charge conservation law. In contrast to this, the sum of the resistive current should not be necessarily zero since it governs the membrane potential dynamics. Thus, estimation of the spatial distribution of the resistive membrane current makes possible the distinction between active and passive sinks and sources of the CSD map and localization of the synaptic input currents, which makes the neuron fire. We validate our reconstruction approach on simulations and demonstrate its application on simultaneous and co-localized extra- and intracellular *in vitro* recordings in the hippocampal CA1 region using *in vitro* rat brain slice preparations.

Recording site placement on planar silicon-based probes affects signal quality in acute neuronal recordings.
Multisite, silicon-based probes are widely used tools to record the electrical activity of neuronal populations. Several physical features of these devices are designed to improve their recording performance. Here, our goal was to investigate whether the position of recording sites on the silicon shank might affect the quality of the recorded neural signal in acute experiments. Neural recordings obtained with five different types of high-density, single-shank, planar silicon probes from anesthetized rats were analyzed. Wideband data were filtered to extract spiking activity, then the amplitude distribution of samples and quantitative properties of the recorded brain activity (single unit yield, spike amplitude and isolation distance) were compared between sites located at different positions of the silicon shank, focusing particularly on edge and center sites. Edge sites outperformed center sites: for all five probe types there was a significant difference in the signal power computed from the amplitude distributions, and edge sites recorded significantly more large amplitude samples both in the positive and negative range. Although the single unit yield was similar between site positions, the difference in spike amplitudes was noticeable in the range corresponding to high-amplitude spikes. Furthermore, the advantage of edge sites slightly decreased with decreasing shank width. Our results might aid the design of novel neural implants in enhancing their recording performance by identifying more efficient recording site placements.

The neural tissue around SU-8 implants: A quantitative in vivo biocompatibility study.
The use of SU-8 material in the production of neural sensors has grown recently. Despite its widespread application, a detailed systematic quantitative analysis concerning its biocompatibility in the central nervous system is lacking. In this immunohistochemical study, we quantified the neuronal preservation and the severity of astrogliosis around SU-8 devices implanted in the neocortex of rats, after a 2 months survival. We found that the density of neurons significantly decreased up

to a distance of 20 µm from the implant, with an averaged density decrease to 24 ± 28% of the control. At 20 to 40 µm distance from the implant, the majority of the neurons was preserved (74 ± 39% of the control) and starting from 40 µm distance from the implant, the neuron density was control-like. The density of synaptic contacts - examined at the electron microscopic level - decreased in the close vicinity of the implant, but it recovered to the control level as close as 24 µm from the implant track. The intensity of the astroglial staining significantly increased compared to the control region, up to 560 µm and 480 µm distance from the track in the superficial and deep layers of the neocortex, respectively. Electron microscopic examination revealed that the thickness of the glial scar was around 5-10 µm thin, and the ratio of glial processes in the neuropil was not more than 16% up to a distance of 12 µm from the implant. Our data suggest that neuronal survival is affected only in a very small area around the implant. The glial scar surrounding the implant is thin, and the presence of glial elements is low in the neuropil, although the signs of astrogliosis could be observed up to about 500 µm from the track. Subsequently, the biocompatibility of the SU-8 material is high. Due to its low cost fabrication and more flexible nature, SU-8 based devices may offer a promising approach to experimental and clinical applications in the future.

Method for spike detection from microelectrode array recordings contaminated by artifacts of simultaneous two-photon imaging.
The simultaneous utilization of electrophysiological recordings and two-photon imaging allows the observation of neural activity in a high temporal and spatial resolution at the same time. The three dimensional monitoring of morphological features near the microelectrode array makes the observation more precise and complex. In vitro experiments were performed on mice neocortical slices expressing the GCaMP6 genetically encoded calcium indicator for monitoring the neural activity with two-photon microscopy around the implanted microelectrodes. A special filtering algorithm was used for data analysis to eliminate the artefacts caused by the imaging laser. Utilization of a special filtering algorithm allowed us to detect and sort single unit activities from simultaneous two-photon imaging and electrophysiological measurement.

Revealing the distribution of transmembrane currents along the dendritic tree of a neuron from extracellular recordings.
Revealing the current source distribution along the neuronal membrane is a key step on the way to understanding neural computations; however, the experimental and theoretical tools to achieve sufficient spatiotemporal resolution for the estimation remain to be established. Here, we address this problem using extracellularly recorded potentials with arbitrarily distributed electrodes for a neuron of known morphology. We use simulations of models with varying complexity to validate the proposed method and to give recommendations for experimental applications. The method is applied to in vitro data from rat hippocampus.

The flexibility and accessibility of induced pluripotent stem cell technology has allowed complex human biology to be reproduced in vitro at high throughput scales. Rapid advances in the technology have led to widespread adoption for the development of in vitro models of neuron electrophysiology to be used in drug discovery and safety. Furthermore, advanced cells preparations, such as spheroids or organoids, are under intense investigation with aims towards establishing mature human phenotypes in vitro. For the establishment of in vitro neuronal models, it is critical to evaluate the structure and function of neurons, synapses, and networks. Here we develop and validate a multiplexed structure-function assay as an efficient approach for evaluating neuronal models in vitro. A planar grid of microelectrodes embedded in the substrate of each well interfaces with cultured cellular networks to continuously monitor both the electrophysiological function and cell structural viability. At the cell-electrode interface, electrical activity from the cells is detected identifying changes in function, while changes in impedance allow the detection of structural effects, such as morphological changes and cell viability. We characterized and validated this multiplexed assay using control compounds known to differentially affect the cell structure and function. All compounds tested altered functional spiking activity. Only tributyltin, glutamate, and Triton X-100 also affected neuronal viability, with Triton X-100 serving as the positive control for complete loss of membrane integrity. These results support the continued development and use of human iPSC-derived neural assays on the Maestro Pro for high throughput drug discovery and safety assessment.

STANDARDIZED QUALITY ASSESSMENTS FOR CHRONIC NEURAL PROBES

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Charlotte Sielaff[1], Antje Kilias[2,3,4], Patrick Ruther[2,5], Ulrich Froriep[1,2,3]
[1]Fraunhofer Institute for Toxicology and Experimental Medicine ITEM, Department Of Implant Systems, Hannover, Germany, [2]University of Freiburg, Department Of Microsystems Engineering (imtek), Freiburg, Germany, [3]University of Freiburg, Bernstein Center Freiburg, Freiburg, Germany, [4]University of Freiburg, Institute For Physiology 1, Cellular And Systemic Neurophysiology, Freiburg, Germany, [5]University of Freiburg, Cluster Of Excellence, Brainlinks-braintools, Freiburg, Germany

Neural probes are essential for diagnosis and treatment of neurological diseases and for mapping of neural circuits in basic research. Their long-term performance, however, is limited through deterioration of the conductive interfaces, scarring, and consequently a successive decrease in signal to noise ratio. To overcome this, aspects such as choice of materials, flexibility, coatings, pre- and postoperative care have been addressed, but there exists no systematic process for the *in vivo* characterization comparing novel probes and materials. Implementation of standardized methods for material and device characterization, probe implantation and explantation, and histological tissue analysis as well as protocols for electrical recording and stimulation, would deeply improve our understanding of the long-term functionality. It would also enable implant developers to ensure long-term performance beyond biocompatibility assessments and reduce animal testing. Consequently, we develop standardized quality assessments suitable for neural implants over long time periods > 30 days, from surgical procedures up to data analyses. We employed methods identified already for a new Michigan-style multi-electrode probe design on which the recording electrodes are located on flexible polyimide wings, combining the benefits of rigid silicone backbones to reach deep brain regions with the advantage of soft materials to minimize the foreign body response. Our results show stable recording quality over long periods of time, but for generalization of quality assessment we require additional data sets and method development to ensure comparability between different probes and materials. This work was supported by the EU Horizon 2020 programme (GA 814654) and by the BMBF.

Introduction Neuropsychiatric conditions such as substance use disorders are associated with behavioural and cognitive impairments arising from disturbed prefrontal neural circuits. Advanced treatments, including brain stimulation, aim at counteracting their chronically recurring courses. While these techniques operate in unidirectional mode, not allowing feedback control, we here developed soft neural interfaces offering multimodal functionality by combining electrocorticographic measurements, electrical/pharmacological stimulation and computational modelling. **Methods** Using 3D-bioprinting of soft silicones and a conductive platinum composite, we fabricated flexible multielectrode arrays for neural recording and stimulation. A microfluidic channel further allowed the cortical application of pharmacological substances. Implanted epidurally above the medial prefrontal cortex of rats, the neuroprosthesis aquired neural activity patterns indicating

stimulus perception, attentive processing and decision making known to be affected in neuropsychiatric disorders. In awake animals, we obtained auditory event-related brain potentials (ERPs) under treatment-naïve conditions and following alcohol intake, cortical electrical stimulation and local application of the anti-relapse medication naltrexone. Machine learning algorithms based on stepwise linear discriminant analysis further allowed advanced identification of treatment effects in single-trial ERP data. **Results** The neuroprosthesis recorded sound-specific neural responses and captured alcohol-induced neural depression indicated by diminished ERP components. Implant-driven electrical stimulation and naltrexone application resulted in enhanced ERP amplitudes. These treatment-induced neural modifications were also accurately identified through the applied computational algorithms. **Conclusions** These findings demonstrate the potential of multifunctional, multimodal neuroprosthetics to monitor and modulate higher-order cognitive function. The combination with computational modelling enables closed-loop feedback control, providing an innovative, comprehensive approach for diagnosing and treating neuropsychiatric symptoms.

Aims: Over the last decades, glial cells' role in neural communication is considered critical in Central Nervous System. In Peripheral Nervous System (PNS), Satellite Glial Cells (SGCs) are emerging as important players in sensory ganglia homeostasis modulation and in inflammation. Our study goal is to develope and validate new technologies to stimulate and record glial cells' functions in vitro. We previously demonstrated that a forest of gold coated silicon nanowires (AuSi/NWs) allows the recording of extracellular activity from in-vivo-like primary astrocyte culture. Here, we translate this approach to PNS using primary co-culture of Dorsal Root Ganglia (DRG) neurons and SGCs on AuSi/NWs devices. **Methods:** DRG co-culture was plated on AuSi/NWs and Flat gold samples were used as control. Cell viability was assessed by fluorescein diacetate/Hoechst staining. Morphological features were evaluated through Scanning electron microscopy. Protein and mRNA expression were measured through quantitative RT-PCR, western blot densitometric analysis and immunofluorescence. **Results:** Cell viability assay at 2 and 5 days in vitro showed that the device enabled the formation of a DRG glia-neuron network without laminin or Matrigel extra coating. mRNA and protein expression analysis demonstrated typical structural features of DRG co-culture in cells grown on AuSi/NWs. GAP43 immunoreactivity underlined an outgrowth regeneration process occurring on AuSi/NWs plated cells. We performed a full characterization of the device's electronic and surface proprieties. **Conclusions:** AuSi/NWs device allows the growing of a DRG glia-neuron network with molecular and morphological characteristics resembling the ones observed in vivo, therefore, representing a powerful tool to study neuron-glia interaction in PNS.

Increased expression of the ATP-gated P2X7 receptor reduces responsiveness to anti-convulsants during status epilepticus in mice.
Refractory status epilepticus is a clinical emergency associated with high mortality and morbidity. Increasing evidence suggests neuroinflammation contributes to the development of drug-refractoriness during status epilepticus. Here, we have determined the contribution of the ATP-gated P2X7 receptor, previously linked to inflammation and increased hyperexcitability, to drug-refractory status epilepticus and its therapeutic potential.

Circulating P2X7 Receptor Signaling Components as Diagnostic Biomarkers for Temporal Lobe Epilepsy.
Circulating molecules have potential as biomarkers to support the diagnosis of epilepsy and to assist with differential diagnosis, for example, in conditions resembling epilepsy, such as in psychogenic non-epileptic seizures (PNES). The P2X7 receptor (P2X7R) is an important regulator of inflammation and mounting evidence supports its activation in the brain during epilepsy. Whether the P2X7R or P2X7R-dependent signaling molecules can be used as biomarkers of epilepsy has not been reported. P2X7R levels were analyzed by quantitative ELISA using plasma samples from controls and patients with temporal lobe epilepsy (TLE) or PNES. Moreover, blood cell P2X7R expression and P2X7R-dependent cytokine signature was measured following status epilepticus in P2X7R-EGFP reporter, wildtype, and P2X7R-knockout mice. P2X7R plasma levels were higher in TLE patients when compared with controls and patients with PNES. Plasma levels of the broad inflammatory marker protein C-Reactive protein (CRP) were similar between the three groups. Using P2X7R-EGFP reporter mice, we

identified monocytes as the main blood cell type expressing P2X7R after experimentally evoked seizures. Finally, cytokine array analysis in P2X7R-deficient mice identified KC/GRO as a potential P2X7R-dependent plasma biomarker following status epilepticus and during epilepsy. Our data suggest that P2X7R signaling components may be a promising subclass of circulating biomarkers to support the diagnosis of epilepsy.

Elevated blood purine levels as a biomarker of seizures and epilepsy.
There is a major unmet need for a molecular biomarker of seizures or epilepsy that lends itself to fast, affordable detection in an easy-to-use point-of-care device. Purines such as adenosine triphosphate and adenosine are potent neuromodulators released during excessive neuronal activity that are also present in biofluids. Their biomarker potential for seizures and epilepsy in peripheral blood has, however, not yet been investigated. The aim of the present study was to determine whether blood purine nucleoside measurements can serve as a biomarker for the recent occurrence of seizures and to support the diagnosis of epilepsy.

Deviant reporter expression and P2X4 passenger gene overexpression in the soluble EGFP BAC transgenic P2X7 reporter mouse model.
The ATP-gated P2X7 receptor is highly expressed in microglia and has been involved in diverse brain diseases. P2X7 effects were also described in neurons and astrocytes but its localisation and function in these cell types has been challenging to demonstrate in situ. BAC transgenic mouse lines have greatly advanced neuroscience research and two BAC-transgenic P2X7 reporter mouse models exist in which either a soluble EGFP (sEGFP) or an EGFP-tagged P2X7 receptor (P2X7-EGFP) is expressed under the control of a BAC-derived P2rx7 promoter. Here we evaluate both mouse models and find striking differences in both P2X expression levels and EGFP reporter expression patterns. Most remarkably, the sEGFP model overexpresses a P2X4 passenger gene and sEGFP shows clear neuronal localisation but appears to be absent in microglia. Preliminary functional analysis in a status epilepticus model suggests functional consequences of the observed P2X receptor overexpression. In summary, an aberrant EGFP reporter pattern and possible effects of P2X4 and/or P2X7 protein overexpression need to be considered when working with this model. We further discuss reasons for the observed differences and possible caveats in BAC transgenic approaches.

High concordance between hippocampal transcriptome of the mouse intra-amygdala kainic acid model and human temporal lobe epilepsy.
Pharmacoresistance and the lack of disease-modifying actions of current antiseizure drugs persist as major challenges in the treatment of epilepsy. Experimental models of chemoconvulsant-induced status epilepticus remain the models of choice to discover potential antiepileptogenic drugs, but doubts remain as to the extent to which they model human pathophysiology. The aim of the present study was to compare the molecular landscape of the intra-amygdala kainic acid model of status epilepticus in mice with findings in resected brain tissue from patients with drug-resistant temporal lobe epilepsy (TLE).

P2X7 Receptor-Dependent microRNA Expression Profile in the Brain Following Status Epilepticus in Mice.
The ionotropic ATP-gated P2X7 receptor is an important contributor to inflammatory signaling cascades the release of Interleukin-1β, as well as having roles in cell death, neuronal plasticity and the release of neurotransmitters. Accordingly, there is interest in targeting the P2X7 receptor for the treatment of epilepsy. However, the signaling pathways downstream of P2X7 receptor activation remain incompletely understood. Notably, recent studies showed that P2X7 receptor expression is controlled, in part, by microRNAs (miRNAs). Here, we explored P2X7 receptor-dependent microRNA expression by comparing microRNA expression profiles of wild-type (wt) and P2X7 receptor knockout mice before and after status epilepticus. Genome-wide microRNA profiling was performed using hippocampi from wt and P2X7 receptor knockout mice following status epilepticus induced by intra-amygdala kainic acid. This revealed that the genetic deletion of the P2X7 receptor results in distinct patterns of microRNA expression. Specifically, we found that in vehicle-injected control mice, the lack of the P2X7 receptor resulted in the up-regulation of 50 microRNAs and down-regulation of 35 microRNAs. Post-status epilepticus, P2X7 receptor deficiency led to the up-regulation of 44 microRNAs while 13 microRNAs were down-regulated. Moreover, there was only limited overlap among identified P2X7 receptor-dependent microRNAs between control conditions

and post-status epilepticus, suggesting that the P2X7 receptor regulates the expression of different microRNAs during normal physiology and pathology. Bioinformatic analysis revealed that genes targeted by P2X7 receptor-dependent microRNAs were particularly overrepresented in pathways involved in intracellular signaling, inflammation, and cell death; processes that have been repeatedly associated with P2X7 receptor activation. Moreover, whereas genes involved in signaling pathways and inflammation were common among up- and down-regulated P2X7 receptor-dependent microRNAs during physiological and pathological conditions, genes associated with cell death seemed to be restricted to up-regulated microRNAs during both physiological conditions and post-status epilepticus. Taken together, our results demonstrate that the P2X7 receptor impacts on the expression profile of microRNAs in the brain, thereby possibly contributing to both the maintenance of normal cellular homeostasis and pathological processes.

Characterization of the Expression of the ATP-Gated P2X7 Receptor Following Status Epilepticus and during Epilepsy Using a P2X7-EGFP Reporter Mouse.
Mounting evidence suggests that the ATP-gated P2X7 receptor contributes to increased hyperexcitability in the brain. While increased expression of P2X7 in the hippocampus and cortex following status epilepticus and during epilepsy has been repeatedly demonstrated, the cell type-specific expression of P2X7 and its expression in extra-hippocampal brain structures remains incompletely explored. In this study, P2X7 expression was visualized by using a transgenic mouse model overexpressing P2X7 fused to the fluorescent protein EGFP. The results showed increased P2X7-EGFP expression after status epilepticus induced by intra-amygdala kainic acid and during epilepsy in different brain regions including the hippocampus, cortex, striatum, thalamus and cerebellum, and this was most evident in microglia and oligodendrocytes. Co-localization of P2X7-EGFP with cell type-specific markers was not detected in neurons or astrocytes. These data suggest that P2X7 activation is a common pathological hallmark across different brain structures, possibly contributing to brain inflammation and neurodegeneration following acute seizures and during epilepsy.

32594159: Parras A, de Diego-Garcia L, Alves M, Beamer E, Conte G, Jimenez-Mateos EM, Morgan J, Ollà I, Hernandez-Santana Y, Delanty N, Farrell MA, O'Brien DF, Ocampo A, Henshall DC, Méndez R, Lucas JJ, Engel T
Polyadenylation of mRNA as a novel regulatory mechanism of gene expression in temporal lobe epilepsy.
Temporal lobe epilepsy is the most common and refractory form of epilepsy in adults. Gene expression within affected structures such as the hippocampus displays extensive dysregulation and is implicated as a central pathomechanism. Post-transcriptional mechanisms are increasingly recognized as determinants of the gene expression landscape, but key mechanisms remain unexplored. Here we show, for first time, that cytoplasmic mRNA polyadenylation, one of the post-transcriptional mechanisms regulating gene expression, undergoes widespread reorganization in temporal lobe epilepsy. In the hippocampus of mice subjected to status epilepticus and epilepsy, we report >25% of the transcriptome displays changes in their poly(A) tail length, with deadenylation disproportionately affecting genes previously associated with epilepsy. Suggesting cytoplasmic polyadenylation element binding proteins (CPEBs) being one of the main contributors to mRNA polyadenylation changes, transcripts targeted by CPEBs were particularly enriched among the gene pool undergoing poly(A) tail alterations during epilepsy. Transcripts bound by CPEB4 were over-represented among transcripts with poly(A) tail alterations and epilepsy-related genes and CPEB4 expression was found to be increased in mouse models of seizures and resected hippocampi from patients with drug-refractory temporal lobe epilepsy. Finally, supporting an adaptive function for CPEB4, deletion of Cpeb4 exacerbated seizure severity and neurodegeneration during status epilepticus and the development of epilepsy in mice. Together, these findings reveal an additional layer of gene expression regulation during epilepsy and point to novel targets for seizure control and disease-modification in epilepsy.

Context-Specific Switch from Anti- to Pro-epileptogenic Function of the P2Y Receptor in Experimental Epilepsy.
Extracellular ATP activates inflammatory responses to tissue injury. It is also implicated in establishing lasting network hyperexcitability in the brain by acting upon independent receptor systems. Whereas the fast-acting P2X channels have well-established roles driving neuroinflammation and increasing hyperexcitability, the slower-acting metabotropic P2Y receptors have received much less attention. Recent studies of P2Y receptor function in seizures and epilepsy have produced contradictory results, suggesting that the role of this receptor during seizure pathology may be highly sensitive to context. Here, by using male mice, we demonstrate that the metabotropic P2Y receptor mediates either proconvulsive or anticonvulsive responses, dependent on the time point of activation in relation to the induction of status epilepticus. P2Y deficiency or a P2Y antagonist (MRS2500) administered before a chemoconvulsant, exacerbates epileptiform activity,

whereas a P2Y agonist (MRS2365) administered at this time point is anticonvulsant. When these drugs are administered after the onset of status epilepticus, however, their effect on seizure severity is reversed, with the antagonist now anticonvulsant and the agonist proconvulsant. This result was consistent across two different mouse models of status epilepticus (intra-amygdala kainic acid and intraperitoneal pilocarpine). Pharmacologic P2Y blockade during status epilepticus reduces also associated brain damage, delays the development of epilepsy and, when applied during epilepsy, suppresses spontaneous seizures, in mice. Our data show a context-specific role for P2Y during seizure pathology and demonstrate that blocking P2Y after status epilepticus and during epilepsy has potent anticonvulsive effects, suggesting that P2Y may be a novel candidate for the treatment of drug-refractory status epilepticus and epilepsy. This is the first study to fully characterize the contribution of a metabotropic purinergic P2Y receptor during acute seizures and epilepsy. The findings suggest that targeting P2Y may offer a potential novel treatment strategy for drug-refractory status epilepticus and epilepsy. Our data demonstrate a context-specific role of P2Y activation during seizures, switching from a proconvulsive to an anticonvulsive role depending on physiopathological context. Thus, our study provides a possible explanation for seemingly conflicting results obtained between studies of different brain diseases where P2Y targeting has been proposed as a potential treatment strategy and highlights that the timing of pharmacological interventions is of critical importance to the understanding of how receptors contribute to the generation of seizures and the development of epilepsy.

On the mechanism of the electrophysiological changes and membrane lesions induced by asbestos fiber exposure in Xenopus laevis oocytes.

The so-called amphibole asbestos fibers are enriched with mineral iron ions, able to stimulate ROS production. We recently reported that crocidolite asbestos was able to interact with the cell membranes of Xenopus laevis oocytes, to alter their electrical membrane properties. Here, we found that applied iron ions (Fe) or HO (for ROS generation) mimicked these effects, suggesting that at least one effect of iron-containing asbestos fiber exposure was mediated by ROS production. Furthermore, combined Fe and HO acted synergistically, producing a membrane effect stronger than that induced by these factors alone. Similar to crocidolite, these changes peaked within 30 minutes of incubation and vanished almost completely after 120 min. However, in the presence of cytochalasin D, which inhibits membrane actin repair mechanisms, crocidolite or applied Fe/HO invariably produced oocyte cell death. While the electrophysiological modifications induced by crocidolite suggested a modification of an intrinsic chloride ion channel, the morphological appearance of the treated oocytes also indicated the formation of membrane "pores"; the effects of asbestos exposure may therefore consist of multiple (not necessarily exclusive) underlying mechanisms. In conclusion, using Xenopus oocytes allowed us for the first time, to focus on a specific membrane effect of crocidolite asbestos exposure, which deserves to be tested also on human lung cell lines. Much available evidence suggests that asbestos fibers damage cells through the production of ROS. Our present data confirm that crocidolite fibers can indeed trigger ROS-mediated damaging effects in the oocyte cell membrane, provided iron ions and HO are available for ROS production.

Understanding how communication between different brain areas supports behavior and cognition is a tremendous neuroscience challenge. Monitoring the electrical activity of neurons is a key technology for advancing the understanding of the brain. Neural implants have evolved at high pace over the last decades with state-of-the-art silicon-based probes like Neuropixels[1] and SiNaps[2]. Despite their success, long-term brain interfacing remains questionable due to the mechanical mismatch between the probe and brain. Micromotions often lead to tissue damage and neural loss. The bending stiffness can be drastically lowered by reducing the Young's modulus and implant size. Advanced cleanroom processes were used to fabricate a high-density 128ch ultra-flexible polyimide probe with <100µm shank width and <3µm thickness. The probe includes low impedance iridiumoxide electrodes and features a modified tip to facilitate the implantation by a wire. Due to the probe's ultra-flexibility a dedicated insertion method had to be developed. The insertion technique is based on a stiff tungsten wire that catches the probe through the modified tip by moving an XYZ-manipulator and uses a camera for visual feedback. The probe is then precisely implanted in the brain by controlling a stepper motor. After implantation the wire is retracted leaving the flexible probe in place. Implantation depths up to 4cm can be reached and the entire system can be mounted on a standard stereotaxic frame. The implantation technique was successfully validated in a phantom brain gel-model and in-vivo in freely moving rodents. [1]Steinmetz N.A. et al. Science._372_(2021)_6539. [2]Angotzi G.N. et al. Microfluidic devices are a valuable tool for modeling *in vitro* neuronal networks allowing neuronal connectivity in physiological and pathological conditions. Here, we present a human Brain-on-Chip of well-characterized human cortical Glutamatergic Neurons in an asymmetric-shape microfluidic device. Our objective is to evaluate the integration and transduction of an immunological signal from monocytes-derived dendritic cells (MoDC) to human cortical glutamatergic neurons. We designed a device composed of three compartments with an asymmetric channel allowing isolation of soma and neurites thanks to microchannels to create an *in vitro* synaptic communication. Human-induced pluripotent stem cell-derived Glutamatergic Neurons are maintained in soma compartments for 21 days. We performed a localized exposition of dendritic cells (MoDC), obtained from human blood isolated monocytes, and differentiated using cytokines and primed with LPS, on either soma or synaptic compartment for 3 hours. The microfluidic device was coupled with MicroElectrode Arrays (MEAs) to confirm the transduction of an immunological signal. We show that this model can be used for quantitative analysis of functional activity according to immuno-neuronal communication. We also analyze the release of neurotransmitters and immune factors. Our data highlight that an electrophysiologic signal was transmitted between two compartments of Glutamatergic Neurons linked by synapses in a bottom-up way when soma is exposed to primed MoDC. In conclusion, this model of BoC opens the field of pharmacological compound screening under physiological conditions. This model could be used totest the effects of compounds on immuno-neuronal signal transduction implicated in a lot of pathology with neurologic and behavioral manifestations.

NOVEL FIELD-EFFECT-TRANSISTOR NANOELECTRODE PROBES FOR ACTIVE INTRACELLULAR ELECTROPHYSIOLOGY: A SIMULATION STUDY

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Federico Leva[1], Pierpaolo Palestri[2], Luca Selmi[1]
[1]University of Modena and Reggio Emilia, Department Of Engineering "enzo Ferrari", Modena, Italy, [2]University of Udine, Polytechnic Department Of Engineering And Architecture, Udine, Italy

Aims. Miniaturization of silicon technology-based nanoelectrode probes for electrophysiology enables high spatial resolution of one or more electrode(s) per neuron while facilitating intracellular access for superior sensitivity to subthreshold signals. To overcome most of the common miniaturization drawbacks of passive electrodes (notably: the reduced signal-to-noise ratio), active electrodes with integrated field-effect-transistors (FETs) need to be used instead. Technology-CAD (TCAD) and multiscale-multiphysics simulation can support the improvement of the electrode device design, yielding complete control of their performance. *Methods.* Based on a finite element modelling (FEM) TCAD, two representative nanoelectrode FET-based devices (i.e., the vertical nanowire-FET (VNW-FET), and the extended-gate silicon-on-insulator FET (EG-SOI-FET)) in intracellular contact with neurons for in-vitro studies are examined. The FEM simulation domain includes a patch of an excitable membrane, confining the cytosol, and surrounded by the electrolyte. The remaining portion of the neuron is accounted for at the circuit level via mixed device-circuit TCAD simulations. *Results.* The drain current transient responses to action potentials (APs) are calculated for nanoelectrodes partly or fully coated and for different neuron insertions. To this end, the FET's threshold voltage is adjusted to maximize the transconductance (gm,MAX) in the middle of the typical AP voltage range. The neuron-device transfer function, for all structures, configurations, and insertions, is essentially frequency independent over the entire AP spectrum and close to the gm,MAX, but quite dependent on the coating design. *Conclusion.* A partial nanoelectrode coating makes the transduction gain dependent on the insertion depth for both devices, resulting in fluctuations of the signal amplitudes.

The central nervous system is organized into different neural circuits, each with particular functions and properties. Studying neural circuits is essential to understanding brain function and neuronal diseases. Microfluidic systems are widely used for reconstructing and studying neural circuits but still need improvement to allow modulation and monitoring of the physiological properties of circuits. In this study, we developed and built a microfluidic device that supports reassembly and electrical modulation of neural circuits. We demonstrated that our microfluidic device system provides a structural platform for corticostriatal (CStr) circuits and a system for modulating and monitoring the physiological function of these circuits. In particular, our microfluidic device measures activity-driven Ca^{2+} dynamics using Ca^{2+} indicators (synaptophysin-GCaMP6f and Fluo5F-AM), as well as activity-driven synaptic transmission using vGlut-pHluorin. Overall, our findings indicate that the advanced microfluidic platform described here is an invaluable tool for studying the physiological properties of specific neural circuits.

ENGINEERING TOOLSET PLATFORM FOR NEUROBIOLOGICAL INTERFACES

POSTER SESSION 04 - SECTION: NOVEL NEURAL INTERFACES FOR STIMULATION & TRACKING

Siyuan Rao
University of Massachusetts Amherst, Biomedical Engineering, Amherst, United States of America

To understand the neural mechanisms and ultimately develop effective intervention approaches for neurological and psychiatric disorders, it is essential to reveal the causal link between behavioral output and neural cellular activity. Engineering approaches provide methodological assistance to establish a toolset platform. Ideally, the toolset platform will be featured with minimal invasiveness to biological tissue, functional longevity, widespread coverage of neural circuits, the capability to manipulate neurons at multiple scales, ranging from individual synapse to broad neural circuits, and the specificity to identify targeted neural populations. We have been developing effective engineering tools at the neurobiological interfaces to investigate neural dynamics. This toolset platform includes two main research directions: precise interventional tools for remotely controlled neuromodulation and real-time recording techniques to monitor neural dynamics. Firstly, a magnetic toolkit for remote neuromodulation, which allows remotely controlled release of pharmacological compounds to modulate targeted neural circuits. This chemomagnetic technique combines magnetic tools and behavioral neuroscience to enable temporally precise modulation of specific neural circuits underlying motivation and social interactions. Secondly, an optical recording system to monitor neural dynamics from multiple sites across the central nervous system in freely behaving mice with simultaneous behavioral output.

México, Mexico, [4]UNAM FES Iztacala, Carrera De Médico Cirujano, Mexico city, Mexico

Voltage-gated sodium channels (Na_V) are known for their fundamental role in action potential firing in excitable cells, such as muscle cells and neurons. However, evidence accumulated in recent years indicates that Na_V's also participate in a variety of cellular processes such as phagocytosis, motility and metastatic activity, although the mechanisms underlying such activities are unknown. Studies from our laboratory indicate that transcription factor mSin3B can interact with sodium channels $Na_V1.2$ and $Na_V1.6$. Here we show that another transcription factor, CTBP1, can also bind these channels in Y2H. We confirm this interaction by co-IP of CTBP1 and $Na_V1.2$ channel from mouse brain proteins extracted with RIPA buffer, using either antibodies raised against the C-terminus of $Na_V1.2$ or antibodies against CtBP1, and testing by western blot. Our results indicate that CTBP1 co-IP with a fragment of >63 kDa, identified by two anti-$Na_V1.2$ antibodies, from nuclear and cytosolic fractions. These antibodies recognize a 250 kDa band (full length channel) and a >63 kDa band in whole lystes, but only the 63 kDa isoform CoIP with CTPB1 from nuclear and cytosolic fractions. Interaction between this $Na_V1.2$ fragment with CTPB1 raises the question about the impact on CtBP1 activity as a transcription factor and as a Golgi-scaffold protein, as well as if this interaction can modify the activity of $Na_V1.2$ at the membrane. Further experiments are needed to better understand this interaction physiological role in neurons and other non excitable cells. **Supported by Conacyt Grant A1-S-36984**

Aims: We previously demonstrated that ultrasound stimulation increases intrinsic excitability of cultured cortical rat neurons, and this effect lasted for at least 8 hours (Clennell et al. 2021. Brain Stimul. 14(2):217-225). We subsequently investigated the effect on whole-cell ion currents, neuronal proteome, and excitatory synaptic transmission.
Methods: Primary rat cortical neurons were stimulated with a 40 second, 200kHz pulsed ultrasound- or sham-stimulation. Whole-cell ion currents were measured under voltage clamp at 0-2, 6-8, 12-14 and 24-26 hours post-stimulation. Total protein and phosphopeptide abundance was analysed by nanoLC MS/MS. Excitatory synaptic transmission was analysed by recording of mEPSCs.
Results: We observed statistically significant increases in whole-cell potassium currents at 0-2hr (p = 0.004), 6-8hr (p = 0.001) and 12-14hr (p < 0.001) post-stimulation. These changes were absent by 24-hours. Conversely, we did not find any significant differences in whole-cell sodium currents at any timepoint. Proteomic analysis revealed no change to total levels of voltage-gated ion channels but did indicate differential phosphorylation specific to $K_v2.1$. Ingenuity Pathway Analysis indicated induction of synaptogenic signalling pathways. This was corroborated by mEPSC recordings indicating 243% increase in mEPSC frequency following stimulation (p < 0.001).
Conclusion: Ultrasound stimulation induces sustained, reversible increases in whole-cell potassium currents suggesting changes to voltage-gated potassium channel function. Proteomic analysis indicates a role for $K_v2.1$ phosphorylation in mediating the effects and suggests induction of synaptogenesis by ultrasound. This is supported by observation of increased excitatory synaptic transmission. These results can inform the application of transcranial ultrasound in experimental and therapeutic settings.

CHANNEL NOISE LEADS TO LARGER STOCHASTIC VOLTAGE FLUCTUATIONS IN THE AXON THAN IN THE SOMA

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Mickael Zbili[1], Rodrigo Perin[2], Henry Markram[1], Werner Van Geit[1]
[1]École polytechnique fédérale de Lausanne, Blue Brain Project, Geneva, Switzerland, [2]École polytechnique fédérale de Lausanne, Laboratory Of Neural Microcircuitry, Lausanne, Switzerland

Neuronal excitability is mediated by voltage-gated ion channels which biophysics are usually described as deterministic phenomena. However, it is well accepted that individual ion channels undergo thermodynamic fluctuations which provoke stochastic transitions between closed and open states. This so-called “channel-noise” leads to stochastic fluctuations of the membrane potential (Vm) and to unpredictability of the neuronal output. Channel noise has been mostly studied through somatic recordings which may underestimate it for two reasons: 1) the somatic capacitance makes individual channels stochastic transitions unlikely to entail observable Vm fluctuations, 2) the large somatic channels amount provokes an averaging of the individual channel stochasticity, leading to a global deterministic behavior. Computational studies have suggested that thinner compartments such as axons express strong voltage fluctuations due to channel noise but this has not been experimentally verified. To answer this question, we performed dual soma-axon whole-cell recordings in cortical layer 5 pyramidal neurons (L5PC). We observed, both in soma and axon, the presence of stochastic fluctuations of subthreshold Vm, presenting larger amplitudes in axon than in the soma. These fluctuations increased with voltage depolarization and decreased following TTX application, strongly suggesting that they were due to channel noise. Moreover, the channel noise was negatively correlated with the diameter of the recorded compartment. Using a detailed L5PC model, we showed that axonal channel noise may have a big impact on both spike initiation and spike propagation dynamics.

OPTICAL INVESTIGATION OF EXCITABILITY AND ION CHANNELS IN LAYER-5 NEOCORTICAL PYRAMIDAL NEURONS

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Fatima Abbas[1], Luiza Filipis[2], Laila Blömer[2], Marco Canepari[2]
[1]Université Grenoble Alpes et CNRS, Laboratoire Interdisciplinaire De Physique (liphy), Saint-Martin D'Héres Cédex, France, [2]UGA/CNRS, Liphy, Saint-Martin-d'Hères, France

Electrical excitability is based on the action potential defined by sequences of voltage changes across the membrane, and its monitoring is critical for understanding the neuronal behavior that underpins brain function. Pyramidal neurons of the layer–5 of the neocortex are a major site of signal integration from different areas of the brain, underlying high-level functions. In particular, ion channels are the main contributors to the initiation, propagation and back-propagation of action potentials (AP) in neurons and given their critical role, genetically defined abnormalities altering their function result in a large set of human diseases known as "channelopathies". Thus, imaging action potentials and ion currents from dendritic and axonal areas at submillisecond time scales and with a precision of a few microns, in combination with selective pharmacological manipulations, is fundamental to investigate the multiple channel isoforms that occupy different parts of the neuron, the activity of an individual ion channel, and how they interact within their native environment to define AP characteristics and shape AP waveforms. Here, we present some examples of novel measurements that are advancing our detailed understanding on the mechanisms underlying excitability in this important neuron. We compare signals in the axon and in the apical dendrite showing how the same channel can contribute to the action potential in different ways in different compartments.

HEAVY DRINKING DURING ADOLESCENCE AFFECTS ETHANOL RESPONSE OF DENTATE GYRUS GRANULE CELLS IN ADULT MOUSE HIPPOCAMPUS

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Nicolas Buelow, Christian Alzheimer, Fang Zheng
University of Erlangen-Nürnberg, Institute Of Physiology And Pathophysiology, Erlangen, Germany

Excessive ethanol consumption during adolescence is regarded as a risk factor for development of alcoholism later in life, but the pathophysiological mechanisms that render adult brain susceptible to ethanol are largely unknown. $GABA_A$ receptors and inwardly rectifying K^+ (IRK) channels are prime targets of ethanol to regulate neural activity. Work from our lab has demonstrated that activin, a member of TGF-β family, controls ethanol potentiation of $GABA_A$ receptors and IRK currents in mouse hippocampus. Elaborating on the latter, we asked here, if adolescent drinking would affect IRK current responses to acute alcohol in hippocampal slices from adult mice, and if activin plays a role as an adaptive factor. Whole-cell voltage-clamp recordings were performed on dentate gyrus granule cells from wild-type mice and transgenic mice, expressing a dominant-negative mutant of activin receptor IB (dnActRIB), which disrupts signaling. We found that, compared to control mice, heavy drinking in dark during postnatal days 32-45 produced a long-lasting sensitization so that, in adulthood, IRK current response to alcohol (30-150 mM) were consistently enhanced. IRK currents were identified by their reversal potential near -90 mV and their suppression by low Ba^{2+}. Granule cells from alcohol-naïve dnActRIB mice responded stronger to acute alcohol than their wild-type counterparts. Moreover, they exhibited pronounced potentiation of IRK response when examined after adolescent drinking paradigm. Our results show that heavy adolescent drinking has a long-lasting impact on how IRK channels of granule cells react upon alcohol re-exposure later in life, and that this process might possibly involve activin receptor signaling.

ACTIVIN REGULATION OF GIRK CURRENT RESPONSE TO ETHANOL IN DENTATE GYRUS GRANULE CELLS REVERSES AFTER ADOLESCENCE

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Sophia Stürzenberger, Christian Alzheimer, Fang Zheng
University of Erlangen-Nürnberg, Institute Of Physiology And Pathophysiology, Erlangen, Germany

G protein-gated inwardly rectifying potassium (GIRK) channels play an essential role in regulating neuronal excitability. While many neurotransmitters/-modulators use Gi/o protein as intermediary to open the channels, GIRKs can also be directly activated by alcohol. In previous work, we have shown that activin, a member of the TGF-β family, modulates $GABA_B$ receptor-evoked GIRK current. To explore if activin also modulates GIRK response to ethanol, we performed whole-cell voltage-clamp recordings from dentate gyrus granule cells (GCs) in dorsal hippocampal slices from adolescent (P37-42) and adult wild-type (wt) mice and transgenic mice, which express a dominant-negative mutant of activin receptors IB (dnActRIB). In wt GCs from both age groups, ethanol induced outward current responses (V_h -70 mV) in a dose-dependent fashion, with juvenile cells exhibiting significantly stronger responses to low ethanol (15 – 30 mM) than adult cells. Ethanol-mediated currents had a reversal potential near -90 mV, were diminished to a large extent by the GIRK-blocker tertiapin Q, and were fully suppressed by low Ba^{2+} (200 µM). Unexpectedly, we found that the effect of activin A (50 ng/ml, pre-incubated for 3-5 h) on ethanol responses was opposite in the two age groups: Whereas activin A enhanced the ethanol-induced current in juvenile slices, the response was decreased in adult slices. The dichotomous effect of activin was completely reversed when re-examined in GCs from adolescent and adult dnActRIB mice, underscoring the essential role of endogenous activin signaling in determining the neural impact of alcohol consumption at different stages of life.

TREK CHANNELS AND THEIR PHYSIOLOGICAL ROLE IN THE INTRACARDIAC NEURONS: FOCUSING ON TEMPERATURE AND INTRACELLULAR ACIDIFICATION

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Ana Campos-Ríos[1], Manuela Rodríguez-Castañeda[1], Diana Rodrigues[2,3], Lola Rueda-Ruzafa[1], Patricia Monteiro[2,3], José Antonio Lamas[1]
[1]University of Vigo, Cinbio, Laboratory Of Neuroscience, Vigo, Spain, [2]University of Minho, Life And Health Sciences Research Institute (icvs) / School Of Medicine, Braga, Portugal, [3]PT Government Associate Laboratory, Icvs/3b's, Braga/Guimarães, Portugal

The intrinsic activity of the intracardiac nervous system is determined by cardiac pacemarkers and is strongly modulated by the sympathetic and parasympathetic branches of the autonomic nervous system. Although general mechanisms controlling cardiac activity have been extensively studied, little is known about the electrical properties and function of parasympathetic neurons in the intracardiac ganglion (ICG). TREK channels, a subfamily of two-pore domain potassium (K2P) channels, are proteins with a crucial role in maintaining resting membrane potential and controlling excitability, but their function in the ICG remains unclear. In this work we investigated the effect of changes in physiological parameters such as increased temperature and intracellular acidification and how these variations affect to cultured mouse ICG neurons behaviour. First, the presence of TREK channels in the ICG was assessed by RT-qPCR and western-blot analysis. Using electrophysiological patch-clamp technique (perforated-patch), passive and active properties were examined at 24 and 37 °C and before and after cytosolic acidification. In the "current-clamp" experiments, the excitability of ICG neurons was clearly reduced when the temperature was increased from 24 to 37 °C, the neurons resulted hyperpolarized, the action potential firing rate decreased, and some action potential characteristics were also affected. The same phenomenon occurred when the cytosolic pH was diminished. Consistently, in "voltage-clamp" both physiological temperature and intracellular acidification induced outward currents and an increase in conductance through K+channels. Altogether, these results highlight the contribution of TREK channels in establishing neuronal excitability properties at physiological temperature and their role as neuroprotective channels.

Are TREK Channels Temperature Sensors?
Internal human body normal temperature fluctuates between 36.5 and 37.5°C and it is generally measured in the oral cavity. Interestingly, most electrophysiological studies on the functioning of ion channels and their role in neuronal behavior are carried out at room temperature, which usually oscillates between 22 and 24°C, even when thermosensitive channels are studied. We very often forget that if the core of the body reached that temperature, the probability of death from cardiorespiratory arrest would be extremely high. Does this mean that we are studying ion channels in dying neurons? Thousands of electrophysiological experiments carried out at these low temperatures suggest that most neurons tolerate this aggression quite well, at least for the duration of the experiments. This also seems to happen with ion channels, although studies at different temperatures indicate large changes in both, neuron and channel behavior. It is known that many chemical, physical and therefore physiological processes, depend to a great extent on body temperature. Temperature clearly affects the kinetics of numerous events such as chemical reactions or conformational changes in proteins but, what if these proteins constitute ion channels and these channels are specifically designed to detect changes in temperature? In this review, we discuss the importance of the potassium channels of the TREK subfamily, belonging to the recently discovered family of two-pore domain channels, in the transduction of thermal sensitivity in different cell types.

Tetrodotoxin: A New Strategy to Treat Visceral Pain?
Visceral pain is one of the most common symptoms associated with functional gastrointestinal (GI) disorders. Although the origin of these symptoms has not been clearly defined, the implication of both the central and peripheral nervous systems in visceral hypersensitivity is well established. The role of several pathways in visceral nociception has been explored, as well

as the influence of specific receptors on afferent neurons, such as voltage-gated sodium channels (VGSCs). VGSCs initiate action potentials and dysfunction of these channels has recently been associated with painful GI conditions. Current treatments for visceral pain generally involve opioid based drugs, which are associated with important side-effects and a loss of effectiveness or tolerance. Hence, efforts have been intensified to find new, more effective and longer-lasting therapies. The implication of VGSCs in visceral hypersensitivity has drawn attention to tetrodotoxin (TTX), a relatively selective sodium channel blocker, as a possible and promising molecule to treat visceral pain and related diseases. As such, here we will review the latest information regarding this toxin that is relevant to the treatment of visceral pain and the possible advantages that it may offer relative to other treatments, alone or in combination.

Contribution of K2P Potassium Channels to Cardiac Physiology and Pathophysiology.
Years before the first two-pore domain potassium channel (K2P) was cloned, certain ion channels had already been demonstrated to be present in the heart with characteristics and properties usually attributed to the TREK channels (a subfamily of K2P channels). K2P channels were later detected in cardiac tissue by RT-PCR, although the distribution of the different K2P subfamilies in the heart seems to depend on the species analyzed. In order to collect relevant information in this regard, we focus here on the TWIK, TASK and TREK cardiac channels, their putative roles in cardiac physiology and their implication in coronary pathologies. Most of the RNA expression data and electrophysiological recordings available to date support the presence of these different K2P subfamilies in distinct cardiac cells. Likewise, we show how these channels may be involved in certain pathologies, such as atrial fibrillation, long QT syndrome and Brugada syndrome.

HOW KV2.1 CONTRIBUTES TO DENDRITE ACTIVE PROPERTIES?

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Anne-Lise Paupiah, Marion Russeau, Imane Moutkine, Marianne Renner
Institut du Fer à Moulin UMR-S1270, Inserm, Paris, France

Kv2 channels, which underlie most of the “delayed-rectifier” K^+ current, were shown to sustain high frequency firing by avoiding depolarization block. Interestingly, the voltage dependence (Vhalf) of Kv2.1 may vary in a ~40mV range depending on phosphorylation of its C-ter, which also affects the formation of patches (clusters) of Kv2.1 at the soma, proximal dendrites and axonal initial segment. Several mutations of KCNB1, coding for Kv2.1, have been described in patients with epileptic encephalopathy. We focused on two mutated forms that introduce a stop codon (Y533* and R583*) before or within the C-ter region responsible for clustering. In cultured pyramidal neurons transfected to express WT or mutated Kv2.1, mutated channels displayed a non-clustered distribution at the cell surface. Single Particle Tracking experiments confirmed the loss of scaffolding interactions that immobilize the channel in clusters. Importantly, both mutations redistributed Kv2.1 throughout the dendritic arbor. As a shift in voltage dependence was reported for the Y533* mutant, we used a detailed biophysical model of a pyramidal CA1 neuron in order to disentangle the consequences of changes in voltage dependence or a modified distribution in dendrites alone. More negative values of Vhalf of a WT Kv2-like conductance (gkdr2) not only decreased excitability but also reduced the impact of backpropagated action potentials (bAP) in the apical dendrite. Redistributing gkdr2 in all dendritic segments also reduced excitability and strongly affected bAPs. Thus, modelling proposes Kv2 as an important actor of the active properties of dendrites, role that may be modified by mutations or phosphorylation.

VOLTAGE-GATED $Ca_v2.2$ CALCIUM ION CHANNELS IN TRPV1 NERVE ENDINGS IN SKIN CONTRIBUTE TO THE RELEASE OF PROINFLAMMATORY MEDIATORS

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Anne-Mary Salib[1], Meredith Crane[2], Amanda Jamieson[2], Diane Lipscombe[1]
[1]Brown University, Department Of Neuroscience, Providence, United States of America, [2]Brown University, Department Of Molecular Microbiology & Immunology, Providence, United States of America

Voltage-gated calcium ion channels (Ca_v) are essential for the transmission of noxious stimuli detected at peripheral nerve endings and the central perception of pain. Recently, the Lipscombe lab showed that capsaicin-induced heat hypersensitivity in peripheral Trpv1 nociceptor nerve endings in skin depends on $Ca_v2.2$ channel activity (DuBreuil et al., 2021). The precise mechanism by which $Ca_v2.2$ channels mediate heat hypersensitivity in peripheral nerve endings is not fully understood, but it is likely that they are the source of calcium that triggers vesicular release of inflammatory signaling molecules from nerve endings. We tested the hypothesis that $Ca_v2.2$ channel activation is necessary for the release of early inflammatory mediators linked to behavioral hypersensitivity to heat and mechanical stimuli. Within 15 minutes of intraplantar capsaicin injections mice exhibit maximal heat and mechanical hypersensitivity and, at the same time point, we observe an associated spike in interleukin-1α (IL-1α) detectable in interstitial fluid of the injected hindpaw. Interleukin IL-1α is an early proinflammatory mediator released from non-neuronal cells. We show that recombinant IL-1α injected directly into the hindpaw of wild type mice induces heat hypersensitivity when compared to vehicle controls (n= 6 per group, p =0.0050). In $Ca_v2.2$ KO mice, capsaicin-induced heat hypersensitivity and IL-1α levels in hindpaw were reduced by 60% as compared to wild type controls (6-8 animals per group; p =0.0400). Our data suggest that $Ca_v2.2$ channels in peripheral nerve endings trigger downstream neuroimmune signaling underlying transient heat hypersensitivity.

The nucleus accumbens and alcoholism: a target for deep brain stimulation.
Alcohol use disorder (AUD) is a difficult to treat condition with a significant global public health and cost burden. The nucleus accumbens (NAc) has been implicated in AUD and identified as an ideal target for deep brain stimulation (DBS). There are promising preclinical animal studies of DBS for alcohol consumption as well as some initial human clinical studies that have shown some promise at reducing alcohol-related cravings and, in some instances, achieving long-term abstinence. In this review, the authors discuss the evidence and concepts supporting the role of the NAc in AUD, summarize the findings from published NAc DBS studies in animal models and humans, and consider the challenges and propose future directions for neuromodulation of the NAc for the treatment of AUD.

Neuromodulatory Treatments for Alcohol Use Disorder: A Review.
Alcohol use disorder (AUD) is a prevalent condition characterized by chronic alcohol-seeking behaviors and has become a significant economic burden with global ramifications on public health. While numerous treatment options are available for AUD, many are unable to sustain long-term sobriety. The nucleus accumbens (NAcc) upholds an integral role in mediating reward behavior and has been implicated as a potential target for deep brain stimulation (DBS) in the context of AUD. DBS is empirically thought to disrupt pathological neuronal synchrony, a hallmark of binge behavior. Pre-clinical animal models and pilot human clinical studies utilizing DBS for the treatment of AUD have shown promise for reducing alcohol-related cravings and prolonging abstinence. In this review, we outline the various interventions available for AUD, and the translational potential DBS has to modulate functionality of the NAcc as a treatment for AUD.

Traumatic brain injury (TBI) often causes cell death and cortical dysfunction in the neighboring area. Interestingly, functional changes also spread to primarily undamaged tissue causing neuronal hyperactivity in the contralateral hemisphere already 24 hours after injury (Le Prieult et al. 2017). In search for the underlying mechanisms here we investigated the role of somatostatin-positive (SST)-GABAergic interneurons in mice. Unilateral TBI was induced under anesthesia by use of a controlled mechanical impact in vivo. We isolated the contralateral cortex after a survival time of 72 h and performed Fluorescence-Activated Cell Sorting (FACS) and Mass Spectrometry (MS) in GFP+-interneurons. Proteomic data showed a TBI-induced putative reciprocal regulation of α subunits of pore-forming L-Type Voltage-gated calcium channel (VGCCs), represented by an expression of CaV1.3 and simultaneous ablation of CaV1.2. Next, we tested whether this switch in α-subunits supported a recovery of the early (24h after TBI) contralateral hyperexcitability, therefore we performed electrophysiological recordings in acute brain slices in presence of a CaV1.3-selective antagonist. Isradipine stabilized the extracellular cortical network activity back to the level of controls at 72 h post-TBI. Furthermore, patch-clamp recordings from somatostatin-positive (SST) interneurons confirmed this switch in VGCC α-subunits. F/I-curves revealed an isradipine sensitive increase in excitability through expression of CaV1.3. In conclusion, the TBI-induced expression of CaV1.3 in VGCCs in SST-interneurons supports the adaptive processes of functional reorganization in the contralateral network after the injury. These mechanisms might affect the later expression of post-traumatic-epilepsy (PTE). This work was supported by a grant to TM (DFG, CRC 1080, C02).

ON THE KINETICS OF CALCIUM CURRENTS AND THE ACTIVATION OF CALCIUM-ACTIVATED POTASSIUM CHANNELS IN LAYER-5 PYRAMIDAL NEURONS

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Laila Blömer, Luiza Filipis, Marco Canepari
UGA/CNRS, Liphy, Saint-Martin-d'Hères, France

Calcium influx via voltage-gated calcium channels (VGCCs) contributes to the shaping of the action potential (AP) by regulating the potassium conductance during the decaying phase. Here we optically analysed the kinetics of the calcium current associated with the AP in the proximal part of the apical dendrite of the layer-5 pyramidal neuron of the somato-sensory cortex of the mouse. We found that this current is mediated by L-type, P/Q-type, N-type, R-type and T-type VGCCs. The selective block of each individual channel decreases the amplitude of the calcium current, except for the N-type VGCC where inhibition produces the opposite effect. We then correlated the optical recording of the AP, using membrane potential imaging, with the calcium current finding that the peak of the AP precedes the peak of the calcium current by 0.5-1 ms. The effect of blocking N-type or L-type VGCCs, as well as the effect of blocking BK or SK calcium-activated potassium channels, was a widening of the AP shape preceding the peak of the calcium current. We concluded that calcium-activated potassium channels are activated by the early calcium influx and we formulate the hypothesis that each potassium channel is specifically coupled to a calcium channel. In particular, N-type VGCCs, although less expressed with respect to other VGCCs, substantially contribute to the potassium conductance associated with the AP repolarisation. More generally, the results of this study may shed new light on functional channel-channel interactions and how the synergy of diverse channels result in the shaping of the AP.

DIFFERENTIAL MODULATION OF GABAA AND GLYCINE RECEPTORS BY GELSEMIUM ALKALOIDS

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Ana María Marileo[1], César Lara[1], Victoria San Martín[1], Anggelo Sazo[1], Jessica Panes[2], Carlos Felipe Burgos[2], Gustavo Moraga-Cid[2], Gonzalo Yévenes[2]

The extracts of the *Gelsemium* genus plants have been used in traditional medicine to treat several diseases. Nevertheless, they also have shown an intrinsic high toxicity. Chemical characterizations of *Gelsemium* extracts have determined that the major active components of these plants are alkaloids, such as gelsemine, koumine, humantenmine, and gelsevirine. Our previous studies have shown that gelsemine can modulate the activity of glycine receptors (GlyRs), a pentameric inhibitory ligand-gated ion channel of the nervous system. Whether other *Gelsemium* alkaloids also modulate GlyRs or other inhibitory channels, such as $GABA_A$ receptors ($GABA_ARs$), is currently unknown. Here, we have explored the effects of gelsemine, koumine, humantenmine, and gelsevirine on $GABA_A$ and glycine receptors using electrophysiological recordings performed on recombinant and native receptors. We have found that these alkaloids differentially modulated $GABA_A$ and glycine receptors. Our preliminary results have shown that gelsevirine has a potentiating effect on the GABA-evoked currents of native $GABA_ARs$. In contrast, we didn't observe any significant effect on glycine-evoked currents on recombinant GlyRs. We found that Gelsemine and koumine have an inhibitory effect over both kinds of receptors. Experiments with humentenmine didn't find a significant effect on the $GABA_ARs$. Finally, molecular modeling suggests that all these alkaloids can bind to the orthosteric site of both receptors. These ongoing experiments will let us explore the alkaloids' effects on different conformations of these receptors, which let us explain some of the toxic effects of these alkaloids and contribute to expanding the pharmacological studies of inhibitory receptors.

Modulation of glycine receptor single-channel conductance by intracellular phosphorylation.
Glycine receptors (GlyRs) are anion-permeable pentameric ligand-gated ion channels (pLGICs). The GlyR activation is critical for the control of key neurophysiological functions, such as motor coordination, respiratory control, muscle tone and pain processing. The relevance of the GlyR function is further highlighted by the presence of abnormal glycinergic inhibition in many pathophysiological states, such as hyperekplexia, epilepsy, autism and chronic pain. In this context, previous studies have shown that the functional inhibition of GlyRs containing the α3 subunit is a pivotal mechanism of pain hypersensitivity. This pathway involves the activation of EP2 receptors and the subsequent PKA-dependent phosphorylation of α3GlyRs within the intracellular domain (ICD), which decrease the GlyR-associated currents and enhance neuronal excitability. Despite the importance of this mechanism of glycinergic dis-inhibition associated with dysfunctional α3GlyRs, our current understanding of the molecular events involved is limited. Here, we report that the activation of PKA signaling pathway decreases the unitary conductance of α3GlyRs. We show in addition that the substitution of the PKA-targeted serine with a negatively charged residue within the ICD of α3GlyRs and of chimeric receptors combining bacterial GLIC and α3GlyR was sufficient to generate receptors with reduced conductance. Thus, our findings reveal a potential biophysical mechanism of glycinergic dis-inhibition and suggest that post-translational modifications of the ICD, such as phosphorylation, may shape the conductance of other pLGICs.

Inhibitory Actions of Tropeines on the α3 Glycine Receptor Function.
Glycine receptors (GlyRs) are chloride-permeable pentameric ligand-gated ion channels. The inhibitory activity of GlyRs is essential for many physiological processes, such as motor control and respiration. In addition, several pathological states, such as hyperekplexia, epilepsy, and chronic pain, are associated with abnormal glycinergic inhibition. Recent studies have

pointed out that positive allosteric modulators targeting the GlyR α3 subunit (α3GlyR) displayed beneficial effects in chronic pain models. Interestingly, previous electrophysiological studies have shown that tropeines, which are a family of synthetic antagonists of the serotonin type 3 receptors (5-HTRs), potentiate the activity of GlyRs conformed by α1 subunits. However, despite its importance as a pharmacological target in chronic pain, it is currently unknown whether the α3GlyR function is modulated by tropeines. Using electrophysiological techniques and molecular docking simulations, here we show that tropeines are inhibitors of the α3GlyR function. Tropisetron, a prototypical tropeine, exerted concentration-dependent inhibitory effects on α3GlyRs at the low micromolar range. In addition, three other tropeines showed similar effects. Single-channel recordings show that tropisetron inhibition is associated with a decrease in the open probability of the ion channel. Molecular docking assays suggest that tropeines preferentially bind to an agonist-free, closed state of the ion channel. The tropeine binding occurs in a discrete pocket around the vicinity of the orthosteric site within the extracellular domain of α3GlyR. Thus, our results describe the pharmacological modulation of tropeines on α3GlyRs. These findings may contribute to the development of GlyR-selective tropeine derivatives for basic and/or clinical applications.

Functional modulation of glycine receptors by the alkaloid gelsemine.
Gelsemine is one of the principal alkaloids produced by the Gelsemium genus of plants belonging to the Loganiaceae family. The extracts of these plants have been used for many years, for a variety of medicinal purposes. Coincidentally, recent studies have shown that gelsemine exerts anxiolytic and analgesic effects on behavioural models. Several lines of evidence have suggested that these beneficial actions were dependent on glycine receptors, which are inhibitory neurotransmitter-gated ion channels of the CNS. However, it is currently unknown whether gelsemine can directly modulate the function of glycine receptors.

Glycine Receptors (GlyRs) are pentameric anion-permeable ligand-gated ion channels. Hypo-functional GlyRs have been related to several pathological states, such as chronic pain and hyperekplexia. The modulation of GlyRs by positive allosteric modulators (PAMs) has emerged as a promising therapeutic approach against chronic pain. However, only few studies have explored the action mechanisms of glycinergic PAMs at the functional level. Here, we studied the mechanisms of modulation of two different types of glycinergic PAMs, which displayed analgesic actions in behavioral studies. By using single-channel and whole-cell electrophysiology of recombinant GlyRs, we focus our functional analyses on the effects of 2,6-di-tert-butylphenol (2,6-DTBP) and of the tricyclic sulfonamide AM-1488. Whole-cell recordings show that both 2,6-DTBP and AM-1488 exerted concentration-dependent potentiation of homomeric GlyRs composed of α1 and α3 subunits. While previous structural data showed that AM-1488 bound to the extracellular domain of the receptor, our preliminary mutagenesis studies combined with molecular modeling showed that the actions of 2,6-DTBP are linked to two binding sites localized on both transmembrane and intracellular domains. Single-channel recordings revealed that the effects of 2,6-DTBP and AM-1488 are associated with different biophysical mechanisms of modulation. Dwell analysis showed that 2,6-DTBP generated longer burst time and longer channel openings, whereas AM-1488 also produced longer burst time but without modifications on the open time. Altogether, our results suggest that different biophysical mechanisms of modulation for PAMs targeting GlyRs are likely related with independent allosteric sites. These findings may contribute to the development of novel glycinergic PAMs with differential modulatory profiles.

Inhibition of the Glycine Receptor alpha 3 Function by Colchicine.
Colchicine is a plant alkaloid that is widely used as a therapeutic agent. It is widely accepted that colchicine reduces the production of inflammatory mediators mainly by altering cytoskeleton dynamics due to its microtubule polymerization inhibitory activity. However, other lines of evidence have shown that colchicine exerts direct actions on the function of ion channels, which are independent of cytoskeleton alterations. Colchicine is able to modify the function of several pentameric ligand-gated ion channels, including glycine receptors (GlyRs). Previous electrophysiological studies have shown that colchicine act as an antagonist of GlyRs composed by the subunit. In addition, it was recently demonstrated that colchicine directly bind to the subunit of GlyRs. Interestingly, other studies have shown a main role of GlyRs on chronic inflammatory pain. Nevertheless, the functional effects of colchicine on the GlyR function are still unknown. Here, by using electrophysiological techniques and bioinformatics, we show that colchicine inhibited the function of the GlyRs. Colchicine elicited concentration-dependent inhibitory effects on GlyRs at micromolar range and decreased the apparent affinity for glycine. Single-channel recordings show that the colchicine inhibition is associated with a decrease in the open probability of the ion channel. Molecular docking assays suggest that colchicine preferentially bind to the orthosteric site in the closed state of the ion channel. Altogether, our results suggest that colchicine is a competitive antagonist of the GlyRs.

Pentameric Ligand-Gated Ion Channels as Pharmacological Targets Against Chronic Pain.
Chronic pain is a common detrimental condition that affects around 20% of the world population. The current drugs to treat chronic pain states, especially neuropathic pain, have a limited clinical efficiency and present significant adverse effects that

complicates their regular use. Recent studies have proposed new therapeutic strategies focused on the pharmacological modulation of G-protein-coupled receptors, transporters, enzymes, and ion channels expressed on the nociceptive pathways. The present work intends to summarize recent advances on the pharmacological modulation of pentameric ligand-gated ion channels, which plays a key role in pain processing. Experimental data have shown that novel allosteric modulators targeting the excitatory nicotinic acetylcholine receptor, as well as the inhibitory GABA and glycine receptors, reverse chronic pain-related behaviors in preclinical assays. Collectively, these evidences strongly suggest the pharmacological modulation of pentameric ligand-gated ion channels is a promising strategy towards the development of novel therapeutics to treat chronic pain states in humans.

Modulation of glycine receptor single-channel conductance by intracellular phosphorylation.
Glycine receptors (GlyRs) are anion-permeable pentameric ligand-gated ion channels (pLGICs). The GlyR activation is critical for the control of key neurophysiological functions, such as motor coordination, respiratory control, muscle tone and pain processing. The relevance of the GlyR function is further highlighted by the presence of abnormal glycinergic inhibition in many pathophysiological states, such as hyperekplexia, epilepsy, autism and chronic pain. In this context, previous studies have shown that the functional inhibition of GlyRs containing the α3 subunit is a pivotal mechanism of pain hypersensitivity. This pathway involves the activation of EP2 receptors and the subsequent PKA-dependent phosphorylation of α3GlyRs within the intracellular domain (ICD), which decrease the GlyR-associated currents and enhance neuronal excitability. Despite the importance of this mechanism of glycinergic dis-inhibition associated with dysfunctional α3GlyRs, our current understanding of the molecular events involved is limited. Here, we report that the activation of PKA signaling pathway decreases the unitary conductance of α3GlyRs. We show in addition that the substitution of the PKA-targeted serine with a negatively charged residue within the ICD of α3GlyRs and of chimeric receptors combining bacterial GLIC and α3GlyR was sufficient to generate receptors with reduced conductance. Thus, our findings reveal a potential biophysical mechanism of glycinergic dis-inhibition and suggest that post-translational modifications of the ICD, such as phosphorylation, may shape the conductance of other pLGICs.

Inhibitory Actions of Tropeines on the α3 Glycine Receptor Function.
Glycine receptors (GlyRs) are chloride-permeable pentameric ligand-gated ion channels. The inhibitory activity of GlyRs is essential for many physiological processes, such as motor control and respiration. In addition, several pathological states, such as hyperekplexia, epilepsy, and chronic pain, are associated with abnormal glycinergic inhibition. Recent studies have pointed out that positive allosteric modulators targeting the GlyR α3 subunit (α3GlyR) displayed beneficial effects in chronic pain models. Interestingly, previous electrophysiological studies have shown that tropeines, which are a family of synthetic antagonists of the serotonin type 3 receptors (5-HTRs), potentiate the activity of GlyRs conformed by α1 subunits. However, despite its importance as a pharmacological target in chronic pain, it is currently unknown whether the α3GlyR function is modulated by tropeines. Using electrophysiological techniques and molecular docking simulations, here we show that tropeines are inhibitors of the α3GlyR function. Tropisetron, a prototypical tropeine, exerted concentration-dependent inhibitory effects on α3GlyRs at the low micromolar range. In addition, three other tropeines showed similar effects. Single-channel recordings show that tropisetron inhibition is associated with a decrease in the open probability of the ion channel. Molecular docking assays suggest that tropeines preferentially bind to an agonist-free, closed state of the ion channel. The tropeine binding occurs in a discrete pocket around the vicinity of the orthosteric site within the extracellular domain of α3GlyR. Thus, our results describe the pharmacological modulation of tropeines on α3GlyRs. These findings may contribute to the development of GlyR-selective tropeine derivatives for basic and/or clinical applications.

Large Intracellular Domain-Dependent Effects of Positive Allosteric Modulators on Glycine Receptors.
Glycine receptors (GlyRs) are members of the pentameric ligand-gated ionic channel family (pLGICs) and mediate fast inhibitory neurotransmission in the brain stem and spinal cord. The function of GlyRs can be modulated by positive allosteric modulators (PAMs). So far, it is largely accepted that both the extracellular (ECD) and transmembrane (TMD) domains constitute the primary target for many of these PAMs. On the other hand, the contribution of the intracellular domain (ICD) to the PAM effects on GlyRs remains poorly understood. To gain insight about the role of the ICD in the pharmacology of GlyRs, we examined the contribution of each domain using a chimeric receptor. Two chimeras were generated, one consisting of the

ECD of the prokaryotic homologue Gloeobacter violaceus ligand-gated ion channel (GLIC) fused to the TMD of the human αGlyR lacking the ICD (Lily) and a second with the ICD (Lily-ICD). The sensitivity to PAMs of both chimeric receptors was studied using electrophysiological techniques. The Lily receptor showed a significant decrease in the sensitivity to four recognized PAMs. Remarkably, the incorporation of the ICD into the Lily background was sufficient to restore the wild-type αGlyR sensitivity to these PAMs. Based on these data, we can suggest that the ICD is necessary to form a pLGIC having full sensitivity to positive allosteric modulators.

Phosphorylation state-dependent modulation of spinal glycine receptors alleviates inflammatory pain.
Diminished inhibitory neurotransmission in the superficial dorsal horn of the spinal cord is thought to contribute to chronic pain. In inflammatory pain, reductions in synaptic inhibition occur partially through prostaglandin E2- (PGE2-) and PKA-dependent phosphorylation of a specific subtype of glycine receptors (GlyRs) that contain α3 subunits. Here, we demonstrated that 2,6-di-tert-butylphenol (2,6-DTBP), a nonanesthetic propofol derivative, reverses inflammation-mediated disinhibition through a specific interaction with heteromeric αβGlyRs containing phosphorylated α3 subunits. We expressed mutant GlyRs in HEK293T cells, and electrophysiological analyses of these receptors showed that 2,6-DTBP interacted with a conserved phenylalanine residue in the membrane-associated stretch between transmembrane regions 3 and 4 of the GlyR α3 subunit. In native murine spinal cord tissue, 2,6-DTBP modulated synaptic, presumably αβ heteromeric, GlyRs only after priming with PGE2. This observation is consistent with results obtained from molecular modeling of the α-β subunit interface and suggests that in α3βGlyRs, the binding site is accessible to 2,6-DTBP only after PKA-dependent phosphorylation. In murine models of inflammatory pain, 2,6-DTBP reduced inflammatory hyperalgesia in an α3GlyR-dependent manner. Together, our data thus establish that selective potentiation of GlyR function is a promising strategy against chronic inflammatory pain and that, to our knowledge, 2,6-DTBP has a unique pharmacological profile that favors an interaction with GlyRs that have been primed by peripheral inflammation.

Functional modulation of glycine receptors by the alkaloid gelsemine.
Gelsemine is one of the principal alkaloids produced by the Gelsemium genus of plants belonging to the Loganiaceae family. The extracts of these plants have been used for many years, for a variety of medicinal purposes. Coincidentally, recent studies have shown that gelsemine exerts anxiolytic and analgesic effects on behavioural models. Several lines of evidence have suggested that these beneficial actions were dependent on glycine receptors, which are inhibitory neurotransmitter-gated ion channels of the CNS. However, it is currently unknown whether gelsemine can directly modulate the function of glycine receptors.

ENLIGHTENING THE GLYCINE RECEPTOR α2 AS A KEY REGULATOR IN THE BRAIN REWARD PATHWAY

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Yana Vella[1], Elisabeth Piccart[1], Öykü Uslu[1], Jelle Hendrix[2], Jean-Michel Rigo[1], Bert Brône[1]

The glycine receptor alpha 2 subunit (GlyRα2) is functionally expressed in the striatal projection neurons (SPNs). SPNs are a convergence point for glutamatergic and dopaminergic input and this signal integration coordinates reward-motivated behavior. Data from our laboratory show that the GlyRα2 modulates SPN activity, thus, targeting GlyRα2 offers great potential to modulate striatum-orchestrated behavior. However, it is unclear how the subcellular localization of GlyRα2 affects its role in regulating SPN activity. We aim to investigate the subcellular localization and dynamics of the GlyRα2 by fusing a genetically encoded yellow fluorescent protein-based chloride-sensor (Zhong S, et al. (2014). PLoS One 9(6): e99095) to a human GlyRα2 (hGlyRα-mClYFP). Using patch clamp, whole-cell glycine induced currents (10, 30, 100, 300, 1000 μM glycine, holding potential -60 mV) of hGlyRα-mClYFP transfected into HEK293 cells were obtained. The EC50 of the hGlyRα-mClYFP current (~400 μM) corresponds with previously published EC50 of the GlyRα2 (~200 μM), indicating normal glycine sensitivity of the chimeric receptor. Chloride induced fluorescent quenching was measured in epifluorescence microscopy and indicated that the fluorescence signal is directly linked to the glycine induced chloride current, witnessed by an EC50 of 170 μM. These experiments suggest that the hGlyRα-mClYFP retains normal whole cell current activity whilst possessing mClYFP sensor properties to detect chloride concentration changes.

OXIDATION SENSITIZES TRPV2 TO CHEMICAL AND HEAT STIMULATION, BUT NOT MECHANICAL STIMULATION

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Koji Shibasaki
University of Nagasaki, Laboratory Of Neurochemistry, Nagasaki, Japan

The transient receptor potential vanilloid 2 (TRPV2) ion channel is activated by a chemical ligand (2-aminoethoxydiphenyl borate; 2-APB), noxious heat and mechanical stimulation. In a heterologous mammalian cell expression system, the oxidant chloramine T (ChT) sensitizes TRPV2 activation in response to 2-APB and heat by oxidation of methionine residues at positions 528 and 607 in rat TRPV2. Here, we used a *Xenopus* oocyte expression system to determine whether ChT-mediated oxidation can also sensitize TRPV2 to mechanical stimulation. In this system, we confirmed that ChT sensitized TRPV2 activation in response to 2-APB and heat, but we detected no sensitization to mechanical stimulation. This result suggests that the activation mechanism of TRPV2 by a chemical ligand and heat differs from that for mechanical stimulation. Further, we demonstrated that two-electrode voltage clamp recording in the *Xenopus* oocyte expression system is an excellent format for high throughput analysis of oxidization of redox-sensitive TRP channels.

COMPUTATIONAL STUDY OF THE EFFECTS OF HCN CHANNEL MODULATION ON L5PC EXCITABILITY

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Tuomo Mäki-Marttunen[1,2], Verónica Mäki-Marttunen[3]
[1]University of Oslo, Department Of Biosciences, Oslo, Norway, [2]Tampere University, Faculty Of Medicine And Health Technology, Tampere, Finland, [3]Leiden University, Cognitive Psychology, Leiden, Netherlands

Dendrites of cortical pyramidal cells are densely populated by hyperpolarization-activated cyclic nucleotide-gated channels, a.k.a. I_h channels. I_h channels are targeted by multiple neuromodulatory pathways and thus are one of the key ion-channel populations regulating the pyramidal cell activity. Previous observations and theories attribute opposing effects of the I_h channels on neuronal excitability due to their mildly hyperpolarized reversal potential. These effects are difficult to measure experimentally due to the fine spatiotemporal landscape of the I_h activity in the dendrites, but computational models provide an efficient tool for studying this question in a reduced but generalizable setting. In this work, we build upon existing biophysically detailed models of thick-tufted layer V pyramidal cells (L5PC) and model the effects of over- and under-expression of I_h channels as well as their neuromodulation by dopamine (gain of I_h function) and acetylcholine (loss of I_h function). We show that I_h channel activity facilitates the action potentials of L5PCs in response to proximal dendritic stimulus while it hinders the action potentials in response to distal dendritic stimulus at the apical dendrite. We also show that the inhibitory action of the I_h channels in L5PCs is due to the interactions between I_h channels and a hot zone of low voltage-activated Ca^{2+}channels at the apical dendrite. Our simulations suggest that a combination of dopaminergic neuromodulation of I_h channels at the proximal apical dendrite and cholinergic modulation at the distal apical dendrite can increase the L5PC excitability more than any of the two neuromodulators alone.

CHRFAM7A: A HUMAN SPECIFIC α7- NICOTINIC ACETYLCHOLINE RECEPTOR GENE

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Gökce Ilayda Söztekin[1], Uwe Maskos[2], Marija Zivaljic[2], Sigismund Huck[1], Petra Scholze[1]

Genome-wide association studies suggest a critical role of the *CHRNA7* (coding for α7 nAChR) and/or *CHRFAM7A* genes in cognitive and psychiatric disorders including schizophrenia and many others. *CHRFAM7A* occurs only in humans and encodes a partially duplicated version of the α7 nAChR (dupα7) subunit lacking the agonist binding site. Our hypothesis is that dupα7 subunit acts as a functional dominant negative regulator and may reduce the α7 nAChR function. In our project, we aim to investigate the functional consequences of *CHRFAM7A* on α7 nAChR in human neurons. To study human specific *CHRFAM7A,* cortical neurons are differentiated from human induced pluripotent stem cells (hiPSCs) with either overexpressing or lacking *CHRFAM7A*. hiPSC-neurons are stained by using fluorescently labelled neuronal markers for molecular characterization and analysed functionally by Fura-2 Ca^{2+}-Imaging and Patch-Clamp electrophysiology. With patch-clamp recordings in the voltage-clamp mode, hiPSC-neurons lacking *CHRFAM7A* responded to depolarizing voltage steps by inward-directed sodium currents and outward-directed potassium currents. After at least 4 weeks of differentiation, these currents formed the basis for trains of action potentials recorded in current-clamp mode. We observed an increase in the frequency of miniature excitatory post-synaptic currents upon application of the α7 nAChR specific agonist PNU-282987 when combined with the PAMII PNU-120596. Fura-2 Ca^{2+}-Imaging revealed that in the presence of TTX, the combined application of PNU-282987 and PNU-120596 increased intracellular Ca^{2+}. This increase was significantly reduced in hiPSC-neurons overexpressing *CHRFAM7A.* In conclusion, we were able to confirm that dupα7 subunit reduces the α7 nAChR function in hiPSC-neurons.

MODULATION BY NEUROSTEROIDS OF THE GABAA RECEPTORS AND KIR CHANNELS EXPRESSED IN OLIGODENDROGLIA

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Ana Gabriela Cárdenas Perez[1], Rogelio Arellano Ostoa[1], Teresa Morales[2], Abraham Cisneros Mejorado[2]
[1]Universidad Nacional Autónoma de México, Instituto De Neurobiología, Querétaro, Mexico, [2]Instituto de Neurobiología, Universidad Nacional Autónoma de México, Departamento De Neurobiología Celular Y Molecular,, Querétaro, Mexico

In the central nervous system, the myelination of axons carried out by oligodendrocytes (OLs) is a fundamental phenomenon for the proper functioning of the system. OLs are differentiated from OPCs through a process that is controlled by several factors. Neuron-OPC communication through distinct neurotransmitters has been shown important for the process, and, for example it is known that OPCs differentiation, as well as OLs maturation, and myelination per se, are phenomena regulated by Ɣ-amino butyric acid (GABA) acting on GABA receptors type A (GABAAR) , and by neurosteroids (NEs), which are GABAAR modulators. The specific effect(s)of NEs on membrane proteins of OLs is unknown, thus, in here our main goal was to characterize the possible effects on two membrane currents that play an important role in the maturation of the oligodendrocytes and the subsequent myelination process, the response generated by GABAAR opening and the activity of Kir channels. For this, we characterized electrophysiologically the current response elicited by GABA (3-10 µM) in cultured rat OPCs with or without Ganaxolone (Gx), a synthetic allopregnanolone analogue, as well as recorded Kir currents in cells which presented characteristics of premyelinating cells from the same cultures. The results show that Gx (100 nM — 1 µM) promotes a robust enhancement of 350 ± 50 % (n=31) of the GABA response and inhibited the Kir current by 90 ± 12 % (n=14). We suggest that NEs modulation of the GABA response and Kir channels might be of importance during oligodendrocyte differentiation and/or maturation.

PATHOGENIC MUTATION GLUN1-N650K IN COMBINATION WITH GLUN2A SUBUNIT CHANGES KINETIC PARAMETERS AND CONDUCTANCE OF NMDA RECEPTORS

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Marharyta Kolcheva[1,2], Stepan Kortus[2], Martin Horak[2], Jakub Netolický[1,2]
[1]Faculty of Science, Charles University in Prague, Department Of Physiology, Prague, Czech Republic, [2]Institute of Experimental Medicine CAS, Neurochemistry, Prague, Czech Republic

AIMS: This study investigated the effect of the pathogenic GluN1-N650K mutation, associated with developmental delay and seizures (doi:10.1111/epi.12987), on the functional and pharmacological properties of NMDARs. **METHODS:** Whole-cell voltage-clamp recordings performed in HEK293 cells transfected with the WT and mutated hGluN1-4a/hGluN2A receptors and hippocampal neurons infected with lentiviruses expressing the WT and mutated YFP-tagged hGluN1 subunits. Immunofluorescence was performed 24 hours after transfection (for HEK293 cells) and 10 days after lentiviral infection (for hippocampal neurons) using an anti-GFP antibody. Excitotoxicity experiments performed in hippocampal neurons (DIV14) by calculating the proportion of pyknotic/non-pyknotic nuclei (staining with Hoechst 33342). **RESULTS:** Our microscopic experiments showed that the GluN1-N650K mutation increased surface expression of GluN1/GluN2A receptors in HEK293 calls and in the hippocampal neurons. Our electrophysiological experiments showed that the GluN1-N650K mutation increased the potency of GluN1/GluN2A receptors for glutamate and glycine. In the presence of physiological concentrations of Mg^{2+}, GluN1-N650K/GluN2A receptors showed stronger potency to memantine but not to ketamine. Moreover, the hGluN1-N650K mutation significantly slowed the binding and unbinding kinetics of memantine and ketamine. Finally, we found that the presence of the GluN1-N650K subunit reduces the level of excitotoxic damage to hippocampal neurons and memantine shows promising neuroprotective effects in the presence of WT and GluN1-N650K subunits. **CONCLUSIONS:** This study indicate that pathogenic GluN1-N650K mutation in the M3 domain of the GluN1 subunit affect the trafficking and functional properties of NMDARs. *This work was supported by a project from the Czech Science Foundation (20-12420S) and the Grant Agency of Charles University (GAUK:320521).*

AIMS: To describe how the pathogenic mutation N650K in the GluN1 subunit, associated with developmental delay and seizures, affects kinetic parameters and conductivity of GluN1/GluN2A NMDA receptors. **METHODS:** HEK293 cells expressing wild-type (WT) or mutated human GluN1-4a/GluN2A receptors were measured using the patch-clamp technique. For the calculation of the probability of opening (Po), single-channel steady-state activity was recorded in cell-attached patches, whereas NMDAR conductivity measurements were performed in pulled outside-out patches. **RESULTS:** The analysis of cell-attached recordings containing WT receptors showed that the distribution of dwell times was best fitted with an average kinetic scheme consisting of two open and five closed states. In contrast, recordings containing mutated receptors were described using only one open state and just four closed states. From the calculated time constants and their areas, we observed ~165-fold reduction of Po of mutated receptors compared to WT receptors. This robust reduction of Po results from a ~10-fold decrease in mean open time and a ~32-fold increase of the mean closed time. From the cell-attached recording, we also observed reduced amplitude for mutated receptors. We confirmed this observation with our conductivity measurements, which showed that the conductance significantly decreased from 52.1±0.8 pS for WT receptors to 36.3±1.0 pS for mutated receptors. **CONCLUSIONS**: This study showed robust changes in kinetic parameters and conductivity in receptors containing pathogenic mutation GluN1-N650K associated with developmental delay and seizures. *This work was supported by a project from the Czech Science Foundation (*20-12420S*) and the Grant Agency of Charles University (GAUK: 306221).*

MECHANOSENSITIVITY OF URINARY BLADDER SMOOTH MUSCLES: THE ROLE OF TREK-1/TRPV4/PIEZO1 CHANNELS

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Semen Yeliashov, Bizhan Sharopov, Anastasia Danshina, Yaroslav Shuba
Bogomoletz institute of physiology, Department Of Neuromuscular Physiology, Kyiv, Ukraine

Urinary bladder mechanosensivity is realized not only via neurogenic and urothelium-dependent mechanisms, but may also rely directly on detrusor smooth muscle cells (DSMC). Here we have investigated the role of mechano-gated ion channels, TREK1, TRPV4, and Piezo1, as possible candidates for mechanoreceptors in DSMC. Membrane currents (I_m) and $[Ca^{2+}]_i$ signals in rat DSMC in response to mechanostimulation (shear stress at 5 nl/s) or application of selective TREK-1, Piezo1, and TRPV4 activators, arachidonic acid (AA, 50 μM), Yoda1 (20 μM) and GSK1016790A (50 μM), respectively, were studied by whole-cell patch-clamp and fluorescence calcium imaging with Fluo-4AM. TREK-1-mediated current was also probed with specific inhibitor, L-methionine (3 mM). DSMC in terms of I_m generated in response to mechanostimulation could be separated onto three groups: 1) nonresponsive (46%), 2) generating outwardly-rectifying, L-methionine-sensitive current with reversal potential V_r~-70 mV (19%), and 3) generating current with quasilinear I-V relationship and V_r~0 mV. Yoda1 application evoked $[Ca^{2+}]_i$ elevation but, surprisingly, inhibited outward component of the I_m rather than activated inward one. GSK1016790A application appeared ineffective in either activating I_m or elevating $[Ca^{2+}]_i$. Application of AA caused drastic increase of inward currents. We conclude that rat DSMC functionally express TREK-1 and Piezo1, but not TRPV4 channels which may shape up myogenic bladder mechanosensitivity. Heterogeneity of DSMC population with respect to the size and type of mechanoactivated I_m may reflect either their origin from different bladder parts or differences in their functional state (degree of contraction). Supported by 2020.02/0189 grant from National Research Foundation of Ukraine.

LIPID ENVIRONMENT IS ESSENTIAL FOR OPTIMAL ACTIVITY OF PLASMA MEMBRANE CA2+ ATPASE IN MURINE BRAIN TISSUE

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Mario Stojanović[1,2], Borna Puljko[1,2], Katarina Ilic[1], Nikolina Maček -Hrvat[3], Kristina Mlinac Jerković[1,2], Svjetlana Kalanj-Bognar[1,2]
[1]School of Medicine, Croatian Institute For Brain Research,, Zagreb, Croatia, [2]School of Medicine, Department Of Chemistry And Biochemistry, Zagreb, Croatia, [3]Institute for Medical Research and Occupational Health, Biochemistry And Organic Analytical Chemistry Unit, Zagreb, Croatia

Plasma membrane calcium ATPase (PMCA) is an integral resident across eukaryotic membrane systems, implicated in miscellaneous brain functions such as equilibrating cellular Ca^{2+} levels and signal transduction. Our preliminary data indicate that Toll-like receptor 2 deficient mice (TLR2D) exhibit differential expression of PMCA isoforms across nervous tissue. Due to firm evidence that P-type ATPases generally require a specialized lipid environment to manage assigned functions, we aimed to track specific PMCA activity and its submembrane distribution in TLR2D compared to wild-type (WT) mice. For that purpose, we used cortical, hippocampal, and cerebellar samples dissected from the TRL2D and WT brains. PMCA activity was measured by spectrophotometry, while PMCA positioning within membranes was investigated in isolated lipid raft and non-raft fractions. The results strongly imply probable interactions between PMCA and membrane lipids. The subfractionation of the membrane gave us a clue that PMCA is shifting through different lipid microenvironments with specific membrane properties. Secondly, the measured variations in the specific PMCA activity between TLR2 KO and the control animal group reflect the fact that P-type ATPases activity correlates with a different lipid-residing environment characterized by different membrane properties. These findings argue that specific PMCA arrangements in a lipid environment fine-tune differential expression of PMCA, thus possibly changing Ca^{2+} signaling and influencing physiological functions of the nervous system in TLR2D mice. Further study will help us understand the exact role and neurophysiological outcome of the interplay between PMCA isoforms and its neighboring membrane lipids in mammalian brain tissue.

HIGH-RESOLUTION PROTEOMICS UNRAVEL A NATIVE FUNCTIONAL UNIT MADE UP OF CAV1.3, SK3 AND HCN2 CHANNELS

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Béatrice Marquèze-Pouey[1], Cécile Bonnaure[1], Maya Belghazi[2], Ophélie Toutendji[1], Dominique Debanne[1], Jean-Marc Goaillard[3]

Aims Pacemaking activity is critical to the function of *substantia nigra pars compacta* (SNc) dopaminergic neurons and is intrinsically driven by several voltage-and Ca^{2+}-dependent channels. However, spontaneous activity pattern was found to be robust to knock-down of Cav1.3 voltage-gated calcium, and calcium activated SK3 channels, suggesting that compensatory mechanisms must occur. Furthermore, co-variation of voltage dependences of I_A (Kv4) and I_H (HCN) was characterized in SNc neurons. Thus, pacemaking stability may potentially be generated by ion channel coordinated regulations taking place in large protein complexes. Methods We performed immunoprecipitation using magnetic bead-coupled antibody against Cav1,2, Cav1.3, HCN2, HCN4, Kv4.3, and SK3 channels from solubilized midbrain wild-type mice membranes or antigen-deleted knock out mice as negative control. After tandem mass spectrometry analysis, quantitative proteomic data were statistically analyzed using the MaxQuant/Perseus framework to decipher significant interactants. Results The already known multiprotein assembly of Kv4.3, kchip4 and DPP6/10 was found, validating the technique. Unexpectedly, we uncovered distinctive interactors for channels with functional and structural similarities such as Cav1.2, Cav1.3 and HCN2, HCN4. The following new potential binding partners were found: Cav1.3 –RiMBP2; Pex5-Cav1.2; HCN4-Sarm1, SK3-TSC1-TSc2; HCN2-AMPAR. Interestingly a Cav1.3 -SK3 and HCN2 super-channel complex was characterized and further confirmed by *in situ* Proximity Ligation Assay. Conclusion We could decipher a calcium-sensing nanodomain where voltage-dependent calcium channels and calcium-sensitive potassium channels would physically interact with cAMP responsive HCN channels themselves closely modulated by calcium-activated adenylate cyclase producing cAMP. This interacting structure could be a molecular basis for pacemaking activity robustness.

Voltage-gated sodium channels (Na_V) best known function is the initiation and propagation of the action potential. However, the expression of different isotypes of this family of proteins in non excitable cells has been documented and even cancer cells. Our research group has found a number of transcription factors (like Sin3B) that interact with the C-terminus of $Na_V1.2$, interestingly, we have found that this region of the channel exhibits a functional nuclear location signal (NLS). This has led us to ask if the interaction with transcription factors may affect the transcription of their targets. Here we evaluated the expression profile of neuroblastoma cells transfected with a plasmid encoding a $Na_V1.2$ CT (229 amino acid peptide tagged with EGFP), and analyzed the mRNA profile using microarray technology. Thus, we found change in the expression of a group of 13 genes involved in the intracellular signaling pathway JAK-STAT. We are currently exploring five up- or down-regulated messengers, IL11, IL6R, STAM, TYK2 and SOCS. Since JAK-STAT pathway is linked to different biological processes such as differentiation, cell proliferation, apoptosis and immune regulation, regulation of these messenger may link the presence of sodium channels to non-canonical roles observed in non-excitable cells, as has been reported from other researchers. **Supported by CONACyT, grant A1-S-36984**

STRUCTURE AND BEHAVIOR OF NAV1.2 AND NAV1.6 C-TERMINUS. A MOLECULAR DYNAMICS ANALYSIS.

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Luis Manuel Arratia Cortes[1], Ana Vega[2], Absalom Zamorano Carrillo[1]
[1]Instituto Politécnico Nacional, Laboratorio De Bioquímica Y Biofísica Computacional, México, Mexico, [2]UNAM FES Iztacala, Carrera De Médico Cirujano, Mexico city, Mexico

Voltage-regulated sodium channels (NaV's) are transmembrane proteins that allow the influx of sodium ions into excitable and non-excitable cells. In the central nervous system (CNS) we find mainly two isoforms, NaV's 1.2 and 1.6, where they key to the action potential initiation and propagation and, in a less understood manner, they are involved in cell motility and proliferation. Multiple proteins can be anchored to different parts of NaV's, however, the terminal carboxyl (C-terminus) is the anchor site that binds more partners, yet very little is known about its structure. Here we used an in silico approach to obtain a molecular model of C-Terminus NaV1.2 and 1.6, where a 3D structure of NaV 1.2 (229 aa) and 1.6 (214 aa). To analyze conformational changes and their biochemical significance we ran molecular dynamics simulations (MDs) at 310 K. Different conformations of the proteins were evidenced during 100 ns. Although both sequences become more compact throughout the MD, NaV1.2 gradually denatures and loses its conformation, while NaV 1.6 remains more stable. Unfolding of the structure may be relevant to regulate C-Terminus' NaV's binding with other proteins. This description helps us to better understand the functionality and stability of NaV's C-terminus and will help to further models of binding and interaction with other proteins. **Supported by CONACyT Grant A1-S-36984, 287002 and IPN-SIP-20220704**

THE DEAFNESS CAUSING PITCH AND AUDIO-1 MUTATIONS AFFECT THE NEUROPLASTIN AND PLASMA MEMBRANE CA2+ ATPASE COMPLEX FUNCTION

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Yi Liang[1], Chenjie Feng[2], Rodrigo Herrera-Molina[3,4], Xiao Lin[1], Dirk Montag[1]
[1]Leibniz-Institut für Neurobiologie, Neurogenetics, Magdeburg, Germany, [2]Ningxia Medical University, School Of Science, Yinchuan, China, [3]Leibniz Institute for Neurobiology, Combinatorial Combinatorial Neuroimaging (cni), Magdeburg, Germany, [4]Universidad Bernardo O'Higgins, Centro Integrativo De Biologia Y Quimica Aplicada, Santiago, Chile

Aims : Neuroplastin (*Nptn*) is essential for hearing functions and for the expression of its binding partner the plasma membrane Ca^{2+} ATPase (PMCA) in hair cells. Mouse mutants carrying either of the single amino acid changes in the *Nptn* sequence *pitch* or *audio1* are deaf. We investigated the effect of the neuroplastin mutations on the expression and function of PMCA. **Methods :** The *pitch* (C315S) and *audio-1* (I122N) neuroplastin protein structures and the interactions with PMCA were predicted by bioinformatic means. Plasmids encoding the two variants were constructed for the two neuroplastin isoforms (Np55 and Np65) and transfected into HEK 293T cells. Expression levels and subcellular location of neuroplastin and PMCA were investigated by Western blot and immuno-histochemistry. Calcium imaging was used to evaluate the effect of the kinetics of electrically-evoked cytosolic calcium transients in cultured primary hippocampal neurons. **Results :** The *pitch* and *audio-1* mutations affect the structure of neuroplastin differently. Transfection of the mutated *Nptn* variants in HEK 293T cells revealed a tendency towards decreased PMCA. Expression of the mutant variants in hippocampal neurons showed the slower restoration of calcium levels after stimulation determined by *in vitro* calcium imaging indicating the impaired function of PMCA. **Conclusions :** We show that the *pitch* and *audio-1* mutations in *Nptn* impair structurally and functionally the association with PMCA. Therefore, in addition to the identified role of neuroplastin in outer hair cell amplification and inner hair cell synaptogenesis, our results indicate that PMCA-dependent calcium dynamic imbalance underlies deafness by the *Nptn* mutations. ***Keywords:*** neuroplastin, PMCA, hearing, hair cells, deafness, calcium

Neuroplastin in Neuropsychiatric Diseases.
Molecular mechanisms underlying neuropsychiatric and neurodegenerative diseases are insufficiently elucidated. A detailed understanding of these mechanisms may help to further improve medical intervention. Recently, intellectual abilities, creativity, and amnesia have been associated with neuroplastin, a cell recognition glycoprotein of the immunoglobulin superfamily that participates in synapse formation and function and calcium signaling. Data from animal models suggest a role for neuroplastin in pathways affected in neuropsychiatric and neurodegenerative diseases. Neuroplastin loss or disruption of molecular pathways related to neuronal processes has been linked to various neurological diseases, including dementia, schizophrenia, and Alzheimer's disease. Here, we review the molecular features of the cell recognition molecule neuroplastin, and its binding partners, which are related to neurological processes and involved in learning and memory. The emerging functions of neuroplastin may have implications for the treatment of diseases, particularly those of the nervous system.

The majority of the cellular functions depends on the concentration of intercellular Ca^{++}. L-type voltage-gated calcium channels (CaV-L) initiate the transfer of calcium into the cell as a result of the potential changes in the membrane, and forms temporary calcium currents necessary for cellular mechanisms. An analysis of the amino acid sequences of the alpha subunits predicts that Ca^{++} channels consist of four similar domains (repeat I-IV) with 6 putative transmembrane segments that assemble to form a central pore. Although *Astacus leptodactylus* (crayfish), is a widely used model animal in neuroscience, information about its genetic properties is rather limited. In this study we have cloned the putative L-type voltage-gated calcium channel mRNA from muscle tissue cDNA libraries of *Astacus leptodactylus*. In order to reveal the sequence, Sanger sequencing and NGS methods were used after following PCR and RACE experiments. The complete sequence was 7060 bp for CaV-L and 5550 bp for the ORF. When the sequence was analyzed in NCBI Conserved Domain Database, the domains relevant to ion selectivity and voltage gating were observed. Besides, the sequence was submitted into the BLASTn platform to examine its similarities with the L-type calcium channel sequences of closely related species. Crayfish putative CaV-L channel is going to be expressed in *Xenopus laevis* oocytes to obtain the expected Ca^{++} currents for functional analyses. The study was supported by Hacettepe University Research Foundation (ref. HU Research Project #15403) and The Scientific and Technological Research Council of Turkey (ref. TUBITAK Project #218S553).

Knockout of zebrafish desmin genes does not cause skeletal muscle degeneration but alters calcium flux.
Desmin is a muscle-specific intermediate filament protein that has fundamental role in muscle structure and force transmission. Whereas human desmin protein is encoded by a single gene, two desmin paralogs (desma and desmb) exist in zebrafish. Desma and desmb show differential spatiotemporal expression during zebrafish embryonic and larval development, being similarly expressed in skeletal muscle until hatching, after which expression of desmb shifts to gut smooth muscle. We generated knockout (KO) mutant lines carrying loss-of-function mutations for each gene by using CRISPR/Cas9. Mutants are viable and fertile, and lack obvious skeletal muscle, heart or intestinal defects. In contrast to morphants, knockout of each gene did not cause any overt muscular phenotype, but did alter calcium flux in myofibres. These results point to a possible compensation mechanism in these mutant lines generated by targeting nonsense mutations to the first coding exon.

CLONING OF ASTACUS LEPTODACTYLUS RYANODINE RECEPTOR GENE

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Hacettepe University Faculty of Medicine, Department Of Biophysics, Ankara, Turkey

Cytoplasmic Ca2+ concentration plays an essential role in many types of cellular function including electro-mechanical coupling in striated muscle fibers. Ryanodine receptor channels (RyR), mediating Ca2+ release from sarcoplasmic reticulum (SR), has a homotetrameric structure. It is the largest ion channel with a size of 2.2 MDa. Vertebrate and invertebrate RyR channels are structurally and functionally similar. Although *Astacus leptodactylus,* narrow-clawed crayfish, is a widely used model animal in neuroscience, information about genetic properties of the animal is rather limited. The present study is focused onto *de novo* cloning of the mRNA of the crayfish RyR channel which encodes the largest ion channel. A hybrid cloning method has been used, referring to the homology between RyR mRNA molecules and the computational assembly of the next generation sequencing data. A complete mRNA molecule of 17562 bp in size has originally been cloned. The putative RyR protein, with 5042 amino acids, has a significant similarity to the sequences reported in other species. Furthermore, the putative sequence possessed many of the conserved domains specific to the RyR channel. Thus, it has been proposed that a mRNA coding RyR channel has originally been cloned in the present study. The 3D protein structure can also be determined by the help of this revealed genetic information, or future mutation studies can be designed. The study was supported by Hacettepe University Research Foundation (HU research project #15403) and The Scientific and Technological Research Council of Turkey (TUBITAK project #218S553).

ELUCIDATING THE INTERACTION BETWEEN GABA-A RECEPTORS AND PHOSPHOLIPASE-C DELTA-1

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Fatma M Taha[1], Shozeb Haider[2], Jasmina N Jovanovic[2]

Benzodiazepines are amongst the most widely prescribed medications for the management of anxiety and the relief of insomnia. They produce their effects through positive allosteric modulation of the GABA-A receptors, the main inhibitory receptors in the brain. Previous studies have demonstrated that dissociation of phospholipase-C delta-1 (PLCD1) from the GABA-A receptor upon chronic administration of diazepam *in-vitro*, triggers a cascade of events leading to the loss of GABAergic inhibitory synapses and the development of pharmacological tolerance to this drug. In this study, we aim to define the specific amino acid residues involved in the interaction between GABA-A receptors and PLCD1. Using Modeller 9v21, computational homology modelling was employed to assign structure to the intracellular loop (ICL) of the beta-3 subunits TM3-4 domain where this is lacking in existing GABA-A receptor crystal structures including beta-3 homopentamer (PDB ID: 4COF), heteropentamer (PDB ID: 6HUG), as well as refining a PLCD1 crystal structure (PDB ID: 2ISD). Protein-protein docking approaches using HADDOCK and ClusPro determined five residues (Q716, K717, Q778, Y779, R780) within the ICL likely to directly mediate the interaction with PLCD1. These residues were mutated to alanine using site-directed mutagenesis and individual beta-3 subunit mutants were co-immunoprecipitated with PLCD1 to determine which of these residues had the most prominent effect. The functional implications of these mutations are currently being tested with cell-surface ELISA and electrophysiology. Determining the specific sites of interaction of PLCD1 with GABA-A receptors, will help direct the ongoing research efforts aimed at the prevention of tolerance development to benzodiazepines.

A CONSERVED REGION AT THE END OF THE N-TERMINAL EXTRACELLULAR DOMAIN OF GABAA RECEPTOR SUBUNITS IS CRUCIAL FOR THE RECEPTOR FORWARD TRAFFICKING

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Banghao Yuan, F Anne Stephenson, Shozeb Haider, Jasmina N Jovanovic
University College London, Ucl School Of Pharmacy, London, United Kingdom

Type A γ-aminobutyric acid receptors ($GABA_ARs$) represent a family of pentameric GABA-gated Cl^-/HCO_3^- ion channels which mediate inhibitory transmission in the central nervous system (CNS). Cell surface expression of $GABA_ARs$, a prerequisite for their function, is dependent on the appropriate assembly of the receptor subunits and their transient interactions with molecular chaperones within the endoplasmic reticulum (ER) and Golgi apparatus. Here we describe a highly conserved amino acid sequence within the extracellular N-terminal domain of the receptor subunits adjoining the first transmembrane domain as a region important for $GABA_AR$ processing within the ER. Structural modelling indicated that this positively charged region is located on the outer surface of the $GABA_AR$ heteropentamer. It's modifications in the α1, β3 and γ2 subunits using insertion or site-directed mutagenesis impair $GABA_AR$ trafficking to the cell surface in heterologous cell systems although they have no effect on subunit assembly. Mutated receptors accumulate in the ER where they associate with calnexin, BiP and Grp94, as shown by co-immunoprecipitation. When compared to the wt receptors, mutated receptors show decreased interaction with calnexin, similar binding to BiP and increased association with Grp94, changes that could not be reversed by treatments with chemical chaperones, protease and proteasome inhibitors. Structural modelling through protein docking revealed close proximity between calnexin and $GABA_ARs$ in this region suggesting that structural alterations caused by mutations may impair their interaction. Thus, this previously uncharacterised region plays an important role in $GABA_AR$ processing in the ER by regulating at least in part their interaction with calnexin.

CLONING OF A PUTATIVE TRANSMEMBRANE CHANNEL LIKE PROTEIN AND A CALCIUM PERMEABLE STRESS GATED CATION CHANNEL LIKE PROTEIN IN ASTACUS LEPTODACTYLUS

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Kaan Arslan, Nazli Coskun Jihad, Berk Saglam, Nuhan Purali
Hacettepe University Faculty of Medicine, Department Of Biophysics, Ankara, Turkey

In this study we have cloned the putative transmembrane channel-like protein(TMC) mRNA and the putative calcium stress gated cation channel like protein (CSC1-like) mRNA from *Astacus leptodactylus* ganglia cDNA libraries with a series of PCR, RACE – PCR experiments, using a set of specific and degenerate primers, and consequent Sanger and next-generation sequencing methods. The target proteins were chosen with refer to their proposed mechanosensitive properties in different species. The complete sequence for TMC was 3133 base-pairs and the ORF was 2497 base-pairs. For the CSC1-like mRNA the complete sequence was 3039 base-pairs and the ORF was 2662 base-pairs. A CDS search in NCBI platform resulted in the respective conserved domains of the related genes. Protein sequences were highly similar to those in the related species. Currently there isn't any crystallographic data for the TMC. However, there are two crystallographic structures with substantial similarity to CSC1-like proteins. Submission of the protein sequences to Alphafold collaborative environment resulted in similar structures to that of a monomer of the OSCA proteins for CSC1-like protein. The TMC protein sequence resulted in a similar structure to that of the mouse and human TMC-1 proteins obtained in the same platform. The study was supported by Hacettepe University Research Foundation (HU research project 15403) and The Scientific and Technological Research Council of Turkey (TUBITAK project 218S553)

POTENTIATION OF THE RAT P2X2, P2X4 AND P2X7 RECEPTORS BY STEROIDAL AMIDES

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Sonja Sivcev[1,2], Barbora Slavikova[3], Eva Kudova[3], Marian Rupert[2,4], Jana Cimicka[2,4], Hana Zemkova[2]
[1]Faculty of Science, Charles University, Department Of Physiology, Prague, Czech Republic, [2]Institute of Physiology ASCR, Laboratory Of Pain Research, Praha - Krc, Czech Republic, [3]Institute of Organic Chemistry and Biochemistry, ASCR, Neurosteroids, Prague, Czech Republic, [4]Charles University, 1st Faculty Of Medicine, Prague, Czech Republic

Aims: Purinergic P2X receptors are ubiquitously expressed and play a role in many physiological and pathological processes including inflammation, pain, and cancer. We tested a hypothesis that a new class of neurosteroids that contain amide structural motifs act as allosteric modulators of P2X. **Methods:** We designed, synthesized and examined 16 synthetic steroidal amides. Whole-cell recordings from HEK293 cells transfected with rat P2X2, P2X4, or P2X7 receptors, and from pituitary cells or hypothalamic neurons endogenously expressing P2X receptors was used. To localize steroid-binding site, alanine scanning mutagenesis of P2X7-TM1 was performed, and the effect of steroids on mutated receptors was examined. **Results:** We found that 8 compounds potentiated equally P2X2, P2X4, and P2X7, while 5 compounds potentiated P2X2 and P2X4 without having a significant effect on P2X7. The remaining 3 compounds were inactive. The most effective compound, 5β-androstran 3α-yl-β-aspartate (10 μM), potentiated P2X receptors to about 350 %., its effect was concentration-dependent, and the agonist concentration-response curves were shifted to the left. The potentiating effect of steroid was dependent on (i) metabolically stable amide moiety at position C-3 of steroidal ring, (ii) on the length of the C-3 dicarboxylic acid substituent and (iii) the presence of free NH_2 which is important determinant for P2X7 potentiation. Significantly lower effect was observed for P2X7-V41A mutant, indicating that it binds possibly in the middle of TM. **Conclusions:** Our work explains the mechanism and site of action for a series of new P2X allosteric modulators and establishes critical TM1 mutants for P2X7 binding-mode characterization.

Path integration (PI) is a fundamental self-motion-based navigation strategy that is highly conserved in mammals. PI involves the integration of self-motion information and is facilitated by the cholinergic system to maintain a consistent representation of the location of self in the environment. Grid cells, mostly found in the medial entorhinal cortex (MEC) Layer II, are believed to support PI by providing an invariant metric system through their spatially tuned hexagonal firing fields. One of the proposed cellular mechanisms of grid cell firing is intrinsic cholinergic-dependent persistent firing that has been shown to be graded up or down in MEC LV/LIII cells following multiple stimuli. To date, however, evidence of temporal integration through persistent firing in LII is still lacking. Besides, the cellular mechanism of persistent firing in MEC LII pyramidal and stellate cells is still controversial. Here, using *in-vitro* whole-cell patch recording, we show that pyramidal and stellate cells similarly support persistent firing via intrinsic mechanisms involving the transient receptor potential canonical (TRPC) 1/4/5 channels. We tested novel and highly specific TRPC channel blockers in cholinergically induced persistent firing in mice MEC LII. The TRPC-4 blocker ML204 and TRPC-4 and -5 blocker Pico145 both significantly inhibited persistent firing while the TRPC5 blocker Clemizole hydrochloride didn't reduce persistent firing. Similarly, AAVshRNA-mediated knockdown of MEC TRPC-4 channels showed a clear inhibition of persistent firing. Furthermore, we evaluated the expression of TRPC-1, -4, and -5 in pyramidal and stellate cells using in-situ hybridization.

TWIK-1 channel works as a heteromer with other channels in the two-pore potassium family. We recently reported that TWIK-1/TREK-1 heteromer mediates astrocytic passive conductance using a knockdown system. However, contrary to expectations, there was no change in the only reported TWIK-1 KO mice. Here we studied in detail why there is no change in the passive conductance of astrocytes in TWIK-1 KO mice. As a result, we found that the deletion of exon2 in the TWIK-1 gene made an in-framed connection between exon1 and exon3 of TWIK-1 and that the truncated TWIK-1 proteins, ΔEx2 TWIK-1, remained stable. When we targeted other undeleted exons of TWIK-1 with shRNA or CRISPR/Cas9 system, the passive conductance of the TWIK-1 KO mice was prominently reduced. In addition, we confirmed through molecular tools and 3D protein modeling that the ΔEx2 TWIK-1 protein heteromers with TREK-1 exhibit a linear IV relationship like the full-length TWIK-1 protein. Therefore, we generated new TWIK-1 KO mice that deleted a portion of the CDS of exon1 and confirmed that passive conduction was significantly reduced in hippocampal astrocytes, as expected. In addition, we found that this new TWIK-1 KO mouse had significantly increased seizure susceptibility in the KA-induced seizure. This result was similar in mice in which the expression of TWIK-1 was selectively reduced only in hippocampal astrocytes. Taken together, these data suggest that the results of previous TWIK-1 KO studies should be reinterpreted, suggesting that the passive conductance of hippocampal astrocytes is strongly related to seizure susceptibility.

Mature hippocampal astrocytes exhibit a linear current-to-voltage (*I-V*) K^+ membrane conductance, which is called a passive conductance. It is estimated to enable astrocytes to keep potassium homeostasis in the brain. We previously reported that the TWIK-1/TREK-1 heterodimeric channels are crucial for astrocytic passive conductance. However, the regulatory mechanism of these channels still remains elusive. Here, we identified Na+/H+ exchange regulator-1 (NHERF-1), a protein highly expressed in astrocytes, as a candidate interaction partner for these channels. NHERF-1 endogenously bound to TWIK-1/TREK-1 in hippocampal cultured astrocytes. When NHERF-1 is overexpressed or silenced, surface expression and activity of TWIK-1/TREK-1 heterodimeric channels were inhibited or enhanced, respectively. Furthermore, we confirmed astrocytic passive conductance was increased in hippocampal slices of NHERF-$1^{+/-}$ mice. Taken together, these finding suggests that NHERF-1 is a key regulator of TWIK-1/TREK-1 heterodimeric channels-mediated astrocytic passive conductance.

PROGRESSIVE HYPERPOLARIZATION-ACTIVATED CATION CURRENT (IH) REDUCTION: A RESPONSE MECHANISM TO DECREASE COCAINE-INDUCED EXCITABILITY IN VTA DA NEURONS.

POSTER SESSION 04 - SECTION: ION CHANNELS & EXCITABILITY

Carlos Jimenez Rivera[1], Karl Bosque-Cordero[2], Rafael Vazquez-Torres[1], Cristhian Calo-Guadalupe[1], Daisy Consuegra-Garcia[1], Giulia Fois[3], François Georges[3]
[1]University of Puerto Rico Medical Sciences Campus, Physiology, San Juan, Puerto Rico, [2]University of Puerto Rico Rio Piedras Campus, Biology, San Juan, Puerto Rico, [3]CNRS UMR 5293, Institut Des Maladies Neurodégénératives, Bordeaux, France

The hyperpolarization-activated cation current (I_h) is a contributing factor of intrinsic excitability in dopaminergic neurons (DA) of the ventral tegmental area (VTA). I_h is activated by hyperpolarization and produces a time-dependent depolarizing current. Our laboratory demonstrated that cocaine sensitization, significantly reduces I_h amplitude in VTA DA neurons. However, the role of I_h in controlling VTA DA excitability is still poorly understood. VTA DA cell's spontaneous activity remains unchanged when compared to the control groups after sensitization. Our hypothesis is that I_h reduction serves as a homeostatic regulator compensating for the cocaine-induced alteration in excitability. Using *in vivo* single-unit extracellular electrophysiology in anesthetized rats, we explored the I_h contribution on acute cocaine-induced spontaneous activity. We perfused an I_h blocker (ZD7288) and evaluated its effect on VTA DA spontaneous firing. I_h blockade significantly reduced acute cocaine-induced firing rate, bursting frequency, and percent of spikes within a burst while significantly increasing the mean interspike interval (ISI). This suggest that I_h blockade can reduce cocaine-induced firing activity in VTA DA neurons through an increase in the mean ISI. Furthermore, using whole-cell patch-clamp, we found a significant reduction in I_h only after 24hours of acute cocaine (15mg/kg). Using a rebound spiking protocol, we determined at different intervals of acute cocaine administration (2hrs, 24hrs and, 24hrs following 7-days cocaine administration) that there was an increase in rebound action potentials. I_h blockade significantly reduced rebound firing. These results suggest that progressive I_h reduction could serve as a homeostatic regulator of cocaine-induced spontaneous firing in VTA DA excitability.

CHARACTERIZATION OF ASTROCYTE REACTIVITY IN A MODEL OF ENCEPHALOPATHY OF PREMATURITY

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Ariane Heydari Olya, Jennifer Hua, Estelle Nicolas, Pierre Gressens, Juliette Van Steenwinckel
Inserm, Umr1141 Neurodiderot, PARIS, France

Premature birth caused by maternal infection represent an increased risk factor of brain lesions affecting both developing gray and white matter, known as encephalopathy of prematurity (EoP), and long-term neurodevelopmental disorders. It has been suggested that the set-up of a pro-inflammatory environment with the secretion of cytokines and chemokines might initiate an inappropriate inflammatory response driven by reactive microglia and astrocytes, which participate to neurodevelopmental disruption. Astrocytes, located at the interface between the brain parenchyma and the blood brain barrier, preserve homeostasis. They also participate in the inflammatory response and go through morphological and functional changes called astrogliosis. However, little is known about astrocytic reactivity during perinatal inflammation. Our team has developed a mouse model of EoP based on systemic injections of IL-1beta (a pro-inflammatory cytokine) reproducing the deficits seen in premature infants. Using this model, we aim to precisely characterize astrocyte reactivity in EoP. Astrocyte subpopulations are highlighted using flow cytometry, emphasizing their heterogeneity. Bulk RNA sequencing of purified astrocytes showed a transcriptomic signature of astrocytes during perinatal inflammation. Analysis of A1/A2 phenotypes by quantitative RT-PCR revealed a pro-inflammatory phenotype of the astrocytic response along time. Significant morphological changes of GFAP+ astrocytes in the subventricular zone have been shown by immunohistochemistry. Functional differences have been studied by quantitative RT-PCR and revealed a decrease of synaptogenesis factors secreted by astrocytes. This in-depth characterization of astrocytes will pave the way for designing new strategies to restore the homeostatic functions of astrocytes and protect the brain of preterm infants.

Astrocytes are the most numerous glial cells in the brain and display long processes contacting both synapses and blood vessels. Perisynaptic astrocytic processes (PAP) form the tripartite synapse with the neuronal compartments and participate in gliotransmission, neurotransmitters recycling and ion homeostasis among others. Astrocytes are highly polarized but how these polarities are set is unknown. Local translation is one of the most conserved mechanism for cell polarity and has been recently characterized in PAPs. However, mechanisms setting local translation in astrocytes remain largely unknown. We aimed at identifying proteins associated with polysomes in astrocytes to study their role in local translation in astrocytes. We combined an astrocyte-specific translating ribosome affinity purification approach with mass Spectrometry. Among identified proteins, we focused on “Receptor for activated protein kinase C” (RACK1), a protein involved in the regulation of translation. We showed that RACK1 is specifically associated with mRNAs such as *kcnj10,* coding for the potassium channel KIR4.1 and enriched in PAPs. *In vitro,* we found that RACK1 targets the kcnj10 5’UTR. In a mouse model deleted for RACK1 in astrocytes, we observed a higher level of KIR4.1 in synaptogliosomes. In a previous analysis, we showed that RACK1 polysomal mRNAs are enriched in PAPs compared to the soma. Thus together with our present results, we propose that RACK1 by binding specifically to Kcnj10 mRNAs may regulate the translation of KIR4.1 in PAPs to control potassium homeostasis at the neuroglial interface and electrophysiological properties of neuronal networks.

ATP STIMULATION REGULATES ASTROCYTE-DERIVED EXTRACELLULAR VESICLE SECRETION AND MIRNA CONTENT

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Rebecca Hekking[1], Yadaly Gassama[2], Alexandre Favereaux[2], Aude Panatier[1]
[1]Neurocentre Magendie, University Of Bordeaux, Inserm U1215, Bordeaux Cedex, France, [2]Interdisciplinary Institute for Neuroscience, University Of Bordeaux, Cnrs Umr5297, Bordeaux Cedex, France

Cerebral function depends on the transmission of chemical signals between neuronal elements at synapses. Over the last two decades, accumulating data have shown that this fundamental process is regulated by astrocytes. Among other functions astrocytes participate in the clearance of ions and neurotransmitters. In addition, these glial cells release gliotransmitters to regulate synaptic functions such as basal synaptic transmission and long-term synaptic plasticity. Clearance and gliotransmission are probably not the only ways through which astrocytes influence neuronal communication. An interesting but under-investigated pathway would be through the release of extracellular vesicles (EVs). EVs are small, double membrane bound vesicles containing proteins, lipids and nucleic acids. To understand the role of EVs during synaptic transmission, it is important to first investigate whether acute stimulation of astrocytes can impact the quantity, size and content of secreted EV. By combining calcium imaging, EVs quantification techniques, electronic microscopy and RNAseq analysis, our data indicate that exposing primary mouse astrocyte cultures to 50µM ATP for 30 min is sufficient to modify the number of EVs released and their miRNA content.

Drug addiction is a biomedical challenge in which molecular and cellular mechanisms underlying drug-seeking behavior are not fully elucidated. However, some evidence suggests that astrocytes are implicated in cocaine addiction. Here, we analyzed the effect of cocaine on astrocytes in the nucleus accumbens, a structure in the ventral striatum implicated in the reward circuit and addictive behavior, and we tested their impact on cocaine-induced behavior. Mice were sensitized to cocaine by daily i.p. injection of cocaine. The locomotion was recorded in an open-field arena and the expression of astrocytic reactivity markers was assessed by immunohistochemistry. We manipulated the astrocyte activity by inhibiting the JAK/STAT signaling pathway by inducing the expression of SOCS3. We found that cocaine sensitization induces morphological changes and triggers the expression of immune-markers of astroglial reactivity. Exploring the potential cause of astrocyte reactivity, we identified the JAK/STAT signaling pathway as instrumental in behavior induced by cocaine sensitization. Our results suggest that blocking the astrocyte reactivity by inhibiting the JAK/STAT signaling pathway might ameliorate drug-seeking behavior, representing a promising novel treatment strategy. ***Keywords:*** *astrocytes, addiction, cocaine, reactivity, JAK/STAT signaling pathway*

Information processing in the brain is generally considered as a neuronal performance. Yet, astrocytes play a crucial role in controlling synapse formation, maturation, activity and elimination, and thus shape synaptic circuits during development. Remarkably, astrocytes regulate critical developmental periods, defined as temporal windows of early postnatal development during which neuronal networks are highly plastic and sensitive to experience. Pioneer data have shown that immature astrocytes are able to re-open a period of strong plasticity when re-implanted in adult visual cortex. However how astrocytes control critical developmental period remains unknown. Here, using a multidisciplinary approach involving molecular biology, immunohistochemistry, intrinsic optical imaging, and electrophysiology, we uncovered a mechanism by which astrocytes maturation control the timing of critical period termination. We indeed discovered an unconventional astroglial pathway controlled by connexin 30 gap junction protein allowing for maturation of inhibitory circuits in the visual cortex, well-known to induce closure of the critical period. Our results provide a novel astroglial mechanism controlling termination of the critical period, which is associated with settling of neuronal circuits, essential for efficient information processing. These data indicate that astrocytes play a major role in the experience-dependent plasticity of brain developing circuits, and point to a novel cellular target to treat neurological disorders involving defects in the closure of critical periods as well as new strategies to re-induce enhanced plasticity in adults and favors rehabilitation after brain damage.

A NOREPINEPHRINE-DEPENDENT GLIAL CALCIUM WAVE TRAVELS IN THE SPINAL CORD UPON ACOUSTOVESTIBULAR STIMULI

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Adeline Orts-Del'Immagine, Mahalakshmi Dhanasekar, François-Xavier Lejeune, Julian Roussel, Claire Wyart
Paris Brain Institute, Icm, Inserm U 1127, Cnrs Umr 7725, Sorbonne Université, Paris, France

Although calcium waves have been widely observed in glial cells, their occurrence *in vivo* during behavior remains less understood. Here, we investigated the recruitment of glial cells in the hindbrain and spinal cord after acousto-vestibular (AV) stimuli triggering escape responses using *in vivo* population calcium imaging in larval zebrafish. We observed that gap-junction-coupled spinal glial network exhibits large and homogenous calcium increases that rose in the rostral spinal cord and propagated bi-directionally towards the spinal cord and towards the hindbrain. Spinal glial calcium waves were driven by the recruitment of neurons and in particular, of noradrenergic signaling acting through α-adrenergic receptors. Noradrenergic neurons of the medulla-oblongata (NE-MO) were revealed in the vicinity of where the calcium wave started. NE-MO were recruited upon AV stimulation and sent dense axonal projections in the rostro-lateral spinal cord, suggesting these cells could trigger the glial wave to propagate down the spinal cord. Altogether, our results revealed that a simple AV stimulation is sufficient to recruit noradrenergic neurons in the brainstem that trigger in the rostral spinal cord two massive glial calcium waves, one travelling caudally in the spinal cord and another rostrally into the hindbrain.

HIV-1 NEUROPATHOGENESIS IS MEDIATED BY EPHRINA3 EXPRESSED ON ASTROCYTES

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Chitra Singal, Paritosh Jaiswal, Anuradha Mehta, Kanza Saleem, Pankaj Seth
National Brain Research Centre, Cellular And Molecular Neuroscience, Gurgaon, India

HIV infection of the central nervous system (CNS) causes dementia and cognitive disorders, termed as HIV-associated neurocognitive disorder (HAND). HIV infects the brain at an early stage, which is corroborated by the presence of HIV-1 Tat protein in the CSF of these patients. Astrocytes being the most abundant cells in the CNS are actively infected by the virus and also serve as reservoir to latent virus. Astrocytes and neurons are in dynamic crosstalk for homeostatic brain functioning and the principle reason behind neuronal death in case of HIV is glutamate excitotoxicity. As astrocytes are bestowed with the responsibility to clear excess glutamate from the synapses through glutamate transporters EAAT1/EAAT2, their inefficiency to do so in case of HIV leads to the accumulation of glutamate, which eventually causes neuronal death. EphrinA3, a ligand expressed on astrocytes, has been known to regulate glutamate transporters via reverse signaling by EphA4, its receptor expressed on neurons. As both the receptor and ligand are present on different cell types, neuron-glia co-culture was adopted as the model system for this study. There was an upregulation observed in EphrinA3 in case of HIV-1 Tat B, with downregulation seen in glutamate transporters EAAT1/EAAT2 as compared to the control. Knockdown of EphrinA3 in presence of HIV-1 Tat B reversed the neurotoxic effects of HIV-1 Tat B transfection. This study highlights the importance of EphrinA3 in HIV-1 Tat B mediated neuronal death, through the regulation the glutamate transporters and extracellular glutamate concentration.

CHOLESTEROL METABOLISM IS MODULATED BY NGF IN AN ASTROCYTE-DERIVED CELL LINE AND EXHIBITS A NEUROPROTECTIVE ROLE AGAINST OXIDATIVE STRESS

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Mayra Colardo[1], Michele Petraroia[1], Daniele Pensabene[2], Letizia Lerza[1], Noemi Martella[1], Grazia Venditti[1], Michela Varone[1], Valentina Pallottini[2], Marco Segatto[1]

Introduction Cholesterol derived from astrocytes is essential for proper neuronal functioning. Recent evidence showed that nerve growth factor (NGF) influences several metabolic processes in brain cells, including astrocytes. Nevertheless, the activity of NGF on glial cholesterol homeostasis is not fully elucidated. **Aim** The aim of this project is to evaluate whether NGF administration could affect cholesterol metabolism in glial cells, and whether this event could influence neuronal survival under oxidative stress conditions. **Methods** U373 astrocyte-derived cell line and N1E-115, a neuroblastoma cell line, were used as experimental models. Fully differentiated N1E-115 were treated with rotenone for 16 hours to induce oxidative stress. Subsequently, N1E-115 were co-cultured with U373 cells, previously treated with NGF for 48 hours. Results were obtained by means of immunological, biochemical and morphological analysis. **Results** NGF administration in U373 cells increases the expression of different proteins and enzymes involved in cholesterol homeostasis network. Furthermore, NGF significantly increases extracellular cholesterol levels and also promotes ApoE secretion in the culture medium. Morphological evaluation demonstrated that NGF-treated astrocytic cells significantly protect N1E-115 neuronal cells from rotenone-induced oxidative stress. Conversely, the effect promoted by NGF stimulation was prevented when neuronal cells were co-cultured with ApoE-silenced U373 cells. **Conclusions** The obtained data suggest that NGF modulates cholesterol metabolism in U373 cells. Moreover, NGF displays a putative neuroprotective role, which is likely mediated by the enhancement of glial ApoE secretion in the culture medium.

APPLICATION OF THE CEFTRIAXONE CHANGES THE GLT-1 DISTRIBUTION AFTER TRAUMATIC BRAIN INJURY

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Yana Naumenko[1], Borys Olifirov[2], Nana Voitenko[3], Tetyana Pivneva[1]
[1]O.O. Bogomolets Institute of Physiology, National Academy of Sciences of Ukraine, Department Of Sensory Signaling, Kyiv, Ukraine, [2]Bogomoletz Institute of Physiology, Department Of Molecular Biophysics, Kyiv, Ukraine, [3]3. Dobrobut Academy Medical School, Scientific Centre, Kyiv, Ukraine

Traumatic brain injury (TBI) is a serious problem whereas its consequences are now considered irreversible. The morphofunctional changes that follow TBI increase the risk of delayed development of neurodegenerative pathologies which can only be slowed down by known treatments. Nevertheless, the beta-lactam antibiotic ceftriaxone has been shown to have a positive effect on neuronal preservation as well as reducing glial reactivity and excitotoxicity. Previous studies have found that ceftriaxone affects the expression of glutamate transporter 1 (GLT-1) which is mainly located on the astrocytic membranes. The effect of the ceftriaxone on the localization of GLT-1on the astrocytes are still unknown. **Aim:** We studied the localization of the GLT-1 on astrocytic membranes in the CA1 area of hippocampus at different time points (3, 7, and 14 days) after mild TBI and application of ceftriaxone. **Methods:** We have used closed head weight drop model of mild TBI, immunohistochemical approaches with GLT-1 and GFAP markers, confocal microscopy, quantitative analysis. **Result and conclusions:** We found that localization of GLT-1 on astrocytic membranes changes due to injury: clusters of the receptor become less compacted, more scattered along the astrocytic branches which possibly affects glutamate reuptake. We also have shown that application of the ceftriaxone changes the GLT-1 distribution after TBI, approaching those in control.

INVESTIGATING THE EFFECTIVENESS OF KEAP1-NRF2 PROTEIN-PROTEIN INTERACTION DISRUPTORS IN PROTECTING HUMAN NEURONAL MODELS OF ALZHEIMER'S DISEASE

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Mohamed Elsharkasi[1], Geoffrey Wells[2], Fiona Kerr[1,3]
[1]Glasgow Caledonian University, Biological And Biomedical Department, Glasgow, United Kingdom, [2]University College London, Department Of Pharmaceutical And Biological Chemistry, London, United Kingdom, [3]Edinburgh Napier University, Department Of Life Sciences, Edinburgh, United Kingdom

Introduction: Classical Nrf2 activators prevent memory-loss in animal models of Alzheimer's Disease (AD), but have adverse effects in humans. Our work has identified a new class of Nrf2 activators, Keap1-Nrf2 disruptors, that prevent Aβ toxicity in mouse neurons. By developing human AD models, we now **aim** to test their relevance to human systems and to investigate the cell-specific mechanisms of their neuroprotective properties. **Methods:** Lund Human Mesencephalic (LUHMES) cells were differentiated to neurons, alone or in co-culture with primary human cortical astrocytes. Astrocytic responses to Keap1-Nrf2 disruptors, 22h and 18e, or classical activators, DMF and CDDO-me were determined by measuring activity of the Nrf2 target NQO1. Neurons or co-cultures were treated with synthetic $A\beta_{42}$ oligomers (Aβ42-O), with or without DMF, at differentiation day 6, and neurite morphology, cell viability and ΔΨm were measured by confocal imaging, CellTitre-Glo and JC-10 assays respectively. **Results:** Nrf2 activation was confirmed in response to 18e, DMF and CDDO-me, but not 22h, in astrocytes. Efficacy was lost in co-cultures, due to high basal astrocytic Nrf2 activity in LUHMES differentiation media. Aβ42-O (2.5-10μM) disrupted neurite morphology, reduced cell viability and increased ΔΨm in neurons alone, but this was not protected by the Nrf2 activator DMF. Preliminary studies suggest that DMF may be neuroprotective in co-cultures depending on the duration of exposure. **Conclusion:** Our studies demonstrate varying potency of Nrf2 activators in astrocytes, and indicate that DMF cannot protect neurons alone against Ab42-O toxicty. Further studies are required to confirm whether this depends on the presence of astrocytes.

DREBRIN CONTROLS SCAR FORMATION AND ASTROCYTE REACTIVITY UPON TRAUMATIC BRAIN INJURY BY REGULATING MEMBRANE TRAFFICKING

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Marta Ornaghi, Juliane Schiweck, Kai Murk, Britta Eickholt
Charité – Universitätsmedizin Berlin, Laboratory Signaling Mechanisms In Brain Development And Disease, Berlin, Germany

The brain of mammals lacks a significant ability to regenerate neurons and is thus particularly vulnerable. To protect the brain from injury and disease, damage control by astrocytes through astrogliosis and scar formation is essential. We recently showed that brain injury in mice triggers an immediate upregulation of the actin-binding protein Drebrin (DBN) in astrocytes, which is essential for scar formation and maintenance of astrocyte reactivity. In turn, DBN loss leads to defective astrocyte scar formation and excessive neurodegeneration following brain injuries. At the cellular level, we show that DBN switches actin homeostasis from ARP2/3-dependent arrays to microtubule-compatible scaffolds, facilitating the formation of RAB8-positive membrane tubules. This injury-specific RAB8 tubular endosomal compartment serves as a hub for the trafficking of surface proteins involved in astrogliosis and adhesion mediators, such as β1-integrin. DBN-mediated RAB8-dependent polarized membrane trafficking controls reactive astrogliosis required to form astrocyte scars and to protect the CNS from traumatic brain injury. We use an *in vitro* scratch injury model of cultured astrocytes to further characterize RAB8-positive tubular endosome trafficking dynamic. The injury-induced RAB8+ tubules increase further in number when astrocytes are briefly cultured under serum starvation conditions. Subsequent refeeding with serum causes the immediate disintegration of membrane tubules and cytoplasmic localization of RAB8, suggesting a critical role of growth factors supply, as well as signaling molecules, in regulating RAB8+ tubular endosome dynamics in injury conditions.

Profilin Isoforms in Health and Disease - All the Same but Different.
Profilins are small actin binding proteins, which are structurally conserved throughout evolution. They are probably best known to promote and direct actin polymerization. However, they also participate in numerous cell biological processes beyond the roles typically ascribed to the actin cytoskeleton. Moreover, most complex organisms express several profilin isoforms. Their cellular functions are far from being understood, whereas a growing number of publications indicate that profilin isoforms are involved in the pathogenesis of various diseases. In this review, we will provide an overview of the profilin family and "typical" profilin properties including the control of actin dynamics. We will then discuss the profilin isoforms of higher animals in detail. In terms of cellular functions, we will focus on the role of Profilin 1 (PFN1) and Profilin 2a (PFN2a), which are co-expressed in the central nervous system. Finally, we will discuss recent findings that link PFN1 and PFN2a to neurological diseases, such as amyotrophic lateral sclerosis (ALS), Fragile X syndrome (FXS), Huntington's disease and spinal muscular atrophy (SMA).

MACROPHAGE-DERIVED AMPHIREGULIN MODULATES ASTROCYTE NETWORK REACTIVITY

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Melissa Cooper[1,2,3], Maria Clara Selles[1,2,3], Shane Liddelow[1,2,4], Moses Chao[1,2,3]
[1]NYU School of Medicine, Neuroscience And Physiology, New York, United States of America, [2]New York University, Center For Neural Science, New York, United States of America, [3]NYU School of Medicine, Skirball Institute, New York, United States of America, [4]NYU School of Medicine, Ophthalmology, New York City, United States of America

During neurodegeneration, astrocytes alter their gap junctional networks to redistribute resources and maintain neuronal function. How is this beneficial reactivity induced? To answer this, we looked at similar mechanisms in other organs and applied them to the nervous system. In the heart, macrophage-derived amphiregulin (AREG) signals upon epidermal growth factor receptor (EGFR) to induce connexin 43 (cx43) phosphorylation and form additional gap junctions during arrhythmia. Like cardiac macrophages, cultured primary microglia (serum-free; n=3 isolations) release AREG in response to stress (LPS, 1ug/ml; p<0.001 vs baseline). Cultured primary astrocytes (serum-free; mRNA n=3 isolations; protein n=5 isolations) respond to AREG (100ng/mL) like cardiac myocytes: they phosphorylate cx43, with a 3-fold increase 9 minutes after AREG administration (p<0.001). Three minutes after AREG administration, cx43 mRNA increases 2-fold; protein levels increase 2-fold by 11 minutes (mRNA p=0.007; protein p≤0.01). AREG also increases membrane-localized astrocyte EGFR 2-fold within a minute (p=0.006) and 3-fold in 7 minutes (p < 0.001). To measure changes in functional network size, astrocytes were cut-loaded with biotin (244Da) and dextran (10kDa). We found a 3-fold increase in astrocyte connectivity 10 min after AREG (p<0.001). Intriguingly, higher levels of AREG (1000ng/mL) have the opposite effect – cx43 mRNA is reduced 2-fold in 3 minutes (p = 0.02), and cx43 protein declines 2-fold within 30 minutes (p=0.01; n=3 isolations). This differential response may dictate whether astrocytes enlarge or contract their network in response to different types of stress.

Astrocyte Networks as Therapeutic Targets in Glaucomatous Neurodegeneration.
Astrocytes are intimately involved in the response to neurodegenerative stress and have become an attractive target for the development of neuroprotective therapies. However, studies often focus on astrocytes as single-cell units. Astrocytes are densely interconnected by gap junctions that are composed primarily of the protein connexin-43 (Cx43) and can function as a broader network of cells. Such networks contribute to a number of important processes, including metabolite distribution and extracellular ionic buffering, and are likely to play an important role in the progression of neurodegenerative disease. This review will focus on the pro-degenerative and pro-survival influence of astrocyte Cx43 in disease progression, with a focus on the roles of gap junctions and hemichannels in the spread of degenerative stress. Finally, we will highlight the specific evidence for targeting these networks in the treatment of glaucomatous neurodegeneration and other optic neuropathies.

Neuroprotection by Wld depends on retinal ganglion cell type and age in glaucoma.
Early challenges to axonal physiology, active transport, and ultrastructure are endemic to age-related neurodegenerative disorders, including those affecting the optic nerve. Chief among these, glaucoma causes irreversible vision loss through sensitivity to intraocular pressure (IOP) that challenges retinal ganglion cell (RGC) axons, which comprise the optic nerve. Early RGC axonopathy includes distal to proximal progression that implicates a slow form of Wallerian degeneration. In multiple disease models, including inducible glaucoma, expression of the slow Wallerian degeneration (Wld) allele slows axon degeneration and confers protection to cell bodies.

Redistribution of metabolic resources through astrocyte networks mitigates neurodegenerative stress.
In the central nervous system, glycogen-derived bioenergetic resources in astrocytes help promote tissue survival in response to focal neuronal stress. However, our understanding of the extent to which these resources are mobilized and utilized during neurodegeneration, especially in nearby regions that are not actively degenerating, remains incomplete. Here

we modeled neurodegeneration in glaucoma, the world's leading cause of irreversible blindness, and measured how metabolites mobilize through astrocyte gap junctions composed of connexin 43 (Cx43). We elevated intraocular pressure in one eye and determined how astrocyte-derived metabolites in the contralateral optic projection responded. Remarkably, astrocyte networks expand and redistribute metabolites along distances even 10 mm in length, donating resources from the unstressed to the stressed projection in response to intraocular pressure elevation. While resource donation improves axon function and visual acuity in the directly stressed region, it renders the donating tissue susceptible to bioenergetic, structural, and physiological degradation. Intriguingly, when both projections are stressed in a WT animal, axon function and visual acuity equilibrate between the two projections even when each projection is stressed for a different length of time. This equilibration does not occur when Cx43 is not present. Thus, Cx43-mediated astrocyte metabolic networks serve as an endogenous mechanism used to mitigate bioenergetic stress and distribute the impact of neurodegenerative disease processes. Redistribution ultimately renders the donating optic nerve vulnerable to further metabolic stress, which could explain why local neurodegeneration does not remain confined, but eventually impacts healthy regions of the brain more broadly.

Progression and Pathology of Traumatic Optic Neuropathy From Repeated Primary Blast Exposure.
Indirect traumatic optic neuropathy (ITON) is a condition that is often associated with traumatic brain injury and can result in significant vision loss due to degeneration of retinal ganglion cell (RGC) axons at the time of injury or within the ensuing weeks. We used a mouse model of eye-directed air-blast exposure to characterize the histopathology of blast-induced ITON. This injury caused a transient elevation of intraocular pressure with subsequent RGC death and axon degeneration that was similar throughout the length of the optic nerve (ON). Deficits in active anterograde axon transport to the superior colliculus accompanied axon degeneration and first appeared in peripheral representations of the retina. Glial area in the ON increased early after injury and involved a later period of additional expansion. The increase in area involved a transient change in astrocyte organization independent of axon degeneration. While levels of many cytokines and chemokines did not change, IL-1α and IL-1β increased in both the ON and retina. In contrast, glaucoma shows distal to proximal axon degeneration with astrocyte remodeling and increases in many cytokines and chemokines. Further, direct traumatic optic neuropathies have a clear site of injury with rapid, progressive axon degeneration and cell death. These data show that blast-induced ITON is a distinct neuropathology from other optic neuropathies.

Antioxidants prevent inflammation and preserve the optic projection and visual function in experimental neurotrauma.
We investigated the role of oxidative stress and the inflammasome in trauma-induced axon degeneration and vision loss using a mouse model. The left eyes of male mice were exposed to over-pressure air waves. Wild-type C57Bl/6 mice were fed normal, high-vitamin-E (VitE), ketogenic or ketogenic-control diets. Mice lacking the ability to produce vitamin C (VitC) were maintained on a low-VitC diet. Visual evoked potentials (VEPs) and retinal superoxide levels were measured in vivo. Tissue was collected for biochemical and histological analysis. Injury increased retinal superoxide, decreased SOD2, and increased cleaved caspase-1, IL-1α, IL-1β, and IL-18 levels. Low-VitC exacerbated the changes and the high-VitE diet mitigated them, suggesting that oxidative stress led to the increase in IL-1α and activation of the inflammasome. The injury caused loss of nearly 50% of optic nerve axons at 2 weeks and astrocyte hypertrophy in mice on normal diet, both of which were prevented by the high-VitE diet. The VEP amplitude was decreased after injury in both control-diet and low-VitC mice, but not in the high-VitE-diet mice. The ketogenic diet also prevented the increase in superoxide levels and IL-1α, but had no effect on IL-1β. Despite this, the ketogenic diet preserved optic nerve axons, prevented astrocyte hypertrophy, and preserved the VEP amplitude. These data suggest that oxidative stress induces priming and activation of the inflammasome pathway after neurotrauma of the visual system. Further, blocking the activation of the inflammasome pathway may be an effective post-injury intervention.

Loss of odor-induced c-Fos expression of juxtaglomerular activity following maintenance of mice on fatty diets.
Diet-induced obesity (DIO) decreases the number of OMP+ olfactory sensory neurons (OSN) in the olfactory epithelium by 25% and reduces correlate axonal projections to the olfactory bulb (OB). Whether surviving OSNs have equivalent odor responsivity is largely unknown. Herein, we utilized c-fos immediate-early gene expression to map neuronal activity and determine whether mice weaned to control (CF), moderately-high fat (MHF), or high-fat (HF) diet for a period of 6 months had changes in odor activation. Diet-challenged M72-IRES-tau-GFP mice were exposed to either a preferred M72 (Olfr160) ligand, isopropyl tiglate, or clean air in a custom-made Bell-jar infusion chamber using an alternating odor exposure pattern generated by a picosprizer™. Mice maintained on fatty diets weighed significantly more and cleared glucose less efficiently

as determined by an intraperitoneal glucose tolerance test (IPGTT). The number of juxtaglomerular cells (JGs) decreased following maintenance of the mice on the MHF diet for cells surrounding the medial but not lateral M72 glomerulus within a 4 cell-column distance. The percentage of c-fos + JGs surrounding the lateral M72 glomerulus decreased in fat-challenged mice whereas those surrounding the medial glomerulus were not affected by diet. Altogether, these results show an asymmetry in the responsiveness of the 'mirror image' glomerular map for the M72 receptor that shows greater sensitivity of the lateral vs. medial glomerulus upon exposure to fatty diet.

Astrocyte remodeling without gliosis precedes optic nerve Axonopathy.
Astroyctes serve myriad functions but are especially critical in white matter tracts, where energy-demanding axons propagate action potentials great distances between neurons. Axonal dependence on astrocytes for even normal function accentuates the critical role astrocytes serve during disease. In glaucoma, the most common optic neuropathy, sensitivity to intraocular pressure (IOP) challenges RGC axons early, including degradation of anterograde transport to the superior colliculus (SC). Astrocyte remodeling presages overt axon degeneration in glaucoma and thus may present a therapeutic opportunity. Here we developed a novel metric to quantify organization of astrocyte processes in the optic nerve relative to axon degeneration in the DBA/2 J hereditary mouse model of glaucoma. In early progression, as axons expand prior to loss, astrocyte processes become more parallel with migration to the nerve's edge without a change in overall coverage of the nerve. As axons degenerate, astrocyte parallelism diminishes with increased glial coverage and reinvasion of the nerve. In longitudinal sections through aged DBA/2 J nerve, increased astrocyte parallelism reflected elevated levels of the astrocyte gap-junction protein connexin 43 (Cx43). In the distal nerve, increased Cx43 also indicated with a higher level of intact anterograde transport from retina to SC. Our results suggest that progression of axonopathy in the optic nerve involves astrocyte remodeling in two phases. In an early phase, astrocyte processes organize in parallel, likely through gap-junction coupling, while a later phase involves deterioration of organization as glial coverage increases and axons are lost.

Axogenic mechanism enhances retinal ganglion cell excitability during early progression in glaucoma.
Diseases of the brain involve early axon dysfunction that often precedes outright degeneration. Pruning of dendrites and their synapses represents a potential driver of axonopathy by reducing activity. Optic nerve degeneration in glaucoma, the world's leading cause of irreversible blindness, involves early stress to retinal ganglion cell (RGC) axons from sensitivity to intraocular pressure (IOP). This sensitivity also influences survival of RGC dendrites and excitatory synapses in the retina. Here we tested in individual RGCs identified by type the relationship between dendritic organization and axon signaling to light following modest, short-term elevations in pressure. We found dendritic pruning occurred early, by 2 wk of elevation, and independent of whether the RGC responded to light onset (ON cells) or offset (OFF cells). Pruning was similarly independent of ON and OFF in the DBA/2J mouse, a chronic glaucoma model. Paradoxically, all RGCs, even those with significant pruning, demonstrated a transient increase in axon firing in response to the preferred light stimulus that occurred on a backdrop of generally enhanced excitability. The increased response was not through conventional presynaptic signaling, but rather depended on voltage-sensitive sodium channels that increased transiently in the axon. Pruning, axon dysfunction, and deficits in visual acuity did not progress between 2 and 4 wk of elevation. These results suggest neurodegeneration in glaucoma involves an early axogenic response that counters IOP-related stress to excitatory dendritic architecture to slow progression and maintain signaling to the brain. Thus, short-term exposure to elevated IOP may precondition the neural system to further insult.

The challenge of regenerative therapies for the optic nerve in glaucoma.
This review arose from a discussion of regenerative therapies to treat optic nerve degeneration in glaucoma at the 2015 Lasker/IRRF Initiative on Astrocytes and Glaucomatous Neurodegeneration. In addition to the authors, participants included Jonathan Crowston, Andrew Huberman, Elaine Johnson, Richard Lu, Hemai Phatnami, Rebecca Sappington, and Don Zack. Glaucoma is a neurodegenerative disease of the optic nerve, and is the leading cause of irreversible blindness worldwide. The disease progresses as sensitivity to intraocular pressure (IOP) is conveyed through the optic nerve head to distal retinal ganglion cell (RGC) projections. Because the nerve and retina are components of the central nervous system (CNS), their intrinsic regenerative capacity is limited. However, recent research in regenerative therapies has resulted in multiple breakthroughs that may unlock the optic nerve's regenerative potential. Increasing levels of Schwann-cell derived trophic factors and reducing potent cell-intrinsic suppressors of regeneration have resulted in axonal regeneration even beyond the optic chiasm. Despite this success, many challenges remain. RGC axons must be able to form new connections with their appropriate targets in central brain regions and these connections must be retinotopically correct. Furthermore, for new axons

penetrating the optic projection, oligodendrocyte glia must provide myelination. Additionally, reactive gliosis and inflammation that increase the regenerative capacity must be outweigh pro-apoptotic processes to create an environment within which maximal regeneration can occur.

Early astrocyte redistribution in the optic nerve precedes axonopathy in the DBA/2J mouse model of glaucoma.

Glaucoma challenges the survival of retinal ganglion cell axons in the optic nerve through processes dependent on both aging and ocular pressure. Relevant stressors likely include complex interplay between axons and astrocytes, both in the retina and optic nerve. In the DBA/2J mouse model of pigmentary glaucoma, early progression involves axonopathy characterized by loss of functional transport prior to outright degeneration. Here we describe novel features of early pathogenesis in the DBA/2J nerve. With age the cross-sectional area of the nerve increases; this is associated generally with diminished axon packing density and survival and increased glial coverage of the nerve. However, for nerves with the highest axon density, as the nerve expands mean cross-sectional axon area enlarges as well. This early expansion was marked by disorganized axoplasm and accumulation of hyperphosphorylated neurofilamants indicative of axonopathy. Axon expansion occurs without loss up to a critical threshold for size (about 0.45-0.50 μm(2)), above which additional expansion tightly correlates with frank loss of axons. As well, early axon expansion prior to degeneration is concurrent with decreased astrocyte ramification with redistribution of processes towards the nerve edge. As axons expand beyond the critical threshold for loss, glial area resumes an even distribution from the center to edge of the nerve. We also found that early axon expansion is accompanied by reduced numbers of mitochondria per unit area in the nerve. Finally, our data indicate that both IOP and nerve expansion are associated with axon enlargement and reduced axon density for aged nerves. Collectively, our data support the hypothesis that diminished bioenergetic resources in conjunction with early nerve and glial remodeling could be a primary inducer of progression of axon pathology in glaucoma.

Aim. Tolerance to analgesia represents a huge limit for the use of opioids in treating chronic pain. Previous *in vivo* studies have shown that ultramicronized palmitoylethanolamide (um-PEA) was able to delay morphine tolerance and increase opioid effectiveness. Since glial cells are involved in tolerance and mast cells are one of the pivotal targets of PEA, we hypothesized that um-PEA counteracts morphine tolerance by controlling the crosstalk between these cell populations. **Methods.** A rat mast cell line, RBL-2H3, and a primary culture of cortical astrocytes were used. Mast cell degranulation was analyzed through β-hexosaminidase, tryptase and histamine release. Gene expression was evaluated by RT-PCR. **Results.** Morphine (30 μM for 30 minutes) induced RBL-2H3 cell degranulation, which was significantly reduced by 18-hour pre-treatment with um-PEA (100 μM). Conditioned media of RBL-2H3 cells highly increased the expression of genes associated with inflammation and pain from morphine-activated astrocytes. Conversely, conditioned media of um-PEA treated RBL-2H3 cells significantly reduced the expression of inflammatory genes (IL-1β and IL-6) and genes associated with pain modulation (ccl2, Serpin 3N and glutamate transporter EAAT2), while upregulating GFAP gene expression. **Conclusion.** Ultramicronized PEA inhibited morphine-induced mast cell degranulation and down-regulated the expression of inflammatory and pain-related genes from astrocytes challenged with mast cell conditioned media, while stimulating protective pathways (i.e., GFAP upregulation). The findings suggest um-PEA may delay morphine tolerance through regulating mast cell-astrocyte crosstalk.

Activated fibroblasts enhance cancer cell migration by microvesicles-mediated transfer of Galectin-1.
Cancer-associated fibroblasts (CAFs) are one of the main components of the stromal compartment in the tumor microenvironment (TME) and the crosstalk between CAFs and cancer cells is essential for tumor progression and aggressiveness. Cancer cells mediate an activation process, converting normal fibroblasts into CAFs, that are characterized by modified expression of many proteins and increased production and release of microvesicles (MVs), extracellular vesicles generated by outwards budding from the cell membrane. Recent evidence underlined that the uptake of CAF-derived MVs changes the overall protein content of tumor cells. In this paper, we demonstrate that tumor activated fibroblasts overexpress Galectin-1 (Gal-1) and consequently release MVs containing increased levels of this protein. The uptake of Gal-1 enriched MVs by tumor cells leads to the upregulation of its intracellular concentration, that strongly affects cancer cell migration, while neither proliferation nor adhesion are altered. Accordingly, tumor cells co-cultured with fibroblasts silenced for Gal-1 have a reduced migratory ability. The present work reveals the key role of an exogenous protein, Gal-1, derived from activated fibroblasts, in cancer progression, and contributes to clarify the importance of MVs-mediated protein trafficking in regulating tumor-stroma crosstalk.

Role of Enteric Glia as Bridging Element between Gut Inflammation and Visceral Pain Consolidation during Acute Colitis in Rats.
Acute inflammation is particularly relevant in the pathogenesis of visceral hypersensitivity associated with inflammatory bowel diseases. Glia within the enteric nervous system, as well as within the central nervous system, contributes to neuroplasticity during inflammation, but whether enteric glia has the potential to modify visceral sensitivity following colitis is still unknown. This work aimed to investigate the occurrence of changes in the neuron-glial networks controlling visceral perception along the gut-brain axis during colitis, and to assess the effects of peripheral glial manipulation. Enteric glia activity was altered by

the poison fluorocitrate (FC; 10 µmol kg i.p.) before inducing colitis in animals (2,4-dinitrobenzenesulfonic acid, DNBS; 30 mg in 0.25 mL EtOH 50%), and visceral sensitivity, colon damage, and glia activation along the pain pathway were studied. FC injection significantly reduced the visceral hyperalgesia, the histological damage, and the immune activation caused by DNBS. Intestinal inflammation is associated with a parallel overexpression of TRPV1 and S100β along the gut-brain axis (colonic myenteric plexuses, dorsal root ganglion, and periaqueductal grey area). This effect was prevented by FC. Peripheral glia activity modulation emerges as a promising strategy for counteracting visceral pain induced by colitis.

VEGF-A/VEGFR-1 signalling and chemotherapy-induced neuropathic pain: therapeutic potential of a novel anti-VEGFR-1 monoclonal antibody.
Neuropathic pain is a clinically relevant adverse effect of several anticancer drugs that markedly impairs patients' quality of life and frequently leads to dose reduction or therapy discontinuation. The poor knowledge about the mechanisms involved in neuropathy development and pain chronicization, and the lack of effective therapies, make treatment of chemotherapy-induced neuropathic pain an unmet medical need. In this context, the vascular endothelial growth factor A (VEGF-A) has emerged as a candidate neuropathy hallmark and its decrease has been related to pain relief. In the present study, we have investigated the role of VEGF-A and its receptors, VEGFR-1 and VEGFR-2, in pain signalling and in chemotherapy-induced neuropathy establishment as well as the therapeutic potential of receptor blockade in the management of pain.

Visceral sensitivity modulation by faecal microbiota transplantation: the active role of gut bacteria in pain persistence.
Recent findings linked gastrointestinal disorders characterized by abdominal pain to gut microbiota composition. The present work aimed to evaluate the power of gut microbiota as a visceral pain modulator and, consequently, the relevance of its manipulation as a therapeutic option in reversing postinflammatory visceral pain persistence. Colitis was induced in mice by intrarectally injecting 2,4-dinitrobenzenesulfonic acid (DNBS). The effect of faecal microbiota transplantation from viscerally hypersensitive DNBS-treated and naive donors was evaluated in control rats after an antibiotic-mediated microbiota depletion. Faecal microbiota transplantation from DNBS donors induced a long-lasting visceral hypersensitivity in control rats. Pain threshold trend correlated with major modifications in the composition of gut microbiota and short chain fatty acids. By contrast, no significant alterations of colon histology, permeability, and monoamines levels were detected. Finally, by manipulating the gut microbiota of DNBS-treated animals, a counteraction of persistent visceral pain was achieved. The present results provide novel insights into the relationship between intestinal microbiota and visceral hypersensitivity, highlighting the therapeutic potential of microbiota-targeted interventions.

Pain Relieving and Neuroprotective Effects of Non-opioid Compound, DDD-028, in the Rat Model of Paclitaxel-Induced Neuropathy.
Chemotherapy-induced neuropathy (CIN) is a major dose-limiting side effect of anticancer therapy that can compel therapy discontinuation. Inadequate analgesic efficacy of current pharmacological approaches requires the identification of innovative therapeutics and, hence, the purpose of this study is to conduct a preclinical evaluation of the efficacy of DDD-028, a versatile pentacyclic pyridoindole derivative, against paclitaxel-induced neuropathic pain. In two separate experiments, DDD-028 was administered per os acutely (1-25 mg kg) or repeatedly (10 mg kg) in paclitaxel-treated rats. The response to mechanical noxious stimulus (paw pressure) as well as to non-noxious mechanical (von Frey) and thermal (cold plate) stimuli was investigated. Acute administration of DDD-028 induced a dose-dependent anti-neuropathic pain effect in all tests performed. Further, repeated daily treatment for 18 consecutive days (starting the first day of paclitaxel administration) significantly reduced the development of pain over time without the development of tolerance to the anti-hyperalgesic effect. Ex vivo analysis showed that DDD-028 was able to reduce oxidative damage of dorsal root ganglia as evidenced by the increase in the level of carbonylated proteins and the decrease in catalase activity. In the lumbar spinal cord, periaqueductal gray matter, thalamus, and somatosensory cortex 1, DDD-28 significantly prevented the activation of microglia and astrocytes. The pharmacodynamic study revealed that the pain-relieving effects of DDD-028 were fully blocked by both the non-selective nicotinic receptor (nAChR) antagonist mecamylamine and by the selective α7 nAChR antagonist methyllycaconitine. In conclusion, DDD-028 was active in reducing paclitaxel-induced neuropathic pain after single or repeated administrations without tolerance development and displaying a double symptomatic and neuroprotective profile. DDD-028 could represent a valuable candidate for the treatment of CIN.

Intranasal Low-Dose Naltrexone Against Opioid Side Effects: A Preclinical Study.
Opioids are broad spectrum analgesics that are an integral part of the therapeutic armamentarium to combat pain in the clinical practice. Unfortunately, together with analgesia, a number of adverse effects can occur such as nausea, vomiting, constipation, gastrointestinal alterations and cognitive impairments. Naltrexone is a competitive antagonist of opioid receptors commonly used to treat opioid addiction; its oral use against agonists side effects is limited by the decrease of opioids-therapeutic efficacy and own adverse effects. The intranasal delivery of naltrexone could offer a quick and effective achievement of CNS based on extracellular mechanisms including perineural and perivascular transport. The aim of the study was to test the efficacy of intranasal low-dose naltrexone in reducing intraperitoneal morphine and oxycodone side effects in rodents. In mice, 1 µg naltrexone intranasally administered 30 min before opioids reduced cognitive impairments and motor alteration induced by 10 mg kg morphine and 60 mg kg oxycodone in the Passive avoidance and Rota rod tests, respectively. Moreover, naltrexone rebalanced opioid-induced reduction of the intestinal transit and latency of feces expulsion as well as food intake inhibition. Importantly, 1 µg naltrexone instillation did not block analgesia as demonstrated by the Hot plate test. In rats, intranasal naltrexone counteracted the opioid-induced pica phenomenon related to emesis and increased water and palatable food intake. The effects were comparable to that achieved by metoclopramide used as reference drug. Treatments did not influence body weight. Lastly, the safety of the intranasal delivery has been checked by hematoxylin-eosin staining that did not show histological alterations of the nasal cavity. In conclusion, intranasal low-dose naltrexone counteracted morphine and oxycodone induced gastrointestinal and CNS side effects without impairing opioid analgesia. It is a candidate to be a valid clinical strategy deserving deep analysis.

Low molecular weight protein tyrosine phosphatase: Multifaceted functions of an evolutionarily conserved enzyme.
Originally identified as a low molecular weight acid phosphatase, LMW-PTP is actually a protein tyrosine phosphatase that acts on many phosphotyrosine-containing cellular proteins that are primarily involved in signal transduction. Differences in sequence, structure, and substrate recognition as well as in subcellular localization in different organisms enable LMW-PTP to exert many different functions. In fact, during evolution, the LMW-PTP structure adapted to perform different catalytic actions depending on the organism type. In bacteria, this enzyme is involved in the biosynthesis of group 1 and 4 capsules, but it is also a virulence factor in pathogenic strains. In yeast, LMW-PTPs dephosphorylate immunophilin Fpr3, a peptidyl-prolyl-cis-trans isomerase member of the protein chaperone family. In humans, LMW-PTP is encoded by the ACP1 gene, which is composed of three different alleles, each encoding two active enzymes produced by alternative RNA splicing. In animals, LMW-PTP dephosphorylates a number of growth factor receptors and modulates their signalling processes. The involvement of LMW-PTP in cancer progression and in insulin receptor regulation as well as its actions as a virulence factor in a number of pathogenic bacterial strains may promote the search for potent, selective and bioavailable LMW-PTP inhibitors.

Carbonic Anhydrase IV Selective Inhibitors Counteract the Development of Colitis-Associated Visceral Pain in Rats.
Persistent pain affecting patients with inflammatory bowel diseases (IBDs) is still very difficult to treat. Carbonic anhydrase (CA) represents an intriguing pharmacological target considering the anti-hyperalgesic efficacy displayed by CA inhibitors in both inflammatory and neuropathic pain models. The aim of this work was to evaluate the effect of inhibiting CA IV, particularly when expressed in the gut, on visceral pain associated with colitis induced by 2,4-di-nitrobenzene sulfonic acid (DNBS) in rats. Visceral sensitivity was assessed by measuring animals' abdominal responses to colorectal distension. Repeated treatment with the selective CA IV inhibitors AB-118 and NIK-67 effectively counteracted the development of visceral pain induced by DNBS. In addition to pain relief, AB-118 showed a protective effect against colon damage. By contrast, the anti-hyperalgesic activity of NIK-67 was independent of colon healing, suggesting a direct protective effect of NIK-67 on visceral sensitivity. The enzymatic activity and the expression of CA IV resulted significantly increased after DNBS injection. NIK-67 normalised CA IV activity in DNBS animals, while AB-118 was partially effective. None of these compounds influenced CA IV expression through the colon. Although further investigations are needed to study the underlying mechanisms, CA IV inhibitors are promising candidates in the search for therapies to relieve visceral pain in IBDs.

Restorative and pain-relieving effects of fibroin in preclinical models of tendinopathy.

The term tendinopathy indicates a wide spectrum of conditions characterized by alterations in tendon tissue homeostatic response and damage to the extracellular matrix. The current pharmacological approach involves the use of nonsteroidal anti-inflammatory drugs and corticosteroids often with unsatisfactory results, making essential the identification of new treatments. In this study, the pro-regenerative and protective effects of an aqueous fibroin solution (0.5-500 µg/mL) against glucose oxidase (GOx)-induced damage in rat tenocytes were investigated. Then, fibroin anti-hyperalgesic and protective actions were evaluated in two models of tendinopathy induced in rats by collagenase or carrageenan injection, respectively. In vitro, 5-10 µg/mL fibroin per se increased cell viability and reverted the morphological alterations caused by GOx (0.1 U/mL). Fibroin 10 µg/mL evoked proliferative signaling upregulating the expression of decorin, scleraxin, tenomodulin ($p < 0.001$), FGF-2, and tenascin-C ($p < 0.01$) genes. Fibroin enhanced the basal FGF-2 and MMP-9 protein concentrations and prevented their GOx-mediated decrease. Furthermore, fibroin positively modulated the production of collagen type I. In vivo, the peri-tendinous injection of fibroin (5 mg) reduced the development of spontaneous pain and hypersensitivity ($p < 0.01$) induced by the intra-tendinous injection of collagenase; the efficacy was comparable to that of triamcinolone. The pain-relieving action of fibroin (peri-tendinous) was confirmed in the model of tendinopathy induced by carrageenan (intra-tendinous) where this fibrous protein was also able to improve tendon matrix organization, normalizing the orientation of collagen fibers. In conclusion, the use of fibroin in tendinopathies is suggested taking advantage of its excellent mechanical properties, pain-relieving effects, and ability to promote tissue regeneration processes.

Metformin is also effective on lactic acidosis-exposed melanoma cells switched to oxidative phosphorylation.
Low extracellular pH promotes in melanoma cells a malignant phenotype characterized by an epithelial-to-mesenchymal transition (EMT) program, endowed with mesenchymal markers, high invasiveness and pro-metastatic property. Here, we demonstrate that melanoma cells exposed to an acidic extracellular microenvironment, 6.7±0.1, shift to an oxidative phosphorylation (Oxphos) metabolism. Metformin, a biguanide commonly used for type 2 diabetes, inhibited the most relevant features of acid-induced phenotype, including EMT and Oxphos. When we tested effects of lactic acidosis, to verify whether sodium lactate might have additional effects on acidic melanoma cells, we found that EMT and Oxphos also characterized lactic acid-treated cells. An increased level of motility was the only gained property of lactic acidic-exposed melanoma cells. Metformin treatment inhibited both EMT markers and Oxphos and, when its concentration raised to 10 mM, it induced a striking inhibition of proliferation and colony formation of acidic melanoma cells, both grown in protons enriched medium or lactic acidosis. Thus, our study provides the first evidence that metformin may target either proton or lactic acidosis-exposed melanoma cells inhibiting EMT and Oxphox metabolism. These findings disclose a new potential rationale of metformin addition to advanced melanoma therapy, e.g. targeting acidic cell subpopulation.

LOW TEMPERATURES DELAY THE EFFECTS OF ISCHEMIA IN CEREBELLAR SLICES

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Xia Li, Romain Helleringer, Lora Martucci, Glenn Dallérac, José-Manuel Cancela, Micaela Galante
University Paris-Saclay, Neuropsi, Cnrs Umr9197, Saclay, France

Cerebral ischemia results in oxygen and glucose deprivation that most commonly occurs after a reduction or interruption of blood supply into the brain. The consequences of cerebral ischemia are complex and involve the loss of metabolic ATP, excessive K+ and glutamate accumulation in the extracellular space, electrolytes imbalance and brain oedema formation. So far, several treatments have been proposed to ameliorate ischemia effects, however only few are effective. Here we focused on the neuroprotective role of lowering the temperature on ischemia mimicked by an episode of Oxygen and Glucose Deprivation (OGD) in cerebellar slices. Our results suggest that lowering the temperature of the extracellular 'milieu' delays both [K+]e raises and tissue swelling, two dreaded consequences of cerebellar ischemia. Moreover, radial glial cells (Bergmann glia) are also sensitive to temperature lowering during OGD. In fact, both membrane depolarisation and morphological change of these glial cells appeared significantly delayed than those observed at more physiological temperatures.

THE APP A673T VARIANT AND THE APOE GENOTYPE AFFECT ASTROCYTE MORPHOLOGY AND CHOLESTEROL METABOLISM IN A MODEL OF ALZHEIMER'S DISEASE

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Pinja Kettunen[1], Johanna Kuusisto[2], Markku Laakso[2], Jari Koistinaho[1], Taisia Rolova[1]

Aims Alzheimer's disease (AD) is the most common cause of dementia worldwide. The A673T mutation in the amyloid precursor protein (APP) reduces beta-amyloid (Aβ) production in neurons and protects its carriers from AD. According to Oksanen et. al. 2017 a familial presenilin-1 mutation increases astrocytic $A\beta_{(1-42)}$ production to the level of neurons and induces functional deficits in astrocytes. Thus, we postulated that the APP A673T variant may excert some its protective effects through altered astrocyte function. Methods We compared APP A673T APOE3/3 astrocytes to APOE3/3 controls and astrocytes carrying the AD risk genotype APOE4/4. First, we differentiated astrocytes from human induced pluripotent stem cells (hIPSCs) and characterized them using immunocytochemistry and qPCR. Then, we analysed astrocyte morphology and cytokine production. Finally, we measured astrocytic cholesterol accumulation with or without docosahexaenoic acid (DHA) and choline supplementation. These compounds are anti-inflammatory and modulate cholesterol metabolism in the brain. Results Our hIPSC-derived astrocytes expressed astrocyte markers, displayed the characteristic astrocyte morphology and secreted cytokines in response to pro-inflammatory stimulation, as expected. Astrocytes carrying the APP A67T variant displayed altered morphology compared to controls. Docosahexaenoic acid and choline supplementation reduced cholesterol accumulation in astrocytes carrying the APOE4/4 genotype or the APP A673T variant but not in APOE3/3 controls. Conclusions Astrocytes carrying the APP variant A673T display altered morphology and responsivity to anti-inflammatory and cholesterol-modulating treatments compared to controls. DHA and choline supplementation also reduces cholesterol accumulation in APOE4/4, which may modulate Aβ production, uptake, and inflammation.

Elevated rates of horizontal gene transfer in the industrialized human microbiome.
Industrialization has impacted the human gut ecosystem, resulting in altered microbiome composition and diversity. Whether bacterial genomes may also adapt to the industrialization of their host populations remains largely unexplored. Here, we investigate the extent to which the rates and targets of horizontal gene transfer (HGT) vary across thousands of bacterial strains from 15 human populations spanning a range of industrialization. We show that HGTs have accumulated in the microbiome over recent host generations and that HGT occurs at high frequency within individuals. Comparison across human populations reveals that industrialized lifestyles are associated with higher HGT rates and that the functions of HGTs are related to the level of host industrialization. Our results suggest that gut bacteria continuously acquire new functionality based on host lifestyle and that high rates of HGT may be a recent development in human history linked to industrialization.

Metabolic and immune dysfunction of glia in neurodegenerative disorders: Focus on iPSC models.
The research on neurodegenerative disorders has long focused on neuronal pathology and used transgenic mice as disease models. However, our understanding of the chronic neurodegenerative process in the human brain is still very limited. It is increasingly recognized that neuronal loss is not caused solely by intrinsic degenerative processes but rather via impaired interactions with surrounding glia and other brain cells. Dysfunctional astrocytes do not provide sufficient nutrients and antioxidants to the neurons, while dysfunctional microglia cannot efficiently clear pathogens and cell debris from extracellular space, thus resulting in chronic inflammatory processes in the brain. Importantly, human glia, especially the astrocytes, differ significantly in morphology and function from their mouse counterparts, and therefore more human-based disease models are needed. Recent advances in stem cell technology make it possible to reprogram human patients' somatic cells to induced

pluripotent stem cells (iPSC) and differentiate them further into patient-specific glia and neurons, thus providing a virtually unlimited source of human brain cells. This review summarizes the recent studies using iPSC-derived glial models of Alzheimer's disease, Parkinson's disease, and amyotrophic lateral sclerosis and discusses the applicability of these models to drug testing. This line of research has shown that targeting glial metabolism can improve the survival and function of cocultured neurons and thus provide a basis for future neuroprotective treatments.

ROLE OF ASTROCYTIC CA2+ SIGNALING IN BRAIN OSCILLATORY ACTIVITY AND MEMORY: IMPLICATIONS FOR NEURODEGENERATIVE DISEASES.

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Aarushi Juyal, Alexandre Tchelingerian, Valentin Ritou, Elsie Moukarzel, Jacques Stinnakre, Cendra Agulhon
CNRS UMR8022 - University of Paris, Integrative Neuroscience & Cognition Center, Paris, France

Astrocytes are the most abundant glial cells in the central nervous system and are in close contact with synapses. In response to neurotransmitters, their intracellular Ca^{2+} levels are increased, leading to the release of neuroactive molecules. In addition, astrocytic Ca^{2+} signaling is dysregulated in Alzheimer's and Huntington's neurodegenerative diseases. Patients' brain neural oscillations and memory are also altered in both diseases. Our main hypothesis is that chronic modulation of astrocytic Ca^{2+} signaling leads to altered release of glutamate or pro-inflammatory factors from astrocytes, and consequent deficits in brain oscillations and memory formation. We have tested this hypothesis *in vivo* using the mouse primary visual cortex as a model system, combined with electrophysiology, chemogenetics, genetically-modified mouse models, and behavior. Data are currently being processed.
Our study could have profound implications in the clinic, as it may lead to a better understanding of the astrocyte role in memory deficits and in the etiology of neurodegenerative diseases.

The tight metabolic cooperation between neurons and astrocytes maintains brain activity and homeostasis. When neuronal activity is increased, astrocytes provide neurons with lactate and different factors to protect them from oxidative stress produced during mitochondrial respiration. However upon neuronal hyperactivation and in response to the increase of reactive oxygen species, neurons produce lipid particles that are then transferred to astrocytes where they accumulate into lipid droplets. Lipid droplets have been linked to many neurodegenerative diseases and a better understanding of the mechanism involved in their formation and utilization is important for the development of therapeutic strategies. In the current study, the metabolic cooperation between astrocytes and neurons during oxidative stress was investigated with a special interest in lipid droplet formation and composition. Here, primary cultures of neurons and astrocytes grown together or in co-culture of primary neurons and astrocytes seeded separately were treated with rotenone. The number of lipid droplets, as well as their size and composition have been evaluated using confocal microscopy and Stimulated Raman Spectroscopy. Our preliminary observations indicate that lactate may be used not only as a signaling molecule but also as a building block of the fatty acids stored in lipid droplets.

THE ELEPHANT IN THE ROOM: A TISSUE-ENGINEERED 3D MODEL TO EXPLORE ASTROCYTE ROLE IN NEURODEGENERATION

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Miguel Morais[1], Eva D. Carvalho[1,2], Marco Araújo[1], Cristina Barrias[1,3], Ana Pego[1,3]

One accepted reason for neuro-regeneration failure in central nervous system (CNS) neurodegenerative diseases is the formation of the scar tissue containing reactive astrocytes. These cells change their phenotype from quiescent to reactive, overexpressing extracellular matrix (ECM) proteins and strongly modifying the biophysical properties of the lesion environment. Although the process is inexorable, it is mutable in time. Our working hypothesis is that the alterations in the matrix caused by reactive astrocytes are a barrier to neuro-regeneration. Here we propose a tissue-engineered model to dynamically recreate the astrogliosis environment. Alginate (ALG) was chosen to mimic the ECM due to its biocompatibility and tunable mechanical properties. ALG modifications with cell adhesive (RGD) and MMP-sensitive (PVGLIG) peptides allowed astrocytes to extend long processes and form a network in a 3D environment (Figure 1), highlighting the biologically relevance of the model. Activation with LPS/IFN-γ led to an increase of *Lcn2* and *Aqp4*, indicating that astrocytes acquired an astrogliosis-like phenotype, with no significant changes in cellular viability, metabolic activity and morphology. To model temporal changes in ECM stiffness, ALG hydrogels were submitted to an external crosslinking stimulus (barium). Barium treatment led to a six-fold increase in the stiffness of the hydrogels. Astrocytic metabolic activity slightly decreased, but the viability remained unchanged. A dramatic alteration in cellular morphology was observed, along with an increased expression of astrogliosis (*Gfap* and *Aqp4)* and mechanosensing (*Piezo1)* related

genes.

ADRENERGIC MODULATION OF AQUAPORIN-4 NANOSCALE DISTRIBUTION AND DYNAMICS IN PRIMARY MOUSE ASTROCYTES

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Anna-Lena Zepernick[1], Mathew Horrocks[2], Juan Varela[3]
[1]University of St Andrews, School Of Biology, St Andrews, United Kingdom, [2]The University of Edinburgh, School Of Chemistry, Edinburgh, United Kingdom, [3]University of St. Andrews, School Of Physics And Astronomy, St. Andrews, United Kingdom

Adrenergic signaling has been shown to regulate the volume of the extracellular space of the brain via aquaporin-4 (AQP4) localized at the end-feet of astrocytes. The mechanisms by which AQP4 regulate changes in the extracellular space volume and cerebrospinal fluid inflow and outflow in the brain remain elusive. This is partly due to the complex dynamics of AQP4 nanoscale cluster assembly and disassembly at the end-feet of astrocytes. Our study aims to evaluate the effect of adrenergic modulation on the localization, mobility and cluster-size of AQP4 in primary astrocytes, both in dissociated cultures and brain slices. To achieve the necessary level of spatial and temporal resolution we used a combination of super-resolution imaging and single-molecule tracking techniques to evaluate changes in localization and mobility of AQP4M23. Our results suggest that adrenergic modulation affects the mobility, localization and cluster size of AQP4 in primary astrocytes. This work will contribute to understand the fundamental mechanisms underlying the volume change of the extracellular space of the brain during sleep.

Focal cortical dysplasia (FCD), a malformation of cortical development, is a primary cause of refractory epilepsy. Neural progenitors from FCD harbor specific mutations in the mTOR pathway of cell activation, leading to a disrupted cerebral cortex assemblage during development. Here we tested whether neural progenitors isolated from brain specimens of epileptic patients suffering from FCDs, integrate into neuronal networks after transplantation in immunodeficient mice and can generate abnormal activity. Following dissociation of brain resections from epileptic patients, we evidence *in vitro* these progenitors in neurosphere cultures. Moreover, we developed a chimeric mice model of FCD by transplanting human cultured human epileptic progenitors in immunodeficient pups. Interestingly, using different electrophysiological *in vivo* and *in vitro* recordings, we found that the xenografted cells integrate in the network of the host cells and were able to recapitulate the abnormal activity patterns recorded in the patient before surgery. Taken together these results highlight a new paradigm to better understand the physiopathological mechanisms underlying genetic epilepsy.

Non-neuronal cells, including astrocytes, contribute to brain function and, together with neurons, form the 'brain active milieu.' We investigated how the astrocytic calcium activity pattern is organized and changes during mouse behavior. The genetically encoded calcium indicator, GCaMP6f, was expressed under the astrocyte-specific promoter in C57BL/6 mice. Two-photon calcium imaging was done either in acute hippocampal slices or on the somatosensory cortex of awake head-fixed mice. Fiber photometry was performed from mouse hippocampi during behavioral tests. We observed spontaneous fluctuations of calcium activity in the astrocytic population in slices. These fluctuations were linked to an increase in areas and spatial density of the individual calcium events. In head-fixed mice, an increase of calcium event areas correlated with an initial phase of animal running, while spatial density changed with running speed. Photometry data revealed that calcium activity in hippocampal astrocytes changes during animal navigation in the open field and social novelty tests. Our findings suggest that properties of astrocytic calcium activity patterns change specifically with animal behavior, prompting a possibility of a causal link. The work is supported by the Russian Science Foundation (grant 20-14-00241).

NITRIC OXIDE PARTICIPATES TO METABOLIC CHANGES IN THE ASTROCYTIC-MICROGLIAL CROSSTALK DURING HYPOTHALAMIC INFLAMMATION

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Francesco Arioli[1], Olaf Jöhren[2]
[1]University of Lübeck, Institute For Experimental And Clinical Pharmacology And Toxicology, Lübeck, Germany, [2]University of Lübeck, Center of Brain Behavior and Metabolism, Institute For Experimental And Clinical Pharmacology And Toxicology, Lübeck, Germany

Aims: Cellular adaptation to low oxygen is mediated by hypoxia inducible factors (HIFs), whose stabilization affects the expression of several target genes involved in different processes such as glycolysis, angiogenesis, cell proliferation and survival. Therefore, we aim to investigate how the physiological oxygen concentrations (3-5% in the brain) are affecting HIFs activity on metabolism in the hypothalamic inflammation. **Methods:** Primary hypothalamic murine glial cells have been cultured for three weeks before treatments at different oxygen conditions. Expression of HIF-1 and its target genes has been assessed by Western blot and qPCR. **Results:** In hypothalamic primary mixed glial culture, HIF-1 is stable and active at hypoxia (1%) as expected but also at physioxia (3%). Following pro-inflammatory stimuli, such as lipopolysaccharide (LPS) or interleukin-1β (IL-1β) HIF-1 expression greatly increased at both physioxia and hypoxia, thereby differentially regulating HIF-1 target genes involved in lactate production and release. Besides the lactate transporter MCT4, the inducible nitric oxide (NO) synthase displayed the most evident upregulation. By using the NO chelating agent cPTIO we confirmed the involvement of NO, known for stabilizing HIF-1 protein, in shifting the cellular metabolism from oxidative phosphorylation to glycolysis after pro-inflammatory stimulation. Furthermore, we evidenced by microglial ablation that HIF-1 activity is also depending on the presence of this cellular population, hinting at a crosstalk with astrocytes. **Conclusion:** We demonstrate the capacity of inflammation to activate HIF-1 in hypothalamic glia and suggest a role for NO in maintaining a positive feedback loop between astrocytes and microglia.

MORPHOLOGICAL AND FUNCTIONAL FAñANAS CELLS CHARACTERIZATION IN THE MOUSE CEREBELLUM.

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Antonin Singer[1], Martin Oheim[1], Isabel Llano[1,2], Abdelali Jalil[1,2], Vincent Armand[1,2]
[1]Univesité de paris, Faculté Des Sciences Fondamentales Et Biomédicales, Paris, France, [2]Université Paris Descartes, Saints Pères Paris Institute For Neurosciences, Paris, France

Fañanas cells or “feathered” cells are cerebellar glia of unknown function. Described more than 100 years ago, they could only made visible through either the gold sublimate impregnation technique of Ramón y Cajal or tedious silver staining methods. The investigation of Fañanas cells with modern techniques has become possible by the recent identification in rat of two potassium channel-related polypeptides, Kv2.2 and Calsenilin (KChIP3), as potential marker proteins for Fañanas cells. While we confirmed the findings of this study, a similar approach in mouse failed. Therefore, in the current work, we used the combination of immunofluorescence and whole-cell patch-clamp recordings for characterizing the morphology and basic electrophysiological properties of these enigmatic cerebellar glia. In transverse slices, we reliably recognized Fañanas cells through the expression of pan-glial markers together with their atypical cell-body localization. Finally, extracellular stimulation in molecular and granular cell layers led to a slow and long-lasting inward current largely resulting from AMPA-receptor activation. Although we are at the beginning of the Fañanas cells investigation, this study cover a new face of the glial organization in the cerebellum.

VASOCONSTRICTOR ENDOTHELIN B RECEPTOR IS PROLIFERATED IN REACTIVE ASTROCYTES IN APP KNOCK-IN MOUSE MODEL OF ALZHEIMER'S DISEASE.

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Jialin Li, Afia Ali
UCL, School Of Pharmacy, London, United Kingdom

Aims: Alzheimer's disease (AD) is associated with cognitive impairment, and is correlated with proliferation of reactive astrocytes, the most abundant glial cells, important for providing neuronal support and regulating cerebral blood flow. The endothelin B receptor (ET_B) is a G protein-coupled receptor (GPCR) for endothelin-1, a potent vasoconstrictor, which is thought to be upregulated due to brain injury. This project aimed to investigate whether there was a change in the ET_B expression levels in reactive astrocytes during the progression of AD. **Method:** The alteration and distribution of reactive astrocytes, indicated by glial fibrillary acidic protein (GFAP) and ET_B in the lateral entorhinal cortex (LEC) and hippocampus CA1 region, were investigated by immunoperoxidase and immunofluorescence using a knock-in mouse model of AD ($APP^{NL-F/NL-F}$) that expresses a mutant form of human amyloid-β (Aβ) precursor protein, age-matched (12-16 months) to wild-type control mice. **Results:** ET_B was shown to be differentially expressed in the wild-type mice, age-matched to $APP^{NL-F/NL-F}$ mice. There was a proliferation of GFAP and ET_B in the LEC and CA1 region in the $APP^{NL-F/NL-F}$ mouse model at 12-16 months, compared with wild-type mice. Furthermore, confocal microscopy revealed a high degree of colocalization of ET_B expression in reactive astrocytes in the AD model compared to the wild-type control mice. **Conclusions:** Our data suggest a direct correlation of reactive astrocytes with ET_B that increased during the pathogenesis of AD astrocytes in cortical regions and could potentially be further investigated as a new drug target for treating AD by improving cerebral blood flow.

NPC1L1-Targeted Cholesterol-Grafted Poly(β-Amino Ester)/pDNA Complexes for Oral Gene Delivery.
Gene vectors for oral delivery encounter harsh conditions throughout the gastrointestinal tract, and the continuous peristaltic activity can quickly remove the vectors, leading to inefficient intestinal permeation. Therefore, vectors have demanding property requirements, such as stability under various pH and, more importantly, efficient uptake in different intestinal segments. In this study, a functional polymer, cholesterol-grafted poly(β-amino ester) (poly[hexamethylene diacrylate-β-(5-amino-1-pentanol)] (CH-PHP)), is synthesized and electrostatically interacted with plasmid DNA to form a CH-PHP/DNA complex (CPNC). This complex is designed to target the Niemann-Pick C1-like receptor, a cholesterol receptor, to improve oral gene delivery efficacy. With the presence of cholesterol, CH-PHP shows mitigated cytotoxicity, enhanced enzyme resistance, and improved gene condensing ability. CPNC further contributes to ≈43.1- and 2.3-fold increases in luciferase expression in Caco-2 cells compared with PNC and Lipo 2000/DNA complexes, respectively. In addition, the in vivo transfection efficacy of CPNC is ≈4.1-, 2.1-, and 1.6-fold higher than that of Lipo 2000/DNA complexes in rat duodenum, jejunum, and ileum, respectively. Therefore, CPNC may be a promising delivery vector for gene delivery, and using a cholesterol-specific endocytic pathway can be a novel approach to achieve efficient oral gene transfection.

Cancer-Cell-Membrane-Coated Nanoparticles with a Yolk-Shell Structure Augment Cancer Chemotherapy.
Despite rapid advancements in antitumor drug delivery, insufficient intracellular transport and subcellular drug accumulation are still issues to be addressed. Cancer cell membrane (CCM)-camouflaged nanoparticles (NPs) have shown promising potential in tumor therapy due to their immune escape and homotypic binding capacities. However, their efficacy is still limited due to inefficient tumor penetration and compromised intracellular transportation. Herein, a yolk-shell NP with a mesoporous silica nanoparticle (MSN)-supported PEGylated liposome yolk and CCM coating, CCM@LM, was developed for chemotherapy and exhibited a homologous tumor-targeting effect. The yolk-shell structure endowed CCM@LM with moderate rigidity, which might contribute to the frequent transformation into an ellipsoidal shape during infiltration, leading to facilitated penetration throughout multicellular spheroids (up to a 23.3-fold increase compared to the penetration of

membrane vesicles). CCM@LM also exhibited a cellular invasion profile mimicking an enveloped virus invasion profile. CCM@LM was directly internalized by membrane fusion, and the PEGylated yolk (LM) was subsequently released into the cytosol, indicating the execution of an internalization pathway similar to that of an enveloped virus. The incoming PEGylated LM further underwent efficient trafficking throughout the cytoskeletal filament network, leading to enhanced perinuclear aggregation. Ultimately, CCM@LM, which co-encapsulated low-dose doxorubicin and the poly(ADP-ribose) polymerase inhibitor, mefuparib hydrochloride, exhibited a significantly stronger antitumor effect than the first-line chemotherapeutic drug Doxil. Our findings highlight that NPs that can undergo facilitated tumor penetration and robust intracellular trafficking have a promising future in cancer chemotherapy.

NEURON TO ASTROCYTE EXOCYTOTIC CROSS-TALK OR DO NEURONS CAN REGULATE ASTROCYTIC GLIOTRANSMISSION?

POSTER SESSION 04 - SECTION: ASTROCYTE FUNCTION AND DYSFUNCTION

Aleksandra Mielnicka
Nencki Institute of Experimental Biology, Braincity, Laboratory Of Neurobiology, Warsaw, Poland

Cross-talk between neuronal connections and astrocytic processes was described by tripartite synapse concept which assumes that neurotransmission can be modulated by mechanisms of gliotransmitters secretion from astrocytes. A lot of controversies arose regarding the process of gliotransmission therefore the aim of our work is take a closer look on astrocytic exocytosis in the presence of neurons. To get an insight into the mechanisms controlling gliotransmission, we use Synaptobrevin2 fused with pH-dependent GFP (pHluorin) to observe astrocytic exocytosis in primary mixed hippocampal cultures as well as in pure astrocytic cultures. Our results indicate that the frequency of vesicular gliotransmission in astrocytes is higher in pure astrocytic cultures than in neuron/astrocyte co-cultures, where blocking neuronal transmission with TTX does not significantly reduce the rate of exocytosis. Nonetheless, we have shown that electrical stimulation of mixed culture increases the frequency of gliotransmitters release even when we block Ca^{2+} release from the endoplasmic reticulum using 2-APB and Ryanodine. Furthermore, activation of group I metabotropic glutamate receptors with DHPG significantly increases exocytosis rate but only in pure astrocytic culture. On the other hand, our results present that incubating cells with Ca^{2+} chelator (BAPTA) decreases the rate of vesicles released in both types of cultures justifying importance of extracellular Ca^{2+} in regulating process of astrocytic exocytosis. To summarize our results there is a correspondence between presence of neurons, Ca^{2+} signal localisation and the efficiency of gliotransmitters release in astrocytes. This study is supported by National Science Centre, Poland grant 2017/26/D/N23/01017.

EVOLUTION INCREASES STRESS-RESPONSE COMPLEXITY IN HIGHER PRIMATES EXTENDING RBFOX1 SPLICING ACTIVITY TO LSD1 MODULATION

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Chiara Forastieri[1], Elena Romito[1], Emanuela Toffolo[1], Maria Paola Bonasoni[2], Francesco Rusconi[1], Elena Battaglioli[1]
[1]University of Milan, Department Of Medical Biotechnology And Translational Medicine, Milan, Italy, [2]Azienda USL-IRCCS di Reggio Emilia, Pathology Unit, Reggio Emilia, Italy

Recent branching (100 MYA) of the mammalian evolutionary tree has enhanced brain complexity and functions at the putative cost of increased emotional circuitry vulnerability. Thus, to better understand psychopathology, a burden for the modern society, novel approaches should exploit evolutionary aspects of psychiatric-relevant molecular pathways. A handful of genes is nowadays tightly associated to psychiatric disorders. Among them, neuronal-enriched RbFOX1 modifies the activity of synaptic regulators in response to neuronal activity, keeping excitability within healthy domains. Thanks to the combination of transcriptional approaches, minigene splicing assay and post-mortem human brain samples analyses, we dissected a higher primates-restricted interaction between RbFOX1 and the transcriptional corepressor Lysine Specific Demethylase 1 (LSD1/KDM1A). A single nucleotide variation (AA to AG) in LSD1 gene appeared in higher primates and humans, endowing RbFOX1 with the ability to promote the alternative usage of a novel 3' AG splice site, which extends LSD1 exon E9 in the upstream intron (E9-long). Exon E9-long regulates LSD1 levels by Nonsense-Mediated mRNA Decay. As reintroduction of the *archaic* LSD1 variant (AA) abolishes E9-long splicing, the novel 3' AG splice site is necessary for RbFOX1 to control LSD1 levels. LSD1 is a homeostatic Immediate Early Genes (IEGs) regulator playing a relevant part in environmental stress-response. In primates and humans, inclusion of LSD1 as RbFOX1 target provides RbFOX1 with the additional ability to regulate the IEGs. These data, together with extensive RbFOX1 involvement in psychiatric disorders and its stress-dependent regulation in male mice, suggest the RbFOX1-LSD1-IEGs axis as an evolutionary recent psychiatric-relevant pathway.

Rationale, Relevance, and Limits of Stress-Induced Psychopathology in Rodents as Models for Psychiatry Research: An Introductory Overview.
Emotional and cognitive information processing represent higher-order brain functions. They require coordinated interaction of specialized brain areas via a complex spatial and temporal equilibrium among neuronal cell-autonomous, circuitry, and network mechanisms. The delicate balance can be corrupted by stressful experiences, increasing the risk of developing psychopathologies in vulnerable individuals. Neuropsychiatric disorders affect twenty percent of the western world population, but therapies are still not effective for some patients. Elusive knowledge of molecular pathomechanisms and scarcity of objective biomarkers in humans present complex challenges, while the adoption of rodent models helps to improve our understanding of disease correlate and aids the search for novel pharmacological targets. Stress administration represents a strategy to induce, trace, and modify molecular and behavioral endophenotypes of mood disorders in animals. However, a mouse or rat model will only display one or a few endophenotypes of a specific human psychopathology, which cannot be in any case recapitulated as a whole. To override this issue, shared criteria have been adopted to deconstruct neuropsychiatric disorders, i.e., depression, into specific behavioral aspects, and inherent neurobiological substrates, also recognizable in lower mammals. In this work, we provide a rationale for rodent models of stress administration. In particular, comparing each rodent model with a real-life human traumatic experience, we intend to suggest an introductive guide to better comprehend and interpret these paradigms.

SRF and SRFΔ5 Splicing Isoform Recruit Corepressor LSD1/KDM1A Modifying Structural Neuroplasticity and Environmental Stress Response.
Ten to 20% of western countries population suffers from major depression disorder (MDD). Stressful life events represent the main environmental risk factor contributing to the onset of MDD and other stress-related neuropsychiatric disorders. In this

regard, investigating brain physiology of stress response underlying the remarkable individual variability in terms of behavioral outcome may uncover stress-vulnerability pathways as a source of candidate targets for conceptually new antidepressant treatments. Serum response factor (SRF) has been addressed as a stress transducer via promoting inherent experience-induced Immediate Early Genes (IEGs) expression in neurons. However, in resting conditions, SRF also represents a transcriptional repressor able to assemble the core LSD1/CoREST/HDAC2 corepressor complex, including demethylase and deacetylase activities. We here show that dominant negative SRF splicing isoform lacking most part of the transactivation domain, namely SRFΔ5, owes its transcriptional repressive behavior to the ability of assembling LSD1/CoREST/HDAC2 corepressor complex meanwhile losing its affinity for transcription-permissive cofactor ELK1. SRFΔ5 is highly expressed in the brain and developmentally regulated. In the light of its activity as negative modulator of dendritic spine density, SRFΔ5 increase along with brain maturation suggests a role in synaptic pruning. Upon acute psychosocial stress, SRFΔ5 isoform transiently increases its levels. Remarkably, when stress is chronically repeated, a different picture occurs where SRF protein becomes stably upregulated in vulnerable mice but not in resilient animals. These data suggest a role for SRFΔ5 that is restricted to acute stress response, while positive modulation of SRF during chronic stress matches the criteria for stress-vulnerability hallmark.

Termination of acute stress response by the endocannabinoid system is regulated through lysine-specific demethylase 1-mediated transcriptional repression of 2-AG hydrolases ABHD6 and MAGL.
Acute environmental stress rarely implies long-lasting neurophysiological and behavioral alterations. On the contrary, chronic stress exerts a potent toxic effect at the glutamatergic synapse whose altered physiology has been recognized as a core trait of neuropsychiatric disorders. The endocannabinoid system (ECS) plays an important role in the homeostatic response to acute stress. In particular, stress induces synthesis of endocannabinoid (eCB) 2-arachidonyl glycerol (2-AG). 2-AG stimulates presynaptic cannabinoid 1 (CB1) receptor contributing to stress response termination through inhibition of glutamate release, restraining thereafter anxiety arousal. We employ mouse models of stress response coupled to gene expression analyses, unravelling that in response to acute psychosocial stress in the mouse hippocampus, ECS-mediated synaptic modulation is enhanced via transcriptional repression of two enzymes involved in 2-AG degradation: α/β-hydrolase domain containing 6 (ABHD6) and monoacylglycerol lipase (MAGL). Such a process is orchestrated by the epigenetic corepressor LSD1 who directly interacts with promoter regulatory regions of Abhd6 and Magl. Remarkably, negative transcriptional control of Abhd6 and Magl is lost in the hippocampus upon chronic psychosocial stress, possibly contributing to trauma-induced drift of synapse physiology toward uncontrolled glutamate transmission. We previously showed that in mice lysine-specific demethylase 1 (LSD1) increases its hippocampal expression in response to psychosocial stress preventing excessive consolidation of anxiety-related plasticity. In this work, we unravel a nodal epigenetic modulation of eCB turn over, shedding new light on the molecular substrate of converging stress-terminating effects displayed by ECS and LSD1.
J Neurochem, 2020; 155

33457471: Longaretti A, Forastieri C, Toffolo E, Caffino L, Locarno A, Misevičiūtė I, Marchesi E, Battistin M, Ponzoni L, Madaschi L, Cambria C, Bonasoni MP, Sala M, Perrone D, Fumagalli F, Bassani S, Antonucci F, Tonini R, Francolini M, Battaglioli E, Rusconi F
LSD1 is an environmental stress-sensitive negative modulator of the glutamatergic synapse.
Along with neuronal mechanisms devoted to memory consolidation -including long term potentiation of synaptic strength as prominent electrophysiological correlate, and inherent dendritic spines stabilization as structural counterpart- negative control of memory formation and synaptic plasticity has been described at the molecular and behavioral level. Within this work, we report a role for the epigenetic corepressor Lysine Specific Demethylase 1 (LSD1) as a negative neuroplastic factor whose stress-enhanced activity may participate in coping with adverse experiences. Constitutively increasing LSD1 activity via knocking out its dominant negative splicing isoform neuroLSD1 (neuroLSD1 mice), we observed extensive structural, functional and behavioral signs of excitatory decay, including disrupted memory consolidation. A similar LSD1 increase, obtained with acute antisense oligonucleotide-mediated neuroLSD1 splicing knock down in primary neuronal cultures, dampens spontaneous glutamatergic transmission, reducing mEPSCs. Remarkably, LSD1 physiological increase occurs in response to psychosocial stress-induced glutamatergic signaling. Since this mechanism entails neuroLSD1 splicing downregulation, we conclude that LSD1/neuroLSD1 ratio modulation in the hippocampus is instrumental to a negative homeostatic feedback, restraining glutamatergic neuroplasticity in response to glutamate. The active process of forgetting provides memories with salience. With our work, we propose that softening memory traces of adversities could further represent a stress-coping process in which LSD1/neuroLSD1 ratio modulation may help preserving healthy emotional references.

CBP IS REQUIRED FOR ESTABLISHING ADAPTIVE EXPERIENCE-INDUCED GENE PROGRAMS IN ADULT EXCITATORY NEURONS

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Sergio Niñerola[1], Michal Lipinski[1], Miguel Fuentes-Ramos[1], Luis M Valor[1], Beatriz Del Blanco[1], Jose P. Lopez-Atalaya[2], Ángel Barco[1]
[1]Instituto de Neurociencias (CSIC-UMH), Molecular Neurobiology And Neuropathology, San Juan de Alicante, Spain, [2]Universidad Miguel Hernández de Elche - Consejo Superior de Investigaciones Científicas (UMH-CSIC), Group Of Cellular Plasticity And Neuropathology, San Juan de Alicante, Spain

The paralogous transcriptional co-activators and lysine acetyltransferases CBP and p300 have been involved in neuronal activity-dependent transcription and plasticity, but their specific roles in adult neurons are not fully understood. Here we investigated the impact in transcription, chromatin acetylation and behavior of eliminating either one of these proteins in excitatory neurons of the adult forebrain. We used inducible forebrain-specific knockout mice for CBP or p300 and studied the role of each one in normal and challenging tasks paradigms. With this aim, we analyzed the effect on the transcriptome and epigenome and studied behavioral response differences in the models. The elimination of CBP, reduced the expression of plasticity genes, dampened activity-driven transcription, and caused memory deficits in different tasks that rely on spontaneous exploratory behavior. In contrary, p300 did not present any abnormality. The importance of CBP became more prominent in paradigms that involved a chronic or recurrent change in transcription, including kindling and neuroadaptation to environmental enrichment, in which CBP loss interfered with the establishment of activity-induced transcriptional and epigenetic changes in response to a stimulus or experience. CBP is required for experience-driven gene programs in adult excitatory neurons. Moreover, comparative analyses in mice lacking the paralog p300 underscored the specificity of CBP function. These new findings on the epigenetic regulation of plasticity-related gene programs by CBP contribute to clarify the strong links between CBP deficiency and the etiology of different brain disorders.

Cardiac and placental mitochondrial characterization in a rabbit model of intrauterine growth restriction.
Intrauterine growth restriction (IUGR) is associated with cardiovascular remodeling persisting into adulthood. Mitochondrial bioenergetics, essential for embryonic development and cardiovascular function, are regulated by nuclear effectors as sirtuins. A rabbit model of IUGR and cardiovascular remodeling was generated, in which heart mitochondrial alterations were observed by microscopic and transcriptomic analysis. We aimed to evaluate if such alterations are translated at a functional mitochondrial level to establish the etiopathology and potential therapeutic targets for this obstetric complication.

Control of protein synthesis and memory by GluN3A-NMDA receptors through inhibition of GIT1/mTORC1 assembly.
De novo protein synthesis is required for synapse modifications underlying stable memory encoding. Yet neurons are highly compartmentalized cells and how protein synthesis can be regulated at the synapse level is unknown. Here, we characterize neuronal signaling complexes formed by the postsynaptic scaffold GIT1, the mechanistic target of rapamycin (mTOR) kinase, and Raptor that couple synaptic stimuli to mTOR-dependent protein synthesis; and identify NMDA receptors containing GluN3A subunits as key negative regulators of GIT1 binding to mTOR. Disruption of GIT1/mTOR complexes by enhancing GluN3A expression or silencing GIT1 inhibits synaptic mTOR activation and restricts the mTOR-dependent translation of specific activity-regulated mRNAs. Conversely, GluN3A removal enables complex formation, potentiates mTOR-dependent protein synthesis, and facilitates the consolidation of associative and spatial memories in mice. The memory enhancement becomes evident with light or spaced training, can be achieved by selectively deleting GluN3A from excitatory neurons during adulthood, and does not compromise other aspects of cognition such as memory flexibility or extinction. Our findings provide

mechanistic insight into synaptic translational control and reveal a potentially selective target for cognitive enhancement. Elife, 2021; 10

TRPA1 Channels Mediate Human Gingival Fibroblast Response to Phenytoin.
Drug-induced gingival enlargement (GE) is a frequent adverse effect observed in patients treated with anticonvulsant, immunosuppressant, and some antihypertensive medications-the antiepileptic phenytoin being the main drug associated with GE due to its high incidence (around 50%). The molecular mechanisms behind drug-induced gingival overgrowth are still unknown. By reverse transcription polymerase chain reaction, we demonstrate that the calcium-permeable ion channels TRPA1, TRPV1, and its capsaicin-insensitive isoform TRPV1b are expressed in human gingival fibroblasts (HGFs), the most abundant cellular type in periodontal tissue. Cultured HGFs responded with intracellular calcium elevations to phenytoin and to the canonical TRPA1 agonist allyl isothiocyanate. Application of phenytoin activated a nonselective cationic current in HGFs with a typical signature for TRPA1 channels. Moreover, this activation was blocked by HC030031, a specific TRPA1 blocker. Similarly, the use of shRNAs against hTRPA1 in HGFs reduced TRPA1 expression and activation by phenytoin. In addition, we show that phenytoin increased intracellular calcium levels in cells transfected with mouse or human TRPA1 channels. Responses to phenytoin were not observed in untransfected cells or cells expressing TRPM8 or TRPV1. The activation of HGFs by phenytoin was markedly reduced in the presence of antioxidant vitamins: ascorbic acid, folic acid, and α-tocopherol. By performing cell proliferation assays, we found that phenytoin did not augment the proliferation rate of HGFs. In contrast, alcian blue and picrosirius red staining of long-term HGFs cultures indicated that phenytoin induces extracellular matrix accumulation of collagen. Collectively, these findings support an important role of TRPA1 channels in phenytoin-induced GE, provide insight into the pathophysiologic mechanism, and offer novel therapeutic opportunities for its treatment. CELL-TYPE SPECIFIC CHROMATIN PROFILING OF HUMAN MDD DISEASE SIGNATURE IDENTIFIES NOVEL EPIGENETIC MECHANISMS OF ASTROCYTE PLASTICITY DRIVING BIDIRECTIONAL STRESS RESPONSE

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Sasha Fulton[1], Jaroslav Bendl[1], John Fullard[2], Amni Al-Kachak[3], Panagiotis Roussos[4], Ian Maze[1]
[1]Icahn School of Medicine at Mount Sinai, Neuroscience, New Yorrk, United States of America, [2]Icahn School of Medicine at Mount Sinai, Nash Family Department Of Neuroscience And Friedman Brain Institute, New York, United States of America, [3]ISMMS, Neuroscience, New York, United States of America, [4]Department of Psychiatry, Icahn School Of Medicine At Mount Sinai, New York, United States of America

The overall risk for developing major depressive disorder (MDD) is determined by a complex interaction between heritable genetic variants and adverse experiences such as stress exposure. Mechanistic understanding of this gene-environment interface requires characterization of epigenomic processes within the unique regulatory context of complex human disease-relevant cell types, but to date this approach has not been applied to MDD. Although relatively understudied in MDD, the orbitofrontal cortex (OFC) integrates homeostatic states, emotion, and reward-stimuli to flexibly guide motivated behavior. Functional imaging studies consistently find significant OFC dysfunction in MDD patients, however, the molecular and cellular substrates underlying these neuroplastic changes in the OFC are not well understood. Here, we use cell population-specific chromatin accessibility profiling to capture the chromatin regulatory signature in MDD orbitofrontal cortex (OFC). We mapped genetic risk for MDD to open chromatin regions (OCRs) in non-neuronal OFC cell-types. Characterization of MDD-specific OCRs revealed a key role for the chromatin remodeling protein ZBTB7A, which facilitates transcription of inflammation genes, and is enriched in astrocytes, though its role in neuropsychiatric disease is unknown. In a series of astrocyte-specific bidirectional viral manipulation studies in preclinical mouse models, we further show that ZBTB7A chromatin remodeling activity specifically in OFC astrocytes is both necessary and sufficient to alter behavioral, transcriptional, and neuronal activity responses to stress. Together, these data demonstrate that epigenetic regulation of inflammatory signaling in astrocytes mediates both maladaptive and neuroprotective responses to stress, with direct implications for the central role of astrocyte plasticity in OFC dysfunction and MDD pathology.

Dopaminylation of histone H3 in ventral tegmental area regulates cocaine seeking.
Vulnerability to relapse during periods of attempted abstinence from cocaine use is hypothesized to result from the rewiring of brain reward circuitries, particularly ventral tegmental area (VTA) dopamine neurons. How cocaine exposures act on midbrain dopamine neurons to precipitate addiction-relevant changes in gene expression is unclear. We found that histone H3 glutamine 5 dopaminylation (H3Q5dop) plays a critical role in cocaine-induced transcriptional plasticity in the midbrain. Rats undergoing withdrawal from cocaine showed an accumulation of H3Q5dop in the VTA. By reducing H3Q5dop in the VTA during withdrawal, we reversed cocaine-mediated gene expression changes, attenuated dopamine release in the nucleus accumbens, and reduced cocaine-seeking behavior. These findings establish a neurotransmission-independent role for nuclear dopamine in relapse-related transcriptional plasticity in the VTA.

Histone H3 dopaminylation in ventral tegmental area underlies heroin-induced transcriptional and behavioral plasticity in male rats.
Persistent transcriptional events in ventral tegmental area (VTA) and other reward relevant brain regions contribute to enduring behavioral adaptations that characterize substance use disorder. Recent data from our laboratory indicate that aberrant accumulation of the newly discovered histone post-translational modification (PTM), H3 dopaminylation at glutamine 5 (H3Q5dop), contributes significantly to cocaine-seeking behavior following prolonged periods of abstinence. It remained unclear, however, whether this modification is important for relapse vulnerability in the context of other drugs of abuse, such

as opioids. Here, we showed that H3Q5dop plays a critical role in heroin-mediated transcriptional plasticity in midbrain regions, particularly the VTA. In rats undergoing abstinence from heroin self-administration (SA), we found acute and persistent accumulation of H3Q5dop in VTA. Attenuation of H3Q5dop during abstinence induced persistent changes in gene expression programs associated with neuronal signaling and dopaminergic function in heroin abstinence and led to reduced heroin-seeking behavior. Interestingly, the observed changes in molecular pathways after heroin SA showed significant yet reversed overlap with the same genes altered in cocaine SA. These findings establish an essential role for H3Q5dop, and its downstream transcriptional consequences, in heroin-induced functional plasticity in VTA.

Epigenetics of Drug Addiction.
Substance use disorders (SUDs) are chronic brain diseases characterized by transitions from recreational to compulsive drug use and aberrant drug craving that persists for months to years after abstinence is achieved. The transition to compulsive drug use implies that plasticity is occurring, altering the physiology of the brain to precipitate addicted states. Epigenetic phenomena represent a varied orchestra of transcriptional tuning mechanisms that, in response to environmental stimuli, create and maintain gene expression-mediated physiological outcomes. Therefore, epigenetic mechanisms represent a convergent regulatory framework through which the plasticity required to achieve an addicted state can arise and then persist long after drug use has ended. In the first section, we will introduce basic concepts in epigenetics, such as chromatin architecture, histones and their posttranslational modifications, DNA methylation, noncoding RNAs, and transcription factors, along with methods for their investigation. We will then examine the implications of these mechanisms in SUDs, with a particular focus on cocaine-mediated neuroepigenetic plasticity across multiple behavioral models of addiction.

Translational Molecular Approaches in Substance Abuse Research.
Excessive abuse of psychoactive substances is one of the leading contributors to morbidity and mortality worldwide. In this book chapter, we review translational research strategies that are applied in the pursuit of new and more effective therapeutics for substance use disorder (SUD). The complex, multidimensional nature of psychiatric disorders like SUD presents difficult challenges to investigators. While animal models are critical for outlining the mechanistic relationships between defined behaviors and genetic and/or molecular changes, the heterogeneous pathophysiology of brain diseases is uniquely human, necessitating the use of human studies and translational research schemes. Translational research describes a cross-species approach in which findings from human patient-based data can be used to guide molecular genetic investigations in preclinical animal models in order to delineate the mechanisms of reward circuitry changes in the addicted state. Results from animal studies can then inform clinical investigations toward the development of novel treatments for SUD. Here we describe the strategies that are used to identify and functionally validate genetic variants in the human genome which may contribute to increased risk for SUD, starting from early candidate gene approaches to more recent genome-wide association studies. We will next examine studies aimed at understanding how transcriptional and epigenetic dysregulation in SUD can persistently alter cellular function in the disease state. In our discussion, we then focus on examples from the literature illustrating molecular genetic methodologies that have been applied to studies of different substances of abuse - from alcohol and nicotine to stimulants and opioids - in order to exemplify how these approaches can both delineate the underlying molecular systems driving drug addiction and provide insights into the genetic basis of SUD.

CONTRIBUTION OF C-FOS EXPRESSION IN THE ARCUATE NUCLEUS TO THE DEVELOPMENT OF OBESITY IN MIRNA-DEFICIENT MICE

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Joanna Przybys, Ali Jawaid, Witold Konopka
Nencki Institute of Experimental Biology, PAS, Braincity, Warsaw, Poland

Conditional/inducible miRNAs deletion from adult forebrain neurons in mice lacking the *Dicer1* gene (Dicer cKO) leads to transient hyperphagia and obesity. The arcuate nucleus (Arc) of the hypothalamus plays a key role in regulation of hunger and satiety via its AgRP and POMC neurons respectively. Here, we show that miRNAs and immediate early gene (IEG) c-*Fos* are intricately involved in this regulation. Fasting of wild-type mice for 24 hours induces a wide-spread expression of *c-Fos* in the Arc indicating its relevance to the activity of Arc. However, contrary to the usual rapid turnover properties of IEGs, c-*Fos* exhibits a strong and persistent expression throughout the fasting period indicating its sensitivity to the state of hunger in the study. To investigate the identity of *c-Fos* as an IEG, we performed optogenetic experiment in well-fed mice. Optogenetic activation of the AgRP neurons in the Arc induced feeding along with increased expression of c-*Fos* that returned to baseline after canonical 6 hours. Furthermore, we detected upregulated c-Fos in the resting phase in hyperphagic Dicer cKO mice. Thus, dysregulation of c-Fos in the Arc could underlie the hyperphagia and resultant obesity in Dicer cKO mice. Overall, our findings indicate an intimate association between miRNAs and the *c-Fos* gene in regulating the activity/plasticity of neurons involved in controlling the body's energy balance. Our ongoing investigations focus on silencing c-Fos in Dicer cKO mice to fully establish its role in mediating the effects of deficient miRNA biogenesis in the Arc on feeding behaviors and whole body metabolism in mice.

REGION-SPECIFIC MICRORNA ALTERATIONS IN MARMOSETS CARRYING SLC6A4 POLYMORPHISMS ARE ASSOCIATED WITH ANXIETY-LIKE BEHAVIOR

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Natalia Popa[1], Angela Roberts[2], Andrea Santangelo[2], Eduardo Gascon[1]

Psychiatric diseases such as depression and anxiety are multifactorial conditions, highly prevalent in western societies. Human studies have identified a number of high-risk genetic variants for these diseases. Among them, polymorphisms in the promoter region of the serotonin transporter gene (SLC6A4) have attracted much attention. However, due to the paucity of experimental models, molecular alterations induced by these genetic variants and how they correlate to behavioral deficits have not been examined. Marmosets have emerged as a powerful model in translational neuroscience to investigate molecular underpinnings of complex behaviors. Here, we took advantage of naturally occurring genetic polymorphisms in marmoset *SLC6A4* gene that have been linked to anxiety-like behaviors. Using FACS-sorted cells from different brain regions, we revealed that marmosets bearing different *SLC6A4* variants exhibit distinct microRNAs signatures in a region of the prefrontal cortex whose activity has been consistently altered in patients with depression/anxiety. We also identified DCC, a gene previously linked to these diseases, as a downstream target of the dysregulated microRNAs. Significantly, we showed that levels of both microRNAs and DCC in this region were highly correlated to anxiety-like behaviors as well as to the response to citalopram, a selective serotonin re-uptake inhibitor and widely prescribed anti-depressant. Our findings establish links between genetic variants, molecular modifications in specific cortical regions and complex behavioral/pharmacological responses, providing new insights into gene-behavior relationships underlying human psychopathology.

Although intensively studied in the last decades, how microRNAs are expressed across different cell types in the brain remains largely unknown. To address this issue, we sought to develop optimized fluorescence reporters that could be expressed in precise cellular subsets and used to accurately quantify miR contents in vivo. Focusing on miR-124, we tested different reporter designs whose efficiency was initially confirmed in vitro. Then, we packed them into AAV vectors and test them in cultured neurons as well in different in vivo settings. Unlike previous reporters, we provide experimental evidence that our optimized designs can faithfully translate miR levels in vitro and in vivo. More importantly, we show that these reporters can be used not only for mapping miRNA expression but also for the prospective identification in vivo of different neuronal subsets. Together, such tools would enable assessing miRNA expression at the single cell resolution and are expected to significantly contribute to future miRNA research.

INDIVIDUAL DIFFERENCES IN DNA METHYLATION ASSOCIATED WITH SENSITIVITY AND RESISTANCE TO THE EXTINCTION OF COCAINE MEMORIES

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Madelyn Baker[1], Caitlin Burgdorf[1], Faten Taki[2], Elizabeth Brindley[2], Anjali Rajadhyaksha[3], Miklos Toth[2]
[1]Weill Cornell Medicine, Department Of Neuroscience, New York, United States of America, [2]Weill Cornell Medicine, Department Of Pharmacology, New York, United States of America, [3]Weill Cornell Medicine, Pediatric Neurology, New York, United States of America

Cocaine addiction is a chronic condition in which craving and drug seeking can be elicited by drug-associated cues. In rodents, this can be modeled using conditioned place preference (CPP) wherein animals acquire a preference for a chamber where they receive cocaine. Once place preference is acquired, the drug-associated memory can be extinguished by repeated exposure to the previously cocaine-paired environment. However, some mice fail to extinguish, continuing to prefer the previously cocaine-paired side. Animals that fail to extinguish the previously drug-associated memory could provide insight into individual differences in vulnerability to drug dependence. To identify a possible underlying epigenetic mechanism, we analyzed the DNA methylomes of the dorsal dentate gyrus of Extinction and Failed Extinction mice. These animals showed differentially methylated regions (DMRs; genomic regions with significantly different methylation between groups). Genome-wide methylation analysis showed that Intermediate Methylated Regions (IMRs; methylation between 15-85%) were hypo- or hyper-methylated after successfully extinguishing the drug-paired memory. An Ingenuity Pathway Analysis of extinction DMRs showed enrichment for genes within an activity-dependent calcium and glutamate pathway. One differentially methylated gene in this pathway is *cacna1c*, which encodes the $Ca_v1.2$ isoform of the L-type voltage-gated calcium channel, a gene implicated in drug dependence. Supporting the role of this methylation data, there was an increase in *cacna1c* mRNA and protein only in animals with successful extinction. Taken together, this preliminary work suggests differences in DNA methylation within the dorsal dentate gyrus could dictate underlying differences that lead to a propensity to develop drug dependence.

Prepubertal and adult male rats differ in the degree and pattern of stress reactive neurons in brain regions that project to the paraventricular nucleus of the hypothalamus.
The hormonal stress response, mediated by the hypothalamic-pituitary-adrenal (HPA) axis, shows greater responsiveness to various stressors in prepubertal compared to adult animals. Though the implications of this age-related change are unclear, this heightened reactivity might contribute to the increase in stress-related dysfunctions observed during adolescence. Interestingly, prepubertal animals show greater stress-induced neural activation compared to adults in the paraventricular nucleus of the hypothalamus (PVN), the area responsible for initiating the hormonal stress response. Thus, it is possible that direct afferents to the PVN, such as the anterior bed nucleus of the stria terminalis (aBST), nucleus of the solitary tract (NTS), posterior BST (pBST), medial preoptic area (MPOA), and dorsomedial nucleus (DMN), contribute to this age-dependent change in reactivity. To investigate these possibilities, two separate experiments were conducted in prepubertal (30 days old) and adult (70 days old) male rats using the retrograde tracer, Fluoro-Gold (FG), and FOS immunohistochemistry to study neural connectivity and activation, respectively. Though there was no difference in the number or size of FG-positive cells in the PVN afferents we examined, we found a significantly greater number of stress-induced FOS-like-positive cells in the aBST and significantly fewer in the DMN in prepubertal compared to adult animals. Together these data suggest that functional, instead of structural, changes in nuclei that project to the PVN may lead to the greater PVN stress responsiveness observed prior to adolescence. Furthermore, these data indicate that nuclei known to directly modulate HPA stress responsiveness show differential activation patterns before and after adolescent development.
Brain Res, 2021; 1760

Adolescent changes in hindbrain noradrenergic A2 neurons in male rats.
During adolescence, the increased susceptibility to stress-related dysfunctions (e.g., anxiety, drug use, obesity) may be

influenced by changes in the hormonal stress response mediated by the hypothalamic-pituitary-adrenal (HPA) axis. We have previously reported that restraint stress leads to significantly prolonged HPA responses in pre-adolescent compared to adult rats. Further, pre-adolescent animals exposed to restraint show greater levels of neural activation than adults in the paraventricular nucleus of the hypothalamus (PVN), a key nucleus integrating information from brain regions that coordinate HPA responses. Here, we examined the potential contribution of the noradrenergic A2 region of the nucleus of the solitary tract (NST) as a contributor to these age-dependent shifts in HPA reactivity. Specifically, we used double-labeled immunohistochemistry for FOS and dopamine-β-hydroxylase (DβH) to measure cellular activation and noradrenergic cells, respectively, before or after restraint stress in pre-adolescent (30days old) and adult (70days old) male rats. We also measured the density of DβH-immunoreactive fibers in the PVN as an index of noradrenergic inputs to this area. We found that pre-adolescent animals have a greater number of DβH-positive cells in the A2 region compared to adults, yet the number and percentage of double-labeled DβH/FOS cells were similar between these two ages. We found no differences between the ages in the staining intensity of DβH-immunoreactive fibers in the PVN. These data indicate there are adolescent-related changes in the number of noradrenergic cells in the A2 region, but no clear association between the increased stress reactivity prior to pubertal maturation and activation of A2 noradrenergic afferents to the PVN.
Brain Res, 2017; 1666

Neuroendocrine stress reactivity of male C57BL/6N mice following chronic oral corticosterone exposure during adulthood or adolescence.

Adolescence is associated with the maturation of the hypothalamic-pituitary-adrenal (HPA) axis, the major neuroendocrine axis mediating the hormonal stress response. Adolescence is also a period in development marked by a variety of stress-related vulnerabilities, including psychological and physiological dysfunctions. Many of these vulnerabilities are accompanied by a disrupted HPA axis. In adult mice, a model of disrupted HPA function has been developed using oral chronic corticosterone administration via the drinking water, which results in various physiological and neurobehavioral abnormalities, including changes in stress reactivity and anxiety-like behaviors. In an effort to further complement and extend this model, we tested the impact of HPA disruption in adolescent mice. We also examined whether this disruption led to different outcomes depending on whether the treatment happened during adolescence or adulthood. In the current set of experiments, we exposed adult (70days of age) or adolescent (30days of age) male C57BL/6N mice to 4 weeks of either 0 or 25µg/ml oral corticosterone via their drinking water. We measured body weight during treatment and plasma corticosterone levels and activation of the paraventricular nucleus (PVN), as indexed by FOS immunohistochemistry, before and after a 30min session of restraint stress. Our data indicate that adolescent animals exposed to chronic corticosterone showed weight loss during treatment, an effect not observed in adults. Further, we found stress failed to elevate plasma corticosterone levels in treated mice, regardless of whether exposure occurred in adulthood or adolescence. Despite this reduced hormonal responsiveness, we found significant neural activation in the PVN of both adult- and adolescent-treated mice, indicating a dissociation between stress-induced peripheral and central stress responses following chronic corticosterone exposure. Moreover, stress-induced neural activation in the PVN was unaffected by chronic corticosterone treatment in adult animals, but led to a hyper-responsive PVN in the corticosterone-treated adolescent animals, suggesting an age-specific effect of corticosterone treatment on later PVN stress reactivity. Together, these experiments highlight the influence of developmental stage on somatic and neuroendocrine outcomes following chronic HPA disruption by noninvasive, oral corticosterone treatment. Given the substantial vulnerabilities to HPA dysfunctions during adolescence this model may prove useful in better understanding these vulnerabilities.

A BIOPHYSICAL MECHANISM FOR EPIGENETIC INHERITANCE OF ENHANCED COMPLEX LEARNING CAPABILITIES

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Samaa Zidan Sweed[1], Alaa Saleh[1], Shai Berlin[2], Jackie Schiller[2], Edi Barkai[1]
[1]University of Haifa, Neurobiology, Haifa, Israel, [2]Technion, Department Of Physiology, Haifa, Israel

Rule learning is mediated by enhanced intrinsic neuronal excitability throughout the neuronal population of the relevant brain areas,which results from decreased conductance of a calcium-dependent potassium current(s), which is induced by metabotropic activation of the GluK2 subtype glutamatergic receptor, mediated by well identified second messenger systems. Here we show that rats trained in a complex olfactory-discrimination pass on trans-generationally to their offspring superb learning capabilities. Such inheritance is also evident when only one of the parents is trained, if fostered by non-trained females and if the F2 or F3 generation is trained,without any training of the F1 generation.Notably, offspring excel also in other, novel tasks. At the cellular level, intracellular neurophysiological recordings show that the intrinsic excitability of CA1 pyramidal neurons of trained rat`s offspring is higher compared to control, as result of reduction in the slow potassium current(s), the same change induced in the brains of the F0 rats after they acquire the rule. Thus, offspring are superb learners since they are born with neurons that show the same biophysical change induced in parents' brains by rule learning. Analysis of mRNA expression levels show that the hippocampi of trained offspring differs from the controls offspring hippocampi in more than 500 genes. In particular,we found downregulation of genes that code for channels that suppress intrinsic excitability, as well as downregulation of genes that code for synaptic receptors. We speculate that these changes create a favorable set point for future increased plasticity, thereby granting trained rats' offspring with superb learning capabilities.

SIRTUINS MODULATORS COUNTERACT MITOCHONDRIAL DYSFUNCTION IN CHEMICAL AND NEONATAL HYPOXIA: IMPLICATION TO NEURODEVELOPMENTAL DISORDERS

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Luiz Felipe Souza E Silva, Amanda Siena, Ana Orellana, Tatiana Rosenstock
University of São Paulo, Institute Of Biomedical Sciences, São Paulo, Brazil

The hypoxia is an environmental factor correlated with complications in neurodevelopment because of mitochondrial dysfunction. Once sirtuins are involved in the regulation of cellular metabolism we investigated whether sirtuins modulators could be a neuroprotective strategy against hypoxia. We used primary neurons of Wistar (control), and Spontaneous Hypertensive Rats (model of neonatal hypoxia and schizophrenia) exposed to chemical hypoxia ($CoCl_2$). The cells were treated with $CoCl_2$ (800 µM and 2 mM) for 24h previously and simultaneously stimulated with Nicotinamide (50 µM), Resveratrol (0.5 µM) and Sirtinol (5 µM) (48h). We measured: calcium levels with Fluo-4-AM (10 µM), mitochondrial membrane potential with TMRE (500 nM), and redox homeostasis. Moreover, genes related to mitochondrial metabolism, dynamics, and biogenesis, as well high-energy compounds levels were investigated. The chemical and neonatal hypoxia induced mitochondrial depolarization, disruption in Ca^{2+} handling, and raising in ROS, *Nfe2l2* and mitochondrial biogenesis and fission gene expression. Hypoxia also induced a decrease in ATP levels and an increase in pyruvate and lactate levels. The previous exposure to all sirtuins modulators reduced ROS, boosted *Nfe2l2* expression, and increased mitochondrial fusion genes expression and pyruvate levels. Altogether, our results suggest that sirtuins modulators could be used as a neuroprotective strategy. These data contribute to a better comprehension of hypoxia effects in neuronal function, adding new bricks to mitochondrial function knowledge and its relation to neurodevelopmental disorders. 2022 - 2018/13814-0 - Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP).

Mitochondrial Dysfunction and Changes in High-Energy Compounds in Different Cellular Models Associated to Hypoxia: Implication to Schizophrenia.
Schizophrenia (SZ) is a multifactorial mental disorder, which has been associated with a number of environmental factors, such as hypoxia. Considering that numerous neural mechanisms depends on energetic supply (ATP synthesis), the maintenance of mitochondrial metabolism is essential to keep cellular balance and survival. Therefore, in the present work, we evaluated functional parameters related to mitochondrial function, namely calcium levels, mitochondrial membrane potential, redox homeostasis, high-energy compounds levels and oxygen consumption, in astrocytes from control (Wistar) and Spontaneously Hypertensive Rats (SHR) animals exposed both to chemical and gaseous hypoxia. We show that astrocytes after hypoxia presented depolarized mitochondria, disturbances in Ca handling, destabilization in redox system and alterations in ATP, ADP, Pyruvate and Lactate levels, in addition to modification in NAD/NADH ratio, and Nfe2l2 and Nrf1 expression. Interestingly, intrauterine hypoxia also induced augmentation in mitochondrial biogenesis and content. Altogether, our data suggest that hypoxia can induce mitochondrial deregulation and a decrease in energy metabolism in the most prevalent cell type in the brain, astrocytes. Since SHR are also considered an animal model of SZ, our results can likewise be related to their phenotypic alterations and, therefore, our work also allow an increase in the knowledge of this burdensome disorder.

DECIPHERING THE ROLE OF A NON-NEURONAL LNCRNA IN AGE-ASSOCIATED CONGNITIVE DISEASES

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Sophie Schröder[1], M. Sadman Sakib[1], Andre Fischer[1,2,3]
[1]German Center for Neurodegenerative Diseases, Department For Epigenetics And Systems Medicine In Neurodegenerative Diseases, Göttingen, Germany, [2]University Medical Center, Department Of Psychiatry And Psychotherapy, Göttingen, Germany, [3]University of Göttingen, Cluster Of Excellence “multiscale Bioimaging: From Molecular Machines To Networks Of Excitable Cells” (mbexc), Göttingen, Germany

Long non-coding RNAs (lncRNAs) are emerging as important regulators of neuronal plasticity and have recently been linked to the onset and progression of neurodegenerative diseases. However, our knowledge about the role of CNS-specific lncRNAs in neuronal and non-neuronal cells is still limited. The aim of this project was to identify cell type specific expression changes of non-neuronal lncRNAs in the context of age-associated neurodegenerative diseases and to characterize their function. To this end we performed an RNA sequencing-based screening in the hippocampus of young and cognitively impaired aged mice. We identified multiple candidate lncRNAs for further analysis and studied their role in the relevant cell types via gain and loss of function approaches. Our data reveals that the candidate lncRNAs regulate several key cellular pathways and could serve as biomarker for cognitive decline and therapeutic interventions via RNA-based medicines.

Aim: The ApoE4 gene has been established as the strongest genetic risk factor for Alzheimer's disease and Dementia with Lewy bodies (DLB). However, the mechanisms by which ApoE4 contributes to aetipathogenesis of either of these diseases remain unclear. ApoE is the major lipoprotein in the CNS, predominately produced by astrocytes, playing an important role in transport and neuronal uptake of cholesterol. We hypothesized that the presence of its e4 allelic variant could impact cellular epigenetic regulations, hence modifying cellular functions. To that aim, we established neuronal and astrocytic acetylation-related epigenomes of ApoE4 and ApoE3 transgenic models with or without inclusion of pathological α-synuclein fibrils – causative agents of DLB neuropathology. **Methods:** The genome-wide epigenomic distribution of two acetylated histone marks (H3K27ac and H3K9ac) was assessed by CUT&Tag followed by deep sequencing, on magnetically isolated hippocampal neurons and astrocytes from ApoE4 and ApoE3 (control) KI murine models. Same methodology was conducted on the aforementioned models 2 months following hippocampal stereotaxic injections of α-synuclein preformed fibrils (PFF) or PBS (control). **Results:** Epigenomic data revealed deacetylation of astrocytic and hyperacetylation of neuronal epigenomic landscapes with matrisome and lipid metabolism pathways as most dysregulated solely under the ApoE4 influence. Introduction of PFFs displayed additional upregulation of neuronal inflammatory pathways regardless of the ApoE genotype, while genes comprising phosphorylation processes and synapse-related functions were found specifically dysregulated by the e4 allelic variant of ApoE. **Conclusion:** Overall, our findings provide differences in cell-type specific epigenetic profiles influenced by either the ApoE4 risk factor and/or α-synuclein PFFs.

UNRAVELLING MOLECULAR EPIGENETIC MECHANISMS IN HUMAN BRAIN DEVELOPMENT

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Ninoslav Pandiloski[1], Christopher Douse[2], Jon Matas[2], Ofelia Karlsson[3], Jenny Johansson[2], Johan Jakobsson[4]
[1]Lund University, Emv, Lund, Sweden, [2]Lund University,, Department Of Experimental Medical Sciences, Lund, Sweden, [3]Lund University, Department Of Experimental Medical Science, Wallenberg Neuroscience Center And Lund Stem Cell Center, Lund, Sweden, [4]Lund University, Department Of Experimental Medical Sciences, Lund, Sweden

Allowing for a dynamic expression of genes, epigenetic regulation plays a key role in human brain development. Thus, identifying mechanisms of epigenetic regulation has an immense importance in developmental neurobiology, where conservation of gene expression patterns is crucial. Dysregulation of the epigenome can lead to devastating consequences by altering the cell's expression profile, both during embryonic and adult neurogenesis. In particular, the aberrant expression of transposable elements (TEs) has been shown to cause neuroinflammation. TEs have contributed to human evolution by acting as non-classical transcription regulators and gene promoters, displaying their ability to cause neuronal variations. This suggests that proper epigenetic regulation of TEs is necessary for healthy brain development. This project investigates the contributions and the mechanistic model of the human silencing hub (HUSH complex) in the regulation of TEs in human neural stem cells. Differential expression analyses was employed to compare control and CRISPRi cells, revealing an upregulation of 295 individual elements (p-adj < 0.05; LFC >=1). Furthermore, analysis of the histone methylation patterns supported the model of HUSH regulating H3K9me3 over its targets, supporting the importance of HUSH in neurogenesis. Future outlooks of this project involve expanding similar strategies to general cell regulators that also control TE activity such as DNMT1, DNMT3A/B and SETDB1. With this project we aim to reach greater understanding of the connection between cell regulators and TEs in human brain development

DYSREGULATION OF THE CHOLESTEROL PATHWAY ALTERS EPIGENOMIC SIGNATURES OF HIPPOCAMPAL NEURONS IN ALZHEIMER'S DISEASE

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Isabel Paiva[1], Jonathan Seguin[1], Brigitte Cosquer[1], Damien Plassard[2], Stephanie Le Gras[2], Laura Tzeplaeff[1], Rafael Alcalá Vida[1], Luc Buée[3], David Blum[3], Jean-Christophe Cassel[1], Karine Merienne[1], Tapas Kundu[4], Anne-Laurence Boutillier[1]
[1]University of Strasbourg, Lnca Umr7364 - Cnrs/unistra, Strasbourg, France, [2]GenomEast Platform, Institut De Génétique Et De Biologie Moléculaire (igbmc), Strasbourg, France, [3]Lille Neuroscience & Cognition, Alzheimer & Tauopathies, Lille, France, [4]Transcription and Disease Laboratory, Molecular Biology and Genetics Unit, Jawaharlal Nehru Centre For Advanced Scientific Research, Bangalore, India

Objectives: Alzheimer's disease (AD), the most common form of dementia, is characterized by the presence of β-amyloid plaques and neurofibrillary tangles (containing hyperphosphorylated Tau protein). Aging is suggested to be the main AD risk factor. Dysregulated epigenetic mechanisms such as histone acetylation have been associated with both aging and AD. However, whether/how aging-deregulated events contribute to AD is unknown. We aimed to establish epigenetic/transcriptomic signatures in physiological and pathological AD/Tau aging. **Methods:** We investigated the marker of active transcription H3K27ac at genome-wide level (ChIP-seq) and transcriptomics (RNA-seq) in the hippocampus of 12-month-old THY-Tau22 mice (tauopathy) as well as 18-*versus* 3-month-old WT mice (aging). **Results:** Epigenomic data revealed opposite H3K27ac enrichments between aging and tauopathy: synaptic transmission and glutamate receptor genes were found enriched in tauopathic hippocampi whereas these regions were depleted in aged ones. At transcriptomic level, while aging and tauopathy shared a common inflammatory signature, cholesterol metabolism-genes were found exclusively decreased in tauopathic mice. Excitingly, epigenetic treatment using the histone acetyltransferase activator CSP-TTK21 restored recognition memory in tauopathic mice. Additionally, this treatment rescued the expression of cholesterol metabolism genes and proper epigenomic signatures, suggesting a link between these two events. **Conclusion:** Overall, our findings suggest that tauopathy is not an exacerbation of the epigenetic drift observed during the aging process but rather an epigenetic/histone acetylation upsurge resulting from the dysregulation of the cholesterol pathway. Further, CSP-TTK21 revealed to be a promising new "epidrug" to counteract memory impairment, through modulation of brain cholesterol biosynthesis, in the pathological condition of AD.

EFFECTS OF ADOLESCENT ETHANOL EXPOSURE ON HIPPOCAMPAL MICRORNA EXPRESSION.

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Ana Vázquez-Ágredos, Fernando Gamiz, Milagros Gallo
University of Granada, Department Of Psychobiology, Institute Of Neurosciences, Center Of Biomedical Research, Armilla, Spain

Ethanol has been shown to induce epigenetic changes with increasing interest in its effect on small non-coding RNAs (about 19-24 nucleotides), known as microRNAs (miRNAs). They can regulate the expression of a wide variety of genes interfering with brain development and function. Despite the fact that alcohol voluntary consumption begins in adolescence and is widely spread at this stage, research on the miRNAs changes produced by alcohol consumption has focused on prenatal exposure. The aim of this study was to explore if the repeated exposure to alcohol during adolescence would alter normal miRNA hippocampal expression patterns that undergo reorganization during this neurodevelopmental period as well as the potential long-term persistence into adulthood. Twenty-two adolescent male rats received intermittent 2g/kg alcohol (AIE) or volume-matched saline (AIS) by intraperitoneal injections on a 2 day on/off schedule from PND-28 to PND-41. Half of the subjects were sacrificed on the last day of AIE/AIS and we extracted the brains to test short-term on the hippocampus. The other half were sacrificed on PND-98 to assess long-term effects in the same area. The design allows us to explore the hippocampal expression patterns of miRNAs related to both alcohol consumption and adolescent brain development. The results are relevant to understanding the epigenetic short- and long-term impact of alcohol intake during adolescence on brain development. Caloric Restriction in Group-Housed Mice: Littermate and Sex Influence on Behavioral and Hormonal Data.
Much of the research done on aging, oxidative stress, anxiety, and cognitive and social behavior in rodents has focused on caloric restriction (CR). This often involves several days of single housing, which can cause numerous logistical problems, as well as cognitive and social dysfunctions. Previous results in our laboratory showed the viability of long-term CR in grouped rats. Our research has studied the possibility of CR in grouped female and male littermates and unrelated CB6F1/J (C57BL/6J × BALBc/J hybrid strain) mice, measuring: (i) possible differences in body mass proportions between mice in and CR conditions (at 70% of), (ii) aggressive behavior, using the number of and as an indicator and social behavior using the as indicator, and (iii) difference in serum adrenocorticotropic hormone (ACTH) concentrations (stress biomarker), under and CR conditions. Results showed the impossibility of implementing CR in unrelated male mice. In all other groups, CR was possible, with a less aggressive behavior (measured only with the number of) observed in the unrelated female mice under CR conditions. In that sense, the ACTH levels measured on the last day of CR showed no difference in stress levels. These results indicate that implementantion of long-term CR in mice can be optimized technically and also related to their well-being by grouping animals, in particular, related mice.

Consummatory Successive Negative Contrast in Rats.
Using animal models in addiction and pain research is pivotal to unravel new pathways and mechanisms for the treatment of these disorders. Reward devaluation through a consummatory successive negative contrast (cSNC) task has shown the ability to reduce physical pain sensitivity (hypoalgesia) and increase oral ethanol consumption in rats. The procedure is based on exposing the experimental animals to a 32% sucrose solution during several sessions (preshift sessions) followed by a devaluation to 4% sucrose during the next few sessions (postshift sessions). The cSNC effect can be monitored by comparing the experimental group to an unshifted control that had access to 4% sucrose throughout the entire experiment (preshift and postshift sessions). The cSNC phenomenon is defined by lower consumption of sucrose in the downshifted group than in the unshifted group during postshfit sessions.

UNCOVERING THE SIGNALING PATHWAYS TO COGNITIVE IMPAIRMENTS AND NEURODEGENERATION IN DOWN SYNDROME BY CELL PROFILING OF THE LOCUS COERULEUS IN TRISOMIC MICE

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Marta Fructuoso[1], Ammara Mohammad[1,2], Riwan Brillet[3], David Akbar[4], Justine Guegan[3], Laura Xicota[1], Marie-Claude Potier[1]
[1]Paris Brain Institute, ICM, Hopital de la Pitie-Salpetriere, Team “alzheimer’s And Prion Diseases”, Paris, France, [2]Paris Brain Institute, Icm-igenseq Genotyping And Sequencing Platform, Paris, France, [3]Paris Brain Institute, Data Analysis Core, Paris, France, [4]Paris Brain Institute, Icm.quant Platform, Paris, France

Alzheimer's disease is frequent and occurs earlier in individuals with Down syndrome (DS) as compared to sporadic AD. The locus coeruleus (LC), the region containing the neurons producing the noradrenaline, degenerates in diseases associated with dementia, such as AD, DS, and Parkinson's disease (PD). Although LC cell loss is associated with aging, DS demented cases exhibit pathology similar to AD brains despite their younger age.
We hypothesized that the risk for dementia in DS could rely on a defective noradrenergic system, partially due to their genetic condition. Using a DS mouse model, here we showed impaired behavior in tasks as compared to control mice. To uncover the signaling pathways that may underlie some of the cognitive deficits, we performed a bulk RNA-sequencing analysis in the LC from individual mice using laser microdissection. This experiment revealed differential expression patterns in LC between genotypes for different biological processes related to subcellular transport.
In parallel, we optimized a protocol for the cell dissociation of fresh LC from adult mice, and performed single cell RNA-sequencing (scRNAseq). Our preliminary analysis revealed more than 5,000 common expressed genes between Bulk-RNAseq and scRNAseq experiments. Moreover, cells clustered in 12 different groups, which suggest a rich cell diversity despite the reduced size of the brain region.
Single-cell profiling of the LC in trisomic mice offers exciting opportunities to reveal molecular basis for neurodegeneration in DS. We hope our work will be useful in understanding dementia in DS but also in AD, and PD, all conditions with LC pathology.

TRANSPOSABLE ELEMENT-MEDIATED LOCAL HETEROCHROMATIN IN X-LINKED DYSTONIA PARKINSONISM

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Vivien Horvath, Marie Jönsson, Raquel Garza, Pia Johansson, Christopher Douse, Johan Jakobsson
Lund University,, Department Of Experimental Medical Sciences, Lund, Sweden

Neurodegenerative disorders affect millions of people worldwide, but in most cases the genetic causes remain poorly understood. In recent years transposable elements (TEs) have been suggested as novel players in the development of neurodegenerative disorders, and the discovery of a polymorphic TE allele causing X-linked Dystonia Parkinsonism (XDP) strengthened this hypothesis. The XDP specific TE was identified in intron 32 of transcriptional regulator gene *TAF*1 and has been associated with its downregulation and the retention of intron 32. We hypothesize that these alterations in transcription and splicing are caused by the formation of a local heterochromatin as a result of the recruitment of TRIM28 to the TE insertion through a KRAB-Zinc Finger protein (KZFP). To study this, we developed a novel, XDP patient derived neuroepithelial like stem (NES) cell model. By using our XDP cell model and the CRISPRi technique first we inhibited the expression of TRIM28, to see its role in *TAF1* gene regulation. We found no effect on the *TAF1* gene expression nor on intron 32 retention, however nearly 300 TE families were up-regulated in the TRIM28 CRIPSRi NES cells. When we inhibited the expression of the KZFP putatively binding the TE insertion, we found recovered *TAF1* expression, but no effect on the intron retention nor on TEs. Our results suggest that the interplay of the TRIM28/KZFP complex is influencing the alterations in *TAF1* expression level while keeping TEs under control. Overall, this exciting finding points to an important role for polymorphic TE insertions in influencing human health.

Distinct subcellular autophagy impairments in induced neurons from Huntington's disease patients.
Huntington's disease (HD) is a neurodegenerative disorder caused by CAG expansions in the huntingtin (HTT) gene. Modelling Huntington's disease is challenging, as rodent and cellular models poorly recapitulate the disease as seen in aging humans. To address this, we generated induced neurons (iNs) through direct reprogramming of human skin fibroblasts, which retain age-dependent epigenetic characteristics. HD-iNs displayed profound deficits in autophagy, characterised by reduced transport of late autophagic structures from the neurites to the soma. These neurite-specific alterations in autophagy resulted in shorter, thinner and fewer neurites specifically in HD-iNs. CRISPRi-mediated silencing of HTT did not rescue this phenotype but rather resulted in additional autophagy alterations in ctrl-iNs, highlighting the importance of wild type HTT in normal neuronal autophagy. In summary, our work identifies a distinct subcellular autophagy impairment in adult patient derived Huntington's disease neurons and provides a new rational for future development of autophagy activation therapies. Drosophila Evolution over Space and Time (DEST): A New Population Genomics Resource.
Drosophila melanogaster is a leading model in population genetics and genomics, and a growing number of whole-genome data sets from natural populations of this species have been published over the last years. A major challenge is the integration of disparate data sets, often generated using different sequencing technologies and bioinformatic pipelines, which hampers our ability to address questions about the evolution of this species. Here we address these issues by developing a

bioinformatics pipeline that maps pooled sequencing (Pool-Seq) reads from D. melanogaster to a hologenome consisting of fly and symbiont genomes and estimates allele frequencies using either a heuristic (PoolSNP) or a probabilistic variant caller (SNAPE-pooled). We use this pipeline to generate the largest data repository of genomic data available for D. melanogaster to date, encompassing 271 previously published and unpublished population samples from over 100 locations in >20 countries on four continents. Several of these locations have been sampled at different seasons across multiple years. This data set, which we call Drosophila Evolution over Space and Time (DEST), is coupled with sampling and environmental metadata. A web-based genome browser and web portal provide easy access to the SNP data set. We further provide guidelines on how to use Pool-Seq data for model-based demographic inference. Our aim is to provide this scalable platform as a community resource which can be easily extended via future efforts for an even more extensive cosmopolitan data set. Our resource will enable population geneticists to analyze spatiotemporal genetic patterns and evolutionary dynamics of D. melanogaster populations in unprecedented detail.

31175824: Villanueva-Cañas JL, Horvath V, Aguilera L, González J
Diverse families of transposable elements affect the transcriptional regulation of stress-response genes in Drosophila melanogaster.
Although transposable elements are an important source of regulatory variation, their genome-wide contribution to the transcriptional regulation of stress-response genes has not been studied yet. Stress is a major aspect of natural selection in the wild, leading to changes in the transcriptional regulation of a variety of genes that are often triggered by one or a few transcription factors. In this work, we take advantage of the wealth of information available for Drosophila melanogaster and humans to analyze the role of transposable elements in six stress regulatory networks: immune, hypoxia, oxidative, xenobiotic, heat shock, and heavy metal. We found that transposable elements were enriched for caudal, dorsal, HSF, and tango binding sites in D. melanogaster and for NFE2L2 binding sites in humans. Taking into account the D. melanogaster population frequencies of transposable elements with predicted binding motifs and/or binding sites, we showed that those containing three or more binding motifs/sites are more likely to be functional. For a representative subset of these TEs, we performed in vivo transgenic reporter assays in different stress conditions. Overall, our results showed that TEs are relevant contributors to the transcriptional regulation of stress-response genes.

Stress response, behavior, and development are shaped by transposable element-induced mutations in Drosophila.
Most of the current knowledge on the genetic basis of adaptive evolution is based on the analysis of single nucleotide polymorphisms (SNPs). Despite increasing evidence for their causal role, the contribution of structural variants to adaptive evolution remains largely unexplored. In this work, we analyzed the population frequencies of 1,615 Transposable Element (TE) insertions annotated in the reference genome of Drosophila melanogaster, in 91 samples from 60 worldwide natural populations. We identified a set of 300 polymorphic TEs that are present at high population frequencies, and located in genomic regions with high recombination rate, where the efficiency of natural selection is high. The age and the length of these 300 TEs are consistent with relatively young and long insertions reaching high frequencies due to the action of positive selection. Besides, we identified a set of 21 fixed TEs also likely to be adaptive. Indeed, we, and others, found evidence of selection for 84 of these reference TE insertions. The analysis of the genes located nearby these 84 candidate adaptive insertions suggested that the functional response to selection is related with the GO categories of response to stimulus, behavior, and development. We further showed that a subset of the candidate adaptive TEs affects expression of nearby genes, and five of them have already been linked to an ecologically relevant phenotypic effect. Our results provide a more complete understanding of the genetic variation and the fitness-related traits relevant for adaptive evolution. Similar studies should help uncover the importance of TE-induced adaptive mutations in other species as well.

Revisiting the Relationship between Transposable Elements and the Eukaryotic Stress Response.
A relationship between transposable elements (TEs) and the eukaryotic stress response was suggested in the first publications describing TEs. Since then, it has often been assumed that TEs are activated by stress, and that this activation is often beneficial for the organism. In recent years, the availability of new high-throughput experimental techniques has allowed further interrogation of the relationship between TEs and stress. By reviewing the recent literature, we conclude that although there is evidence for a beneficial effect of TE activation under stress conditions, the relationship between TEs and the eukaryotic stress response is quite complex.

Cool Headed Individuals Are Better Survivors: Non-Consumptive and Consumptive Effects of a Generalist Predator on a Sap Feeding Insect.

Non-consumptive effects (NCEs) of predators are part of the complex interactions among insect natural enemies and prey. NCEs have been shown to significantly affect prey foraging and feeding. Leafhopper's (Auchenorrhyncha) lengthy phloem feeding bouts may play a role in pathogen transmission in vector species and also exposes them to predation risk. However, NCEs on leafhoppers have been scarcely studied, and we lack basic information about how anti-predator behaviour influences foraging and feeding in these species. Here we report a study on non-consumptive and consumptive predator-prey interactions in a naturally co-occurring spider-leafhopper system. In mesocosm arenas we studied movement patterns during foraging and feeding of the leafhopper Psammotettix alienus in the presence of the spider predator Tibellus oblongus. Leafhoppers delayed feeding and fed much less often when the spider was present. Foraging movement pattern changed under predation risk: movements became more frequent and brief. There was considerable individual variation in foraging movement activity. Those individuals that increased movement activity in the presence of predators exposed themselves to higher predation risk. However, surviving individuals exhibited a 'cool headed' reaction to spider presence by moving less than leafhoppers in control trials. No leafhoppers were preyed upon while feeding. We consider delayed feeding as a "paradoxical" antipredator tactic, since it is not necessarily an optimal strategy against a sit-and-wait generalist predator.

EVALUATION OF REPEAT EXPRESSION OVER LIFESPAN REVEALS AGE CONTRIBUTES TO INCREASED HERV-K EXPRESSION IN THE HUMAN, NEUROTYPICAL BRAIN

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Repetitive sequences, or repeats, comprise over 50% of the human genome and influence it through a variety of mechanisms. Repeat expression is highly regulated by cells, therefore, dysregulated repeat expression can alter a tissue's transcriptome. The neurotypical brain has the highest detectable level of repeat expression, and dysregulated repeat expression has been linked to aging and several neurodegenerative disorders, including multiple sclerosis and Alzheimer's disease. It is unclear how repeat dysregulation contributes to disease etiology, as our current understanding relies on limited data from non-human models, peripheral tissues, and post-mortem tissue from limited timepoints. Consequently, the field has struggled to contextualize repeat expression in neurological disease without a comprehensive understanding of repeat expression over the lifespan of the neurotypical brain. Here, we leverage our large cohort spanning the human lifespan, containing post-mortem brain samples obtained from 395 unique individuals across caudate nucleus, dorsolateral prefrontal cortex, and hippocampus, to catalogue repeat expression across the lifespan of the neurotypical brain. Using differential expression, we identify differentially expressed repeats (DERs) dysregulated with brain age. We find HERV-K is a DER, upregulated from 0-15 to 60+ years across all three brain regions, making it a potential transcriptional signature of neurotypical aging. Importantly, we find expression of select repeats downregulated with age. In addition to serving as a resource to the scientific community, this work proves global assessment of repeat behavior across age, tissue, and repeat class is necessary to contextualize disease-specific observations.

Retroelement-derived RNA and its role in the brain.
Comprising ~40% of the human genome, retroelements are mobile genetic elements which are transcribed into RNA, then reverse-transcribed into DNA and inserted into a new site in the genome. Retroelements are referred to as "genetic parasites", residing among host genes and relying on host machinery for transcription and evolutionary propagation. The healthy brain has the highest expression of retroelement-derived sequences compared to other somatic tissue, which leads to the question: how does retroelement-derived RNA influence human traits and cellular states? While the functional importance of upregulating retroelement expression in the brain is an active area of research, RNA species derived from retroelements influence both self- and host gene expression by contributing to chromatin remodeling, alternative splicing, somatic mosaicism and translational repression. Here, we review the emerging evidence that the functional importance of RNA derived from retroelements is multifaceted. Retroelements can influence organismal states through the seeding of epigenetic states in chromatin, the production of structured RNA and even catalytically active ribozymes, the generation of cytoplasmic ssDNA and RNA/DNA hybrids, the production of viral-like proteins, and the generation of somatic mutations. Comparative sequencing suggests that retroelements can contribute to intraspecies variation through these mechanisms to alter transcript identity and abundance. In humans, an increasing number of neurodevelopmental and neurodegenerative conditions are associated with dysregulated retroelements, including Aicardi-Goutieres syndrome (AGS), Rett syndrome (RTT), Amyotrophic Lateral Sclerosis (ALS), Alzheimer's disease (AD), multiple sclerosis (MS), schizophrenia (SZ), and aging. Taken together, these concepts suggest a larger functional role for RNA derived from retroelements. This review aims to define retroelement-derived RNA, discuss how it impacts the mammalian genome, as well as summarize data supporting phenotypic consequences of this unique RNA subset in the brain.

Evaluation of both exonic and intronic variants for effects on RNA splicing allows for accurate assessment of the effectiveness of precision therapies.
Elucidating the functional consequence of molecular defects underlying genetic diseases enables appropriate design of therapeutic options. Treatment of cystic fibrosis (CF) is an exemplar of this paradigm as the development of CFTR modulator therapies has allowed for targeted and effective treatment of individuals harboring specific genetic variants. However, the mechanism of these drugs limits effectiveness to particular classes of variants that allow production of CFTR protein. Thus, assessment of the molecular mechanism of individual variants is imperative for proper assignment of these precision therapies. This is particularly important when considering variants that affect pre-mRNA splicing, thus limiting success of the existing protein-targeted therapies. Variants affecting splicing can occur throughout exons and introns and the complexity of the process of splicing lends itself to a variety of outcomes, both at the RNA and protein levels, further complicating assessment of disease liability and modulator response. To investigate the scope of this challenge, we evaluated splicing and downstream effects of 52 naturally occurring CFTR variants (exonic = 15, intronic = 37). Expression of constructs containing select CFTR intronic sequences and complete CFTR exonic sequences in cell line models allowed for assessment of RNA and protein-level effects on an allele by allele basis. Characterization of primary nasal epithelial cells obtained from individuals harboring splice variants corroborated in vitro data. Notably, we identified exonic variants that result in complete missplicing and thus a lack of modulator response (e.g. c.2908G>A, c.523A>G), as well as intronic variants that respond to modulators due to the presence of residual normally spliced transcript (e.g. c.4242+2T>C, c.3717+40A>G). Overall, our data reveals diverse molecular outcomes amongst both exonic and intronic variants emphasizing the need to delineate RNA, protein, and functional effects of each variant in order to accurately assign precision therapies.

Potentially lethal cystic fibrosis gene variant in the orangutan.
A syndrome of chronic upper and lower airway disease leading to increased morbidity and mortality occurs primarily in captive orangutans. Similarities in symptoms to the inherited human respiratory disease, cystic fibrosis, led us to hypothesize that orangutan respiratory disease is a result of variants in the Cystic Fibrosis Transmembrane Conductance Regulator (CFTR) gene. We identified the nonsense variant, c.484A>T (p.Lys162X), in heterozygosity in an unaffected orangutan. Analysis of the pedigree of this orangutan confirmed that both his sire and deceased fetus also harbored the c.484A>T allele. An expression minigene harboring c.484A>T produced no full-length CFTR protein in HEK293 cells. Finally, the c.484A>T CFTR messenger RNA abundance was severely reduced in primary nasal epithelial cells of the orangutan indicating that c.484A>T (p.Lys162X) is potentially lethal. Genetic screening of the captive orangutan population could be used to prevent transmission of this potentially lethal variant, and thus aid in the conservation of this critically endangered species.

Correlating Cystic Fibrosis Transmembrane Conductance Regulator Function with Clinical Features to Inform Precision Treatment of Cystic Fibrosis.
The advent of precision treatment for cystic fibrosis using small-molecule therapeutics has created a need to estimate potential clinical improvements attributable to increases in cystic fibrosis transmembrane conductance regulator (CFTR) function. To derive CFTR function of a variety of genotypes and correlate with key clinical features (sweat chloride concentration, pancreatic exocrine status, and lung function) to develop benchmarks for assessing response to CFTR modulators. CFTR function assigned to 226 unique genotypes was correlated with the clinical data of 54,671 individuals enrolled in the Clinical and Functional Translation of CFTR (CFTR2) project. Cross-sectional FEV% predicted measurements were plotted by age at which measurement was obtained. Shifts in sweat chloride concentration and lung function reported in CFTR modulator trials were compared with function-phenotype correlations to assess potential efficacy of therapies. CFTR genotype function exhibited a logarithmic relationship with each clinical feature. Modest increases in CFTR function related to differing genotypes were associated with clinically relevant improvements in cross-sectional FEV% predicted over a range of ages (6-82 yr). Therapeutic responses to modulators corresponded closely to predictions from the CFTR2-derived relationship between CFTR genotype function and phenotype. Increasing CFTR function in individuals with severe disease will have a proportionally greater effect on outcomes than similar increases in CFTR function in individuals with mild disease and should reverse a substantial fraction of the disease process. This study provides reference standards for clinical outcomes that may be achieved by increasing CFTR function.

Decreased mRNA and protein stability of W1282X limits response to modulator therapy.
Cell-based studies have shown that W1282X generates a truncated protein that can be functionally augmented by modulators. However, modulator treatment of primary cells from individuals who carry two copies of W1282X generates no functional CFTR. To understand the lack of response to modulators, we investigated the effect of W1282X on CFTR RNA transcript levels.

Capitalizing on the heterogeneous effects of CFTR nonsense and frameshift variants to inform therapeutic strategy for cystic fibrosis.
CFTR modulators have revolutionized the treatment of individuals with cystic fibrosis (CF) by improving the function of existing protein. Unfortunately, almost half of the disease-causing variants in CFTR are predicted to introduce premature termination codons (PTC) thereby causing absence of full-length CFTR protein. We hypothesized that a subset of nonsense and frameshift variants in CFTR allow expression of truncated protein that might respond to FDA-approved CFTR modulators. To address this concept, we selected 26 PTC-generating variants from four regions of CFTR and determined their consequences on CFTR mRNA, protein and function using intron-containing minigenes expressed in 3 cell lines (HEK293, MDCK and CFBE41o-) and patient-derived conditionally reprogrammed primary nasal epithelial cells. The PTC-generating variants fell into five groups based on RNA and protein effects. Group A (reduced mRNA, immature (core glycosylated) protein, function <1% (n = 5)) and Group B (normal mRNA, immature protein, function <1% (n = 10)) variants were unresponsive to modulator treatment. However, Group C (normal mRNA, mature (fully glycosylated) protein, function >1% (n = 5)), Group D (reduced mRNA, mature protein, function >1% (n = 5)) and Group E (aberrant RNA splicing, mature protein, function > 1% (n = 1)) variants responded to modulators. Increasing mRNA level by inhibition of NMD led to a significant amplification of modulator effect upon a Group D variant while response of a Group A variant was unaltered. Our work shows that PTC-generating variants should not be generalized as genetic 'nulls' as some may allow generation of protein that can be targeted to achieve clinical benefit.

Residual function of cystic fibrosis mutants predicts response to small molecule CFTR modulators.
Treatment of individuals with cystic fibrosis (CF) has been transformed by small molecule therapies that target select pathogenic variants in the CF transmembrane conductance regulator (CFTR). To expand treatment eligibility, we stably expressed 43 rare missense CFTR variants associated with moderate CF from a single site in the genome of human CF bronchial epithelial (CFBE41o-) cells. The magnitude of drug response was highly correlated with residual CFTR function for the potentiator ivacaftor, the corrector lumacaftor, and ivacaftor-lumacaftor combination therapy. Response of a second set of 16 variants expressed stably in Fischer rat thyroid (FRT) cells showed nearly identical correlations. Subsets of variants were identified that demonstrated statistically significantly higher responses to specific treatments. Furthermore, nearly all variants studied in CFBE cells (40 of 43) and FRT cells (13 of 16) demonstrated greater response to ivacaftor-lumacaftor combination therapy than either modulator alone. Together, these variants represent 87% of individuals in the CFTR2 database with at least 1 missense variant. Thus, our results indicate that most individuals with CF carrying missense variants are (a) likely to respond modestly to currently available modulator therapy, while a small fraction will have pronounced responses, and (b) likely to derive the greatest benefit from combination therapy.

Functional Assays Are Essential for Interpretation of Missense Variants Associated with Variable Expressivity.
Missense DNA variants have variable effects upon protein function. Consequently, interpreting their pathogenicity is challenging, especially when they are associated with disease variability. To determine the degree to which functional assays inform interpretation, we analyzed 48 CFTR missense variants associated with variable expressivity of cystic fibrosis (CF). We assessed function in a native isogenic context by evaluating CFTR mutants that were stably expressed in the genome of a human airway cell line devoid of endogenous CFTR expression. 21 of 29 variants associated with full expressivity of the CF phenotype generated <10% wild-type CFTR (WT-CFTR) function, a conservative threshold for the development of life-limiting CF lung disease, and five variants had moderately decreased function (10% to ~25% WT-CFTR). The remaining three variants in this group unexpectedly had >25% WT-CFTR function; two were higher than 75% WT-CFTR. As expected, 14 of

19 variants associated with partial expressivity of CF had >25% WT-CFTR function; however, four had minimal to no effect on CFTR function (>75% WT-CFTR). Thus, 6 of 48 (13%) missense variants believed to be disease causing did not alter CFTR function. Functional studies substantially refined pathogenicity assignment with expert annotation and criteria from the American College of Medical Genetics and Genomics and Association for Molecular Pathology. However, four algorithms (CADD, REVEL, SIFT, and PolyPhen-2) could not differentiate between variants that caused severe, moderate, or minimal reduction in function. In the setting of variable expressivity, these results indicate that functional assays are essential for accurate interpretation of missense variants and that current prediction tools should be used with caution.

Systematic Computational Identification of Variants That Activate Exonic and Intronic Cryptic Splice Sites.

We developed a variant-annotation method that combines sequence-based machine-learning classification with a context-dependent algorithm for selecting splice variants. Our approach is distinctive in that it compares the splice potential of a sequence bearing a variant with the splice potential of the reference sequence. After training, classification accurately identified 168 of 180 (93.3%) canonical splice sites of five genes. The combined method, CryptSplice, identified and correctly predicted the effect of 18 of 21 (86%) known splice-altering variants in CFTR, a well-studied gene whose loss-of-function variants cause cystic fibrosis (CF). Among 1,423 unannotated CFTR disease-associated variants, the method identified 32 potential exonic cryptic splice variants, two of which were experimentally evaluated and confirmed. After complete CFTR sequencing, the method found three cryptic intronic splice variants (one known and two experimentally verified) that completed the molecular diagnosis of CF in 6 of 14 individuals. CryptSplice interrogation of sequence data from six individuals with X-linked dyskeratosis congenita caused by an unknown disease-causing variant in DKC1 identified two splice-altering variants that were experimentally verified. To assess the extent to which disease-associated variants might activate cryptic splicing, we selected 458 pathogenic variants and 348 variants of uncertain significance (VUSs) classified as high confidence from ClinVar. Splice-site activation was predicted for 129 (28%) of the pathogenic variants and 75 (22%) of the VUSs. Our findings suggest that cryptic splice-site activation is more common than previously thought and should be routinely considered for all variants within the transcribed regions of genes.

Loss of carbonic anhydrase XII function in individuals with elevated sweat chloride concentration and pulmonary airway disease.

Elevated sweat chloride levels, failure to thrive (FTT), and lung disease are characteristic features of cystic fibrosis (CF, OMIM #219700). Here we describe variants in CA12 encoding carbonic anhydrase XII in two pedigrees exhibiting CF-like phenotypes. Exome sequencing of a white American adult diagnosed with CF due to elevated sweat chloride, recurrent hyponatremia, infantile FTT and lung disease identified deleterious variants in each CA12 gene: c.908-1 G>A in a splice acceptor and a novel frameshift insertion c.859_860insACCT. In an unrelated consanguineous Omani family, two children with elevated sweat chloride, infantile FTT, and recurrent hyponatremia were homozygous for a novel missense variant (p.His121Gln). Deleterious CFTR variants were absent in both pedigrees. CA XII protein was localized apically in human bronchiolar epithelia and basolaterally in the reabsorptive duct of human sweat glands. Respiratory epithelial cell RNA from the adult proband revealed only aberrant CA12 transcripts and in vitro analysis showed greatly reduced CA XII protein. Studies of ion transport across respiratory epithelial cells in vivo and in culture revealed intact CFTR-mediated chloride transport in the adult proband. CA XII protein bearing either p.His121Gln or a previously identified p.Glu143Lys missense variant localized to the basolateral membranes of polarized Madin-Darby canine kidney (MDCK) cells, but enzyme activity was severely diminished when assayed at physiologic concentrations of extracellular chloride. Our findings indicate that loss of CA XII function should be considered in individuals without CFTR mutations who exhibit CF-like features in the sweat gland and lung.

LINE-1 EXPRESSION AND ORF1P INTERACTOME IN THE BRAIN UNDER PHYSIOLOGICAL AND PATHOLOGICAL CONDITIONS

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Tom Bonnifet, Rania Znaidi, Olivia Massiani-Beaudoin, Rajiv L. Joshi, Julia Fuchs
College De France, Center For Interdisciplinary Research In Biology, PARIS, France

Aims. The expression and regulation of transposable elements (TEs) in the brain remain poorly characterized. We are exploring the potential contribution of LINE-1 (L1) retrotransposon and encoded proteins (ORF1p/ORF2p) in aging-associated neurodegenerative diseases (NDs) such as Parkinson disease (PD) and Alzheimer's disease (AD). **Methods**. We use bioinformatic, biochemical and imaging analyses to quantify the transcript and protein levels of L1 (including at the locus level) and other TEs in the brains of healthy and PD/AD patients, correlating these with established disease-markers. The distribution of ORF1p in mouse and human brain was investigated by immunohistochemistry with cutting-edge analysis methods on large-scale image acquisition and by cell fractionation. Mass-Spectrometry quantifications and co-immunoprecipitation experiments were performed to decipher the interactome of ORF1p in neurons. **Results and Conclusion**. We found widespread expression of ORF1p in neurons of mice and humans. Several TEs including specific L1 elements are disease-specifically dysregulated in AD and PD and correlations with markers of these NDs and known TE regulators are being characterized. In subcellular fractionation of human neurons, ORF1p was detected in the cytosolic but also, stress-dependently, in the chromatin fraction, suggesting that ORF1p translocates to the nucleus during aging and possibly in PD/AD. In human dopaminergic neurons in culture, ORF1p protein partners form a clustered network linked to mRNA processing, ribosome biogenesis, and nucleocytoplasmic transport. Following stress, additional clusters emerge which concern nuclear envelope and transcription factor binding. These results point to novel so far unsuspected roles of ORF1p in the nucleus under physiological and pathological conditions.

Aims Neurotransmitter dopamine is critically involved in many physiological functions in the brain and its dysregulation is linked to several pathological states. A loss of dopaminergic innervations is a key feature of Parkinson's disease, while enhanced dopaminergic tone has been speculated to contribute to the pathogenesis of schizophrenia and Huntington's disease. The aim of this study was to perform an unbiased identification of protein network related to dopamine signaling. **Methods** We applied proteomic 2D-DIGE analysis of striatal tissue from genetic mouse model of persistent hyperdopaminergia, the dopamine transporter knock-out (DAT-KO) mice, and from pharmacogenetic model of dopamine deficiency, the dopamine-deficient DAT-KO (DDD) mice. **Results** By DIGE analysis, we identified 11 proteins that were significantly altered in DAT and/or in DDD mice. Intriguingly, DAVID analysis revealed that several proteins involved in acetylation processes were changed and, generally, DAT-KO mice presented a pattern of acetylated proteins that was significantly different from one found in DDD mice. We observed an up-regulation of several subtypes of histone deacetylase (HDAC) in DAT-KO mice, but not in DDD-mice. An acute increase of dopamine induced by amphetamine administration was able to induce a similar pattern of HDAC expression. Strikingly, pharmacological inhibition of HDAC activity in DAT-KO mice decreased the level of phosphorylated tau and prevented the development of neurodegenerative phenotype and mortality spontaneously present in DAT-KO mice. **Conclusions** Our data suggest an unappreciated role for dopamine in the regulation of HDAC and a contribution of this process to dopamine-dependent postsynaptic neurodegeneration.

[1]Regional Neurogenetic Centre (CRN) - ASPCZ, Department Of Primary Care, Lamezia Terme (CZ), Italy, [2]University of Calabria, Department Of Biology, Ecology And Earth Sciences, Rende, Italy

Background. Alzheimer's Disease (AD) is the most widespread neurodegenerative disorder. To date the exact cause of sporadic AD (sAD) is still not fully known. It has been shown that Single Nucleotide Polymorphisms (SNPs) of the Nerve Growth Factor Receptor (*NGFR/p75NTR*) gene could represent risk factors for sAD. However, only a few studies have investigated this relationship with conflicting results.
Aims. The general aim of this study was to better characterize the association between *NGFR/p75NTR* SNPs and sAD.
Methods. This case-control association study was conducted in a Southern Italian cohort consisting of sAD patients and 119 age- and sex-matched controls. Nineteen tag-SNPs were selected and genotyped TaqMan SNP genotyping assays. The associations between tag-SNPs and the risk of sAD were assessed by logistic regression models.
Results. Some variants, such as the functional *rs2072446*, were found associated to sAD, with a significant decrease/increase of the minor allele frequency compared to controls, suggesting either a protective or a risk-increasing effect in the developing of sAD.
Conclusion. Our results reveal a new role of *NGFR/p75NTR* in sAD from a genetic perspective. *NGFR/p75NTR* SNPs analysis should be considered for the genetic screening of sAD.

A Novel Mutation (D395A) in Valosin-Containing Protein Gene Is Associated With Early Onset Frontotemporal Dementia in an Italian Family.
Inclusion body myopathy (IBM) with Paget's disease of bone (PDB) and/or frontotemporal dementia (FTD) (IBMPFD) was recently identified as rare autosomal dominant disorder due to mutations in gene. However, mutations have also been documented in patients with amyotrophic lateral sclerosis (ALS), Charcot-Marie-Tooth type 2 (CMT2) disease, and hereditary spastic paraplegia (HSP), underlining the heterogeneity of the phenotypes due to mutations. In this study, we reported a novel missense heterozygous variant c.1184A > C (.D395A) in exon 10 of gene identified in three patients (two sisters and one brother) belonging to an Italian family. The patients underwent a detailed clinical evaluation including medical history, neurological examination, and neuropsychological assessment. Brain's morphologic and functional analysis was also performed. The whole picture was consistent with the criteria of behavioral variant frontotemporal dementia (bvFTD) without IBM and PBD. Our report confirms the high degree of heterogeneity of disease. A analysis should be considered for the genetic screening of familial bvFTD with an early onset also in absence of IBM or PDB signs.

Developmental delay in motor skill acquisition in Niemann-Pick C1 mice reveals abnormal cerebellar morphogenesis.
Niemann-Pick type C1 (NPC1) disease is a lysosomal storage disorder caused by defective intracellular trafficking of exogenous cholesterol. Purkinje cell (PC) degeneration is the main sign of cerebellar dysfunction in both NPC1 patients and animal models. It has been recently shown that a significant decrease in Sonic hedgehog (Shh) expression reduces the proliferative potential of granule neuron precursors in the developing cerebellum of Npc1 (-/-) mice. Pursuing the hypothesis that this developmental defect translates into functional impairments, we have assayed Npc1-deficient pups belonging to the milder mutant mouse strain Npc1 (nmf164) for sensorimotor development from postnatal day (PN) 3 to PN21. Npc1 (nmf164) / Npc1 (nmf164) pups displayed a 2.5-day delay in the acquisition of complex motor abilities compared to wild-type (wt) littermates, in agreement with the significant disorganization of cerebellar cortex cytoarchitecture observed between PN11

and PN15. Compared to wt, Npc1 (nmf164) homozygous mice exhibited a poorer morphological differentiation of Bergmann glia (BG), as indicated by thicker radial shafts and less elaborate reticular pattern of lateral processes. Also BG functional development was defective, as indicated by the significant reduction in GLAST and Glutamine synthetase expression. A reduced VGluT2 and GAD65 expression also indicated an overall derangement of the glutamatergic/GABAergic stimulation that PCs receive by climbing/parallel fibers and basket/stellate cells, respectively. Lastly, Npc1-deficiency also affected oligodendrocyte differentiation as indicated by the strong reduction of myelin basic protein. Two sequential 2-hydroxypropyl-β-cyclodextrin administrations at PN4 and PN7 counteract these defects, partially preventing functional impairment of BG and fully restoring the normal patterns of glutamatergic/GABAergic stimulation to PCs.These findings indicate that in Npc1 (nmf164) homozygous mice the derangement of synaptic connectivity and dysmyelination during cerebellar morphogenesis largely anticipate motor deficits that are typically observed during adulthood.

A marked paucity of granule cells in the developing cerebellum of the Npc1(-/-) mouse is corrected by a single injection of hydroxypropyl-β-cyclodextrin.
In this study we show that postnatal development of cerebellar granule neurons (GNs) is defective in Npc1(-/-) mice. Compared to age-matched wild-type littermates, there is an accelerated disappearance of the external granule layer (EGL) in these mice. This is due to a premature exit from the cell cycle of GN precursors residing at the level of the EGL. As a consequence, the size of cerebellar lobules of these mice displays a 20%-25% reduction compared to that of age-matched wild-type mice. This size reduction is detectable at post-natal day 28 (PN28), when cerebellar GN development is completed while signs of neuronal atrophy are not yet apparent. Based on the analysis of EGL thickness and the determination of proliferating GN fractions at increasing developmental times (PN8-PN14), we trace the onset of this GN developmental defect during the second postnatal week. We also show that during this developmental time Shh transcripts undergo a significant reduction in Npc1(-/-) mice compared to age-matched wild-type mice. In light of the mitogenic activity of Shh on GNs, this observation further supports the presence of defective GN proliferation in Npc1(-/-) mice. A single injection of hydroxypropyl-β-cyclodextrin at PN7 rescues this defect, restoring the normal patterns of granule neuron proliferation and cerebellar lobule size. To our knowledge, these findings identify a novel developmental defect that was underappreciated in previous studies. This defect was probably overlooked because Npc1 loss-of-function does not affect cerebellar foliation and causes the internal granule layer and molecular layer to decrease proportionally, giving rise to a normally appearing, yet harmoniously smaller, cerebellum.

Assessing the fear of recurrence using the Cancer Worry Scale in a sample of Italian breast cancer survivors.
The fear of cancer recurrence (FCR) is one of the most reported problems by cancer survivors. A valid instrument to detect this issue could be useful to identify cancer survivors who are more vulnerable to developing FCR and related adverse outcomes (e.g., anxiety). The present study aimed to evaluate FCR in a sample of Italian breast cancer survivors using an Italian version of the 8-item Cancer Worry Scale (CWS) in order to establish a cut-off for the use in clinical settings.

Mean differences and individual changes in nursing students' attitudes toward statistics: The role of math background and personality traits.
Nursing students have compulsory statistics courses in their degree program, but they usually have negative attitudes toward statistics that may hinder their learning. The present study aims: (i) to investigate nurse students' attitudes toward statistics and the relationships with mathematical background and personality traits; (ii) to stress individual changes in attitude that occur during the course; and (iii) to explore if mathematical background and personality traits influence these changes. We adopted a one-group pre-post survey study. Fifty nursing students were enrolled in an introductory statistics course at the Sapienza University of Rome in Italy during the 2018-2019 academic year. Participants were surveyed at the beginning and end of the course administering a multidimensional measure of attitude toward statistics. Multiple regression analyses were run to establish the relative impact of mathematical background and Big Five personality factors on attitude components, as well as the changes in these attitude components. Results confirmed the predictive role of mathematic competence on some attitude dimensions and showed that also personality traits influenced attitudes toward statistics. However, the observed changes in attitudes during the course were minimally influenced by these factors. Findings suggest that course pedagogy can enhance students' attitudes regardless their mathematical background and personality.

A Comparison of Behavioral and Psychological Symptoms of Dementia (BPSD) and BPSD Sub-Syndromes in Early-Onset and Late-Onset Alzheimer's Disease.
Behavioral and psychological symptoms of dementia (BPSD) have a large impact on the quality of life of patients with Alzheimer's disease (AD). Few studies have compared BPSD between early-onset (EOAD) and late-onset (LOAD) patients, finding conflicting results.

Amyloid Precursor Protein A713T Mutation in Calabrian Patients with Alzheimer's Disease: A Population Genomics Approach to Estimate Inheritance from a Common Ancestor.
Mutation A713T in the amyloid precursor protein (APP) has been linked to cases of Alzheimer's disease (AD), cerebral amyloid angiopathy (CAA) and cerebrovascular disease. Despite its rarity, it has been observed in several families from the same geographical area, in the Calabria region in Southern Italy. Genotyping of 720,000 genome-wide SNPs with the HumanOmniExpress BeadChip was performed for six patients that were representative of apparently unrelated Calabrian families, as well as a Belgian subject of Italian descent (all with the same A713T mutation and disease). Their genomic structure and genetic relationships were analyzed. Demographic reconstruction and coalescent theory were applied to estimate the time of the most recent common ancestor (tMRCA) among patients. Results show that all A713T carriers fell into the genetic variability of Southern Italy and were not more closely related to each other than to any other healthy Calabrian individual. However, five out of seven patients shared a 1.7 Mbp-long DNA segment centered on the A713T mutation, making it possible to estimate a tMRCA for its common origin in the Calabrian region dating back over 1000 years. The analysis of affected individuals with methodologies based on human population genomics thus provides informative insights in support of clinical observations and biomedical research.

FUNCTIONAL CHARACTERIZATION OF MITOCHONDRIAL BETA-OXIDATION GENES IN DROSOPHILA NERVOUS SYSTEM

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Lesley Pow-Hing[1], Nicole Sanhueza[1], Guilherme Gischkow Rucatti[1], Francisco Muñoz-Carvajal[1], Mario Sanhueza[1,2]
[1]Universidad Mayor, School Of Biotechnology, Santiago, Chile, [2]Universidad Mayor, Faculty Of Sciences, Temuco, Chile

Lipid metabolic dysregulation in the brain is a commonality between the aging process and the onset of neurodegenerative disorders. Despite the emerging evidence linking altered lipostasis with pre-symptomatic stages of neurodegeneration, so far no molecular mechanism has been associated with these observations. Furthermore, the mitochondrial beta-oxidation has not been fully studied in the context of degenerative processes of the nervous system. Here we perform a comprehensive in silico analysis of *Drosophila melanogaster* genes involved in beta-oxidation, and we functionally characterize their role in the nervous system. Using publicly available databases, we explored sequence homology, interaction networks and expression maps to filter 75 candidate genes, and obtained a *bonafide* group including the most relevant proteins for each enzymatic step of beta-oxidation. We then analyzed their expression in *Drosophila* brains and identified that the whole pathway is down-regulated in aged flies. To study a functional role of these genes in the nervous system, we down-regulated their expression in neurons and confirmed that they are required not only for neuronal integrity as observed through immunofluorescence, but also for functional adult flies after measuring lifespan and motor performance. These phenotypes correlated with an altered distribution and concentration of neuronal lipids, as observed with neutral lipid dyes in brains down-regulating selected genes. Finally, we observed that these mutant brains also carried altered mitochondria number and morphology compared to controls. These data suggest a non-canonical role of beta-oxidation in neurons that could provide clues on pathomechanisms of neurodegenerative diseases.

ELUCIDATING THE ROLE OF FUS AND FMRP IN REGULATING SYNGAP1 EXPRESSION IN HUMAN IPSC-DERIVED NEURONS

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Maria Cristina Benedetti, Alessandro Rosa
Università di Roma La Sapienza, Department Of Biochemistry Science "a. Rossi Fanelli", Roma, Italy

SYNGAP1 is a major dendritic signalling protein that regulates synaptic plasticity and neuronal maturation during a specific developmental window. Loss of-function mutations in SYNGAP1 result in Intellectual Disability, Autism Spectrum Disorder, and epilepsy. So far, SYNGAP1 has been mainly characterized in mouse models, however species-specific regulatory mechanisms lead to the production of functionally different transcript isoforms. Thus, it is necessary to study this gene in the context of a human model system. The aim is to elucidate the regulation of SYNGAP1 expression and its function in synaptic plasticity using human induced pluripotent stem cell (hiPSC)-derived neurons. Previous studies in murine models have shown that FUS, an RNA binding protein (RBP) involved in amyotrophic lateral sclerosis, positively regulates the expression of SYNGAP1 by 3'UTR binding, thus promoting dendritic spine maturation and cognitive function. However, PAR-CLIP data produced in our lab on hiPSC-derived motoneurons show that FUS binds the translated region of SYNGAP1 mRNA while a mutant FUS protein (P525L) binds the 3'UTR. Moreover, we found that the Fragile X Syndrome-linked RBP FMRP negatively regulates SYNGAP1 expression in hiPSC-derived cortical neurons. A recent model proposes that FUS and FMRP share common targets, which they regulate in opposite way, and that their balance is crucial for proper neuronal protein expression. Thus, investigation of the role of these RBPs in regulating SYNGAP1 expression would allow to have a better understanding of SYNGAP1 physiological roles and how dysregulation of these circuits in nervous system diseases possibly leads to altered dendritic spine and neuronal network formation.

Heart failure patients often suffer from cognitive dysfunctions. The underlying molecular mechanisms are not well understood. In a recent study from our group, we have employed 3 months old CamKIIδC-overexpressing transgenic mice (CamKIIδCTG) as a model for heart failure and showed that these mice develop an impairment of hippocampus-dependent memory function which is accompanied by specific changes of epigenetic gene expression. Interestingly, at 6 months of age memory impairment was diminished, despite the fact that cardiac phenotypes persisted and massive gene-expression changes were detected in the hippocampus. However, the hippocampal gene-expression changes were fundamentally different to the data obtained from 3 months old mice and suggest the induction of a compensatory response. Further analysis point to a key role of a compensatory microRNA network in mediating this effect. In conclusion, our results suggest that better understanding of these microRNA networks may provide novel therapeutic targets to manage heart failure related cognitive dysfunctions.

PERINATAL EXPOSURE TO TITANIUM NANOPARTICLES INDUCES ABNORMAL BREATHING IN THE OFFSPRING OF MICE

POSTER SESSION 04 - SECTION: EPIGENETICS OF THE NERVOUS SYSTEM

Marie Boulain, Didier Morin, Laurent Juvin
Univ. Bordeaux, Incia, Bordeaux CEDEX, France

The use of titanium dioxide nanoparticles (TiO_2 NPs) has increase significantly over the last decades, and these particles are now present in many daily consumer products. Recent studies in rodents have shown that perinatal exposure to TiO_2 NPs has deleterious consequences on the development of the offspring. In addition to these, epigenetic modifications of newborns' DNA have also been reported suggesting trans-generational effects. However, whether the development of postnatal respiration is altered by TiO_2 NPs perinatal exposure had still to be determined. Here, F0 dams were perinatally exposed to TiO_2 NPs at 100 and 200 mg/kg via voluntary food intake. We show that F1 newborns' breathing rate was slower in comparison to non-exposed animals. This difference in breathing rhythmicity was observed both in females and males during at least 11 days after birth. We also report an increase of the proportion of F1 newborns that produced apneas during this time window. Similar observations were made when the exposure was limited to the postnatal period, identifying lactation as a critical time period for TiO_2 NPs adverse effects on postnatal breathing development. Finally, TiO_2 NPs-induced breathing deficits were transmitted from F1 females to the F2 generation. In addition, perinatal re-exposure of F1 females to TiO_2 NPs aggravated breathing deficits in F2 males. To conclude, perinatal exposure to TiO_2 NPs alters postnatal respiration of the offspring over several generations.

Aim: Our sense of orientation is critical for our survival in changing environments. It depends on flexibly integrating self-motion signals with external sensory cues. However, the circuit dynamics and mechanisms that update head direction (HD) representations with incoming visual information remain poorly understood. Retrosplenial cortex (RSC) is a key region for flexible encoding of variables that guide spatial navigation, including HD. We hypothesized that updates for HD representation first appear in RSC, due to its dense connections with visual areas, and are then conveyed to the anterodorsal nucleus of thalamus (ADn), the obligatory thalamic relay of HD to the rest of the brain. **Methods:** We simultaneously recorded single units in RSC and ADn in freely behaving mice navigating a circular arena, where a prominent visual cue was manipulated. We implemented a GLM to decode HD from the recorded units and determined the temporal correlation between the two representations. Finally, we assessed anatomical connectivity through monosynaptic rabies tracing and functional connectivity through spike cross correlation. **Results:** We observed that, despite differences in HD coding, HD representations in the two regions were nearly synchronous during rotation of a visual cue and during locomotion in darkness. Anatomical and functional monosynaptic connectivity were consistent with a strong feedforward drive of HD information from ADn to RSC, with surprisingly little top-down feedback in the corticothalamic direction. **Conclusions:** Our results provide direct evidence for a coordinated global HD reference update across cortex and thalamus and of the underlying functional circuit connectivity that supports this coordination.

Aims: Arginase converts arginine (Arg) to ornithine (Orn). Brain distribution of arginase isoenzymes (Arg1 and Arg2) is poorly defined, although striatum is highly enriched in Arg2. Nevertheless, the role of this enzyme in striatal functioning is not understood. The aim of this study was to determine detailed Arg2 distribution within the striatum and to establish the importance of Arg2 for striatal Arg metabolism. **Methods:** Protein levels were analyzed by western blot, and their localization by immunohistochemistry. The concentrations of amino acids were measured with HPLC, and nitrates and nitrites (NOx; cellular nitric oxide (NO) indicator) with fluorimetric assay. The experiments were performed on wild-type and Arg2 knock-out (Arg2 KO) mice. **Results:** Striatal Arg2 expression appears to be specific for some fraction of medium spiny neurons (MSNs; mostly in cell bodies), and is lacking in interneurons, glia and other subpopulations of MSNs. As expected, Arg2 is present in the mitochondria. The absence of Arg2 leads to the accumulation of Arg, however it doesn't affect the content of other related amino acids. No effect of Arg2 loss on NOx levels is observed. **Conclusions:** This study shows neuronal Arg2 localization in the striatum, limited to a defined population of MSNs. Arg2 controls levels of striatal Arg, however the absence of effect of Arg2 loss on Orn content may indicate that a compensatory mechanism is activated to maintain physiological levels of Orn. Arginase may potentially compete with NO synthase for their common substrate, Arg, although striatal Arg2 appears not to affect NO synthesis.

WE AGE WHAT WE EAT: EXACERBATED MEMORY DECLINE AND DISRUPTED SYNAPTIC PLASTICITY PROMPTED BY A CHRONIC HIGH-CALORIC DIET

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Sara L. Paulo[1,2], Catarina Miranda-Lourenço[1,2], Rita F. Belo[1,2], Rui S. Rodrigues[1,2], Sara R Tanqueiro[1,2], João Fonseca-Gomes[1,2], Vera Geraldes[3,4], Isabel Rocha[3,4], Ana M. Sebastião[1,2], Sara Xapelli[1,2], Maria J. Diógenes[1,2]
[1]Faculdade de Medicina, Universidade de Lisboa, Instituto De Farmacologia E Neurociências, Lisboa, Portugal, [2]Instituto de Medicina Molecular João Lobo Antunes, Universidade De Lisboa, Faculdade De Medicina, Lisboa, Portugal, [3]Faculdade de Medicina, Universidade de Lisboa, Instituto De Fisiologia, Lisbon, Portugal, [4]Universidade de Lisboa, Centro Cardiovascular Da Universidade De Lisboa, Lisbon, Portugal

The alarming increase in the consumption of fat and sugar over the last decades, leading to overweight and obesity, is associated with a higher risk of metabolic and cardiovascular diseases. Recent evidence links this type of diet with a deleterious effect on cognition and synaptic function. However, whether obesity presents an additional risk factor for cognitive impairment in the elderly remains to be determined. Thus, we aimed at unravelling the effects of a chronic high caloric diet (HCD) upon synaptic plasticity and memory performance of aged rats. Male rats were fed an HCD from 1 to 24 months of age. All analyses were performed at 24 months old. HCD-fed aged rats were obese (***p<0.001, n=6-7), and behaviour assessment revealed significant long-term memory impairment in the novel object recognition test, compared to age-matched controls (*p<0.05, n=6). Field excitatory postsynaptic potentials, recorded from hippocampal slices, showed decreased magnitude of long-term potentiation in HCD aged rats (*p<0.05, n=5-6). This was accompanied by a reduction in the hippocampal levels of the brain-derived neurotrophic factor receptors TrkB full-length (TrkB-FL) (*p<0.05, n=7). In contrast, no changes were observed in the number of immature doublecortin immune-positive cells (p>0.05, n=3). These results highlight that a chronic HCD leading to obesity can exacerbate age-associated cognitive decline, possibly due to impaired synaptic plasticity, which might in turn be associated with deficits related to TrkB-FL signalling.

Cannabinoid Actions on Neural Stem Cells: Implications for Pathophysiology.
With the increase of life expectancy, neurodegenerative disorders are becoming not only a health but also a social burden worldwide. However, due to the multitude of pathophysiological disease states, current treatments fail to meet the desired outcomes. Therefore, there is a need for new therapeutic strategies focusing on more integrated, personalized and effective approaches. The prospect of using neural stem cells (NSC) as regenerative therapies is very promising, however several issues still need to be addressed. In particular, the potential actions of pharmacological agents used to modulate NSC activity are highly relevant. With the ongoing discussion of cannabinoid usage for medical purposes and reports drawing attention to the effects of cannabinoids on NSC regulation, there is an enormous, and yet, uncovered potential for cannabinoids as treatment options for several neurological disorders, specifically when combined with stem cell therapy. In this manuscript, we review in detail how cannabinoids act as potent regulators of NSC biology and their potential to modulate several neurogenic features in the context of pathophysiology.

Adult Neural Stem Cells as Promising Targets in Psychiatric Disorders.
The development of new therapies for psychiatric disorders is of utmost importance, given the enormous toll these disorders pose to society nowadays. This should be based on the identification of neural substrates and mechanisms that underlie disease etiopathophysiology. Adult neural stem cells (NSCs) have been emerging as a promising platform to counteract brain damage. In this perspective article, we put forth a detailed view of how NSCs operate in the adult brain and influence brain homeostasis, having profound implications at both behavioral and functional levels. We appraise evidence suggesting that adult NSCs play important roles in regulating several forms of brain plasticity, particularly emotional and cognitive flexibility, and that NSC dynamics are altered upon brain pathology. Furthermore, we discuss the potential therapeutic value of utilizing

adult endogenous NSCs as vessels for regeneration, highlighting their importance as targets for the treatment of multiple mental illnesses, such as affective disorders, schizophrenia, and addiction. Finally, we speculate on strategies to surpass current challenges in neuropsychiatric disease modeling and brain repair.

High Caloric Diet Induces Memory Impairment and Disrupts Synaptic Plasticity in Aged Rats.
The increasing consumption of sugar and fat seen over the last decades and the consequent overweight and obesity, were recently linked with a deleterious effect on cognition and synaptic function. A major question, which remains to be clarified, is whether obesity in the elderly is an additional risk factor for cognitive impairment. We aimed at unravelling the impact of a chronic high caloric diet (HCD) on memory performance and synaptic plasticity in aged rats. Male rats were kept on an HCD or a standard diet (control) from 1 to 24 months of age. The results showed that under an HCD, aged rats were obese and displayed significant long-term recognition memory impairment when compared to age-matched controls. Ex vivo synaptic plasticity recorded from hippocampal slices from HCD-fed aged rats revealed a reduction in the magnitude of long-term potentiation, accompanied by a decrease in the levels of the brain-derived neurotrophic factor receptors TrkB full-length (TrkB-FL). No alterations in neurogenesis were observed, as quantified by the density of immature doublecortin-positive neurons in the hippocampal dentate gyrus. This study highlights that obesity induced by a chronic HCD exacerbates age-associated cognitive decline, likely due to impaired synaptic plasticity, which might be associated with deficits in TrkB-FL signaling.

REGULATION OF THE APOPTOSIS/AUTOPHAGY SWITCH BY PROPIONIC ACID IN VENTROMEDIAL HYPOTHALAMUS OF RATS WITH TYPE 2 DIABETES MELLITUS

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Yulia Osadchuk[1], Yuliia Klys[2], Yuri Chaikovsky[1], Iryna Ryzhko[3], Larysa Natrus[3]
[1]Bogomolets National Medical University, Histology And Embryology, Kyiv, Ukraine, [2]Bogomolets National Medical University, Research Institute Of Experimental And Clinical Medicine, Kyiv, Ukraine, [3]Bogomolets National Medical University, Department Of Modern Technologies Of Medical Diagnostics And Treatment, Kyiv, Ukraine

Aim: The balance between autophagy and apoptosis in hypothalamus may be disrupted upon type 2 diabetes mellitus (T2DM). Since propionic acid (PA) exerts neuroprotective effects, the aim was to investigate its effects on apoptosis/autophagy switch in the ventromedial hypothalamus (VMH) in a T2DM rat model. **Methods:** Male Wistar rats were divided into untreated control rats and rats in which T2DM was induced. The untreated T2DM rats were compared to a group that received metformin, a group that received sodium salt of PA and a group that got PA+metformin. Western blotting, RT-PCR, transmission electron microscopy and immunohistochemical staining were from VMH tissue were performed. **Results:** T2DM-induced apoptosis and mitoptosis, enlarged ER tubules/cisterns were observed in VMH, andaccompanied by imbalance of pro- and anti-apoptotic factors. Elevation of pro-apoptotic Bax and caspase-3, decrease in autophagy marker LC3 and anti-apototic Bcl-xl were observed in VMH of T2DM rats. Metformin and PA partially improved VMH ultrastructural changes by reducing mitochondrial swelling and diminishing the number of apoptotic neurons. Metformin inhibited neuronal apoptosis, however accumulation of lipofuscin. Elevated number of autophagosomes was associated with LC3, Beclin-1 and Bcl-xl increase and decrease in Bax and caspase-3 in VMH of T2DM rats. PA switched cell fate from apoptosis to autophagy by elevating LC3 and Beclin-1 levels and increasing Bcl-xl that altogether may represent adaptive response to T2DM-induced apoptosis. **Conclusions:** T2DM was associated with apoptosis activation leading to impairments in VMH. PA+metformin may be effective against diabetes-induced cell death by switching apoptosis to autophagy in VMH.

STRUCTURAL ORGANIZATION OF SUBFORNICAL ORGAN'S NEUROTRANSMITTER SYSTEMS IN ADULT RATS

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Valeria Razenkova, Dmitrii Korzhevskii
Federal State Budgetary Scientific Institution "Institute of Experimental Medicine" (FSBSI "IEM"), Department Of General And Particular Morphology, Saint Petersburg, Russian Federation

The subfornical organ (SFO) is located in the roof of the third ventricle and, as one of the circumventricular organs (CVOs) of the brain, is involved in cardiovascular regulation and body fluid homeostasis regulation by blood-brain communication. Although researchers demonstrate interest in the SFO, a comprehensive analysis of its neurotransmitter systems has not been conducted. The aim of this study was to examine SFO transmitter systems using immunohistochemical methods. The brain of adult (4-6 months) male Wistar rats approximately at the 1.4 mm behind Bregma was examined (n=3). Antibodies against glutamate decarboxylase 67 (GAD67), tyrosine hydroxylase (TH) and choline acetyltransferase (ChAT) were used in order to visualize GABA-, catecholamine- and cholinergic structures respectively. It was established that SFO harbors both GABA- and catecholaminergic structures within. GABAergic neurons tend to locate in the peripheral regions near ventricle and GABAergic terminals are ubiquitous within SFO. In contrast, no TH-positive cell bodies were observed there. Catecholaminergic fibers mostly occur in the medial area of SFO and also found to contact its fenestrated capillaries and ependymal cells. However, SFO seems to completely lack ChAT-immunopositive neurons and projections. Thus, our observations allow further description of the SFO connectivity and offer great promise for understanding integrative complexity of its organization and functions. The reported study was funded by RSF according to the research project № 22-25-00105, https://rscf.ru/project/22-25-00105/.

Increased dopamine transmission and adult neurogenesis in trace amine-associated receptor 5 (TAAR5) knockout mice. Trace amine-associated receptors (TAARs) are a class of sensory G protein-coupled receptors that detect biogenic amines, products of decarboxylation of amino acids. The majority of TAARs (TAAR2-TAAR9) have been described mainly in the olfactory epithelium and considered to be olfactory receptors sensing innate odors. However, there is recent evidence that one of the members of this family, TAAR5, is expressed also in the limbic brain areas receiving projection from the olfactory system and involved in the regulation of emotions. In this study, we further characterized a mouse line lacking TAAR5 (TAAR5 knockout, TAAR5-KO mice) that express beta-galactosidase mapping TAAR5 expression. We found that in TAAR5-KO mice the number of dopamine neurons, the striatal levels of dopamine and its metabolites, as well as striatal levels of GDNF mRNA, are elevated indicating a potential increase in dopamine neuron proliferation. Furthermore, an analysis of TAAR5 beta-galactosidase expression revealed that TAAR5 is present in the major neurogenic areas of the brain such as the subventricular zone (SVZ), the subgranular zone (SGZ) and the less characterized potentially neurogenic zone surrounding the 3rd ventricle. Direct analysis of neurogenesis by using specific markers doublecortin (DCX) and proliferating cell nuclear antigen (PCNA) revealed at least 2-fold increase in the number of proliferating neurons in the SVZ and SGZ of TAAR5-KO mice, but no such markers were detected in mutant or control mice in the areas surrounding the 3rd ventricle. These observations indicate that TAAR5 involved not only in regulation of emotional status but also adult neurogenesis and dopamine transmission. Thus, future TAAR5 antagonists may exert not only antidepressant and/or anxiolytic action but may also provide new treatment opportunity for neurodegenerative disorders such as Parkinson's disease.

FLEXIBILITY WITHIN THE STIMULATION OF NEURONAL METABOLISM BY CA2+

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Ankit Dhoundiyal, Vanessa Goeschl, Helmut Kubista, Matej Hotka
Center of Physiology and Pharmacology, Department Of Neurophysiology And Neuropharmacology, Medical University Of Vienna, Vienna, Austria

Aims: Ca^{2+} influx during neuronal excitation stimulates energy production by increasing NADH shuttling through Malate aspartate shuttle (MAS) and Glycerol-3-phosphate shuttle (G3PS) or by acting on the TCA cycle enzymes after entering the mitochondria via the mitochondrial calcium uniporter (MCU). Our experiments aimed to investigate the significance of these components of neuronal metabolic machinery under different intensities of electrical activation. **Methods**: Hippocampal neuronal cultures derived from newborn rats were subjected to electric field stimulation at DIV14-21. The induced electrical activity and the metabolic changes in individual neurons were measured via live-cell imaging using fluorescent biosensors. Pharmacological agents were used to modulate various components of the neuronal metabolic machinery. **Results**: Our results show that neuronal bioenergetics is modulated by the intensity of induced neuronal activity. Stimulation of NADH shuttling by cytosolic Ca^{2+} rises sustained the energy demand at low workload, while mitochondrial calcium uptake and TCA cycle stimulation was observed only during higher workload. Moreover, neurons can compensate for the loss of any one Ca^{2+}-dependent pathways by increasing the activity of remaining pathways. Our data demonstrate that in the worst case G3PS alone can suffice to maintain cellular ATP levels during neuronal stimulation, because its activity increases during pharmacological inhibition of MAS and MCU. **Conclusions**: Metabolic flexibility in neurons is achieved by a dynamic interplay between various components of the neural metabolic machinery. Unexpectedly, much of this flexibility arises from the activity of G3PS, which appears to provide a back-up system activated during neuronal energetic crisis. **Acknowledgements:** FWF,Project P-33797

The human brain weighs only 2% of the total body mass, yet it uses about 20% of our energy. Most of the energy is consumed by neuronal activity at presynaptic boutons in axons. Mitochondria have been believed to play a main role in the production of this energy, ATP. However, it has been shown that only 50% of presynaptic boutons are associated with the mitochondria in cortical excitatory neurons. Moreover, recently, it has been reported that glycolysis, which is independent of mitochondria, could maintain presynaptic ATP levels. Therefore, it remains unclear to what extent the axonal mitochondria contribute to the ATP supply in neuronal activity. To examine the ATP production capacity of axonal mitochondria, we focused on the amount of mitochondrial DNA (mtDNA), which encodes parts of essential respiratory chain complex proteins, in each axonal mitochondrion. We aimed to determine the amount of mtDNA in single mitochondria by using quantitative PCR. To selectively isolate single axonal mitochondria from primary neuron culture, we developed a novel microscope by combining the scanning ion conductance microscope (SICM) with the fluorescence microscope. In this conference, I would like to report the characteristics of axonal mitochondria isolated by the SICM-Fluorescence

microscope.

CHOLESTEROL HOMEOSTASIS IN BRAIN FROM SAMP8 MICE: AGE-DEPENDENT EFFECT OF RESVERATROL IN CHOLESTEROL REGULATION

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Cholesterol displays a large variety of biological functions. In brain it represents ca. 23% of the total body cholesterol. Its presence and ability to regulate the fluidity of plasma membrane is crucial for the maintaining of correct neurotransmission. Cholesterol homeostasis has been reported to be dysregulated in neurodegeneration, but underlying mechanisms involved are poorly known. On the other hand, resveratrol (RSV) is an antioxidant polyphenol with neuroprotective properties. Therefore, the aim of this work was to study the age-related molecular implications of cholesterol uptake, efflux, transport and *de novo* synthesis and the effect of RSV on the cholesterol homeostasis in brain from SAMP8 mice, an animal model of aging and Alzheimer's disease. Results clearly showed an age-related increase of free-cholesterol in plasma membrane and ApoE, whereas LDL receptor, HMG-CoA-Reductase, HMG-CoA-C1 Synthase and ABCA1 transporter remained unaltered with age. On the other side, RSV treatment exhibited a different effect on cholesterol metabolism depending on age. While levels of free-cholesterol were not affected by RSV, mechanisms related to cholesterol uptake, efflux, transport and *de novo* synthesis were differently affected. In younger RSV-treated mice, LDL receptor, HMG CoA-Reductase and HMG-CoA-C1 Synthase were significantly decreased and increased, respectively, whereas ApoE and ABCA1 transporter remain unchanged. However, ApoE and HMG CoA-C1 Synthase were reduced, whereas LDL receptor, ABCA1 transporter and HMG CoA-Reductase remained unchanged in older RSV-treated mice. In conclusion, age is a prominent factor that causes cholesterol homeostasis dysregulation in brain and RSV treatment exhibited a different effect on cholesterol metabolism depending on age.

Synaptic communication is a highly energy consuming process which is central to the functioning of the brain. It is highly plastic and thus subject to variations in firing intensity and timing. Hence, energy production must also be flexible and coordinated with synaptic activity. In the pre-synapse, this process of on-demand energy production takes place mainly in the mitochondria and is driven by calcium entry into the mitochondrial matrix during firing. Although the mechanism and importance of mitochondrial calcium influx in controlling synaptic Adenosine triphosphate (ATP) production has been established, how mitochondria ensure that matrix calcium (Ca^{2+}) levels are rapidly restored to normal levels remains poorly understood. Our project aims to understand the mechanisms and importance of calcium export in axonal mitochondria. Combining genetic and optical tools with electrophysiological stimulation, we show that the protein ***Letm1*** (Leucine Zipper and EF-Hand Containing Transmembrane Protein 1), located on the inner mitochondrial matrix, regulates calcium efflux. Knockdown of Letm1 leads to increased mitochondrial calcium dwell-time, subsequently leading to excessive activity-dependent ATP production and the accumulation of presynaptic ATP in firing synapses. With respect to its effect on overall presynaptic function, knockdown of Letm1 does not change the vesicle fusion or endocytosis rates but leads to an excessive release of the neurotransmitter glutamate. Indeed, mutations in Letm1 have been linked to the occurrence of epilepsy in human patients. In the future, we aim to characterize and establish the link between mitochondrial calcium retention and the production of the neurotransmitter glutamate.

DOSE-DEPENDENT DIFFERENTIAL EFFECTS OF INTERMITTENT KETOSIS ESTABLISHED BY MEDIUM-CHAIN TRIGLYCERIDE SUPPLEMENTATION ON COGNITIVE PARAMETERS IN RATS

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Sechenov Institute of Evolutionary Physiology and Biochemistry of the Russian Academy of Sciences, Multidisciplinary Laboratory Of Neurobiology, Saint Petersburg, Russian Federation

Aims: Medium-chain triglycerides (MCT) demonstrated a range of neuroprotective effects, mostly attributed to their ketogenic properties. However, the exact mechanisms of the MCT effects on the brain and the scope of targetable deficits and cognitive functions are largely unknown. Long-term metabolic consequences of MCT supplementation in cognition-enhancing doses have not been rigorously investigated. **Methods:** We administered MCT oil (1, 3, or 6 g/kg/day) or water (control) orogastrically to 2.5-m.o. male Wistar rats for 28 days, without limiting access to standard chow, and assessed working memory in Y-maze, behavior in the Open Field, spatial learning in Morris water maze (MWM), and weight of internal organs. In a separate experiment, we evaluated the effects of MCT (3 g/kg) or lard (3 g/kg, control) supplementation for 28 days on blood biochemical parameters. **Results:** In Y-maze, MCT-1 and MCT-3 treatment improved working memory. In MWM, MCT-6 treatment improved spatial memory. The MCT-6 treatment increased liver weight and the brown/white adipose tissue ratio. Chronic MCT treatment (3 g/kg) did not affect the blood levels of glucose, lactate, pyruvate, acetoacetate, β-hydroxybutyrate, total and HDL cholesterol, triglycerides, malondialdehyde, and aspartate transaminase and alanine transaminase activities. **Conclusions:** Chronic MCT supplementation of regular chow demonstrated a non-uniform dose-dependent effect on the measured cognitive parameters. For spatial memory, the effect disappeared at the highest dose, which was also associated with changes in organ weight and adipose tissue metabolism. Further detailed studies are needed to better understand the neuroprotective effects of MCT. Supported by Russian Science Foundation (RSF, project no. 19-75-10076).

Low-dose lipopolysaccharide (LPS) inhibits aggressive and augments depressive behaviours in a chronic mild stress model in mice.
Aggression, hyperactivity, impulsivity, helplessness and anhedonia are all signs of depressive-like disorders in humans and are often reported to be present in animal models of depression induced by stress or by inflammatory challenges. However, chronic mild stress (CMS) and clinically silent inflammation, during the recovery period after an infection, for example, are often coincident, but comparison of the behavioural and molecular changes that underpin CMS vs a mild inflammatory challenge and impact of the combined challenge is largely unexplored. Here, we examined whether stress-induced behavioural and molecular responses are analogous to lipopolysaccharide (LPS)-induced behavioural and molecular effects and whether their combination is adaptive or maladaptive.

Postnatal LPS Challenge Impacts Escape Learning and Expression of Plasticity Factors Mmp9 and Timp1 in Rats: Effects of Repeated Training.
Bacterial intoxication associated with inflammatory conditions during development can impair brain functions, in particular evolutionarily novel forms of memory, such as explicit learning. Little is known about the dangers of early-life inflammation on more basic forms of learning, for example, the acquisition of motor escape abilities, which are generally better preserved under pathological conditions. To address this limitation in knowledge, an inflammatory response was elicited in Wistar pups by lipopolysaccharide (LPS) injections (25 μg/kg) on postnatal days P15, P18 and P21. The acquisition of escape behaviour

was tested from P77 by active avoidance footshock model and water maze. Open-field behaviour and blood corticosterone levels were also measured. Rat brain tissue was collected from pups 2 h post-injection and from adult rats which either underwent escape training on P77-P81 or remained untrained. mRNA levels of developmental brain plasticity factors MMP-9 and TIMP-1 were investigated in the medial prefrontal cortex and ventral/dorsal hippocampus. LPS-challenged rats displayed moderately deficient escape responses in both memory tests, increased freezing behaviour and, surprisingly, reduced blood cortisol levels. Mmp9 and Timp1, and their ratio to one another, were differentially altered in pups versus adult untrained rats but remained unchanged overall in rats trained in either learning task. Together, our data indicate that systemic pro-inflammatory response during early postnatal development has long-lasting effects, including on the acquisition of motor escape abilities and plasticity factor expression, into adulthood. Our data suggest that altered stress response could possibly mediate these deviations and repeated training might generate positive effects on plasticity under the employed conditions.

Prefrontal mRNA expression of long and short isoforms of D2 dopamine receptor: Possible role in delayed learning deficit caused by early life interleukin-1β treatment.
Long (D2L) and short (D2S) isoform of the D2 dopamine receptor are believed to play different roles in behavioral regulation. However, little is known about differential regulation of these isoforms mRNA expression during the process of learning in physiological and pathological states. In this study, we have investigated the combined effect of training in active avoidance (AA) paradigm and chronic early life treatment with pro-inflammatory cytokine interleukin (IL)-1β (1μg/kg i.p., P15-21) on D2S and D2L dopamine receptor mRNA expression in the medial prefrontal cortex (mPFC) of adult rats. We have shown differential regulation of D2 short and long mRNA isoform expression in the mPFC. There was no effect of AA-training on D2S mRNA expression, while D2L mRNA was downregulated in AA-trained control (intact and saline-treated) animals, and this effect was not observed in rats treated with IL-1β. D2S mRNA expression level negatively correlated with learning ability within control (saline-treated and intact) groups but not in IL-1β-treated animals. Thus, prefrontal expression of distinct D2 dopamine receptor splice variants is supposed to be implicated in cognitive decline caused by early life immune challenge.

Pro-neurogenic, Memory-Enhancing and Anti-stress Effects of DF302, a Novel Fluorine Gamma-Carboline Derivative with Multi-target Mechanism of Action.
A comparative study performed in mice investigating the action of DF302, a novel fluoride-containing gamma-carboline derivative, in comparison to the structurally similar neuroprotective drug dimebon. Drug effects on learning and memory, emotionality, hippocampal neurogenesis and mitochondrial functions, as well as AMPA-mediated currents and the 5-HT6 receptor are reported. In the step-down avoidance and fear-conditioning paradigms, bolus administration of drugs at doses of 10 or 40 mg/kg showed that only the higher dose of DF302 improved long-term memory while dimebon was ineffective at either dosage. Short-term memory and fear extinction remained unaltered across treatment groups. During the 5-day predation stress paradigm, oral drug treatment over a period of 2 weeks at the higher dosage regimen decreased anxiety-like behaviour. Both compounds supressed inter-male aggression in CD1 mice, the most eminent being the effects of DF302 in its highest dose. DF302 at the higher dose decreased floating behaviour in a 2-day swim test and after 21-day ultrasound stress. The density of Ki67-positive cells, a marker of adult neurogenesis, was reduced in the dentate gyrus of stressed dimebon-treated and non-treated mice, but not in DF302-treated mice. Non-stressed mice that received DF302 had a higher density of Ki67-positive cells than controls unlike dimebon-treated mice. Similar to dimebon, DF302 effectively potentiated AMPA receptor-mediated currents, bound to the 5-HT6 receptor, inhibited mitochondrial permeability transition and displayed cytoprotective properties in cellular models of neurodegeneration. Thus, DF302 exerts multi-target effects on the key mechanisms of neurodegenerative pathologies and can be considered as an optimized novel analogue of the neuroprotective agent dimebon.

Insulin downregulates C3 gene expression in human HepG2 cells through activation of PPARγ.
C3 is an acute phase protein, and thus its plasma concentration increases quickly and drastically during the onset of inflammation. Insulin plays a complex role in inflammation. Elevated level of plasma C3 was shown to correlate with heightened fasting insulin levels and insulin resistance and appears to be a risk factor for the cardiovascular disease and atherosclerosis. The main source of plasma C3 is liver. Nothing is known about effects of insulin on C3 gene expression and protein secretion by hepatocytes. In light of these data we asked if insulin is capable of regulating C3 production in

hepatocytes. Here we show that insulin downregulates C3 gene expression in human hepatoma cells HepG2 through activation of PI3K, mTORC1, p38 and MEK1/2 signaling pathways. Transcription factors PPARα, PPARγ, HNF4α and NF-κB are important contributors to this process. Insulin activates PPARγ through PI3K/Akt/mTORC1 pathway, which results in PPARγ binding to DR4 and DR0 cis-acting elements within the C3 promoter and subsequent displacement of HNF4α and PPARα from these sites. As a result PPARα/NF-κB complex, which exists on C3 promoter, is broken down and C3 gene expression is downregulated. The data obtained can potentially be used to explain the molecular mechanism underlying the correlation between heightened level of plasma C3 and insulin resistance in humans.

Developmental prefrontal mRNA expression of D2 dopamine receptor splice variants and working memory impairments in rats after early life Interleukin-1β elevation.
Long (D2L) and Short (D2S) isoforms of D2 dopamine receptor differ in their biochemical and physiological properties, which could affect functioning of prefrontal cortex. Contribution of distinct D2 dopamine receptor isoforms to cognitive dysfunctions and its developmental regulation are currently not fully elucidated. In the present study, we evaluated developmental mRNA expression of D2S/D2L dopamine receptor isoforms within the rat medial prefrontal cortex (mPFC) in the model of neurodevelopmental cognitive dysfunction. Working memory performance (Y-maze spontaneous alternations) and D2S/D2L mRNA expression in the mPFC (by qRT-PCR) were evaluated in juvenile (P27), adolescent (P42-47) and adult (P75-90) rats after chronic early life treatment with proinflammatory cytokine interleukin (IL)-1β (1 μg/kg i.p. daily P15-21). It was shown that IL-1β elevation during the 3rd week of life leads to working memory deficit originating in juvenile animals and persisting into adulthood. D2S mRNA expression was strongly downregulated during adolescence, and such downregulation was exaggerated in animals injected with IL-1β during P15-21. Early life IL-1β administrations influenced developmental changes in the D2S/D2L mRNA ratio. This measure was found to be decreased in adolescent and adult control (intact and vehicle-treated) rats compared to juvenile control, while in the case of IL-1β-treated animals, the decrease in D2S/D2L ratio was observed only in adulthood but not in adolescence compared to juvenile rats. During the adolescence, D2S mRNA expression was downregulated and D2S/D2L ratio was upregulated in the mPFC of rats treated with IL-1β during the 3rd week of life compared to controls. Based on these data we conclude that changes in the developmental expression of D2 dopamine receptor splice variants within mPFC may underlie long-lasting cognitive deficit associated with neonatal pathology.

Neonatal Exposure to Bacterial Lipopolysaccharide Affects Behavior and Expression of Ionotropic Glutamate Receptors in the Hippocampus of Adult Rats after Psychogenic Trauma.
According to the two-hit hypothesis of psychoneuropathology formation, infectious diseases and other pathological conditions occurring during the critical periods of early ontogenesis disrupt normal brain development and increase its susceptibility to stress experienced in adolescence and adulthood. It is believed that these disorders are associated with changes in the functional activity of the glutamatergic system in the hippocampus. Here, we studied expression of NMDA (GluN1, GluN2a, GluN2b) and AMPA (GluA1, GluA2) glutamate receptor subunits, as well as glutamate transporter EAAT2, in the ventral and dorsal regions of the hippocampus of rats injected with LPS during the third postnatal week and then subjected to predator stress (contact with a python) in adulthood. The tests were performed 25 days after the stress. It was found that stress altered protein expression in the ventral, but not in the dorsal hippocampus. Non-stressed LPS-treated rats displayed lower levels of the GluN2b protein in the ventral hippocampus vs. control animals. Stress significantly increased the content of GluN2b in the LPS-treated rats, but not in the control animals. Stress also affected differently the exploratory behavior of LPS-injected and control rats. Compared to the non-stressed animals, stressed control rats demonstrated a higher locomotor activity during the 1st min of the open field test, while the stressed LPS-injected rats displayed lower locomotor activity than the non-stressed rats. In addition, LPS-treated stressed and non-stressed rats spent more time in the open arms of the elevated plus maze and demonstrated reduced blood levels of corticosterone. To summarize the results of our study, exposure to bacterial LPS in the early postnatal ontogenesis affects the pattern of stress-induced changes in the behavior and hippocampal expression of genes coding for ionotropic glutamate receptor subunits after psychogenic trauma suffered in adulthood.

[The administration of interleukin-1beta during early postnatal develop ment impairs FGF2, but not TIMP1, mRNA expression in brain structures of adult rats].
According to the Neurodevelopmental hypothesis, the long-lasting cognitive deficit in schizophrenia and other types of neuropathology may occur by injurious factors, such as hypoxia, traumas, infections that take place during pre- and postnatal development, at least at early stages. These pathological conditions are often associated with the high production of pro-inflammatory cytokine interleukin-1B (IL-1B) by the cells of immune and nervous systems. We investigated the expression of

genes involved in the neuroplastic regulation (Fgf2 and Timp2) in medial prefrontal cortex and dorsal and ventral regions of hippocampus of adult rats that were treated with IL-1beta between P15 and P21. The learning impairment in IL-1beta-treated rats is accompanied by lower FGF-2 mRNA levels in medial prefrontal cortex and ventral (not dorsal) hippocampus, but TIMP-1 was not affected. No differences in TIMP-1 and FGF-2 mRNA expressions were observed in untrained IL-1beta-treated when compared to control rats.

[The influence of neonatal interleukin-1beta increase on the formation of adult rats' spatial memory].
Children's and adults' cognitive dysfunctions are frequently caused by various types of pathology such as birth injuries, hypoxias, and infections suffered in prenatal and early postnatal periods of ontogenesis. These abnormal conditions trigger high production of proinflammatory cytokines by the cells of nervous and immune systems. The role of interleukin-1 beta (IL-1beta), one of such proteins, in the formation of cognitive deficit in early ontogenesis is not sufficiently studied. In present research it was revealed that administration of IL-1beta during the third week of postnatal ontogenesis impaired the learning of adult rats in Morris Water Maze. The differences between rats of control and experimental groups were observed during the training of searching for hidden platform and during the alteration of formed reflex (when the platform was in a different place). Meanwhile the spatial extinction has not been disrupted. The nature of experimental rats' learning abnormalities allows us to assume that the mechanisms of long-term but not short-term spatial memory are damaged in this experimental situation.

ELECTROPHYSIOLOGICAL CHARACTERIZATION AND COMPUTATIONAL MODELING OF INSULIN PRODUCING CELLS IN DROSOPHILA

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Federico Cascino Milani[1], Lorenzo Fontolan[2], Sabine Fischer[3], Jan Ache[1]
[1]Julius-Maximilians Universität Würzburg, Neurobiology And Genetics, Würzburg, Germany, [2]Janelia Research Campus, Romani Lab, Ashburn, United States of America, [3]Universität Würzburg, Center For Computational And Theoretical Biology, Würzburg, Germany

Insulin Producing Cells (IPCs) are an important population of modulatory neurons in the insect brain that release Insulin-like Peptides (ILPs). ILPs have been demonstrated to play a key role in metabolic homeostasis, aging, development, and the modulation of behavior in different species, including *Drosophila melanogaster*, our model of choice. Quantifying IPC activity dynamics is crucial to developing an understanding of insulin signaling, but this task is quite challenging: IPCs are interconnected with a complex network of neuromodulatory neurons that have a wide variety of effects on IPCs and form numerous direct and indirect reciprocal connections. Due to the complexity of this system, an experimental approach is insufficient to develop a comprehensive understanding of the neural mechanisms that underlie the modulation of IPC activity, and thus insulin release. Theoretical models are powerful tools to study the dynamics of such interactions in a coherent framework. Hence, we decided to use a combined approach of electrophysiological characterization and computational modeling of IPCs and the complex network they are part of. Our aim is to develop a conductance-based neuron model of IPCs and some of their key pre- and postsynaptic partners. To feed our model, we use data collected in patch-clamp recordings of individual IPCs quantifying their intrinsic electrophysiological properties combined with optogenetic functional connectivity experiments. This data-driven model will allow us to analyze how neuromodulators produce circuit-level changes that affect the IPC network. These results will contribute to broaden our understanding of neuromodulation and metabolism in general.

DIETARY EFFECTS ON THE ACTIVITY OF INSULIN PRODUCING CELLS IN DROSOPHILA

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Rituja Bisen, Jan Ache
Julius-Maximilians Universität Würzburg, Neurobiology And Genetics, Würzburg, Germany

Insulin signaling plays a key role in controlling metabolic homeostasis. In addition, insulin is heavily implicated in processes underlying reproduction, aging and stress resistance. Insulin producing cells (IPCs) in *Drosophila* are functionally analogous to mammalian pancreatic beta cells and produce different *Drosophila* insulin like peptides (DILPs) during different stages of a fly's lifespan. In the adult fly, release of these DILPs is dependent on nutrient availability. Nutrient sensing is vital for metabolic control. Fuel substrates such as glucose serve immediate energy demanding processes such as locomotion, mating, etc. *Drosophila* IPCs are hypothesized to play a role in sensing hemolymph glucose levels cell-autonomously. Therefore, we set out to perform an *in-vivo* electrophysiological study of nutrient sensing in Drosophila IPCs. To label IPCs for patch-clamp recordings, we used a Dilp2-Gal4 driver line to express GFP in IPCs of the adult *Drosophila* brain. Using these flies, we performed targeted *in-vivo* patch-clamp recordings from IPCs while perfusing the brain with artificial hemolymph containing different concentrations of glucose and other sugars. Furthermore, we exposed flies to different diets and quantified their effects on IPC activity. In addition to quantifying the different dietary effects, we explored the effects of aging on IPC activity. We found that nutritional state and aging strongly affected IPC activity. However, varying extracellular glucose levels caused no significant changes in their activity. This indicates that, although dietary sugars have strong effects on IPC activity, IPCs are not sensitive to local changes in extracellular glucose levels *in-vivo*.

BEHAVIORAL STATE-DEPENDENT MODULATION OF INSULIN-PRODUCING CELLS IN DROSOPHILA

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Sander Liessem[1], Martina Held[1], Till Bockemühl[2], Jan Ache[1]
[1]Julius-Maiximilians Universität Würzburg, Neurobiology And Genetics, Würzburg, Germany, [2]University of Cologne, Department Of Biology, Cologne, Germany

Insulin plays a pivotal role in metabolic control, neuromodulation, and aging, but its release dynamics are not well understood. We used *Drosophila melanogaster* to study effects of locomotion on the activity of insulin-producing cells (IPCs). Using a combination of *in-vivo* patch-clamp recordings, calcium imaging, and optogenetics, we found that IPCs were inhibited during walking and flight. This modulation was graded, such that the inhibition was stronger during flight – the more energy-demanding behavior. A resulting decrease in insulin levels would support the mobilization of fuel stores and the suppression of anabolic processes during locomotion. IPC activity was increased immediately after cessation of locomotion. This rebound could contribute to replenishing muscle glycogen stores. Surprisingly, IPC modulation preceded the onset of locomotion, suggesting a feedforward mechanism impinging on IPCs. This was further supported by *ex-vivo* recordings combined with optogenetic activation of motor circuits, which revealed that IPC inhibition neither requires actual behavior, nor decreased blood sugar levels – a simple motor command was sufficient to inhibit IPCs. In a nutshell, we add the behavioral state to the list of factors regulating IPC activity in *Drosophila*. These rapid changes in IPC activity precede locomotion and may serve an increased metabolic demand. Moreover, high insulin levels are known to decrease the sensitivity of olfactory sensory neurons in flies. Hence, the inhibition of IPCs could lead to a disinhibition of olfactory sensory neurons, which could increase the likelihood of locating food sources during locomotion. Thus, behavioral state-dependent IPC modulation might enable differential sensorimotor processing.

Pyruvate carboxylase (PC) is a mitochondrial, biotin-containing enzyme catalyzing the ATP-dependent synthesis of oxaloacetate from pyruvate and bicarbonate. PC has an important anaplerotic role in sustaining the brain metabolism because it compensate for TCA cycle intermediates loss and prevent a collapse of the mitochondrial metabolism. Based on the studies performed on animal models, the expression of PC was assigned to be glia-specific. We probed the cultured human astrocytes and brain sections with antibodies against PC to study PC distribution among human neural cells. Additionally, we tested the importance of PC for the viability of cultured human astrocytes by applying the PC inhibitor 3-chloropropane-1,2-diol (CPD). Our results establish the presence of PC in cultured astrocytes and brain tissue. In addition to astrocytes, a subpopulation of the neurons in the cerebral cortex appeared to bear PC. CPD negatively affected the viability of astrocytes in culture, which could be reversed by supplementation of media with citrate, malate, and other metabolites from the TCA cycle. Our results confirmed the expected expression of PC by human astrocytes in culture and brain parenchyma. In addition to astrocytes, a subpopulation of the neurons in the cerebral cortex appeared to express PC. Furthermore, the enzymatic activity of PC is crucial for sustaining the viability of cultured astrocytes. This work was supported by the Slovak Research and Development Agency under Contract No. APVV-18-0088 and VEGA 1/0255/20.

Expression of 3-Methylcrotonyl-CoA Carboxylase in Brain Tumors and Capability to Catabolize Leucine by Human Neural Cancer Cells.
Leucine is an essential, ketogenic amino acid with proteinogenic, metabolic, and signaling roles. It is readily imported from the bloodstream into the brain parenchyma. Therefore, it could serve as a putative substrate that is complementing glucose for sustaining the metabolic needs of brain tumor cells. Here, we investigated the ability of cultured human cancer cells to metabolize leucine. Indeed, cancer cells dispose of leucine from their environment and enrich their media with the metabolite 2-oxoisocaproate. The enrichment of the culture media with a high level of leucine stimulated the production of 3-hydroxybutyrate. When C-leucine was offered, it led to an increased appearance of the heavier citrate isotope with a molar mass greater by two units in the culture media. The expression of 3-methylcrotonyl-CoA carboxylase (MCC), an enzyme characteristic for the irreversible part of the leucine catabolic pathway, was detected in cultured cancer cells and human tumor samples by immunoprobing methods. Our results demonstrate that these cancer cells can catabolize leucine and furnish its carbon atoms into the tricarboxylic acid (TCA) cycle. Furthermore, the release of 3-hydroxybutyrate and citrate by cancer cells suggests their capability to exchange these metabolites with their milieu and the capability to participate in their metabolism. This indicates that leucine could be an additional substrate for cancer cell metabolism in the brain parenchyma. In this way, leucine could potentially contribute to the synthesis of metabolites such as lipids, which require the withdrawal of citrate from the TCA cycle.

Expression of pyruvate carboxylase in cultured human astrocytoma, glioblastoma and neuroblastoma cells.
Pyruvate carboxylase (PC) is an enzyme catalyzing the conversion of pyruvate to oxaloacetate, which possesses anaplerotic role in cellular metabolism. The expression of PC was confirmed in cells of several cancer types, in which it ensures several cellular functions, such as growth and division. To investigate the expression of PC in human astrocytoma, glioblastoma and neuroblastoma cells we applied the immunodetection methods. The results of the Western blot analysis and

immunocytochemical detection revealed the presence of PC in human astrocytoma, glioblastoma and neuroblastoma cells. Furthermore, application of PC inhibitor, 3-chloro-1,2-dihydroxypropane (CDP), negatively impacts the viability of astrocytoma cells. The cytotoxic effect of CDP could be partially reversed by application of citrate, 2-oxoglutarate and malate in incubation media. Our results revealed that astrocytoma, glioblastoma and neuroblastoma cells are equipped with PC, which might significantly contribute by its anaplerotic activity to sustain the metabolism of cancer cells.

Background: Methylglyoxal (MGO), a by-product of glycolysis, is a major precursor in the formation of advanced glycation end products (AGEs) and are associated with cognitive impairment. MGO can be formed endogenously during diabetes and degraded to D-lactate by the glyoxalase (Glo) system. MGO can also be increased by dietary intake. The impact of dietary MGO on the brain is, however, unknown. Method: Adult male C57Bl/6J mice were treated with MGO (1mmol/L, drinking water) or not (control) for 3 months (n=16/group). Glo-1 protein activity was quantified as conversion rate of MGO into S-D-lactoylglutathione. MGO was measured using UHPLC-MS/MS in plasma and brain. Brain gene expression was analysed with RT-PCR. Plasma inflammatory markers were measured by ELISA. Results: Dietary MGO led to a reduction in non-fasting glucose ($p<0.0001$) and an increase in plasma levels of insulin ($p<0.0002$), leptin ($p<0.02$), CRP ($p=0.005$), IL-10 ($p=0.03$) and TNFα ($p=0.02$). Plasma MGO was unchanged, but in the subcortical region we found a 50% decrease in MGO content ($p<0.0001$). Expression and activity of Glo-1 and Glo-2 mRNA expression was unchanged, while Glo-1 activity was decreased by 9% in subcortical regions ($p=0.0016$). In cortical and subcortical regions we found a decrease in MCP-1 mRNA ($p=0.005$ and $p=0.02$) and an increase in the cortical synaptophysin mRNA ($p=0.03$). Conclusion: MGO intake decreased brain MGO content, which was associated with a reduction of the expression of inflammatory marker MCP-1 in the brain. The reduction of MGO in the brain may be indirectly due to dietary MGO induced metabolic changes.

Achieving brain clearance and preventing neurodegenerative diseases-A glymphatic perspective.
Age-related neurodegenerative diseases are a growing burden to society, and many are sporadic, meaning that the environment, diet and lifestyle play significant roles. Cerebrospinal fluid (CSF)-mediated clearing of brain waste products via perivascular pathways, named the glymphatic system, is receiving increasing interest, as it offers unexplored perspectives on understanding neurodegenerative diseases. The glymphatic system is involved in clearance of metabolic by-products such as amyloid-β from the brain, and its function is believed to lower the risk of developing some of the most common neurodegenerative diseases. Here, we present magnetic resonance imaging (MRI) data on the heart cycle's control of CSF flow in humans which corroborates findings from animal studies. We also review the importance of sleep, diet, vascular health for glymphatic clearance and find that these factors are also known players in brain longevity.

Metabolic status has a well-documented influence on peripheral organs' physiology and pathology; however mounting evidence suggests that it can also affect brain function. For example, brain resilience to aging is enhanced by caloric restriction, and ketogenic diets have been used to treat neurological diseases. Unfortunately, little is known about the impact of metabolic stimuli on brain tissue at a molecular level. Recent data obtained in liver tissue suggest that beta-hydroxybutyrate (BHB) can be a key signaling molecule regulating gene transcription. Thus, we adopted a ketogenic metabolic challenge, 48 hrs of fasting, and then assessed lysine beta-hydroxybutyrylation (K-bhb) levels in proteins extracted from the cerebral cortex. Fasting enhanced K-bhb in a variety of proteins and on histone H3. ChIP-seq experiments showed that K9 beta-hydroxybutyrylation of H3 (H3K9-bhb) was significantly enriched by fasting on more than 8000 DNA loci. Transcriptomic analysis showed that H3K9-bhb on enhancers and promoters correlated with active gene expression. Since one of the most enriched functional annotations both at the epigenetic and transcriptional level was “circadian rhythms", we studied the expression of core-clock genes in the cortex during fasting. We found that the diurnal oscillation of specific transcripts was modulated at distinct times of the day along the circadian cycle. Moreover, fasting caused long-lasting changes in diurnal locomotro behaviour. Thus, our results suggest that fasting dramatically impinges on the cerebral cortex transcriptional and epigenetic landscape, and BHB acts as a powerful epigenetic molecule in the brain through direct and specific histone marks remodelling in neural tissue cells.

THE INHIBITION OF DREAM PROTEIN AS A POTENTIAL TREATMENT AGAINST METABOLIC SYNDROME AND ITS ASSOCIATED NEUROLOGIC SIGNS.

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

José Manuel Hernández Curiel[1], Ángel Carrión Rodríguez[2]
[1]Universidad Pablo de Olavide, Physiology, Anatomy And Molecular Biology Department, Seville, Spain, [2]Universidad Pablo de Olavide, Physioloy, Anatomy And Cellular Biology Department, Seville, Spain

High fat diet (HFD) chronic intake induces metabolic syndrome in mice, characterized by a body weight increase and insulin resistance (IR). Obesity is a risk factor in the development of neurodegenerative diseases, neuropsychiatric disorders and is associated with cognitive decline. DREAM/kchip3/calsenilin (DREAM) is a multifunctional protein that belong to neuronal Ca2+ sensors family. Previous studies have demonstrated the relevance of DREAM in nociception and in learning and memory processes. In the present study we characterize the consequences of DREAM, genetic or pharmacologic, inhibition in the metabolic and behavioural alterations caused by HFD intake in mice. Our results showed that chronic pharmacological and genetic DREAM inhibition block the metabolic syndrome development, and both of its neurologic comorbidity symptoms: the anxiety-related behaviour, and the cognition deficiency. Also, pharmacologic DREAM inhibition when metabolic syndrome is established did not affect metabolic parameter but improved metabolic syndrome-related neurologic alterations. Therefore, in this study we demonstrate: DREAM inhibition may be a potential treatment to restore neurological symptoms related with metabolic syndrome; and to block metabolic syndrome induced by HFD intake.

ASTROCYTIC GLUT1 ABLATION IMPROVES SYSTEMIC GLUCOSE METABOLISM AND PRESERVES MEMORY THROUGH ENHANCED INSULIN-STIMULATED ATP RELEASE

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Carlos G. Ardanaz, María J. Ramírez, Elena Puerta, Maite Solas
University of Navarra, Pharmacology And Toxicology, Pamplona, Spain

Aims: Brain glucose supply is controlled by glucose transporter GLUT1, highly expressed in astrocytes. Ablating vascular GLUT1 leads to brain hypometabolism and impaired cognition, but this approach cannot discriminate between insufficient glucose supply and vascular breakdown-derived effects. Such question is the focus of the present work, which aims to elucidate the relevance of astrocytic GLUT1 to glucose metabolism and cognition. **Methods:** *In vitro*, cellular metabolism was examined using an extracellular flux analyzer (Seahorse). *In vivo*, astrocyte-specific gene ablation was performed using tamoxifen-inducible Cre/LoxP approaches. ^{18}F-FDG PET, glucose tolerance, insulin secretion and fasting-induced hyperphagia were characterized. Memory was assessed using the Novel Object Recognition and Morris Water Maze tasks. Purinergic agonists or antagonists were intracerebroventricularly administered before each task. ATP levels were determined using microdialysis. **Results:** GLUT1-ablated astrocytes featured reduced glucose uptake and glycolysis, but intact ATP production. Unexpectedly, mice subjected to astrocytic GLUT1 deletion (GLUT1$^{\Delta GFAP}$) showed increased CNS glucose utilization and improved metabolic status, being more efficient at suppressing hyperphagia and readjusting systemic glucose levels after hyperglycemia. Moreover, GLUT1$^{\Delta GFAP}$ mice performed memory tasks adequately. Remarkably, GLUT1-ablated astrocytes showed enhanced insulin receptor (IR) expression and insulin-stimulated ATP release. Blocking brain purinergic signaling was sufficient to prevent GLUT1$^{\Delta GFAP}$-induced metabolic and cognitive abilities. Concomitant ablation of GLUT1 and IR in astrocytes exerted the same effect, which could be rescued upon brain purinergic stimulation. **Conclusion:** Astrocytic GLUT1 ablation drives brain and systemic glucose metabolism towards a more efficient glucose-handling phenotype and promotes memory resilience, requiring enhanced astrocytic IR-dependent ATP release for these features. .

SULPIRIDE, ANTAGONIST OF D2 DOPAMINE RECEPTOR IMPROVES GLUCOSE ABSORPTION AND INSULIN TOLERANCE, AND ALTERS THE METABOLIC RATE OF MALE C57BL/6 MICE.

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Sulpiride, a selective antagonist of the dopamine D2 receptors, is a second-generation antipsychotic commonly used in the treatment of schizophrenia, depression, and gastroparesis. However, second-generation antipsychotics have been linked to detrimental effects on metabolism, such as increased body weight and hyperglycemia in humans. In male rats on a control chow diet, long term administration of sulpiride induced fatty liver and insulin resistance, and when combined with a high fat diet (HFD), sulpiride treatment resulted in exacerbated hyperglycemia and hyperinsulinemia, with unaltered body weight compared with controls fed an HFD. Here, we evaluated whether the metabolic effects of sulpiride involve actions of this drug on respiratory quotient and energy expenditure in mice. We used 8 week-old C57BL/6 male mice, treated with sulpiride (30 mg/kg/day) during 30 days and evaluated indirect calorimetry with metabolic cages during the last week of sulpiride administration. Interestingly, we found that sulpiride neither altered body weight gain nor caloric intake, but improved insulin tolerance, decreased glucose levels in fasting and posprandial conditions, and diminished serum triglyceride levels. Moreover, sulpiride decreased the respiratory quotient at daytime indicating the use of other sources of energy beyond carbohydrates, and decreased energy expenditure during the night. Together, these results suggest that sulpiride improves metabolic parameters, which is in contradiction to the notion of sulpiride being deleterious for metabolism. These differences may relate to the high doses of sulpiride used as antipsychotic. More research is needed to elucidate the mechanisms that trigger the opposite metabolic effects of sulpiride.

METABOLIC SYNDROME STATUS AND FITNESS DETERMINE THE ASSOCIATION OF INSULIN RESISTANCE WITH ABNORMAL BRAIN FUNCTIONAL DYNAMICS AND COGNITION IN PRE-DIABETES

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Karel Lopez Vilaret, Mercedes Atienza Ruiz, José Luis Cantero, Marina Fernandez Alvarez
Pablo de Olavide University, Department Of Physiology, Anatomy And Cell Biology, Seville, Spain

Altered brain functional dynamics in type-2 diabetes is associated with insulin resistance (IR). Here we study whether this relationship can be evidenced in earlier stages such as pre-diabetes, whether it depends on metabolic syndrome status (MS) and/or cardiorespiratory fitness (CRF), and whether it explains variability in cognitive performance. The cross-sectional study included 144 cognitively healthy adults (79 females, 55-78 years), 71 of whom were pre-diabetic. We applied vertex-level linear regression analysis of the entire cortex to test if IR, assessed by the Homeostasis Model Assessment (HOMA-IR), was associated with abnormalities in short- and long-range functional connectivity density (srFCD and lrFCD) hubs and whether these hubs showed altered functional coupling in pre-diabetes as a function of CRF and MS. HOMA-IR and pre-diabetes were associated with reduced srFCD and lrFCD in the left and right medial orbitofrontal cortices (mOFC), respectively. The former was mainly evident in individuals with higher CRF and the latter in individuals with better MS, but neither of these anomalies was related to cognition. Pre-diabetics with lower CRF showed grater coupling between the right mOFC and superior frontal gyrus with increased HOMA-IR that was associated with better cognition; whereas pre-diabetics with worse MS showed greater lrFCD in the left cuneus with increased HOMA-IR that was associated with worse cognition. Results suggests that pre-diabetes and IR may alter functional dynamics within vulnerable networks in Alzheimer’s disease, which might be necessary for maintaining cognitive functioning in individuals with worse CRF and MS.

Background - Both kidney and brain are highly susceptible to vascular injury as a result of exposure to vascular risk factors such as hypertension, diabetes, and obesity. Patients with kidney dysfunction are known to have a higher prevalence of cerebrovascular disease. Microvascular dysfunction, subsequent vessel rarefaction, and inflammation are suggested to be involved in this cerebro-renal connection. However, the underlying mechanisms and causative pathways are yet unknown. Our group has demonstrated the presence of cognitive dysfunction and diabetic nephropathy in Obese ZSF1 rats, making this model suitable to study renal and cerebral small vessel disease. **Aim -** To study the sequential relationship between renal and cerebral microvascular dysfunction and rarefaction induced by common risk factors in Obese vs Lean ZSF1 rats. **Methods –** Microvascular dysfunction and expression of inflammatory mediators will be characterized in renal and cerebral tissues from ZSF1 rats at three different time points. The 3D architecture and density of the microcirculation in whole brains and kidneys will be studied using tissue clearing technique combined with 2-photon and light sheet microscopies. Furthermore, mass spectrometry imaging with molecular histology will be used to investigate the pro-inflammatory lipid mediators associated with microvascular dysfunction. **Expected results -** We expect to show that capillary rarefaction and inflammation occur conjointly in renal tissue first and in brain tissue thereafter, related to the progressive expression of a set of pro-inflammatory mediators. The results of this ongoing study will contribute to identifying new inflammatory drivers which wire kidney dysfunction and cerebral vascular pathology together.

Aims The winemaking procedure results in the production of stems, a by-product that is harmful for the environment. Simultaneously, grape stems are rich in polyphenols and, therefore, they are putatively beneficial for human health. The aim of the present study was to investigate the effect of the grape stems extract on behavior, metabolism (plasma biomarkers), redox status (liver and brain regions) and on the activity of two isoforms of acetylcholinesterase (brain regions) of adult male mice. **Methods** The grape stem extract was derived from a native Greek vine, namely Mavrodaphne and was rich in polyphenols (205.2 mg/g extract). The stem extract was administrated orally (gavage, 100 mg/Kg body weight) for 28 days (long-term). Behavior analysis was assessed by using the open-field test, followed by video-tracking software (Any-maze 6.3) analysis. Metabolism parameters were determined with a clinical chemistry analyzer, while antioxidant analysis was performed by determining the SOD activity. Acetylcholinesterase activity was determined in both salt-soluble and detergent-soluble in the brain, by using Ellman's colorimetric method. **Results** Anxiolytic-like behavior was observed after the stem extract administration. This long-term administration had no effect on mice's metabolism. Stem extract treatment showed antioxidant effect and reduced acetylcholinesterase activity of both isoforms in various brain regions. **Conclusion** In conclusion, long term administration of grape stem extract, rich in polyphenols, appears to have anxiolytic, antioxidant as well as acetylcholinesterase inhibitory activity.

In vivo quantification and pharmacokinetic studies of cotinine in mice after smoke exposure by LC-MS/MS.
A sensitive analytical method was developed and validated for the quantification of cotinine in mouse plasma after exposure to smoke of 0.5, 1.0, and 1.5 commercially available cigarettes, using liquid chromatography tandem mass spectrometry. The method was validated over a linear concentration range of 0.075-20.0 ng/mL with the R value being higher than 0.99. Both the precision (coefficient of variation; %) and accuracy (relative error; %) were within acceptable criteria of <15%. The lower limit of quantification (LLOQ) for cotinine was 0.075 ng/mL with sufficient specificity, accuracy, and precision. Following exposure to 0.5, 1.0, and 1.5 cigarette smoke, it was observed that the AUC and the C increased linearly as the doses increased. The pharmacokinetics of cotinine was found linear for the range of 0.5-1.5 commercial cigarette smoke. The quantification of the concentration of cotinine in mouse plasma after smoke exposure will facilitate future behavioral and toxicological experiments in animals and may prove useful in predicting cotinine levels in humans during smoking.

Effect of rutin on anxiety-like behavior and activity of acetylcholinesterase isoforms in specific brain regions of pentylenetetrazol-treated mice.
The aim of the present study was to investigate the effect of rutin administration (100 mg/kg/day) to pentylenetetrazol (PTZ)-treated Balb-c mice (60 mg/kg/day), with respect to anxiety-like behavior using both open-field and elevated plus-maze (EPM) tests, and acetylcholinesterase (AChE) activity in salt-soluble (SS) fraction and detergent-soluble (DS) fraction of the cerebral cortex, hippocampus, striatum, midbrain, and diencephalon. Our results demonstrated that the administration of PTZ in 3 doses and the induction of seizures increased significantly anxiety behavior of mice and reduced significantly DS-AChE activity in all brain regions examined, while the reduction in the SS fraction was brain region-specific. Rutin administration to

normal mice did not affect their behavior, while it induced a brain region-specific reduction in SS-AChE and a significant decrease in DS-AChE in all brain regions. We demonstrated for the first time that pretreatment of PTZ-mice with rutin (PTZ + Rutin group) prevented the manifestation of anxiety and induced interestingly a further significant reduction on the SS- and DS-AChE activities only in the cerebral cortex and striatum, in comparison with PTZ group. Our results show that rutin exhibits an important anxiolytic effect and an anticholinesterase activity in specific brain areas in the seizure model of PTZ.

ABLATION OF CAROTID BODY ACTIVITY PREVENTS COGNITIVE DYSFUNCTION AND DECREASES ALPHA-SYNUCLEIN LEVELS IN THE BRAIN OF AN ANIMAL MODEL OF DYSMETABOLISM

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Adriana Mateus Capucho, Ana Chegão, Bernardete Melo, Fátima Martins, Joana Sacramento, Natalia Madeira, Rosalina Fonseca, Hugo Miranda, Silvia Conde
CEDOC- NMS, NOVA Medical School, Cedoc, Lisboa, Portugal

Type 2 diabetes (T2D) is an important risk factor for neurodegenerative disorders. Importantly, the overactivation of the carotid bodies (CBs) was identified in both prediabetes and T2D animal models, and the abolishment of CB activity was shown to prevent and reverse dysmetabolic states. We hypothesize that the abolishment of CBs activity, via resection of carotid sinus nerve (CSN), can ameliorate the neurodegenerative processes associated to dysmetabolism. Male Wistar rats were fed a high fat-high sucrose (HFHSu), or normal chow (NC) diet. Fourteen weeks post-diet, animals were divided and submitted to CSN ablation or sham surgery. Animals were kept under diet for more 7 weeks. Metabolic and behavioural parameters were evaluated. After sacrifice, brains were collected for protein analysis. HFHSu animals decreased the time spent in the novel arm in the y-maze test in comparison with the NC group. CSN denervated HFHSu animals spend similar time in the novel arm when compared to the NC animals.In block test at 20 weeks of diet, HFHSu animals sniff less time the novel block when compared to NC animals, and CSN resection did not modify this effect.Considering that the brain regions most related to cognitive functions are the prefrontal cortex and the hippocampus we evaluated the levels of some proteins herein. Both in the prefrontal cortex and in the hippocampus, the HFHSu animals exhibit increased levels of alpha-synuclein and APP when compared to NC, and CSN resection was able to restore it. Ablation of CBs activity prevent neurodegenerative processes by improving metabolic function.

CYTOPROTECTIVE EFFECTS OF CORDYCEPIN AGAINST OXIDATIVE STRESS-INDUCED DNA DAMAGE AND APOPTOSIS IN C6 GLIAL CELLS

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Sung Ok Kim[1], Min Yeong Park[2], Yung-Hyun Choi[3]
[1]Kyungsung University, Food And Nutrition, Busan, Korea, Republic of, [2]Dong-eui University, Anti-aging Research Center, Busan, Korea, Republic of, [3]Dong-Eui University, Biochemistry, Busan, Korea, Republic of

Aim: Cordycepin is one of the active ingredients extracted from the fungi of genus *Cordyceps*, which have been used for traditional herbal remedies. In this study, we examined the effect of cordycepin on the proliferation and apoptosis of H_2O_2-induced oxidative stress in C6 glial cells and its mechanism of action. **Methods**: To investigate the antioxidant effects of cordycepin in H_2O_2 oxidative stressed C6 cells, we measured the levels of ROS and apoptosis by flow cytometry, and also DNA damage by DNA fragmentation assay, comet assay and 8-OHdG analysis. To elucidate the mechanism underlying the effect of cordycepin the expression of genes involved in the expression of antioxidative regulators was also investigated by immune blotting. **Results and Conclusions**: The results demonstrated that preincubation of C6 glial cells with cordycepin prior to H_2O_2 stimulation inhibited cytotoxicity, comet tail formation, chromatin condensation, phospho-histone γH2AX and 8-OHdG expressions, suggesting that it prevents H_2O_2-induced ROS accumulation, cellular DNA damage and apoptotic cell death. Cordycepin also restored H_2O_2-induced mitochondrial dysfunction and prevented apoptosis by Bax/Bcl-2 ratio. Interestingly, the expression of Nrf2 was significantly increased by cordycepin in the presence of H_2O_2, which was associated with a marked increase in expression of HO-1. Additionally, the preventive effects of cordycepin were significantly abolished by zinc protoporphyrin, a HO-1 specific inhibitor, indicating that cordycepin activates the Nrf2/HO-1 axis in C6 glial cells to protect against oxidative stress. These findings suggest that cordycepin may protect glial cells against oxidative stress-induced injury through activation of the Nrf2/HO-1 signaling pathway.

Aims: Metabolic alterations have been reported in neurodegenerative disorders as a consequence of disease. However, research suggests that these alterations occur before disease onset and may be integral to early disease mechanisms. Fused in sarcoma (FUS) is an RNA binding protein that is ubiquitously expressed. *FUS* mutations are implicated in amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD). FUSDelta14 mutation causes an aggressive form of juvenile ALS. Heterozygosity in the partially humanized FUSDelta14 mouse causes late onset motor neuron degeneration with minimal phenotypes. Homozygous mice die at birth. We aim to generate homozygous mice and evaluate the effect of *FUS* mutations in disease and its role in lipid dysregulation as a pathomechanism. **Methods:** FUSDelta14 homozygous mice were generated in a defined F1 hybrid background of C57Bl/6JxDBA/2J. Comprehensive behavioural tests (metabolic, motor and cognitive) and RNA-sequencing on brain, spinal cord, white and brown adipose tissue, liver and tibialis muscle were conducted at a pre-symptomatic disease stage. **Results:** Homozygous FUSDelta14 mice are smaller than heterozygous and wild-type littermates. The brain is the most transcriptionally altered tissue with dysregulation in neuronal activity and function. At 9-weeks, homozygous mice showed structural brain changes and cognitive impairment. These mice also displayed early systemic metabolic alterations, from increases in fat depots to a fat fuel preference. Targeted transcriptomic analysis revealed widespread lipid metabolism dysregulation. **Conclusions:** The FUSDelta14 mutation causes early central lipid metabolic alterations that have an impact on phenotypes, placing lipid dysregulation as one of the main pathological mechanisms in the ALS-FTD spectrum of disorders.

Introduction/Aim: The anorexigenic adipokine leptin controls energy homeostasis through its hypothalamic action, however in a context of diet-induced obesity (DIO) circulating leptin quickly fails to reach its target neurons in the mediobasal hypothalamus (MBH). Interestingly it has been shown that tanycytes, ependymoglial cells lining the floor of the third ventricle, endocytose blood-borne leptin from the external zone of the median eminence and shuttle it into the MBH. AMPK-activated protein kinase (AMPK) is a known regulator of both cellular and whole-body energy homeostasis. Interestingly, in the hypothalamus, it has been demonstrated that AMPK mediates peripheral hormones-actions over their central control of metabolism. Considering the relevant role of AMPK in the control of cellular energy balance and its implication in energy metabolism, here we investigate whether pharmacological AMPK modulation plays a role in tanycyte-mediated shuttling of blood-borne leptin into the MBH. **Methods/Results:** Using tanycyte primary cultures from rats, we tested if leptin uptake and secretion by tanycytes is regulated by AMPK. Pharmacological activation of AMPK potentiates tanycytic leptin transcytosis while its inhibition reduces it. Since it has been previously described that ERK-pathway is involved in the release of the leptin taken up by tanycytes, we also assessed whether AMPK modulation induces ERK activation, but neither AMPK activation nor its inhibition had any effects on ERK phosphorylation. **Conclusions:** Taking into account the promising *in vitro* results, we are next investigating whether pharmacological and genetically modulation of AMPK alters circulating leptin transport into the MBH of DIO mice. COMPARTMENTATION OF POLYAMINE METABOLISM IN HIPPOCAMPAL SUBREGIONS

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Aleksandra Kaczyńska[1], Agata Dalka[1], Katarzyna Skowrońska[2], Paula Vázquez Sufuentes[1], Martyna Podgajna[1], Aleksandra Owczarek[1], Magdalena Zielińska[2], Michał Węgrzynowicz[1]
[1]Mossakowski Medical Research Institute, Polish Academy of Sciences, Laboratory Of Molecular Basis Of Neurodegeneration, Warsaw, Poland, [2]Mossakowski Medical Research Institute, Polish Academy of Sciences, Department Of Neurotoxicology, Warsaw, Poland

Aims: Polyamines are polyvalent cations involved, among others, in neurotransmission and neuroprotection. Hippocampus contains high levels of polyamines, but their distribution and roles in this structure are not well understood. The aim of this study was to determine the precise localization of polyamine metabolic machinery within the hippocampus in order to establish the potential involvement of polyamines in specific functions and phenotypes of selected hippocampal subregions. A special attention was given to arginase 2 (Arg2), an enzyme supplying ornithine (Orn), a major substrate for polyamine synthesis.
Methods: Allen Brain Atlas of mouse gene expression was used to explore the spatial distribution of mRNA of polyamine metabolism-related genes. Next, the experiments were performed using WT mice and mouse line with Arg2 gene knockout. Localization of selected proteins was studied using immunohistochemistry. The protein levels were determined with western blotting. The amino acid content was measured by HPLC.
Results: According to the Allen Brain Atlas, CA2 subregion appears to display a unique profile of expression of polyamine-related genes. As confirmed by immunohistochemistry, Arg2 protein is specifically expressed in pyramidal neurons of CA2, and absent in other cell types and other regions. Loss of Arg2 results in accumulation of arginine (Arg) and reduction of Orn.
Conclusions: These results suggest strict compartmentation of polyamine metabolism in the hippocampal subregions. Neuronal Arg2 in CA2 appears to be a key source of Orn for local polyamine synthesis, what may support specific phenotypes of this region, including high synaptic stability and decreased sensitivity to neurotoxic insults.

MYELIN LIPIDS AS NERVOUS SYSTEM ENERGY RESERVES

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Ebrahim Asadollahi, Klaus-Armin Nave
Max-Planck-Institute for Multidisciplinary Sciences, Neurogenetics, Göttingen, Germany

Neuronal functions and impulse propagation depend on the continuous supply of glucose. Surprisingly, the mammalian brain has no obvious energy stores, except for astroglial glycogen granules. Oligodendrocytes make myelin for rapid axonal impulse conduction and also support axons metabolically with lactate. Here, we show that myelin itself, a lipid-rich membrane compartment, becomes a local energy reserve when glucose is lacking. In the mouse optic nerve, a model white matter tract, myelinating oligodendrocytes survive glucose deprivation far better than astrocytes. Surviving starvation required oxygen and fatty acid beta-oxidation. Importantly, fatty acid oxidation also contributes to axonal ATP generation and nerve conductivity. This metabolic support by fatty acids is an oligodendrocyte function, involving mitochondria and myelin-associated peroxisomes, as shown with mice lacking Mfp2. To study reduced glucose availability *in vivo* without physically starving mice, we deleted the Slc2a1 gene from mature oligodendrocytes. This caused a significant decline of the glucose transporter GLUT1 from the myelin compartment leading to myelin sheath thinning. We suggest a model of myelin dynamics in which normal lipid turnover can buffer axonal energy metabolism under low glucose conditions. This may explain the gradual loss of myelin in a range of neurodegenerative diseases with underlying hypometabolism.

L-SERINE-MEDIATED PKM2 ALLOSTERIC REGULATION COORDINATES L-SERINE SYNTHESIS, GLYCOLYTIC RATE AND LACTATE RELEASE

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Emmanuel Than-Trong, Gilles Bonvento
CNRS - CEA, Mircen, Fontenay-aux-Roses, France

Lactate and L-serine are both 3-carbon metabolites produced from the glycolytic processing of glucose. Whereas lactate corresponds to the end product of glycolysis, L-serine is derived from 3-phosphoglycerate, a glycolytic intermediate. In the brain, both compounds are mainly produced by astrocytes, glial cells endowed with the ability to regulate their glycolytic flux. Interestingly, both metabolites are also signalling molecules. Neuronal activity stimulates astrocytic glycolysis and results in the production of lactate that supports neurons' energetic needs, increases their excitability and favours memory consolidation by potentiating neuronal NMDA receptors through still unknown mechanisms. L-serine is a direct precursor for the NMDA receptor co-agonists D-serine and glycine and, as such, indirectly contributes to synaptic plasticity and memory. Together, the converging inputs of both L-serine and lactate on NMDA receptor activity highlights the potential relevance of a tight coordination between lactate and L-serine production. Interestingly, in astrocytes, the last irreversible step of glycolysis is catalysed by the M2 isoform of pyruvate kinase (PKM2), which was previously reported to be allosterically activated by L-serine in cancer cell lines, thus suggesting a potential mechanism for coordinating L-serine with lactate production. Here, by using a combination of intracellular and extracellular lactate and pyruvate nanosensors expressed in primary astrocytes, we show that the allosteric activation of PKM2 by L-serine stimulates glycolysis and triggers the release of lactate. Those preliminary results suggest that the allosteric regulation of PKM2 by L-serine may provide a mean to match the NMDA receptor activity of neurons with their appropriate energy supply.

P. Pavlov Department Of Physiology, Saint Petersburg, Russian Federation

RT-qPCR has become the gold standard in mRNA expression analysis. It requires an accurate choice of reference genes (RGs) for adequate normalization. The aim of this study was to validate the RGs for qPCR experiments in the brain of adult Wistar rats in the model of mild ketosis established through intermittent fasting (6 h a day) and supplementation with medium chain triglycerides (MCT) oil (2 ml/kg, i.g.; equivolume volume in controls) for 1 month. The mRNA expression of 9 RGs (*Actb, B2m, Gapdh, Hprt1, Pgk1, Ppia, Rpl13a, Sdha, Ywhaz*) was measured in the medial prefrontal cortex (mPFC), dorsal (DH) and ventral (VH) hippocampus. We used the RefFinder® online tool to asses RG stability. The most stably expressed RGs were found to be *Ppia, Actb,* and *Rpl13a* in the mPFC; *Rpl13a, Ywhaz* , and *Pgk1* in the DH; *Ywhaz, Sdha* , and *Ppia* in the VH. The stabilities of the examined RGs were lower in the DH compared to the VH and the mPFC. When normalized to the three most stably expressed RGs, the *Gapdh* mRNA was upregulated, while the *Sdha* mRNA was downregulated in the mPFC of MCT-fed animals. Thus, the RGs expression stability strongly depends on the examined brain regions. The dorsal and ventral hippocampal areas differ in RG stability rankings, which should be taken into account in the RT-qPCR experimental design. The study was funded by the Russian Science Foundation (RSF), project no. 19-75-10076.

The maintenance of energy homeostasis requires communication between the hypothalamus and peripheral organs. The latter send messages about their metabolic status to the hypothalamic arcuate nucleus, which integrates and respond according to these signals. The modulation of this access is done in part via the blood-arcuate nucleus interface whose permeability is regulated after a 24-hour fast, linking oestrogens, energy metabolism and the access of peripheral signals to the arcuate nucleus. While many studies focus on the dialogue between adipose tissue and the hypothalamus via leptin access to the arcuate nucleus, few studies have focused on the liver-hypothalamus axis. In this study we are interested in the action of oestrogens on hepatic metabolism and the consequences on the hypothalamic regulation of energy metabolism. Indeed, in the liver, the expression of the alpha receptor (ERα) regulates lipid and carbohydrate metabolism as well as the secretion of hepatokines. We hypothesize that hepatic ERα is involved in energy metabolism regulated by the liver-brain axis and that among the different molecules secreted by the liver under the influence of oestrogens, there is a factor allowing the modulation of the permeability of the blood-arcuate nucleus interface. The preliminary studies indicate that the absence of the hepatic receptor alters the increase in permeability of the blood-arcuate nucleus interface normally induced by fasting. Thus, the hepatic ERα would be involved in regulating the access of peripheral signals to their brain targets and would contribute to the regulation of energy metabolism by the hypothalamus.

EARLY LIFE ADVERSITY AND A SEX-SPECIFIC POLYGENIC RISK SCORE FOR ALTERED FASTING INSULIN ARE ASSOCIATED WITH EXECUTIVE FUNCTIONING

POSTER SESSION 04 - SECTION: THE BRAIN AND METABOLISM

Aashita Batra[1], Guillaume Elgbeili[2], Eamon Fitzgerald[2], Sachin Patel[2], Darina Czamara[3], Irina Pokhvisneva[2], Michael Meaney[2,4,5,6], Elisabeth Binder[3], Patricia Silveira[2,4]
[1]McGill University, Integrated Program In Neuroscience, Montreal, Canada, [2]Douglas Mental Health University Institute, Ludmer Centre Of Neuroinformatics And Mental Health, Verdun, Canada, [3]Max Planck Institute of Psychiatry, Translational Research In Psychiatry, Munich, Germany, [4]McGill University, Psychiatry, Montreal, Canada, [5]Yong Loo Lin School of Medicine, National University Of Singapore, Singapore, Singapore, [6]Singapore Institute for Clinical Sciences and Brain, Translational Neuroscience Program, Singapore, Singapore

Considering the high prevalence of co-morbidity between altered metabolism and executive function problems (e.g. obesity and ADHD), we hypothesized that 1) the genetic background associated with altered fasting insulin (FI) and ADHD could be shared; 2) if (1) is rejected, interactive models between the genetic background associated with altered FI and childhood environment would better predict executive functions. Using conjunctional false discovery rate, we found no shared SNPs between the FI GWAS and ADHD GWAS. (2) We calculated polygenic risk scores (PRS) from the sex-specific FI GWAS and identified the threshold that best predicted insulin levels in male and female in ALSPAC children [N_{males}=1,901, $N_{females}$=1,834; $p_{t\text{-}intial\text{-}males}$= 0.05 (11,121 SNPs), $p_{t\text{-}intial\text{-}females}$=0.15 (27,202 SNPs)], further refining it to only include SNPs significantly associated with insulin levels [$p_{t\text{-}refined\text{-}males}$=635 SNPs, $p_{t\text{-}refined\text{-}females}$=1,449 SNPs]. Phewas was run to identify executive functions predicted by the interaction between the refined PRS (rPRS) and early adversity at different ages and attention-related outcomes were highlighted in multiple cohorts (MAVAN, GUSTO, ABCD, UKB). To assess whether there is direct causal relationship between fasting insulin levels and attention, we used mendelian randomization (MR). Two-sample MR analysis using an inverse-variance-weighted fixed-effects approach between the sex-specific FI GWAS and the sex-specific ADHD GWAS suggests that there is no causal effect between the traits in either males [p=0.06] or females [p=0.18]. This solidifies our hypothesis that the relationship between altered fasting insulin and executive function is not direct but especially relevant after early life adversity exposure, which we plan to inspect in our future work.

Cerebral ischemia is a multifactorial pathology characterized by different events evolving in time. The acute injury, characterized by a massive increase of extracellular glutamate levels, is followed by a secondary brain injury that develops from hours to days after ischemia. Previous data obtained by our laboratory demonstrated that both adenosine A_{2A} and A_{2B} receptor agonists, CGS21680 and BAY60-6583, chronically administered, are protective after transient cerebral ischemia in the rat, by contrasting the secondary inflammatory damage. Aim of our study was to assess the putative neuroprotective effects of the newly synthetized A_{2A}/A_{2B} receptor mixed agonist, MRS3997, chronically administered (0.1 mg/kg, i.p., twice/day for 7 days) after transient (1 hour) focal cerebral ischemia induced by middle cerebral artery occlusion (MCAo) in the rat. Behavioural, histological and immunohistochemical experiments were performed to evaluate damage parameters after ischemia. Chronic treatment with MRS3997 significantly improved neurological deficit, up to 7 days after tMCAo ($P<0.03$). Seven days after ischemia, A_{2A}/A_{2B} receptor mixed agonist has significantly reduced the volume of ischemic brain damage in cortex and striatum ($P<0.04$) and reduced the activation of microglial cells and the astrogliosis in perischemic areas. These preliminary results show that synergic stimulation of A_{2A} and A_{2B} receptors reduces the ischemic brain damage and improves the neurological deficit. Further experiments are needed to confirm the hypothesis that the simultaneous activation of A_{2A} and A_{2B} receptors located both on brain cells and on blood cells could potentially be more protective than A_{2A} and A_{2B} receptor agonists administered individually.

BRAIN DAMAGE IN APOE -/- MICE WITH CHRONIC CEREBRAL HYPOPERFUSION: PARTICIPATION OF SIRT1, SIRT3 AND IGF1

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Tetiana Lapikova-Bryhinska[1], Tetiana Voznesenskaya[2], Katerina Rozova[3], Helen Purnyn[4], Vitalii Maslov[4], Serhii Olefir[5], Olha Harmatina[3]
[1]Bogomoletz Institute of Physiology NAS of Ukraine, General And Molecular Pathophysiology, Kyiv, Ukraine, [2]Bogomoletz institute of Physiology NAS of Ukraine, Department Of Immunophysiology, Kyiv, Ukraine, [3]Bogomoletz Institute of Physiology, Department Of Hypoxic States Investigation, Kyiv, Ukraine, [4]Bogomoletz institute of Physiology NAS of Ukraine, Department Of Neuronal Networks Physiology, Kyiv, Ukraine, [5]Bogomolets National Medical University, Department Of Neurosurgery, Kyiv, Ukraine

Chronic cerebral hypoperfusion (CCH) is the cause of most cerebrovascular diseases. Apolipoprotein E (ApoE) is an important risk factor for atherosclerosis, myocardial ischemia, and Alzheimer's disease. The aim of present study was to investigate sirtuin-dependent mechanisms underlying CCH-induced brain damage in ApoE-/- mice. Methods: The experiments were performed on 6-weeks old C57 wild type (WT) and ApoE-/- male mice. A model of chronic cerebral hypoperfusion by permanent unilateral occlusion of the common carotid artery was used to mimic chronic hypoxic/ischemic states. In 8 weeks after occlusion, histological changes in the hippocampus were observed by hematoxylin and eosin staining. DNA neurons damages were assessed using the DNA comet assay. SIRT1, SIRT3, IGF1 were detected by RT-PCR assay. Results: ApoE-/- animals displayed increased of injured hippocampal neurons and DNA neurons damage (due to 3 classes of DNA comets) after CCH, as compared to controls. WT mice were severely affected: we observed increased damage of the hippocampus of the CCH and 3-4 classes of DNA comets as compared to controls. Moreover, in the brain of WT mice exposed to CCH sharply reduced levels of SIRT1 by 89%, SIRT3 by 91%, IGF1 by 90% expressions respectively, and these levels were reduced by 15%, 31%, 29% respectively in ApoE-/- mice under the same conditions. Conclusions: We conclude that ApoE exerts an injurious action in CCH-induced brain damage affecting SIRT1, SIRT3, and IGF1 expression; it may be a target of therapeutic strategies in hypoxic/ischemic states treatment.
Keywords: chronic cerebral hypoperfusion, ApoE, SIRT1, SIRT3, IGF1, brain damage.

Genotype Associations with the Different Phenotypes of Atopic Dermatitis in Children.
This study deals with detecting the associations of atopic dermatitis' (AD) phenotypes in children: alone or combined with seasonal allergic rhino-conjunctivitis (SARC) and/or perennial allergic rhinitis (PAR), and/or with bronchial asthma (BA) with single nucleotide polymorphisms (SNP) of filaggrin (FLG), thymic stromal lymphopoietin (TSLP) and orsomucoid-like-1 protein 3 (ORMDL3) genes. Male and female pediatric patients aged from 3 to 18 years old were recruited into the main (AD in different combinations with SARC, PAR, BA) and control groups (disorders of digestives system, neither clinical nor laboratory signs of atopy). Patients were genotyped for SNP of rs_7927894 FLG, rs_11466749 TSLP, rs_7216389 ORMDL3 variants. Statistically significant associations of the increased risk were detected of AD combined with SARC and/or PAR and AD combined with BA (possibly, SARC and/or PAR) with C/T rs_7927894 FLG and T/T rs_7216389 ORMDL3 genotypes. Genotype C/C rs_7927894 FLG significantly decreases the risk of AD combined with SARC and/or PAR by 2.56 fold. Several genotypes' associations had a trend to significance: C/C rs_7216389 ORMDL3 decreases and C/T rs_7216389 ORMDL3 increases the risk for developing AD alone phenotype; A/G rs_11466749 TSLP decreases the risk of AD combined with BA (possibly, SARC and/or PAR) phenotype development.

Altered biogenesis of microRNA-1 is associated with cardiac dysfunction in aging of spontaneously hypertensive rats.
Currently we face the issues of aging-associated pathologies, particularly those leading to heart failure. With that in mind, in current research we focus on aging and hypertension combination as a widely spread threating problem. In a row with

functional and morphological characterization of these aging- and hypertension-associated cardiac changes, we evaluate biogenesis of microRNA-1 being one of major microRNAs in the heart. The aim of this study was to check the hypothesis if dysregulation of microRNA-1 biogenesis is associated with heart failure in aged and especially aged hypertensive rats. The experiments were carried out on male SHR and Wistar rats of age 6 months (young) and 18 months (old). The evaluation of hemodynamic parameters was performed in heart left ventricles of narcotized rats using the ultra-small 2F catheter. The development of fibrosis was determined using light and electron microscopy. Levels of mature and immature forms of microRNA-1 and mRNA encoding the proteins involved in its biogenesis were determined using reverse transcription and quantitative PCR. Aging of both Wistar and SHRs is accompanied with altered hemodynamic parameters compared with correspondent younger mates. SHRs, especially old ones, demonstrated significant heart fibrosis. In aged animals, the level of primary microRNA-1 in Wistar rats were 7 times higher ($p < 0.05$) and in SHR 17 times higher ($p < 0.05$) in comparison with young rats of the same strain. We also observed 22 times higher level of immature microRNA-1 in the heart of Wistar and 5.9 times higher level for aged hypertensive rats ($p < 0.05$) compared to young rats. At the same time, the level of mature microRNA-1 occurred 2.5 and 3.2 times lower in respective groups ($p < 0.05$). In the current study, we observe the significant dysregulation of microRNA-1 processing in the heart associated with aging and arterial hypertension.

shRNA-Induced Knockdown of a Bioinformatically Predicted Target IL10 Influences Functional Parameters in Spontaneously Hypertensive Rats with Asthma.
One of the most common comorbid pathology is asthma and arterial hypertension. For experimental modeling of comorbidity we have used spontaneously hypertensive rats with ovalbumin (OVA)-induced asthma. Rats were randomly divided into three groups: control group, OVA-induced asthma group; OVA-induced asthma + IL10 shRNA interference group. Target gene (IL10) was predicted by ANDSystem. We have demonstrated that RNA-interference of IL10 affected cardiovascular (tested using Millar microcatheter system) as well as respiratory functions (tested using force-oscillation technique, Flexivent) in rats. We have shown that during RNA-interference of IL10 gene in vivo there were changes in both cardiac and lung function parameters. These changes in the cardiovascular parameters can be described as positive. But the more intensive heart workload can lead to exhaust and decompensation of the heart functions. Knockdown of IL10 gene in asthma modeling induces some positive changes in respiratory functions of asthmatic animals such as decreased elastance and increased compliance of the lungs, as well as less pronounced pathomorphological changes in the lung tissue. Thus, we provide the data about experimentally confirmed functionality changes of the target which was in silico predicted to be associated with both asthma and hypertension - in our new experimental model of comorbid pathology.

OXYGEN AND GLUCOSE DEPRIVATION INDUCES UNCONVENTIONAL TRANSLOCATION OF ER-RESIDENT PROTEIN TO THE NEURONAL SURFACE.

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Charlotte Lechevallier[1], Hortense Triniac[1], Denis Vivien[1], Eloïse Lemarchand[2], Benoît Roussel[1]
[1]Inserm U1237, University Of Caen Bb@c, Caen, France, [2]INSERM U1237, University Of Caen Bb@c, CAEN, France

Aims: Disruption of proteostasis is a major consequence of ischemic stroke, causing a disruption of calcium homeostasis and an endoplasmic reticulum (ER) stress. This latter promotes the translocation of the ER resident chaperone GRP78 to the neuronal surface where it appears to act as a receptor for unsuspected proteins. For example, we shown that tissue-type plasminogen activator (tPA), binds to cell surface GRP78 to promote neuroprotection during stroke. The aim of this study is to understand the mechanism of translocation of GRP78 to the neuronal surface. Methods: Both PC12 cells and mouse primary cortical neurons have been subjected to various stresses including ER stress inducers, autophagy modulators, and oxygen and glucose deprivation (OGD, an in vitro model of ischemia). Proteostasis (including ER stress and autophagy), GRP78 translocation and secretory pathways have been investigated in these conditions by western blot, cross-linking and immunoprecipitation, and confocal imagery following lentiviral transduction. Results: Biotinylation of total cell surface protein and avidin pull-down showed that both ER stress and autophagy inducers as well as OGD increase chaperone proteins (GRP78 and GRP94) and their translocation to the cell surface. Treatment with blockers of the classic secretory pathway (ER to Golgi) did not affect the translocation of chaperones. Conclusions: Our results indicate that pharmacological dysregulation of proteostasis and OGD induce a translocation of chaperones from the ER to the cell surface (mainly GRP78 and GRP94) through an unconventional secretory pathway.

THE ROLE OF THE HYPOXIA-INDUCIBLE FACTOR 2α IN FOCAL CEREBRAL ISCHEMIA

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Vincent Von Oepen, Joachim Fandrey, Tristan Leu
University of Duisburg-Essen, Institute Of Physiology, Essen, Germany

Insufficient blood flow in stroke interferes the brain from proper oxygenation, leading to the stabilization of hypoxia-inducible factors (HIFs). To determine the role of HIFs in stroke, particularly HIF-2α, we use an *in vivo* mouse model called tMCAO (transient middle cerebral artery occlusion) and an *in vitro* model with human SH-SY5Y cells. On both, *Hif-2α* deficient and wild type mice, tMCAO was performed for two hours and protein and RNA samples were collected of ischemic and control brains. To simulate stroke in SY5Y cell culture, oxygen-glucose-deprivation (OGD) experiments were performed under almost anoxic conditions (0.2% oxygen) and without glucose for up to 4 hours following reperfusion. Prior to reperfusion, either Roxadustat or a selective HIF-2α inhibitor (PT-2358) were administered. First results show a significant increased expression of HIF-2α regulated neurotrophic factors already after one hour of hypoxia, while the inhibition of HIF-2α during reperfusion leads to significantly less cell death. Our preliminary results lead us to the conclusion that HIF-2α might influence the outcome during hypoxia and reperfusion in a time-dependent manner. In future experiments we want to figure out the effects of HIF-2α during stroke and reperfusion by analyzing more HIF-2α target genes via qPCR, as well as getting more insights of the HIF-2α regulation by Western Blot analysis.

PARTIAL PRESSURE OF OXYGEN AND CEREBRAL BLOOD FLOW IN THE BRAINS OF CONSCIOUS, FREELY MOVING RATS DURING HYPOXEMIA.

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Rawan Barakat, Ghanim Al-Khaledi, Marian Turcani, Kamal Matar, Al-Sarraf, Zoran Redzic
Kuwait University, Physiology, Kuwait, Kuwait

Background: Low pressure of O_2 in inspired air (PiO_2) causes CNS dysfunction, however, it is unclear how PO_2 in the brain (PtO_2) and cerebral blood flow (CBF) change when PiO_2 is low. **Aim**: To explore PtO_2, CBF and lactate in the brains of conscious, freely moving rats during hypoxemia caused by low PiO_2. **Methods** PtO_2 or CBF sensors were implanted in the associated motor cortices of SD rats, and, after a recovery period, measurements were recorded before and during 48h hypoxemia (8% O_2 in N_2 in O_2-Control *In-Vivo* Cabinet equipped with gas analyzer), with or without CO_2 scrubbing protocol being applied. Blood, CSF and brain samples were collected at various time points to estimate lactate concentrations. Data was compared by paired or unpaired t-test; $p<0.05$ was set as a level of significance. **Results:** PtO_2 was 49.5±0.52 mmHg when PiO_2 was normal. Reduced PiO_2 caused hypoxia in the brains, which was evident from a sharp decline in PtO_2, reaching ≤10±2.09 mmHg after 2.5h, and from an increase in lactate concentrations in the brain and CSF ($p<0.05$). However, PtO_2 increased steadily after 3h, reaching 27.6±0.15 and 16.5±0.55 mmHg ($p<0.05$) after 48h, without and with CO_2 scrubbing protocol being applied, respectively. Lactate in the brain and CSF remained elevated, while pial and capillary CBF did not change during the time course of hypoxemia. **Conclusion:** The ability of the rat brain to adapt to hypoxemia was largely related to the degree of hyperventilation, which depended on P_{CO2}, rather than the increase in the CBF.

EVALUATION OF P53 EXPRESSION AND INTERACTION WITH HDAC2 IN THE ACUTE PERIOD AFTER PHOTOTHROMBOTIC STROKE IN RATS

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Moez Eid, Svetlana Batalshchikova, Valeria Guzenko, Svetlana Demyanenko
Southern Federal University, Laboratory Of Molecular Neurobiology, Rostov-on-Don, Russian Federation

Aims. The aim of our work was to study the change in the level of the apoptosis regulator p53 protein and its interaction with histone deacetylase 2 (HDAC2) in the perifocal region of photothrombotic stroke (PTS) 4 hours and 7 days after injury. **Methods.** Western blotting was used to study the level of p53 in the nuclear and cytoplasmic fractions of the penumbra after PTS. Colocalization of p53 with class I HDACs was assessed by immunofluorescence microscopy. We also assessed the interaction between p53 and HDAC2 using Duolink Proximity Ligation Assay (PLA) followed by fluorescence microscopy. **Results.** The level of p53 increased in the nuclear fraction of the penumbra by 1.5 times 4 hours after PTS. However, 7 days after PTS, its content in the nuclei did not differ from that in sham-operated animals. P53 increased in the cytoplasmic fraction by 3 times on the first day and did not change on the 7th day after PTS. P53 was found in neurons 4 hours and 7 days later, but not in astrocytes or macrophages. Immunofluorescence microscopy showed that the cellular and intracellular localization of p53 coincided with HDAC2. Interaction between p53 and HDAC2 was detected in the perifocal region 4 hours after photothrombotic stroke in rats. **Conclusions.** Our results indicate the increased p53 expression and its interaction with HDAC2 in the acute period after photothrombotic stroke in rats. The study was supported by the Russian Science Foundation (grant No. 21-15-00188).

The Role of p53 Protein in the Realization of the Exogenous Heat Shock Protein 70 Anti-Apoptotic Effect during Axotomy.
The search for effective neuroprotective agents for the treatment of neurotrauma has always been of great interest to researchers around the world. Extracellular heat shock protein 70 (eHsp70) is considered a promising agent to study, as it has been demonstrated to exert a significant neuroprotective activity against various neurodegenerative diseases. We showed that eHsp70 can penetrate neurons and glial cells when added to the incubation medium, and can accumulate in the nuclei of neurons and satellite glial cells after axotomy. eHsp70 reduces apoptosis and necrosis of the glial cells, but not the neurons. At the same time, co-localization of eHsp70 with p53 protein, one of the key regulators of apoptosis, was noted. eHsp70 reduces the level of the p53 protein apoptosis promoter both in glial cells and in the nuclei and cytoplasm of neurons, which indicates its neuroprotective effect. The ability of eHsp70 to reverse the proapoptotic effect of the p53 activator WR1065 may indicate its ability to regulate p53 activity or its proteosome-dependent degradation.

THE ROLE OF α-KETOGLUTARATE/MTOR-MEDIATED SIGNALING PATHWAYS IN MAINTAINING THE VIABILITY OF BRAIN CELLS IN NORMAL AND ISCHEMIC CONDITIONS

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Olha Kostiuchenko, Galyna Skibo, Iryna Lushnikova
Bogomoletz Institute of Physiology, Department Of Cytology, Kyiv, Ukraine

Most brain diseases are accompanied by circulatory failure and subsequent ischemia/reperfusion injury. The pathogenesis involves such processes as glutamate excitotoxicity, ion imbalance, oxidative stress, apoptosis, autophagy, etc. Investigation of the role of the mTOR-mediated signaling pathway (mammalian target of rapamycin (mTOR) is a key regulator of cellular metabolism including autophagy) in neuroprotective mechanisms has been the subject of numerous studies. In the context of ischemia-induced autophagy, the relationship between mTOR- and AKG-mediated signaling (α-ketoglutarate (AKG)) is assumed, but many aspects of this interaction have not yet been elucidated. This study presents an analysis of AKG/mTOR-mediated neuroprotection in ischemia model in vitro using transient oxygen-glucose deprivation (OGD) or glutamate excitotoxicity in hippocampal cell cultures. Using LDH/MTS assays, we monitored cell viability and mitochondrial activity with/without AKG and rapamycin (mTOR inhibitor) treatment. It was found that treatment with AKG and rapamycin, both separately and together, increased the viability of hippocampal cell cultures, which was reduced under conditions of OGD or glutamate. This was accompanied by an increase in PSD95 immunoreactivity at an early stage of the study (1 h after damage to OGD or glutamate), which may indicate the activation of synaptogenesis. In addition, an increase in LC3 (marker of autophagy) immunoreactivity was detected at 4 hours, indicating a delayed activation of autophagy. In our experimental model, AKG and rapamycin caused unidirectional effects, with the action of AKG being comparable to mTOR blocking. Thus, our results point to the important role of AKG/mTOR-mediated signaling pathways in maintaining neuronal viability under ischemic conditions.

Diet-induced changes in brain structure and behavior in old gerbils.
Aging is associated with many physiological alterations such as changes in metabolism, food intake and brain dysfunction. Possible ways to correct age-related brain dysfunction using dietary treatments still remains undeveloped. The aim of our research was to investigate whether long-term dietary treatment with 2-oxoglutarate (2-OX), which is involved in many regulatory pathways, together with pancreatic-like enzymes of microbial origin (PLEM), which ensure appropriate digestion and absorption of nutrients, affects age-related changes in the brain morphology and cognitive function in old Mongolian gerbils.

MODULATING REDUCED FOLATE CARRIER 1 GENE EXPRESSION CHANGES BLOOD-RETINA BARRIER IN HEALTHY AND ISCHEMIC MICE RETINA

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Gokce Gurler[1], Nevin Belder[1], Mustafa Beker[2], Melike Sever-Bahcekapili[1], Gokhan Uruk[1], Ertugrul Kilic[2], Muge Yemisci[1,3,4]
[1]Hacettepe University, The Institute Of Neurological Sciences And Psychiatry, Ankara, Turkey, [2]Istanbul Medipol University, Physiology, Istanbul, Turkey, [3]Hacettepe University, Graduate School Of Health Sciences, Ankara, Turkey, [4]Hacettepe University, Faculty Of Medicine, Department Of Neurology, Ankara, Turkey

Background: Retina has similar microcirculation characteristics like the brain, and harbors inner blood-retina barrier (iBRB) resembling blood-brain barrier including pericytes. Reduced Folate Carrier-1 (RFC1) is an abundant folate transporter in pericytes as shown by a few transcriptomic studies. However, RFC1 protein presence and its functions in retinal microvessels and pericytes have never been investigated. Here, after detecting RFC1 protein in retinal microvessels, we genetically modified RFC1 in vivo, to examine its roles in healthy and ischemic mice retina. **Method:** We used whole mount retinas, and trypsin digest preparations of adult Swiss albino mice. RFC1 was overexpressed by intravitreally delivered RFC1-expressing(n=6) and control(n=6) lentivirus. To knockdown RFC1, we delivered RFC1-targeted custom designed Accell short interfering RNA (RFC1-siRNA)(n=6) and scrambled(control)(n=6) siRNA intravitreally. Retinal ischemia was induced for 1-hour by applying $FeCl_3$ to central retinal artery for control(n=6) and genetically modified groups(n=6). We used RT-qPCR and Western blotting to determine RFC1. Endothelia(CD31), pericytes(PDGFR-beta, CD13, NG2), tight-junctions(occludin), major basement membrane protein(collagen-4) and RFC1 were determined immunohistochemically. Vessels(Lectin) and nuclei(Hoechst-33258) were also visualized. **Results:** We demonstrated that RFC1 protein is abundant in retinal endothelia and pericytes. RFC1-expressing lentivirus upregulated RFC1 levels resulting in upregulation of occludin and collagen-4, and the pre-treatment rescued decreased occludin and collagen-4 in retinal ischemia. RFC1-siRNA mediated knock-down caused occludin and collagen-4 reduction. Besides, knocking down RFC1 before retinal ischemia demolished iBRB integrity compared to control ischemic group, observed by IgG immunostainings. **Conclusion:** Thus, we suggest that RFC1 is pivotal to stabilize iBRB in health and ischemia. Aims: We investigated the expression of the glial protein S100b, Brain Natriuretic Peptide (BNP) and its precursor proBNP in clots removed by mechanical thrombectomy from 160 patients with Acute Ischemic Stroke (AIS). We studied the association of S100b, BNP and proBNP with stroke etiologies (atheroembolic versus cardioembolic) and with post-thrombectomy intracranial haemorrhage (PTIH). **Methods:** Mechanically extracted thrombi were collected by endovascular thrombectomy at collaborating stroke centres in Ireland, Sweden, Hungary and Greece, formalin-fixed and shipped to NUI Galway for analysis. Gross photos of each clot were taken and extracted clot area (ECA) was measured using ImageJ. Clots were analysed by histology (Martius Scarlet Blue; red and white blood cells, fibrin, platelets) and immunohistochemistry (S100b, BNP and proBNP). Orbit Image Analysis was used for quantification of whole slide scans. The non-parametric Kruskal-Wallis test was used for statistical analysis. **Results:** We did not find any difference in BNP or proBNP expression in atheroembolic versus cardioembolic clots (BNP: 0.19[0.03-1.27]mm2 vs 0.17[0.02-1.14]mm2, P=0.751; proBNP: 0.07[0.03-0.23]mm2 vs 0.04[0.01-0.11]mm2, P=0.081). Similarly, S100b expression was not affected by aetiology, however S100b was significantly higher in clots from patients with PTIH compared to the non-PTIH group (0.33[0.08-0.85]mm2 vs 0.07[0.02-0.27]mm2, P=0.014*). **Conclusion:** BNP, proBNP and S100b were expressed at similar levels in atheroembolic and cardioembolic clots and were not indicative of stroke aetiology. However, higher expression of S100b occurred with PTIH reflecting blood brain barrier dysfunction. Funded by Science Foundation Ireland (Grant number 13/RC/2073_2) and Cerenovus

CONTRIBUTION OF CIRCULATING TISSUE-TYPE PLASMINOGEN ACTIVATOR (TPA) TO CEREBRAL PHYSIOPATHOLOGY.

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Jonathane Furon, Florent Lebrun, Quentin Gérard, Mervé Yetim, Cyrille Orset, Denis Vivien, Carine Ali
Normandie University, UNICAEN, Inserm, @Caen-Normandie (BB@C), UMR-S U1237, Physiopathology and Imaging of Neurological Disorders (PhIND), Gip Cyceron, Institut Blood And Brain, Caen, France

Aims. Intravenous injection of recombinant tissue-type plasminogen activator (tPA) as a thrombolytic agent has revolutionized the management of ischemic stroke patients. Several observations suggest that tPA, either endogenous (neuronal and endothelial) or exogenous may also worsen the loss of integrity of nerve cells and of the blood/brain interface during stroke, thus limiting the benefit of thrombolysis. However, the respective role of the neuronal tPA versus blood tPA in the cerebrovascular physiopathology is not well known. **Methods**. We sought to develop a tool to either selectively remove tPA in the circulation or in the brain parenchyma. We performed parabiosis between tPA deficient mice (tPA NULL) and/or wild-type mice (tPA WT). Then, neurovascular coupling (NVC) and stroke damages were investigated by measuring cerebral blood flow in response to whiskers stimulation and measuring infarct volumes by MRI in thrombin-induced stroke, respectively. **Results**. Our data reveal a reduced NVC in Null/Null parabionts compared to WT/WT parabionts. The deficit was absent in Null/WT couples. In the stroke model, observed in Null/Null parabionts displayed larger infarct volumes compared to WT/WT littermates. In heterotypic Null/WT parabionts, stroke damages in the WT partner were similar to those in WT/WT couples. Interestingly, stroke damages in the Null partner were lower than in the Null/Null parabionts, but bigger than in the WT/WT parabionts. **Conclusions.** All together, these data suggest that circulating tPA (but not parenchymal tPA) participates in NVC. On the other hand, our findings show that parenchymal tPA has deleterious effects during stroke, while circulating tPA is beneficial.

Mirosław Mossakowski Research Institute Polish Academy of Sciences, Department Of Neurochemistry, Warsaw, Poland

Birth asphyxia occurs when the brain blood flow is impaired (ischemia) and oxygen supply is arrested (hypoxia). Hypoxia-ischemia (HI) results in damage of the central nervous system leading to neonatal death or developmental disorders. A recent study has shown that group II metabotropic glutamate receptors (mGluR2/3) activation can provide neuroprotection against HI but the mechanism of this effect is still not clear. **Aims:** This study aimed to establish the anti-apoptotic effect of mGluR2/3 agonists in an experimental model of birth asphyxia. **Methods:** The animal model of HI on 7-day old rat pups was used. Specific agonists of mGluR2 (LY 379268) and mGluR3 (NAAG) were injected intraperitoneally 1 h or 6 h after HI. The weight deficit of the ischemic brain hemisphere was measured and the expression of Bax, Bcl-2, HTR/OMI was examined. The expression of trophic factors GDNF, BDNF, TGF-beta was also measured. **Results:** The application of each agonist decreased brain tissue weight loss in the ischemic hemisphere independently on the time of application (from 40% in HI to 15 - 20% in treated). Both agonists applied 1h or 6h after HI increased expression of Bcl-2 and decreased expression of Bax and HtrA2/OMI proteins compared to untreated HI. mGluR2/3 agonists decreased expression of TGF-beta and GDNF and increased BDNF in the ischemic hemisphere compared to HI. **Conclusions:** The results show that activation of mGluR2 or mGluR3 in a short time after H-I insult triggered neuroprotective mechanisms and reduced apoptotic processes initiated by HI in the developing brain.

INTRA-ARTERIAL MESENCHYMAL STEM CELL THERAPY REGULATES AQUAPORIN 4 TO ALLEVIATE PERIFOCAL VASOGENIC EDEMA POST-STROKE IN ANIMAL MODEL OF ISCHEMIC STROKE

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Aishika Datta, Deepaneeta Sarmah, Pallab Bhattacharya
National Institute of Pharmaceutical Education and Research - Ahmedabad (NIPER-A), Pharmacology And Toxicology, Gandhinagar, India

Background: Post-stroke vasogenic edema following blood brain barrier (BBB) disruption and upregulation of aquaporin 4 (AQP4) water transport channels are well reported. Previous studies from our lab have demonstrated that intra-arterial (IA) administration of $1*10^5$ mesenchymal stem cell (MSCs) is neuroprotective. Protein kinase C δ (PKCδ) plays an important role to exacerbate ischemic reperfusion injury. Therefore, our study aims to decipher the possible molecular mechanism of post-stroke vasogenic edema alleviation by regulating AQP4 expression via modulation of PKCδ following IA MSCs administration. **Materials and Methods:** Ovariectomized female SD rats were infused $1*10^5$ IA MSCs at 6 h post-middle cerebral artery occlusion. Following 24 h of stroke, neurodeficit scores and motor functions were evaluated and animals were sacrificed. Brains were harvested for estimation of infarct size, edema and BBB damage. Cortical brain regions were harvested for further biochemical and molecular studies. **Results:** Administration of IA MSCs exhibited neuroprotection as evident by the reduction of infarct size, edema and improvement in functional outcome. Reduction in gene and consequent protein expression of AQP4 and PKCδ were observed within cortical brain region following IA MSCs administration. **Discussion and conclusion:** Vasogenic edema is one of the factors that contributes to high post-stroke mortality. Our study provides a preliminary evidence of IA MSCs mediated alleviation of post-stroke vasogenic edema by regulating AQP4 via modulation of PKCδ, thereby rendering neuroprotection. The novelty of our study lies in using IA MSCs intervention post-stroke to resolve vasogenic edema which is clinically relevant.

Intra-arterial Stem Cell Therapy Diminishes Inflammasome Activation After Ischemic Stroke: a Possible Role of Acid Sensing Ion Channel 1a.
Studies from our lab demonstrated that 1 × 10 intra-arterial mesenchymal stem cells (IA MSCs) at 6 h following ischemic stroke are efficacious owing to its maximum homing due to elevated stromal derived factor 1 (SDF1) in the tissue. Further, IA MSCs could abate the infarct progression, improve functional outcome, and decrease expression of calcineurin by modifying neuronal Ca channels following ischemic stroke. Since stroke pathology also encompasses acidosis that worsens the condition; hence, the role of acid sensing ion channels (ASICs) in this context could not be overlooked. ASIC1a being the major contributor towards acidosis triggers Ca ions overload which progressively contributes towards exacerbation of neuronal injury following ischemic insult. Inflammasome involvement in ischemic stroke is well reported as activated ASIC1a increases the expression of inflammasome in a pH-dependent manner to trigger inflammatory cascade. Hence, the current study aimed to identify if IA MSCs can decrease the production of inflammasome by attenuating ASIC1a expression to render neuroprotection. Ovariectomized Sprague Dawley (SD) rats exposed to middle cerebral artery occlusion (MCAo) for 90 min were treated with phosphate-buffered saline (PBS) or 1 × 10 MSCs IA at 6 h to check for the expression of ASIC1a and inflammasome in different groups. Inhibition studies were carried out to explore the underlying mechanism. Our results demonstrate that IA MSCs improves functional outcome and oxidative stress parameters, and decreases the expression of ASIC1a and inflammasomes in the cortical brain region after ischemic stroke. This study offers a preliminary evidence of the role of IA MSCs in regulating inflammasome by modulating ASIC1a.

Endovascular Stem Cell Therapy Post Stroke Rescues Neurons from Endoplasmic Reticulum Stress-Induced Apoptosis by Modulating Brain-Derived Neurotrophic Factor/Tropomyosin Receptor Kinase B Signaling.
Ischemic stroke is devastating, with serious long-term disabilities affecting millions of people worldwide. Growing evidence

has shown that mesenchymal stem cells (MSCs) administration after stroke provides neuroprotection and enhances the quality of life in stroke patients. Previous studies from our lab have shown that 1 × 10 MSCs administered intra-arterially (IA) at 6 h post stroke provide neuroprotection through the modulation of inflammasome and calcineurin signaling. Ischemic stroke induces endoplasmic reticulum (ER) stress, which exacerbates the pathology. The current study intends to understand the involvement of brain-derived neurotrophic factor/tropomyosin receptor kinase B (BDNF/TrkB) signaling in preventing apoptosis induced by ER stress post stroke following IA MSCs administration. Ischemic stroke was induced in ovariectomized female Sprague Dawley rats. The MSCs were administered IA, and animals were sacrificed at 24 h post stroke. Infarct area, neurological deficit score, motor coordination, and biochemical parameters were evaluated. The expression of various genes and proteins was assessed. An inhibition study was also carried out to confirm the involvement of BDNF/TrkB signaling in ER stress-induced apoptosis. IA-administered MSCs improved functional outcomes, reduced infarct area, increased neuronal survival, and normalized biochemical parameters. mRNA and protein expression of ER stress markers were reduced, while those of BDNF and TrkB were increased. Reduction in ER stress-mediated apoptosis was also observed. The present study shows that IA MSCs administration post stroke provides neuroprotection and can modulate ER stress-mediated apoptosis via the BDNF/TrkB signaling pathway.

Sirtuin-1 - Mediated NF-κB Pathway Modulation to Mitigate Inflammasome Signaling and Cellular Apoptosis is One of the Neuroprotective Effects of Intra-arterial Mesenchymal Stem Cell Therapy Following Ischemic Stroke.
Stroke results in long term serious disability that affect millions across the globe. Several clinical and preclinical studies have reinforced the therapeutic use of stem cells in stroke patients to enhance their quality of life. Previous studies from our lab have demonstrated that 1*10 allogeneic bone marrow-derived mesenchymal stem cells (BM-MSCs) when given intraarterially (IA) render neuroprotection by modulating the expression of inflammasomes. Sirtuins are a class of important deacylases having a significant role in cellular functioning. Sirtuin-1 (SIRT-1) is an important enzyme essential for regulating cellular metabolism, which is reduced following an ischemic episode. The present study aims to unviel the role of MSCs in regulating the brain SIRT-1 levels following stroke and the involvement of SIRT-1 in regulating inflammasome signaling to reduce cellular apoptosis towards rendering neuroprotection.

Neuroimmune crosstalk and evolving pharmacotherapies in neurodegenerative diseases.
Neurodegeneration is characterized by gradual onset and limited availability of specific biomarkers. Apart from various aetiologies such as infection, trauma, genetic mutation, the interaction between the immune system and CNS is widely associated with neuronal damage in neurodegenerative diseases. The immune system plays a distinct role in disease progression and cellular homeostasis. It induces cellular and humoral responses, and enables tissue repair, cellular healing and clearance of cellular detritus. Aberrant and chronic activation of the immune system can damage healthy neurons. The pro-inflammatory mediators secreted by chief innate immune components, the complement system, microglia and inflammasome can augment cytotoxicity. Furthermore, these inflammatory mediators accelerate microglial activation resulting in progressive neuronal loss. Various animal studies have been carried out to unravel the complex pathology and ascertain biomarkers for these harmful diseases, but have had limited success. The present review will provide a thorough understanding of microglial activation, complement system and inflammasome generation, which lead the healthy brain towards neurodegeneration. In addition to this, possible targets of immune components to confer a strategic treatment regime for the alleviation of neuronal damage are also summarized.

Migraine and Ischemic Stroke: Deciphering the Bidirectional Pathway.
Migraine and stroke are common, disabling neurological conditions with several theories being proposed to explain this bidirectional relationship. Migraine is considered as a benign neurological disorder, but research has revealed a connection between migraine and stroke, predominantly those having migraine with aura (MA). Among migraineurs, females with MA are more susceptible to ischemic stroke and may have a migrainous infarction. Migrainous infarction mostly occurs in the posterior circulation of young women. Although there are several theories about the potential relationship between MA and stroke, the precise pathological process of migrainous infarction is not clear. It is assumed that cortical spreading depression (CSD) might be one of the essential factors for migrainous infarction. Other factors that may contribute to migrainous infarction may be genetic, hormonal fluctuation, hypercoagulation, and right to left cardiac shunts. Antimigraine drugs, such as ergot alkaloids and triptans, are widely used in migraine care. Still, they have been found to cause severe

vasoconstriction, which may result in the development of ischemia. It is reported that patients with stroke develop migraines during the recovery phase. Both experimental and clinical data suggest that cerebral microembolism can act as a potential trigger for MA. Further studies are warranted for the treatment of migraine, which may lead to a decline in migraine-related stroke. In this present article, we have outlined various potential pathways that link migraine and stroke.

Nanotechnology in the diagnosis and treatment of stroke.
Increasing developments in the field of nanotechnology have ignited its use in stroke diagnosis and treatment. The benefits of structural modification, ease of synthesis, and biocompatibility support the use of nanomaterials in the clinic. The pathophysiology of stroke is complex, involving different brain regions; hence, therapeutic agents are required to be delivered to specific regions. Nanoparticles (NPs) can be engineered to help improve the delivery and release of therapeutic agents in a localized manner, especially in the penumbra. This contributes not only to therapy, but also to neurosurgery and neuroimaging. Nanomaterials also offer high efficacy with few adverse effects. In this review, we provide a concise summary of the caveats associated with nanotechnology with respect to stroke therapy and diagnosis.

Post-stroke depression: Chaos to exposition.
Cerebral ischemia contributes to significant disabilities worldwide, impairing cognitive function and motor coordination in affected individuals. Stroke has severe neuropsychological outcomes, the major one being a stroke. Stroke survivors begin to show symptoms of depression within a few months of the incidence that overtime progresses to become a long-term ailment. As the pathophysiology for the progression of the disease is multifactorial and complex, it limits the understanding of the disease mechanism completely. Meta-analyses and randomized clinical trials have shown that intervening early with tricyclic antidepressants and selective serotonin receptor inhibitors can be effective. However, these pharmacotherapies possess several limitations that have given rise to newer approaches such as brain stimulation, psychotherapy and rehabilitation therapy, which in today's time are gaining attention for their beneficial results in post-stroke depression (PSD). The present review highlights numerous factors like lesion location, inflammatory mediators and genetic abnormalities that play a crucial role in the development of depression in stroke patients. Further, we have also discussed various mechanisms involved in post-stroke depression (PSD) and strategies for early detection and diagnosis using biomarkers that may revolutionize treatment for the affected population. Towards the end, along with the preclinical scenario, we have also discussed the various treatment approaches like pharmacotherapy, traditional medicines, psychotherapy, electrical stimulation and microRNAs being utilized for effectively managing PSD.

Glial Cells Response in Stroke.
As the second-leading cause of death, stroke faces several challenges in terms of treatment because of the limited therapeutic interventions available. Previous studies primarily focused on metabolic and blood flow properties as a target for treating stroke, including recombinant tissue plasminogen activator and mechanical thrombectomy, which are the only USFDA approved therapies. These interventions have the limitation of a narrow therapeutic time window, the possibility of hemorrhagic complications, and the expertise required for performing these interventions. Thus, it is important to identify the contributing factors that exacerbate the ischemic outcome and to develop therapies targeting them for regulating cellular homeostasis, mainly neuronal survival and regeneration. Glial cells, primarily microglia, astrocytes, and oligodendrocytes, have been shown to have a crucial role in the prognosis of ischemic brain injury, contributing to inflammatory responses. They play a dual role in both the onset as well as resolution of the inflammatory responses. Understanding the different mechanisms driving these effects can aid in the development of therapeutic targets and further mitigate the damage caused. In this review, we summarize the functions of various glial cells and their contribution to stroke pathology. The review highlights the therapeutic options currently being explored and developed that primarily target glial cells and can be used as neuroprotective agents for the treatment of ischemic stroke.

Advances in Studies on Stroke-Induced Secondary Neurodegeneration (SND) and Its Treatment.
The occurrence of secondary neurodegeneration has exclusively been observed after the first incidence of stroke. In humans and rodents, post-stroke secondary neurodegeneration (SND) is an inevitable event that can lead to progressive neuronal loss at a region distant to initial infarct. SND can lead to cognitive and motor function impairment, finally causing dementia.

The exact pathophysiology of the event is yet to be explored. It is seen that the thalami, in particular, are susceptible to cause SND. The reason behind this is because the thalamus functioning as the relay center and is positioned as an interlocked structure with direct synaptic signaling connection with the cortex. As SND proceeds, accumulation of misfolded proteins and microglial activation are seen in the thalamus. This leads to increased neuronal loss and worsening of functional and cognitive impairment.

Cell Death Pathways in Ischemic Stroke and Targeted Pharmacotherapy.
Ischemic stroke is one of the significant causes of morbidity and mortality, affecting millions of people across the globe. Cell injury in the infarct region is an inevitable consequence of focal cerebral ischemia. Subsequent reperfusion exacerbates the harmful effect and increases the infarct volume. These cellular injuries follow either a regulated pathway involving tightly structured signaling cascades and molecularly defined effector mechanisms or a non-regulated pathway, also known as accidental cell death, where the process is biologically uncontrolled. Classical cell death pathways are long established and well reported in several articles that majorly define apoptotic cell death. A recent focus on cell death study also considers investigation on non-classical pathways that are tightly regulated, may or may not involve caspases, but non-apoptotic. Pathological cell death is a cardinal feature of different neurodegenerative diseases. Although ischemia cannot be classified as a neurodegenerative disease, it is a cerebrovascular event where the infarct region exhibits aberrant cell death. Over the past few decades, several therapeutic options have been implicated for ischemic stroke. However, their use has been hampered owing to the number of limitations that they possess. Ischemic penumbral neurons undergo apoptosis and become dysfunctional; however, they are salvageable. Thus, understanding the role of different cell death pathways is crucial to aid in the modern treatment of protecting apoptotic neurons.

INHIBITION OF SIGNAL TRANSDUCER AND ACTIVATOR OF TRANSCRIPTION 3 (STAT3) – A PROMISING NEUROPROTECTION STRATEGY FOR NEONATAL HYPOXIC-ISCHAEMIC BRAIN DAMAGE

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Konstantina Tetorou, Claudia Sisa, Sigrun Lange, Mariya Hristova
University College London, Institute For Women's Health, London, United Kingdom

Hypoxic-ischaemic encephalopathy (HIE) is a leading cause of child mortality and morbidity. The only currently available treatment for neonatal hypoxia-ischaemia (HI) is therapeutic hypothermia which has limited effectiveness and application. Thus, there is a need for alternative therapies for neonatal HI brain damage. HI strongly up-regulates Signal Transducer and Activator of Transcription 3 (STAT3) in the immature brain. We have previously shown that neuronal or astroglial STAT3-deletion reduce cell death, tissue loss, glial activation in a postnatal day 7 (P7) HI mouse model, suggesting detrimental effect of STAT3 in neonatal HI. Moreover, pre-insult STAT3-blockade at tyrosine 705 (Y705) with JAK2-inhibitor WP1066 reduces microglial and astroglial activation to a more moderate degree, but similarly to the cell-specific deletions. The P7 mouse is considered slightly pre-term, while the P9 corresponds to term when compared to the human fetus. Therefore, we aimed to investigate whether inhibition of STAT3 phosphorylation at Y705 will provide neuroprotection in the P9 mouse similarly to the P7 model. We hypothesized that pharmacological STAT3 Y705 inhibition immediately post-HI will provide neuroprotection in the neonatal P9 mouse. We subjected P9 mice to unilateral carotid artery ligation and 60min hypoxia, and then treated them with different doses of WP1066, compared with non-treated controls.WP1066 treatment reduced brain tissue loss, cell death, microglial and astroglial activation at a dose of 80µg/g body weight, however doses of 40µg/g and 160µg/g were not neuroprotective. In conclusion, the application of WP1066 as a neuroprotective agent in the regulation of STAT3 phosphorylation may be a promising new strategy in neonatal HIE.

Current Therapies for Neonatal Hypoxic-Ischaemic and Infection-Sensitised Hypoxic-Ischaemic Brain Damage.
Neonatal hypoxic-ischaemic brain damage is a leading cause of child mortality and morbidity, including cerebral palsy, epilepsy, and cognitive disabilities. The majority of neonatal hypoxic-ischaemic cases arise as a result of impaired cerebral perfusion to the foetus attributed to uterine, placental, or umbilical cord compromise prior to or during delivery. Bacterial infection is a factor contributing to the damage and is recorded in more than half of preterm births. Exposure to infection exacerbates neuronal hypoxic-ischaemic damage thus leading to a phenomenon called infection-sensitised hypoxic-ischaemic brain injury. Models of neonatal hypoxia-ischaemia (HI) have been developed in different animals. Both human and animal studies show that the developmental stage and the severity of the HI insult affect the selective regional vulnerability of the brain to damage, as well as the subsequent clinical manifestations. Therapeutic hypothermia (TH) is the only clinically approved treatment for neonatal HI. However, the number of HI infants needed to treat with TH for one to be saved from death or disability at age of 18-22 months, is approximately 6-7, which highlights the need for additional or alternative treatments to replace TH or increase its efficiency. In this review we discuss the mechanisms of HI injury to the immature brain and the new experimental treatments studied for neonatal HI and infection-sensitised neonatal HI.

CANNABINOIDS AND CEREBRAL ISCHEMIA: EXPERIMENTAL STUDIES IN AN IN VITRO MODEL.

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Costanza Mazzantini, Elisa Landucci, Domenico Pellegrini-Giampietro
University of Florence, Department Of Health Sciences, Section Of Clinical Pharmacology And Oncology, Florence, Italy

Introduction: Cannabinoids are implicated in a number of physiological and pathological mechanisms in the central nervous system. However, their role in mechanisms leading to neurodegeneration following cerebral ischemia is yet unclear. Many studies have produced conflicting results on cannabinoids putative protective and/or toxic effects. Aim: We examined the effects of natural Cannabis extracts or selected cannabinoids and their possible pharmacological mechanism in an *in vitro* model of cerebral ischemia. Methods: We investigated the effects of two Cannabis extracts (Bedrocan and FM2) or selected cannabinoids, Δ9-tetrahydrocannabinol (THC), cannabidiol (CBD), and cannabigerol (CBG) in rat organotypic hippocampal slices exposed to Oxygen and Glucose Deprivation (OGD), an *in vitro* model of forebrain global ischemia. Cell death in the CA1 subregion of slices was quantified by propidium iodide fluorescence. To gain deeper the possible mechanism of action underlying THC toxicity and/or CBD protection in our model, we used specific antagonists of CB1, CB2, TRPV1, TRPV2, 5-HT1A and PPAR receptors, at concentrations that displayed no effect when used alone. Results: When present in the incubation medium the Bedrocan extract or THC exacerbated, whereas the FM2 extract or cannabidiol attenuated CA1 injury induced by OGD. CB1 receptor antagonists prevented Δ9-THC toxicity; TRPV2, 5-HT1A, and PPAR antagonists blocked the neuroprotective effect of cannabidiol. Conclusions: Our results suggest that cannabinoids play different roles in the mechanisms of post-ischemic neuronal death. In particular, appropriate concentrations of CBD or CBD/THC ratios may represent a valid therapeutic intervention in the treatment of post-ischemic neuronal death.

Preparation of Liposomal Formulations for Ocular Delivery of Thymoquinone: In Vitro Evaluation in HCEC-2 e HConEC Cells.
Thymoquinone (TQ) is the main constituent of L. essential oil. In vitro studies have shown its protective effect against HO-induced oxidative stress in human retinal pigment epithelium cells, and in vivo experiments have demonstrated its effect in decreasing corneal neovascularization and reducing the inflammation in an experimental dry eye model in mice. Its therapeutic use is limited by poor bioavailability, low solubility, and scarce permeability. In this study, two liposomal formulations have been developed, both of which consist of phosphatidylcholine and Plurol Oleique, a liquid lipid, and one of which is coated with 0.1% / hyaluronic acid (HA) to increase both TQ solubility and its ocular therapeutic potential. Each formulation has a size <200 nm and an EE% around 70%, determined by scattering techniques and the HPLC-DAD analytical method, respectively, and they result in a 2-fold increase in TQ solubility. HA-coated liposomes are stable over 2 months at +4 °C, and coated and uncoated liposomes present a gradual and prolonged release of TQ. Two cell lines, human corneal epithelial cells (HCEC-2) and human conjunctival epithelial cells (HConEC) were used to investigate the safety of the liposomal formulations. Uptake studies were also performed using fluorescent liposomes. Both liposomes and, in particular, HA-coated liposomes reduce the TQ toxicity observed at high doses in both HCEC-2 and HConEC cells, and both formulations increase the absorption at the cellular level and especially at the nucleus level, with a more pronounced effect for HA-coated liposomes.

Neuroprotective Effects of Cannabidiol but Not Δ-Tetrahydrocannabinol in Rat Hippocampal Slices Exposed to Oxygen-Glucose Deprivation: Studies with Extracts and Selected Cannabinoids.
(1) Background: Over the past 10 years, a number of scientific studies have demonstrated the therapeutic potential of cannabinoid compounds present in the and plants. However, their role in mechanisms leading to neurodegeneration following cerebral ischemia is yet unclear. (2) Methods: We investigated the effects of extracts (Bedrocan, FM2) or selected cannabinoids (Δ-tetrahydrocannabinol (THC), cannabidiol (CBD), and cannabigerol) in rat organotypic hippocampal slices exposed to oxygen-glucose deprivation (OGD), an in vitro model of forebrain global ischemia. Cell death in the CA1 subregion of slices was quantified by propidium iodide fluorescence, and morphological analysis and tissue organization were

examined by immunohistochemistry and confocal microscopy. (3) Results: Incubation with the Bedrocan extract or THC exacerbated, whereas incubation with the FM2 extract or cannabidiol attenuated CA1 injury induced by OGD. Δ-THC toxicity was prevented by CB1 receptor antagonists, the neuroprotective effect of cannabidiol was blocked by TRPV2, 5-HT1A, and PPARγ antagonists. Confocal microscopy confirmed that CBD, but not THC, had a significant protective effect toward neuronal damage and tissue disorganization caused by OGD in organotypic hippocampal slices. (4) Conclusions: Our results suggest that cannabinoids play different roles in the mechanisms of post-ischemic neuronal death. In particular, appropriate concentrations of CBD or CBD/THC ratios may represent a valid therapeutic intervention in the treatment of post-ischemic neuronal death.

Neuroprotective Effects of Thymoquinone by the Modulation of ER Stress and Apoptotic Pathway in In Vitro Model of Excitotoxicity.
Experimental evidence indicates that the activation of ionotropic glutamate receptors plays an important role in neurological disorders' models such as epilepsy, cerebral ischemia and trauma. The glutamate receptor agonist kainic acid (KA) induces seizures and excitotoxic cell death in the CA3 region of the hippocampus. Thymoquinone (TQ) is the most important component of the essential oil obtained from black cumin (L.) seeds. It has many pharmacological actions including antioxidant, anti-inflammatory, and anti-apoptotic effects. TQ was used in an in vitro experimental model of primary cultures where excitotoxicity was induced. Briefly, rat organotypic hippocampal slices were exposed to 5 μM KA for 24 h. Cell death in the CA3 subregions of slices was quantified by measuring propidium iodide fluorescence. The cross-talk between TQ, ER stress and apoptotic pathways was investigated by Western blot. In untreated slices TQ (10 μM) induced a significant increase on the PSD95 levels and it decreased the excitotoxic injury induced by KA. Additionally, TQ was able to ameliorate the KA-induced increase in unfolded proteins GRP78 and GRP94 expression. Finally, TQ was able to partially rescue the reduction of the KA-induced apoptotic pathway activation. Our results suggest that TQ modulates the processes leading to post-kainate neuronal death in the CA3 hippocampal area.

Co-expression of the SARS-CoV-2 entry receptors ACE2 and TMPRSS2 in healthy human conjunctiva.
The purpose of this study was to evaluate the expression of the SARS-CoV-2 receptors ACE2 and TMPRSS2 in an immortalized human conjunctival epithelial cell line and in healthy human conjunctiva excised during ocular surgery, using Western blot, confocal microscopy and immunohistochemistry. The Western blot showed that ACE2 and TMPRSS2 proteins were expressed in human immortalized conjunctival cells, and this was confirmed by confocal microscopy images, that demonstrated a marked cellular expression of the viral receptors and their co-localization on the cell membranes. Healthy conjunctival samples from 11 adult patients were excised during retinal detachment surgery. We found the expression of ACE2 and TMPRSS2 in all the conjunctival surgical specimens analyzed and their co-localization in the superficial conjunctival epithelium. The ACE2 Western blot levels and immunofluorescence staining for ACE2 were variable among specimens. These results suggest the susceptibility of the conjunctival epithelium to SARS-CoV-2 infection, even though with a possible interindividual variability.

A new ophthalmic formulation containing antiseptics and dexpanthenol: In vitro antimicrobial activity and effects on corneal and conjunctival epithelial cells.
Antibiotic resistance is increasing even in ocular pathogens, therefore the interest towards antiseptics in Ophthalmology is growing. The aim of this study was to analyze the in vitro antimicrobial efficacy and the in vitro effects of an ophthalmic formulation containing hexamidine diisethionate 0.05%, polyhexamethylene biguanide (PHMB) 0.0001% disodium edetate (EDTA) 0.01%, dexpanthenol 5% and polyvinyl alcohol 1.25% (Keratosept, Bruschettini, Genova, Italy) on cultured human corneal and conjunctival cells. The in vitro antimicrobial activity was tested on Staphylococcus aureus, Methicillin-Resistant Staphylococcus aureus (MRSA), Pseudomonas aeruginosa, Streptococcus pneumoniae, Streptococcus pyogenes and Streptococcus mitis. For each microbial strain 10 μL of a 0.5 MacFarland standardized bacterial inoculum were incubated at 25 °C with 100 μL of ophthalmic solution for up to 6 h. After different periods of time, samples were inoculated on blood agar with 5% sheep blood. Moreover, a 0.5 MacFarland bacterial inoculum was seeded in triplicate on Mueller-Hinton Agar or on Mueller-Hinton Fastidious Agar; then a cellulose disc soaked with 50 μL of ophthalmic solution was applied on the surface of agar and plates were incubated for 18 h at 37 °C, in order to evaluate the inhibition of bacterial growth around the disc. Human corneal and conjunctival epithelial cells in vitro were incubated for 5, 10 and 15 min with Keratosept or its components. The cytotoxicity was assessed through the release of cytoplasmic enzyme lactate dehydrogenase (LDH) into

the medium immediately after exposure to the drugs; the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay was performed to evaluate the metabolic cell activity. Our results show that Keratosept ophthalmic solution gave an average logarithmic (log) reduction of bacterial load of 2.14 ± 0.35 within 6 h of exposure (p-value < 0.05 versus control saline solution). On agar plates, all microbial strains, excluding P. Aeruginosa, showed an inhibition zone of growth around the Keratosept-soaked discs. Keratosept and its components after 5 and 10 min did not show any cytotoxic effect on cultured corneal and conjunctival cells, and only after 15 min a significant reduction of cell viability and an increase of cytotoxicity compared to control (vehicle) was seen; dexpanthenol 5% and polyvinyl alcohol accelerated the wounding of corneal cells in vitro. In conclusion, Keratosept showed good antimicrobial activity on the tested strains; the ophthalmic solution and its components were safe and non-toxic for the corneal and conjunctival epithelial cells for 5 and 10 min at the concentrations analyzed, and dexpanthenol 5% and polyvinyl alcohol promoted the wounding of corneal cells.

3-Iodothyronamine Affects Thermogenic Substrates' Mobilization in Brown Adipocytes.
We investigated the effect of 3-iodothyronamine (T1AM) on thermogenic substrates in brown adipocytes (BAs). BAs isolated from the stromal fraction of rat brown adipose tissue were exposed to an adipogenic medium containing insulin in the absence (M) or in the presence of 20 nM T1AM (M+T1AM) for 6 days. At the end of the treatment, the expression of p-PKA/PKA, p-AKT/AKT, p-AMPK/AMPK, p-CREB/CREB, p-P38/P38, type 1 and 3 beta adrenergic receptors (β1-β3AR), GLUT4, type 2 deiodinase (DIO2), and uncoupling protein 1 (UCP-1) were evaluated. The effects of cell conditioning with T1AM on fatty acid mobilization (basal and adrenergic-mediated), glucose uptake (basal and insulin-mediated), and ATP cell content were also analyzed in both cell populations. When compared to cells not exposed, M+T1AM cells showed increased p-PKA/PKA, p-AKT/AKT, p-CREB/CREB, p-P38/P38, and p-AMPK/AMPK, downregulation of DIO2 and β1AR, and upregulation of glycosylated β3AR, GLUT4, and adiponectin. At basal conditions, glycerol release was higher for M+T1AM cells than M cells, without any significant differences in basal glucose uptake. Notably, in M+T1AM cells, adrenergic agonists failed to activate PKA and lipolysis and to increase ATP level, but the glucose uptake in response to insulin exposure was more pronounced than in M cells. In conclusion, our results suggest that BAs conditioning with T1AM promote a catabolic condition promising to fight obesity and insulin resistance.
Biology (Basel), 2020; 9

N-(3-Ethoxy-phenyl)-4-pyrrolidin-1-yl-3-trifluoromethyl-benzamide (EPPTB) prevents 3-iodothyronamine (T1AM)-induced neuroprotection against kainic acid toxicity.
Thyroid hormone and thyroid hormone metabolites, including 3-iodothyronamine (T1AM) and 3-iodothyroacetic acid (TA1), activate AKT signaling in hippocampal neurons affording protection from excitotoxic damage. We aim to explore whether the mechanism of T1AM neuroprotection against kainic acid (KA)-induced excitotoxicity included the activation of the trace amine associated receptor isoform 1 (TAAR1), one of T1AM targets. Rat organotypic hippocampal slices were exposed to vehicle (Veh) or to 5 μM kA for 24 h in the absence or presence of 0.1, 1 and 10 μM T1AM or to 0.1, 1 and 10 μM T1AM and 1 μM N-(3-Ethoxy-phenyl)-4-pyrrolidin-1-yl-3-trifluoromethyl-benzamide (EPPTB), the only available TAAR1 antagonist, or to 1 μM T1AM in the absence or in the presence of 10 μM LY294002, an inhibitor of phosphoinositide 3-kinases (PI3Ks). Cell death was evaluated by measuring propidium iodide (PI) levels of fluorescence 24 h after treatment. In parallel, the expression levels of p-AKT and p-PKA were evaluated by Western blot analysis of slice lysates. The activity of mitochondrial monoamine oxidases (MAO) was assayed fluorimetrically. 24 h exposure of slices to T1AM resulted in the activation of AKT and PKA. KA exposure induced cell death in the CA3 region and significantly reduced p-AKT and p-PKA levels. The presence of 1 and 10 μM T1AM significantly protected neurons from death and conserved both kinase levels with the essential role of AKT in neuroprotection. Furthermore, EPPTB prevented T1AM-induced neuroprotection, activation of PKA and AKT. Of note, in the presence of EPPTB T1AM degradation by MAO was reduced. Our results indicate that the neuroprotection offered by T1AM depends, as for TA1, on AKT activation but do not allow to conclusively indicate TAAR1 as the target implicated.

Over the past 15 years, therapeutic hypothermia has proven to have potential to be one of the most attractive therapies for ischemic stroke, however, uncertainty around why and how hypothermia (32°C) provides protection is still a challenge. In a recent study our group has demonstrated for the first time that 32°C activates Nrf2, a major regulator of antioxidant gene transcription, in normoxic cells and provides protection from oxidative stress presumably by orchestrating adaptive responses to redox stress. The aim of the current study is to understand whether hypothermia mitigates the dangers posed by reductive equivalents. To study hypothermia in cell culture, cells were incubated at 32°C or kept at 37°C under normoxia or hypoxia (1% O2) followed by different downstream applications like biochemistry, molecular biology, and novel cellular gas flux system for measuring CO2 and O2 flux. We found that hypoxia reduces ATP/ADP ratio at 37°C while 32°C increased ATP/ADP ratio in both normoxic and hypoxic cells. In line with previous observations, we found that lipid content was increased by hypoxia, which are chemically more stable depos of reductive power. However, mild hypothermia prevented hypoxia-dependent increase in lipid content. In addition, hypothermia introduced during anoxia enhanced the recovery of respiration. This study addresses an important question on why hypothermia is effective in reducing hypoxic tissue damage. It suggests that hypothermia alleviates reductive stress by improving recovery of respiration after anoxia, maintaining ATP/ADP ratio, reducing lipid content, a conceptually novel and largely overlooked phenomenon at the root of ischemia reperfusion injury.

Aims: General anaesthesia (A) in paediatric patients is extensively used nowadays, although it still represents a debatable concern, especially in the context of its co-occurrence with other clinical conditions, such as perinatal asphyxia (PA). Our experimental study investigates hippocampal glial activation and inflammation secondary to PA or A alone, and to combined exposure (PAA). Methods: On postnatal day (PND) 6, we exposed Wistar rats to 90-minute of either asphyxia (PA) or normoxia, and on PND-15 to 180-minute of either sevoflurane anaesthesia (A) or normoxia. Hippocampal tissue was immediately harvested thereafter from each of the 4 groups (control, PA, A, PAA; 15 animals/group), and S-100B and IL-1B were assessed by ELISA. Results: Our results revealed an increased hippocampal level of S-100B consecutive to PA, A, and combined PAA exposure, showing that both PA and A significantly contribute to glial activation, however with no cumulative effect. The hippocampal level of IL-1B was increased consecutive to PA, was not impacted by A alone when compared to control, and was decreased in PAA group when compared to PA group. Conclusions: Our study pointed out that PA has a deleterious effect on the immature hippocampus by increasing glial activation and neuroinflammation, while A alone produces only glial activation. When combined, PA and A do not potentiate reciprocally. Further studies are needed to better understand the controversial general anaesthesia impact in pathophysiological conditions like PA, to ultimately increase the patients' safety. This research was supported by the Romanian Minister of Education, Project No. PN-III-P1-1.2-PD-2019-1219.

THE EFFECT OF MINOCYCLINE ON THE ISCHEMIC AREA AND IMPROVED MOTOR FUNCTION IN CORTICAL MODEL OF PHOTO THROMBOTIC ISCHEMIC STROKE IN RATS.

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Katarzyna Pawletko[1], Aniela Grajoszek[2], Halina Jędrzejowska-Szypułka[1], Jarosław Barski[2]
[1]School of Medicine in Katowice, Medical University of Silesia, Department Of Physiology, Katowice, Poland, [2]Medical University of Silesia, Department For Experimental Medicine, Katowice, Poland

Background And Aims Still stroke is a leading cause of death worldwide. In survivors, it can result in long-term disabilityin with various severity ranges. Strokes account for great amount of mortality and morbidity worldwide. Minocycline, by launching plethora of neuroprotective mechanisms may be beneficial as the treatment. Therefore, it is important to search for neuroprotection mechanisms that would allow to extend the therapeutic window and develop new strategies for treating ischemic strokes. The first aim was to investigate the effect of minocycline on penumbra and nesrosis. Our second goal was to examine the effect of treatment on the condition of ischemic rats
Methods Photothrombotic focal ischemia of motor cortex was produced in 72 male Long-Evans rats. We tested different time windows: 24h, 48h and 7 days after stroke induction. Half of the experimental groups received an intravenous dose of minocycline (1 mg / 1 kg b.w / 1ml solution, 10 minutes after stroke). CatWalk XT, Grip Strength-test and elevated runway-tests were performed. These functional tests were applied before and after ischemic stroke.
Results In groups with minocycline we observed statistically significant improvement of speed of walking, correctness of the stepping pattern and fewer foot slips compared to the untreated groups. Necrosis were localized by immunohistochemical techniques and staining by Nissl technique. The size, shape and area of the necrosis were measured. The greatest changes were observed in the time groups 7 days. **Conclusions** Minocycline improves motor function in ischemic rats. Minocycline action also correlates with size and shape of necrosis.

EFFECTS OF NUCLEAR RECEPTOR REV-ERBα/β ON ISCHEMIC BRAIN INJURY IN MICE

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Mustafa Beker, Serdar Altunay, Aysun Caglayan, Ertugrul Kilic
Istanbul Medipol University, Physiology, Istanbul Turkey, Turkey

Nuclear receptor Rev-Erbα/β plays an essential role not only in the regulation of the circadian rhythm but also in the regulation of many cellular functions such as metabolism, glial activation, and inflammation. In addition, recent studies show that Rev-Erbα/β may have an important role in neurodegenerative diseases. Thus, we explored the role of nuclear receptor Rev-Erbα/β in neuronal injury after focal cerebral ischemia in mice. For this aim, we produced lentivirus to overexpress or inhibit the Rev-Erbα/β protein expression. Viral particles were intrastriatally administered to male 10-12 weeks old C57BL/6j mice. Ten days after, mice were subjected to 30 min or 90 min of intraluminal middle cerebral artery occlusion (MCAO) and 72 h or 24 h reperfusion, respectively. Overexpression of Rev-Erbα/β decreased brain infarct volume, brain swelling, blood-brain barrier leakage, which was evaluated by serum IgG extravasation. However, inhibition of Rev-Erbα/β only increased infarct volume after 90 min of MCAO. In addition, neuronal survival and disseminated neuronal injury were evaluated by NeuN staining and TUNEL staining, respectively. It was observed that the number of surviving neurons increased, and the DNA fragmented cells decreased in the overexpression groups. However, in the inhibition groups, neuronal survival decreased, and DNA fragmentation increased after 30 min of MCAO. We provide evidence that the regulation of nuclear receptor Rev-Erbα/β straightforwardly affects brain infarct volume, brain swelling, neurological deficits, neuronal survival, and DNA fragmentation after ischemic brain injury. This study is supported by TUBITAK (219S913).

Phosphodiesterase 10A Is a Critical Target for Neuroprotection in a Mouse Model of Ischemic Stroke.
Phosphodiesterase 10A (PDE10A) hydrolyzes adenosine 3',5'-cyclic monophosphate (cAMP) and guanosine 3',5'-cyclic monophosphate (cGMP). It is highly expressed in the striatum. Recent evidence implied that PDE10A may be involved in the inflammatory processes following injury, such as ischemic stroke. Its role in ischemic injury was unknown. Herein, we exposed mice to 90 or 30-min middle cerebral artery occlusion, followed by the delivery of the highly selective PDE10A inhibitor TAK-063 (0.3 mg/kg or 3 mg/kg) immediately after reperfusion. Animals were sacrificed after 24 or 72 h, respectively. Both TAK-063 doses enhanced neurological function, reduced infarct volume, increased neuronal survival, reduced brain edema, and increased blood-brain barrier integrity, alongside cerebral microcirculation improvements. Post-ischemic neuroprotection was associated with increased phosphorylation (i.e., activation) of pro-survival Akt, Erk-1/2, GSK-3α/β and anti-apoptotic Bcl-xL abundance, decreased phosphorylation of pro-survival mTOR, and HIF-1α, MMP-9 and pro-apoptotic Bax abundance. Interestingly, PDE10A inhibition reduced inflammatory cytokines/chemokines, including IFN-γ and TNF-α, analyzed by planar surface immunoassay. In addition, liquid chromatography-tandem mass spectrometry revealed 40 proteins were significantly altered by TAK-063. Our study established PDE10A as a target for ischemic stroke therapy.

Interaction of melatonin and Bmal1 in the regulation of PI3K/AKT pathway components and cellular survival.
The circadian rhythm is driven by a master clock within the suprachiasmatic nucleus which regulates the rhythmic secretion of melatonin. Bmal1 coordinates the rhythmic expression of transcriptome and regulates biological activities, involved in cell metabolism and aging. However, the role of Bmal1 in cellular- survival, signaling, its interaction with intracellular proteins, and how melatonin regulates its expression is largely unclear. Here we observed that melatonin increases the expression of Bmal1 and both melatonin and Bmal1 increase cellular survival after oxygen glucose deprivation (OGD) while the inhibition of Bmal1 resulted in the decreased cellular survival without affecting neuroprotective effects of melatonin. By using a planar surface immunoassay for PI3K/AKT signaling pathway components, we revealed that both melatonin and Bmal1 increased phosphorylation of AKT, ERK-1/2, PDK1, mTOR, PTEN, GSK-3αβ, and p70S6K. In contrast, inhibition of Bmal1 resulted in decreased phosphorylation of these proteins, which the effect of melatonin on these signaling molecules was not affected by

the absence of Bmal1. Besides, the inhibition of PI3K/AKT decreased Bmal1 expression and the effect of melatonin on Bmal1 after both OGD in vitro and focal cerebral ischemia in vivo. Our data demonstrate that melatonin controls the expression of Bmal1 via PI3K/AKT signaling, and Bmal1 plays critical roles in cellular survival via activation of survival kinases.

Time-of-Day Dependent Neuronal Injury After Ischemic Stroke: Implication of Circadian Clock Transcriptional Factor Bmal1 and Survival Kinase AKT.
Occurrence of stroke cases displays a time-of-day variation in human. However, the mechanism linking circadian rhythm to the internal response mechanisms against pathophysiological events after ischemic stroke remained largely unknown. To this end, temporal changes in the susceptibility to ischemia/reperfusion (I/R) injury were investigated in mice in which the ischemic stroke induced at four different Zeitgeber time points with 6-h intervals (ZT0, ZT6, ZT12, and ZT18). Besides infarct volume and brain swelling, neuronal survival, apoptosis, ischemia, and circadian rhythm related proteins were examined using immunohistochemistry, Western blot, planar surface immune assay, and liquid chromatography-mass spectrometry tools. Here, we present evidence that midnight (ZT18; 24:00) I/R injury in mice resulted in significantly improved infarct volume, brain swelling, neurological deficit score, neuronal survival, and decreased apoptotic cell death compared with ischemia induced at other time points, which were associated with increased expressions of circadian proteins Bmal1, Perl, and Clock proteins and survival kinases AKT and Erk-1/2. Moreover, ribosomal protein S6, mTOR, and Bad were also significantly increased, while the levels of PRAS40, negative regulator of AKT and mTOR, and phosphorylated p53 were decreased at this time point compared to ZT0 (06:00). Furthermore, detailed proteomic analysis revealed significantly decreased CSKP, HBB-1/2, and HBA levels, while increased GNAZ, NEGR1, IMPCT, and PDE1B at midnight as compared with early morning. Our results indicate that nighttime I/R injury results in less severe neuronal damage, with increased neuronal survival, increased levels of survival kinases and circadian clock proteins, and also alters the circadian-related proteins.

Effects of normobaric oxygen and melatonin on reperfusion injury: role of cerebral microcirculation.
In order to protect the brain before an irreversible injury occurs, penumbral oxygenation is the primary goal of current acute ischemic stroke treatment. However, hyperoxia treatment remains controversial due to the risk of free radical generation and vasoconstriction. Melatonin is a highly potent free radical scavenger that protects against ischemic stroke. Considering its anti-oxidant activity, we hypothesized that melatonin may augment the survival-promoting action of normobaric oxygen (NBO) and prevent brain infarction. Herein, we exposed mice to 30 or 90 min of intraluminal middle cerebral artery occlusion (MCAo) and evaluated the effects of NBO (70% or 100% over 90 min), administered either alone or in combination with melatonin (4 mg/kg, i.p.), on disseminate neuronal injury, neurological deficits, infarct volume, blood-brain barrier (BBB) permeability, cerebral blood flow (CBF) and cell signaling. Both NBO and particularly melatonin alone reduced neuronal injury, neurological deficits, infarct volume and BBB permeability, and increased post-ischemic CBF, evaluated by laser speckle imaging (LSI). They also improved CBF significantly in the ischemic- core and penumbra, which was associated with reduced IgG extravasation, DNA fragmentation, infarct volume, brain swelling and neurological scores. Levels of phosphorylated Akt, anti-apoptotic Bcl-xL, pro-apoptotic Bax and endothelial nitric oxide synthase (NOS) were re-regulated after combined oxygen and melatonin delivery, whereas neuronal and inducible NOS, which were increased by oxygen treatment, were not influenced by melatonin. Our present data suggest that melatonin and NBO are promising approaches for the treatment of acute-ischemic stroke, which encourage proof-of-concept studies in human stroke patients.

Div. – Department Of Experimental And Clinical Biomedical Sciences “mario Serio”, Florence, Italy, [3]University of Florence, Department Of Health Sciences, Section Of Clinical Pharmacology And Oncology, Florence, Italy

Background: Brain photobiomodulation (PBM) is an innovative treatment for a variety of neurological conditions, including cerebral ischemia. However, the capability of PBM for ischemic stroke needs to be further explored and its mechanisms of action remain currently unclear. **Aim**: to identify a treatment protocol capable of inducing neuroprotection and to investigate the molecular mechanisms activated by a dual-wavelength near infrared (NIR) laser source in an organotypic hippocampal slice model of hypoxia/ischemia. **Methods**: Hippocampal slices were exposed to oxygen and glucose deprivation (OGD) for 30 min followed by NIR laser treatment (fluence 3.71, 7.42, or 14.84 J/cm2; wavelengths 808 nm and 905 nm) delivered immediately, 30 min or 60 min after OGD. Neuronal injury, CA1 confocal microscopy and western blot analysis were assessed 24 h later. **Results**: NIR laser treatment attenuates OGD neurotoxicity once applied immediately or 30 min after OGD, suggesting a therapeutic window. Western blot analysis of proteins involved in neuroinflammation (iNOS, COX-2, NFkB subunit p65, and Bcl-2) and in glutamatergic-mediated synaptic activity (vGluT1, EAAT2, GluN1, and PSD95) showed that the protein modifications induced by OGD were reverted by NIR laser application. Moerover, CA1 confocal microscopy revealed that the profound morphological changes induced by OGD were reverted by NIR laser radiation **Conclusions**: NIR laser radiation reduces OGD neurotoxicity in organotypic hippocampal slices through attenuation of inflammatory mechanisms. These findings shed light on molecular definition of NIR neuroprotective mechanisms, thus underlining the potential benefit of this technique for the treatment of cerebral ischemia.

SPREADING DEPOLARIZATION DISRUPTS NEUROVASCULAR COUPLING AFTER GLOBAL CEREBRAL ISCHEMIA IN MICE

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Armand Rafael Bálint[1], Ferenc Bari[2], Eszter Farkas[1], Ákos Menyhárt[1]
[1]HCEMM-USZ Cerebral Blood Flow and Metabolism Research Group, Albert Szent-Györgyi School of Medicine and Faculty of Science and Informatics, University of Szeged, Department Of Cell Biology And Molecular Medicine, Szeged, Hungary, [2]Albert Szent-Györgyi School of Medicine and Faculty of Science and Informatics, University of Szeged, Department Of Medical Physics And Informatics, Szeged, Hungary

Introduction: Neurovascular coupling (NVC) is weak or absent upon acute ischemic stroke (AIS). The mechanistic basis of NVC dysfunction might be the evolution of spreading depolarization (SD), that causes vasoconstriction and lesion progression in AIS. Here, we show that SD occurrence disrupts functional hyperemia during NVC despite reperfusion after AIS. **Methods:** Male C57BL/6 mice (n=11) were anesthetized with isoflurane (0.6-1.2%). A baseline of 10 min was followed by a transient (45 min) bilateral common carotid artery occlusion (2VO) and a subsequent 60 min reperfusion. Cerebral blood flow (CBF) variations were captured using laser speckle contrast imaging (LASCA). After 60 min reperfusion, NVC function was evaluated under isoflurane (0.1%)-medetomidine (0.1 mg/kg) anesthesia by whisker stimulation (~2Hz). SHAM operated animals served as control. **Results:** Low CBF (<20%) early under ischemia favored spontaneous SD evolution (CBF <20% vs. >30%, SD vs. no SD; 16 SDs in 9 mice). SDs occurred in both hemispheres (bilateral) in 7, and in one hemisphere (unilateral) in 2 mice. In concert, functional hyperemia was diminished in 7, and was unilaterally intact in 2 mice (hyperemia amplitude: 8.73±3.01 vs. 17.16±6.21 %; bilateral vs. unilateral). The amplitude of unilaterally intact functional hyperemia was comparable to SHAM mice (17.16±6.21 vs. 16.71 %, unilateral vs. SHAM). **Discussion:** Our data demonstrate that SD evolution impairs NVC after AIS. SD is known to trigger vasoconstriction, called spreading oligemia that might diminish NVC function. We propose the pharmacological attenuation of spreading oligemia to improve NVC function after AIS.

NEUROPROTECTION MEDIATED BY REMOTE ISCHEMIC POSTCONDITIONING IS IMPAIRED IN ZUCKER DIABETIC FATTY RATS MODEL

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Klaudia Petrová, Jana Končeková, Miroslav Gottlieb, Petra Bonová
Institute of Neurobiology of Biomedical Research Center SAS, Department Of Neurodegenerarion, Plasticity And Repair, Bratislava, Slovak Republic

Obesity is associated with increasing risk of ischemic stroke. Accordingly, the project aimed to investigate the neuroprotective effect of remote ischemic postconditioning (RIPostC) in obese rats. Male lean and obese Zucker diabetic fatty (ZDF) rats were subjected to 90 minutes of right middle artery occlusion (MCAO) followed by 24 h of reperfusion. Animals were then randomized into 2 groups: hind-limb ischemia treated (ischemic tolerance) and untreated. Although the infarct volume in obese rats was about 113 % higher compared to lean rats in the ischemia group, there were no significant differences among ischemic and tolerance group. Since oxidative stress have substantial role in the expansion of poststroke brain injury, total fragmented DNA in peripheral lymphocytes was measured by Comet Assay. Our results did not confirm the incidence of DNA strand breaks elevation in cell exposed to ischemia of both lean and obese groups, neither after the RIPostC intervention. However, a significantly higher level of oxidative stress was determined in the obese animals, even before the surgery. Assessment of oxidative stress between control and ischemic group revealed down-regulation of SOD activity in both groups without any significant differences between lean and obese group. We did not detect changes in CAT activity among all groups. In contrast, we observed a rapid increase of glutamate levels in peripheral blood in obese group compared to lean group. However, the glutamate level did not change in ischemic groups, neither after the RIPostC. This project was supported by research grants: VEGA 2/0073/21, 2/0096/22 and IMTS: 313011V344

Potential Effect of (L.) Zopf Extract and Metabolite Physodic Acid on Tumour Microenvironment Modulation in MCF-10A Cells.
Lichens comprise a number of unique secondary metabolites with remarkable biological activities and have become an interesting research topic for cancer therapy. However, only a few of these metabolites have been assessed for their effectiveness against various in vitro models. Therefore, the aim of the present study was to assess the effect of extract (L.) Zopf (PSE) and its metabolite physodic acid (Phy) on tumour microenvironment (TME) modulation, focusing on epithelial-mesenchymal transition (EMT), cancer-associated fibroblasts (CAFs) transformation and angiogenesis. Here, we demonstrate, by using flow cytometry, Western blot and immunofluorescence microscopy, that tested compounds inhibited the EMT process in MCF-10A breast cells through decreasing the level of different mesenchymal markers in a time- and dose-dependent manner. By the same mechanisms, PSE and Phy suppressed the function of Transforming growth factor beta (TGF-β)-stimulated fibroblasts. Moreover, PSE and Phy resulted in a decreasing level of the TGF-β canonical pathway Smad2/3, which is essential for tumour growth. Furthermore, PSE and Phy inhibited angiogenesis in a quail embryo chorioallantoic model, which indicates their potential anti-angiogenic activity. These results also provided the first evidence of the modulation of TME by these substances.

Oxidative Stress-Induced DNA Damage and Apoptosis in Clove Buds-Treated MCF-7 Cells.
In recent decades, several spices have been studied for their potential in the prevention and treatment of cancer. It is documented that spices have antioxidant, anti-inflammatory, immunomodulatory, and anticancer effects. The main mechanisms of spices action included apoptosis induction, proliferation, migration and invasion of tumour inhibition, and sensitization of tumours to radiotherapy and chemotherapy. In this study, the ability of clove buds extract (CBE) to induce oxidative stress, DNA damage, and stress/survival/apoptotic pathways modulation were analysed in MCF-7 cells. We demonstrated that CBE treatment induced intrinsic caspase-dependent cell death associated with increased oxidative stress mediated by oxygen and nitrogen radicals. We showed also the CBE-mediated release of mitochondrial pro-apoptotic factors,

signalling of oxidative stress-mediated DNA damage with modulation of cell antioxidant SOD (superoxide dismutase) system, and modulation activity of the Akt, p38 MAPK, JNK and Erk 1/2 pathways.

The Newly Synthetized Chalcone L1 Is Involved in the Cell Growth Inhibition, Induction of Apoptosis and Suppression of Epithelial-to-Mesenchymal Transition of HeLa Cells.
Over the past decades, natural products have emerged as promising agents with multiple biological activities. Many studies suggest the antioxidant, antiangiogenic, antiproliferative and anticancer effects of chalcones and their derivatives. Based on these findings, we decided to evaluate the effects of the newly synthetized chalcone L1 in a human cervical carcinoma cell (HeLa) model. Presented results were obtained by western blot and flow cytometric analyses, live cell imaging and antimigratory potential of L1 in HeLa cells was demonstrated by scratch assay. In the present study, we proved the role of L1 as an effective agent with antiproliferative activity supported by G2/M cell cycle arrest and apoptosis. Moreover, we proved that L1 is involved in modulating Transforming Growth Factor-β1 (TGF-β) signal transduction through Smad proteins and it also modulates other signalling pathways including Akt, JNK, p38 MAPK, and Erk1/2. The involvement of L1 in epithelial-to-mesenchymal transition was demonstrated by the regulation of N-cadherin, E-cadherin, and MMP-9 levels. Here, we also evaluated the effect of conditioned medium from BJ-5ta human foreskin fibroblasts in HeLa cell cultures with subsequent L1 treatment. Taken together, these data suggest the potential role of newly synthesized chalcone L1 as an anticancer-tumour microenvironment modulating agent.

Pro-Apoptotic Potential of (L.) Extract and Isolated Physodic Acid in Acute Lymphoblastic Leukemia Model In Vitro.
Acute lymphoblastic leukemia (ALL) is the most frequently diagnosed type of leukemia among children. Although chemotherapy is a common treatment for cancer, it has a wide range of serious side effects, including myelo- and immunosuppression, hepatotoxicity and neurotoxicity. Combination therapies using natural substances are widely recommended to attenuate the adverse effects of chemotherapy. The aim of the present study was to investigate the anti-leukemic potential of extract from the lichen (L.) (PSE) and isolated physodic acid (Phy) in an in vitro ALL model. A screening assay, flow cytometry and Western blotting were used to analyze apoptosis occurrence, oxidative stress, DNA damage and stress/survival/apoptotic pathway modulation induced by the tested substances in Jurkat cells. We demonstrate for the first time that PSE and Phy treatment-induced intrinsic caspase-dependent cell death was associated with increased oxidative stress, DNA damage and cell cycle arrest with the activation of cell cycle checkpoint proteins p53, p21 and p27 and stress/survival kinases p38 MAPK, JNK and PI3K/Akt. Moreover, using peripheral T lymphocytes, we confirmed that PSE and Phy treatment caused minimal cytotoxicity in normal cells, and therefore, these naturally occurring lichen secondary metabolites could be promising substances for ALL therapy.

Genistein Improves Skin Flap Viability in Rats: A Preliminary In Vivo and In Vitro Investigation.
Selective estrogen receptor modulators (SERMs) have been developed to achieve beneficial effects of estrogens while minimizing their side effects. In this context, we decided to evaluate the protective effect of genistein, a natural SERM, on skin flap viability in rats and in a series of in vitro experiments on endothelial cells (migration, proliferation, antioxidant properties, and gene expression profiling following genistein treatment). Our results showed that administration of genistein increased skin flap viability, but importantly, the difference is only significant when treatment is started 3 days prior the flap surgery. Based on our in vitro experiments, it may be hypothesized that the underlying mechanism may rather by mediated by increasing SOD activity and Bcl-2 expression. The gene expression profiling further revealed 9 up-regulated genes (angiogenesis/inflammation promoting: CTGF, CXCL5, IL-6, ITGB3, MMP-14, and VEGF-A; angiogenesis inhibiting: COL18A1, TIMP-2, and TIMP-3). In conclusion, we observed a protective effect of genistein on skin flap viability which could be potentially applied in plastic surgery to women undergoing a reconstructive and/or plastic intervention. Nevertheless,

further research is needed to explain the exact underlying mechanism and to find the optimal treatment protocol.

PROTECTIVE EFFECT OF SYNTHETIC MACAMIDE AGAINST MORPHOLOGICAL AND NEUROLOGICAL DEFICIT INDUCED BY FOCAL BRAIN ISCHEMIC STROKE INJURY

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Flavia A. Castro-Garcia, Katerin Taboada-Rosell, Luis Alfaro, Grace E. Pardo, Luis F. Pacheco-Otalora
Universidad Andina del Cusco, Instituto Cientifico Uac, Cusco, Peru

Stroke is one of the leading causes of death and disability worldwide. Previous studies have demonstrated the neuroprotective effect of pentane extract of *Lepidium meyenii* (maca) as well as its isolate macamides. Along these lines, this study aims to ascertain the protective effect of macamide N-benciloctadecanamida on morphological conservation and neurological deficits. For this purpose, we use the MCAO model to induce the stroke on Sprague Dawley rats, during surgery an intraperitoneal dose of 3 mg/ kg macamide (MCH1) was administered before the occlusion; this dose was repeated every 24 hours for 10 days. A battery of neurological evaluations was applied on day 3 and day 10 after the stroke, showing significantly different results both times between rats treated with MCH1 and vehicle (VH). On day 3, motor functions were affected more severely than sensitivity functions, this was observed more so in forelimbs than hindlimbs. On day 10, the VH group was the only one still manifesting a significant sensitive hindlimbs asymmetry. Our results obtained from the coronal section of brain stain with 2% of 2, 3, 5-triphenyltetrazolium-chloride solution showed a significant difference in the conservation of sensorimotor areas between the VH and MCH1 group. These findings suggest the protective effect of macamide against brain damage during the stroke, as well as the conservation of sensorimotor function

MODULATING MICROGLIA PHAGOCYTOSIS

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Helike Lõhelaid[1], Mikko Airavaara[2]
[1]University of Helsinki, Hilife/neuroscience Center, Helsinki, Finland, [2]University of Helsinki, Faculty Of Pharmacy, Helsinki, Finland

Ischemic stroke is one of the leading causes of death and disability in adults. Currently, there are no effective drugs to promote the
functional recovery from stroke. Adequate healing of the damaged brain area depends on clearance of cell and myelin debris, but this
process is slow and perturbs with neuronal regeneration. Thus, enhancing phagocytosis could improve removal of cell debris. We have created a small library of lentiviral vectors encoding different genes related to phagocytosis or recruitment of microglia/macrophages, namely Monocyte chemoattractant protein 1 (MCP1), three isoforms of Macrophage colony-stimulating factor (M-CSF), Complement Component 3 (C3), Complement Component 3a (C3a), Adhesion G protein-coupled receptor E1 (Emr1/ADGRE1/F4/80), MER receptor tyrosine kinase (MerTK) and Mesencephalic astrocyte-derived neurotrophic factor (MANF). Their effect on phagocytosis and induction of inflammation are tested in microglia (BV2) after transient transfection *in vitro* by phagocytosis assay and cytokine (TNFa, IL-6 and IL10) ELISAs. The highest effect on phagocytosis was deteced with LV-MerTK, LV-MCSF32-E and LV-MCSF1-E while LV-C3a and LV-Emr1 transfections enhanced phagocytosis over 80% of the induction of the positive control. In parallel, LV-MANF and LV-MerTK were equally potent in enhancing TNFa and IL-6. In summary, this is the first study to compare the effect of different chemotactic and phagocytosis related proteins enhancing phagocytosis and changing the inflammatory profile of microglia.

TARGETING OXIDATIVE STRESS AND PROLYL HYDROXYLASE DOMAIN INHIBITION AS NEUROPROTECTIVE STRATEGIES AGAINST HYPOXIA IN ISOLATED RAT HIPPOCAMPAL SLICES.

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Niamh Moreton, John O'Connor
University College Dublin, Conway Institute Of Biomolecular And Biomedical Sciences, Dublin, Ireland

The contribution of hypoxia and oxidative stress to the pathophysiology of acute ischemic stroke (AIS) are well established and can lead to disruptions in synaptic signaling. Hypoxia and oxidative stress lead to the neurotoxic overproduction of reactive oxygen species (ROS) and the stabilization of hypoxia inducible factors. Antioxidant compounds and prolyl-4-hydroxylase domain enzyme inhibitors (PHDI) have been shown to have a preconditioning and neuroprotective effect against an ischemic insult. Therefore, this study explores the effects of the ROS scavenger, MnTMPyP, and the PHDI, DMOG, on synaptic transmission post hypoxia in isolated rat hippocampal slices using electrophysiological techniques and organotypic hippocampal slice cultures. We report for the first time an acute deleterious effect of MnTMPyP (25µM) on synaptic transmission post hypoxia, an effect specific to the CA1 region of the hippocampus. This effect was attenuated through the co-application of the adenosine A1 receptor antagonist, DPCPX (200nM), and the NMDA receptor antagonist, AP5 (10µM), suggesting pre- and post-synaptic effects. Interestingly, our organotypic data demonstrates a protective role for MnTMPyP, where slices had significantly less cell death post hypoxia compared to controls. Additionally, we provide evidence for a protective role for DMOG (1mM) on synaptic signaling post hypoxia, an effect that appears to be post-synaptic. Taken together, our results suggest a crucial role for ROS and PHDs in maintaining synaptic integrity during episodes of hypoxic stress. These new findings may help to disambiguate the complex interaction between synaptic signaling and hypoxia informing novel therapies for the treatment of AIS.

EARLY APPLICATION OF CATHODAL-TDCS IN A MOUSE MODEL OF BRAIN ISCHEMIA RESULTS IN FUNCTIONAL IMPROVEMENT AND PERILESIONAL MICROGLIA MODULATION

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Laura Cherchi, Daniela Anni, Mario Buffelli, Marco Cambiaghi
University of Verona, Neuroscience, Biomedicine And Movement Sciences, Verona, Italy

Aims. Treatment of acute ischemic stroke is mostly limited to thrombolysis, which unfortunately can be applied only to a minority of cases because of its narrow therapeutic window (<6 hrs). Hence, new therapeutic strategies capable of modulating the ischemic pathophysiology (including the inflammatory response) that can be applied beyond the time window for thrombolysis, are urgently needed. In the last few decades, non-invasive neuromodulatory techniques, such as transcranial direct current stimulation (tDCS), have emerged as an effective treatment for chronic stroke and could be a promising tool for acute/subacute stroke as well. The purpose of this project is to study the effects of early cathodal tDCS (C-tDCS) on motor functionality and microglia activation in a mouse model of ischemic stroke. *Methods.* Photothrombotic stroke was induced in Cx3CR1$^{GFP/+}$ mice and C-tDCS applied 6 hours after unilateral M1 ischemia. Motor functionality was tested with the cylinder and foot-fault tests, while the density and activation state of microglia cells were evaluated via 3D imaging quantifications. *Results.* Though tDCS application did not decrease the lesion volume at 48 hours, the functionality of the affected forelimb was significantly higher in the C-tDCS group *vs* sham treated mice. C-tDCS treatment also reduced microglia density in the perilesional area, and induced a resting microglial phenotype with ramified morphology, increased total processes length, process branch points and terminal process branches, *vs* the sham group. *Conclusions.* C-tDCS applied beyond the conventional time window for thrombolysis can significantly ameliorate functional deficits and reduce microglia activation in the perilesional ischemic area.

NEUROPROTECTIVE EFFECT OF SODIUM BUTYRATE – THE HDAC INHIBITOR - ON THE ACTIVATION OF THE COMPLEMENT SYSTEM IN RAT MODEL OF NEONATAL ASPHYXIA

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Karolina Ziabska, Teresa Zalewska, Joanna Sypecka, Malgorzata Ziemka-Nalecz
Mossakowski Medical Research Institute Polish Academy of Sciences, Neurorepair Department, Warszawa, Poland

Background: One of the key pathogenic factors in hypoxic-ischemic (HI) brain injury is the complement system. Complement usually protects against infection and promotes tissue repair, but can cause tissue damage if over-activated. Histone deacetylase inhibitor (HDACi) - sodium butyrate (SB), provides protection associated with reduction of inflammation. Therefore pharmacological modifications of complement activation could potentially create new therapeutic approach to reduce brain damage after neonatal HI. **Aim:** The main purpose of this study was to examine the effect of SB treatment on complement activation and synapse elimination after neonatal hypoxia-ischemia. **Methods:** Cerebral HI was induced in seven-day-old Wistar rats by permanent unilateral ligation of the common carotid artery followed by 60 min hypoxia (7.6% O2). HDACi - Sodium butyrate (SB) (300 mg/kg bw) was administered on a 5-day regimen with the first injection administered immediately after hypoxia exposure. **Results:** We observed increased expression some of the complement system genes after HI, which decreased significantly after SB treatment. Additionally, expression some of the synaptic proteins decreased after HI, and returned to the control level after SB administration. HI induced brain tissue damage and a disturbance in synaptic morphology. In animals treated with SB, the tissue had normal morphology of neurons and synaptic connections. **Conclusion:** The results obtained in this study suggested the neuroprotective effect of SB by reduction the activity of complement system proteins as well as the protection of synaptic proteins and synaptic connections. Aims It has been shown that infarcts can exert effects remotely from the initial lesion, notably through disconnections. We hypothesise that progressive iron accumulation within disconnected thalamic nuclei precedes and is associated with long term neurodegeneration. Methods Six weeks-old mice (n=56 total) were submitted to photo-thrombosis surgery (or sham procedure) to induce a cortical stroke and *in vivo* MRI was acquired at 72h, 2, 4, 6 and 8 weeks. R2*, a proxy of iron, was computed from a multi-echo T2* sequence. Images of each timepoint were co-registered and wrapped to the Allen/Hikishima atlas to allow R2* and volume quantification within nuclei known to project toward the infarcted region (posterior, ventro-postero-medial and ventro-postero-lateral). Tractography was also computed from post-mortem MRI to confirm such projections and quantify fiber degenerations. After euthanasia, immunofluorescence, iron mass spectrometry (MS) and qPCR analyses were performed to assess iron-linked processes, neuronal death and glial and inflammatory responses. Results R2* values in disconnected thalamic nuclei displayed a significant peak at 2/4 weeks, preceding and significantly correlating to long term volumetric loss. Histological analyses, qPCR and MS also suggested a fluctuant thalamic response in terms of neuronal death, inflammation, iron uptake and ferroptosis. Conclusion These data support our hypothesis that iron dynamically accumulates in disconnected areas, and may accelerate cell death, promoting remote neurodegeneration in a vicious circle involving one or more processes. Iron might serve as a future predictive tool and as a potential therapeutic target for

neuroprotection.

In aneurysmal subarachnoid hemorrhage (SAH), cerebral vasospasm (CVS) and neuroinflammation are known associated with delayed ischemia, but addressing these symptoms does not improve the bad neurological outcome of patients. Urotensin II (UII) is a vasoactive peptide activating the UT receptor, involved in brain vascular pathologies and inflammation. We first established that high plasma level of UII in SAH patients is a predictive factor of CVS. Here we investigated the critical role of UT, especially brain border-associated macrophages (BAMs), on the CVS and neuroinflammation leading to cognitive impairment in a mouse model of SAH. We used a double intracisternal blood injection SAH procedure in $UT^{+/+}$ and KO-$UT^{-/-}$ or humanized $UT^{h+/h+}$ C57Bl/6 mice. Increased expression of UT and UII were neural and myeloid cells as in meninges and inflamed endothelial compartments with mouse brain slices in 2D and 3D immunofluorescence. We highlighted early and delayed vascular hypoperfusion (fUS) and CVS or large arteries, neurovascular inflammation (MPIO-VCAM-1 MRI) and outcome (cognitive, depressive and sensitivomotor behaviors). Mechanistically, we studied meninges plasticity *via in vivo* siRNA injection, involvement of BAM in CVS by depletion (clodronate)/replacement (BMDMs) strategies, and prevention of cognitive deficits by using UT antagonists/biased ligands. We identified UT as a critical regulator of SAH-driven CVS, neuroinflammation and behavioral disorders. UT activation by meningeal and perivascular macrophages worsens vascular defects and subsequent neurological deficits and UT expressed in meningeal fibroblasts contributes to cognitive impairment after SAH. Importantly, pharmacological UT antagonism in a humanized UT mouse model entirely prevents CVS, neuroinflammation and behavioral disorders post-SAH.

THE EFFECTS OF THE SOD MIMETIC, MNTMPYP, ON SYNAPTIC SIGNALLING AND VIABILITY IN AN IN VITRO RAT OGD MODEL.

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Martina Puzio, John O'Connor
Conway Institute University College Dublin, School Of Biomolecular And Biomedical Science, DUBLIN, Ireland

Oxidative stress plays an important role in ischemia-reperfusion injury (IRI). Antioxidants have been shown to have beneficial effects during increased levels of reactive oxygen species in ischemic stroke. Therefore, this study investigated the effects of the antioxidant and SOD mimetic, MnTMPyP on synaptic transmission and neuronal viability in an oxygen-glucose deprivation (OGD) rat stroke model. Field excitatory post-synaptic potentials (fEPSPs) were elicited by stimulation of the Schaffer collateral pathway in young rat CA1 hippocampal slices. During OGD hippocampal slices were perfused with glucose-free aCSF bubbled with 95% N_2/5% CO_2 for 20 min. Organotypic hippocampal slices were obtained from P7-11 rat pups. Slices were exposed to 1 hr of OGD with a glucose-free media before staining with 2µM Propidium Iodide (PI). Images were taken 40 min later. All data are presented as mean value±SEM. 25µM MnTMPyP had no effect on the OGD-induced depression of synaptic transmission (23.0±10% vs control 21.2±3.0%) but significantly impaired recovery post OGD (15.2±2.1% compared to controls 70.0±11.3%, n=5). Interestingly, application of a lower concentration of MnTMPyP (2.5µM), did not attenuated the depression (24.4±6.6% vs controls 21.2±3.0%) but gave rise to a faster and full recovery of synaptic transmission after OGD (89.0±9.0% compared to controls 70.0±11.3%, n=5). Furthermore, in the organotypic slice cultures, MnTMPyP improved the viability of hippocampal cells after 1hr OGD compared to untreated slices (25.0±5.4% vs controls 60.0±9.0%). In conclusion, MnTMPyP protected neuronal viability and synaptic signalling in hippocampal slices. Whether MnTMPyP will play an important role in IRI remains to be determined.

Introduction: Germinal matrix-intraventricular hemorrhage (GM-IVH) is one of the most severe neurological pathologies affecting preterm newborns (PTNB) and causing serious alterations in their neurodevelopment. To date, there are no effective treatments for GM-IVH. **Objectives**: We proposed to study the short- and long-term effects of VP3.15, an inhibitor of the glucogen sintase 3-β (GSK3-β) enzyme that has shown neuroprotective effects in other neurodegenerative and inflammatory diseases. **Methods**: GM-IVH is induced by unilateral intracerebroventricular injection of collagenase to P7 CD1 mice. Animals are treated with VP3.15 (10 mg/kg/day) i.p., or vehicle for 7 days. Short (P14) and long-term (P110) postmortem studies are performed to evaluate brain and cerebellar atrophy by cresyl violet and calbindin staining. Neuronal density using NeuN-DAPI immunostaining is also evaluated. Behavioral studies are performed prior to sacrifice at P110 and spatial learning and memory, as well as episodic memory are assessed in the Morris water maze and new object discrimination test. **Results**: VP3.15 treatment reduces brain atrophy, reducing cortical thinning and ventricular enlargement. It also improves neuronal density in the cortex, the subventricular zone and the ipsilateral cerebellar trunk in our murine model of GM-IVH. Interestingly, our results show that spatial and episodic memory are also improved after VP3.15 treatment. **Conclusion**: VP3.15 treatment limits brain atrophy and cognitive impairment in our model, supporting further studies on the neuroprotective role of VP3.15 in GM-IVH of PTNB. **Funding**: I + D + i Programa operativo del Fondo Europeo de Desarrollo Regional FEDER Andalucía 2014–2020 (FEDER-UCA18–107189).

Germinal Matrix-Intraventricular Hemorrhage of the Preterm Newborn and Preclinical Models: Inflammatory Considerations.
The germinal matrix-intraventricular hemorrhage (GM-IVH) is one of the most important complications of the preterm newborn. Since these children are born at a critical time in brain development, they can develop short and long term neurological, sensory, cognitive and motor disabilities depending on the severity of the GM-IVH. In addition, hemorrhage triggers a microglia-mediated inflammatory response that damages the tissue adjacent to the injury. Nevertheless, a neuroprotective and neuroreparative role of the microglia has also been described, suggesting that neonatal microglia may have unique functions. While the implication of the inflammatory process in GM-IVH is well established, the difficulty to access a very delicate population has lead to the development of animal models that resemble the pathological features of GM-IVH. Genetically modified models and lesions induced by local administration of glycerol, collagenase or blood have been used to study associated inflammatory mechanisms as well as therapeutic targets. In the present study we review the GM-IVH complications, with special interest in inflammatory response and the role of microglia, both in patients and animal models, and we analyze specific proteins and cytokines that are currently under study as feasible predictors of GM-IVH evolution and prognosis.

Liraglutide Reduces Vascular Damage, Neuronal Loss, and Cognitive Impairment in a Mixed Murine Model of Alzheimer's

Disease and Type 2 Diabetes.
Alzheimer's disease is the most common form of dementia, and epidemiological studies support that type 2 diabetes (T2D) is a major contributor. The relationship between both diseases and the fact that Alzheimer's disease (AD) does not have a successful treatment support the study on antidiabetic drugs limiting or slowing down brain complications in AD. Among these, liraglutide (LRGT), a glucagon-like peptide-1 agonist, is currently being tested in patients with AD in the Evaluating Liraglutide in Alzheimer's Disease (ELAD) clinical trial. However, the effects of LRGT on brain pathology when AD and T2D coexist have not been assessed. We have administered LRGT (500 μg/kg/day) to a mixed murine model of AD and T2D (APP/PS1xdb/db mice) for 20 weeks. We have evaluated metabolic parameters as well as the effects of LRGT on learning and memory. analysis included assessment of brain amyloid-β and tau pathologies, microglia activation, spontaneous bleeding and neuronal loss, as well as insulin and insulin-like growth factor 1 receptors. LRGT treatment reduced glucose levels in diabetic mice (db/db and APP/PS1xdb/db) after 4 weeks of treatment. LRGT also helped to maintain insulin levels after 8 weeks of treatment. While we did not detect any effects on cortical insulin or insulin-like growth factor 1 receptor m-RNA levels, LRGT significantly reduced brain atrophy in the db/db and APP/PS1xdb/db mice. LRGT treatment also rescued neuron density in the APP/PS1xdb/db mice in the proximity (= 0.008) far from amyloid plaques (< 0.001). LRGT reduced amyloid plaque burden in the APP/PS1 animals (< 0.001), as well as Aβ aggregates levels (= 0.046), and tau hyperphosphorylation (= 0.009) in the APP/PS1xdb/db mice. Spontaneous bleeding was also ameliorated in the APP/PS1xdb/db animals (= 0.012), and microglia burden was reduced in the proximity of amyloid plaques in the APP/PS1 and APP/PS1xdb/db mice (< 0.001), while microglia was reduced in areas far from amyloid plaques in the db/db and APP/PS1xdb/db mice (< 0.001). This overall improvement helped to rescue cognitive impairment in AD-T2D mice in the new object discrimination test (< 0.001) and Morris water maze (< 0.001). Altogether, our data support the role of LRGT in reduction of associated brain complications when T2D and AD occur simultaneously, as regularly observed in the clinical arena.

PROFOUND ALTERATIONS IN BRAIN TISSUE LINKED TO HYPOXIC EPISODE AFTER DEVICE IMPLANTATION.

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Lucas Kumosa, Jens Schouenborg
Lund University, Neuronano Research Center, Lund, Sweden

To enable authentic interfacing with neuronal structures in the brain, preventing alterations of tissue during implantation of devices is critical. By transiently implanting oxygen microsensors into rat cortex cerebri for 2 h, substantial and long lasting (>1 h) hypoxia is routinely generated in surrounding tissues; this hypoxia is linked to implantation generated compressive forces. Preferential loss of larger neurons and reduced metabolic components in surviving neurons indicates decreased viability one week after such hypoxic, compressive implantations. By devising an implantation method that relaxes compressive forces; magnitude and duration of hypoxia generated following such an implantation are ameliorated and neurons appear similar to naïve tissues. In line with these observations, astrocyte proliferation was significantly more pronounced for more hypoxic, compressive implantations. Surprisingly, astrocyte processes were frequently found to traverse cellular boundaries into nearby neuronal nuclei, indicating injury induction of a previously not described astrocyte-neuron interaction. Found more frequently in less hypoxic, force-relaxed insertions and thus correlating to a more beneficial outcome, this finding may suggest a novel protective mechanism. In conclusion, substantial and long lasting insertion induced hypoxia around brain implants, a previously overlooked factor, is linked to significant
adverse alterations in nervous tissue.

INHIBITION OF NEURONAL AUTOPHAGY CONTRIBUTES TO REDUCED ISCHEMIC BRAIN DAMAGE IN RATS

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Dinesh Tripathi, Sunita Tiwari, Chetna Mishra
King George's Medical University, Physiology, Lucknow, India

Introduction: Emerging evidence suggests a strong correlation between apoptosis, autophagy and their pathological processes in cerebral ischemic injury particularly in diabetes. Oxidative stress and blood brain barrier dysfunction are one of the important factors causing disability and mortality in stroke patients, which have a significant impact on diabetic induced stroke progression. Citral have been reported to antioxidant and anti-inflammatory activity. The aim of this study was to investigated the therapeutic effects of citral against ischemic stroke in hyperglycemic rats and its role in modulating autophagy. **Methods**: Hyperglycemia was induced by intraperitoneal (i.p) injection of streptozotocin (35 mg/kg) in male Sprague Dawley (SD) rats and rats were subjected to middle cerebral artery occlusion (MCAO) for 1 hour. Citral was administered at 3 hours after the induction of MCAO. Lipid profile, blood glucose, Neurological deficit, oxidative stress makers (MDA & GSH), blood brain barrier (BBB) permeability and brain edema, were measured. Additionally, RT-PCR and western blot analysis of Bcl-2, Beclin-1 and LC3 were examined. **Result:** Citral significantly reduced brain edema, BBB integrity, oxidative damage and ameliorated neurologic outcome in rats. Citral treatment significantly decreased serum glucose level, serum TG, TC and serum LDL. Citral decreased apoptosis and autophagy via down-regulation of the LC3 and Beclin-1 expression. **Conclusion:** Our finding suggests that citral attenuates cerebral ischemic injury in hyperglycaemic rats and promotes functional recovery via its antioxidant, anti-apoptosis, and anti-autophagy properties, may have a therapeutic potential for stroke prevention in diabetic settings.

Effects of citral on oxidative stress and hepatic key enzymes of glucose metabolism in streptozotocin/high-fat-diet induced diabetic dyslipidemic rats.
Phytochemicals such as polyphenols, alkaloids, and terpenoids, protect against the development of early stages and complications of diabetes mellitus according to various reports. The aim of this study was to measure the anti-dyslipidemic and anti-diabetic effects of Citral on high-fat-diet (HFD) and streptozotocin (STZ) induced diabetic dyslipidemic rats and to see also its effect on carbohydrate metabolic regulatory enzymes in the liver.

Blood-brain barrier dysfunction in ischemic stroke: targeting tight junctions and transporters for vascular protection.
The blood-brain barrier (BBB) is a physical and biochemical barrier that precisely controls cerebral homeostasis. It also plays a central role in the regulation of blood-to-brain flux of endogenous and exogenous xenobiotics and associated metabolites. This is accomplished by molecular characteristics of brain microvessel endothelial cells such as tight junction protein complexes and functional expression of influx and efflux transporters. One of the pathophysiological features of ischemic stroke is disruption of the BBB, which significantly contributes to development of brain injury and subsequent neurological impairment. Biochemical characteristics of BBB damage include decreased expression and altered organization of tight junction constituent proteins as well as modulation of functional expression of endogenous BBB transporters. Therefore, there is a critical need for development of novel therapeutic strategies that can protect against BBB dysfunction (i.e., vascular protection) in the setting of ischemic stroke. Such strategies include targeting tight junctions to ensure that they maintain their correct structure or targeting transporters to control flux of physiological substrates for protection of endothelial homeostasis. In this review, we will describe the pathophysiological mechanisms in cerebral microvascular endothelial cells that lead to BBB dysfunction following onset of stroke. Additionally, we will utilize this state-of-the-art knowledge to provide insights on novel pharmacological strategies that can be developed to confer BBB protection in the setting of ischemic stroke.

Aims: In this study, it was aimed to examine the histopathological structure of thrombus in acute ischemic stroke. **Methods**: 90 patients who underwent mechanical thrombectomy were included. Detailed clinical information were recorded. Thrombi were stained with Hematoxylin-Eosin (H&E) and Martius Scarlet Blue (MSB) for fibrin and erythrocyte contents. Fiji and Orbit programs were used for image analysis. CD3, CD20, CD45 and CD34 stainings were performed to examine T and B lymphocytes, total leukocytes and endothelial cells in thrombus. One thrombus section from each patient was used for each staining. Differences between groups were analyzed with t-test or Mann-Whitney U, correlation analyzes were performed with Pearson or Spearman tests. **Results**: From all 90 thrombi, 63 (70%) were considered fibrin-dominant, and 27 (30%) were erythrocyte-dominant.There was no difference in fibrin or erythrocyte-dominant thrombus rates between Fiji and Orbit programs and two different staining methods, H&E and MSB. CD3/CD45 and CD20/CD45 ratios were negatively correlated with the percentage of fibrin (p=0.003, p=0.001) and positively correlated with the percentage of erythrocyte (p=0.003, p=0.001). Similarly, CD3/CD45 and CD20/CD45 ratios were lower in fibrin-dominant thrombi (p=0.001, p=0.007). The number of endothelial cells stained with CD34 was positively correlated with symptom-to-door, symptom-to-puncture and symptom-to-recanalization times (p=0.022, p=0.001, p=0.001), but not with duration of procedure. **Conclusions**: It has been determined that leukocyte subtype contents of thrombi, as well as fibrin/erythrocyte contents, may be associated with the pathophysiology of stroke. Further investigation of the thrombus content in subsequent studies is important to elucidate the pathophysiology of acute ischemic stroke.

EFFECTS OF TLR2 DEFICIENCY ON NEUROINFLAMMATION AFTER ISCHEMIC LESION IN THE MOUSE BRAIN - WORSE FUNCTIONAL OUTCOME AND MORE INFLAMMATION THAN IN WILD TYPE CONTROLS?

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Sanja Srakočić, Paula Josić, Rok Ister, Siniša Škokić, Anton Glasnović, Marina Radmilović Dobrivojević, Srecko Gajovic
University of Zagreb School of Medicine, Croatian Institute For Brain Research, Zagreb, Croatia

Tlr2 (Toll-like receptor 2) in the brain is located in microglia, and involved in innate immunity recognising the damage-associated molecular patterns after ischemia. It is postulated that inhibition of the Tlr2-mediated signalling will reduce the neuroinflammatory response and subsequently reduce the post-ischemic brain damage. In our study we compared Tlr2 deficient (knock-out) mice to their wild type controls and analyzed the brain consequences of transient MCAO (middle cerebral artery occlusion) for 28 days using in vivo magnetic resonance and biolumescence imaging. Moreover, we created Tlr2 deficient mice with Tlr2 promoter driven bioluminescence reporter, provding an insight in neuroinflammmation in vivo. The functional outcome was provided by neurological deficit scoring, and inflammatory status was determined by flow cytometry of the mouse brain and cytokine levels in the blood. Although one would expect reduced neuroinflammation in Tlr2 deficient mice after ischemia and subsequent benefits to the animals, the results were controversial. The ischemic lesion was bigger in Tlr2 deficient animals, however their survival was better. The neurological deficit score was worse in Tlr2 deficient animals. Moroever, the Tlr2 bioluminescence being a marker of neuroinflammation was higher in Tlr2 deficient animals, which was partially confirmed by flow cytometry. Among cytokines, IL-23 and IL-1alpha were higher in the blood, and none of the analysed cytokines was reduced in Tlr2 deficient animals. The statistical modelling showed that Tlr2 deficient mice were worse than the wild type controls, however they recovered faster. In conclusion, the effects of Tlr2 deficiency are complex and indicate multiple aspects of neuroinflammation in post-ischemic brain damage and repair.

THE NEUROPROTECTIVE EFFECTS OF PHOSPHOGLYCERATE MUTASE 5 ARE MEDIATED BY DECREASING OXIDATIVE STRESS IN HT22 HIPPOCAMPAL CELLS AND GERBIL HIPPOCAMPUS

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

In Koo Hwang[1], Hyo Young Jung[2], Hyun Jung Kwon[3], Woosuk Kim[4], Kyu Ri Hahn[1], Yeo Sung Yoon[1], Dae Won Kim[3]
[1]Seoul National University College of Veterinary Medicine, Department Of Anatomy And Cell Biology, Seoul, Korea, Republic of, [2]Chungnam National University College of Veterinary Medicine, Department Of Anatomy, Daejeon, Korea, Republic of, [3]Gangneung National University College of Dentistry, Department Of Biochemistry And Molecular Biology, Gangneung, Korea, Republic of, [4]Konkuk University College of Veterinary Medicine, Department Of Anatomy, Seoul, Korea, Republic of

Phosphoglycerate mutase 5 (PGAM5), a glycolytic enzyme, plays an important role in cell death and in the regulation of mitochondrial dynamics. In this study, we investigated the effects of PGAM5 against oxidative stress in HT22 hippocampal cells and ischemic damage in the gerbil hippocampus to elucidate the roles of PGAM5 in oxidative and ischemic stress. Constructs were designed with a PEP-1 expression vector to facilitate the intracellular delivery of PGAM5 proteins. We observed time- and concentration-dependent increases in the intracellular delivery of PEP-1-PGAM5 protein, but not its control protein (PGAM5), in HT22 cells, and morphologically demonstrated the cytoplasmic localization of the transduced protein, which was stably expressed in the cytoplasm after 12 h of PEP-1-PGAM5 treatment. PEP-1-PGAM5 treatment significantly ameliorated cell death, reactive oxygen species formation, and DNA fragmentation induced by H2O2 treatment in HT22 cells. In addition, PEP-1-PGAM5 treatment significantly alleviated ischemia-induced hyperlocomotion and neuronal death in the hippocampal CA1 region 1 and 4 days after ischemia, respectively. Microglial activation induced by ischemia was also mitigated by treatment with 1.0 mg/kg PEP-1-PGAM5. At 3 h after ischemia, PEP-1-PGAM5 treatment significantly ameliorated increases in lipid peroxidation, as assessed by malondialdehyde and hydroperoxide levels, and decreases in glutathione levels (increases in glutathione disulfide, oxidized form of glutathione) in the hippocampus. The neuroprotective effects of PEP-1-PGAM5 are partially mediated by a reduction in oxidative stress, such as the formation of reactive oxygen species.

Aim The *in-vivo* MRI study of juvenile rats aims to detect neuroradiological structural and volumetric changes consequently to moderate perinatal hypoxic brain lesion. Methods Sixteen male Wistar Han (RccHan: WIST) rats were subjected to moderate hypoxia (8% O_2, 92% N_2/2h, 8 treated and 8 control) on the first postnatal day (P1). On P15, MRI T2-weighted scans were obtained *in-vivo*, and brain volume was quantified after manual delineation of regions of interest, using ITK-SNAP and custom scripts in Python 3.8. In addition,16 post-hypoxia (8 males, 8 females) and 15 control (7 males, 8 females) rats were sacrificed on P50, brains were instantly isolated and immediately weighed on a digital scale. Due to the sex-related difference in size, brain mass was compared separately in males and females by Student t-test. Results The rats subjected to hypoxia show an indicative increase in olfactory bulbs volume fraction (VF) median from the total brain volume (TBV; 4.36 ± 0.47% and 4.55 ± 0.37%, p=0.0734). We found no difference between groups in the TBV or ventricular system VF medians. Post-hypoxic adult animals displayed a slight but significant increase in the brain mass in both males (1.81 ± 0.06 g and 1.72 ± 0.03 g, respectively, p=0.0032) and females (1.67 ± 0.05 g and 1.54 ± 0.15 g, respectively, p=0.0448), in comparison to control rats. Conclusion Further investigation is needed to understand the underlying mechanisms of demonstrated brain volume and mass changes after moderate perinatal hypoxia. Program In Medical Neuroscience, College Of Medical Science And Technology, Taipei, Taiwan

Aims: According to the World Health Organization (WHO), stroke is the second global causes of death and responsible for approximately 11 % of total deaths in 2019. Currently, acute stroke have limited treatment modalities. After ischemic stroke occurs, a robust inflammation response initiates within minutes and persists for days and alters neurological prognosis. Our previous studies demonstrated pomalidomide exerted anti-neuroinflammatory effect against brain damage. In this study, we demonstrate administration of inflammatory mediators, pomalidomide and its analogs, 3,6 & 1,6 dithiopomalidomide (DP) markedly decreased the brain infract size and improved body asymmetry through pyroptosis and ferroptosis. Methods: We treated the rats after middle cerebral artery occlusion (MCAo) with pomalidomide, 3,6-DP & 1,6-DP. The cytokine interleukin-1β (IL-1β), interleukin-6 (IL-6) and Tumor necrosis factor-α (TNF-α) were assessed by multiplex assays kit. In addition, inflammasomes NLRP3, anti-oxidant enzyme SOD2 and catalase were analyzed by ELISA. Results: Post-MCAo administration of all drugs lowered pro-inflammatory TNF-α, IL-1β, and IL-6 levels, and reduced stroke-induced postural asymmetry and infarct size. Moreover, expressions of inflammasomes NLRP3 and pyroptosis-related cytokines were reduced after treatments. In contrast, levels of ferroptosis-related anti-oxidation enzymes catalase and SOD2 were enhanced. Conclusions: These results showed pyroptosis and ferroptosis are involved in the neuro-inflammatory modulation of pomalidomide and its analogs after ischemic brain injury. It implicated considerable pathways as a further potential therapeutic approach for ischemic stroke and other brain-related disorders. The understanding of the mechanisms behind effect of Pomalidomide shows beneficial outcomes to provide the current treatment of ischemia via protection of injured neurons.

CUTAMESINE EFFECT IN A LONG-TERM MCAO RAT MODEL

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Alba Puente-Sanz[1], Amanda Herrero-González[1], Berta Anuncibay-Soto[2], Arsenio Fernández-López[1]
[1]University of León, Molecular Biology And Cellular Biology, León, Spain, [2]Imperial College of London, Department Of Life Sciences, London, United Kingdom

Aims
Cutamesine has been described to play a neuroprotective role in acute stroke models. Here we present for the first time that cutamesine maintains this neuroprotection in a long-term ischemia model (15-days reperfusion).
Methods
Transient middle cerebral artery occlusion (tMCAO) was carried out in 12 week-old-male Sprague Dawley rats as previously described (Santos-Galdiano et al., 2018, J. Pharmacol. Exp. Ther. 367(3):528-542). Two experimental groups underwent 60 and 45 minutes of occlusion treated with cutamesine, as well as vehicle and sham groups were compared.
Cutamesine 10 µg/kg was administered 1 hour after reperfusion, once a day for 6 days. The vehicle group received sterile saline parallely to the cutamesine-treated group. The assays included behavioral tests (cylinder, adhesive removal, hanging wire, and apomorphine-induced rotation tests), apoptosis marker transcript, and magnetic resonance imaging (MRI) studies.
Results
Cutamesine improved the outcome in behavioral tests in animals subjected to 60-minutes occlusion while this effect was not observed in 45-minutes occlusion.
Cutamesine decreased apoptosis markers in the penumbra of animals underwent 45-minutes (but not in 60-minutes) occlusion, consistently with a decreasing trend in plasma levels of C reactive protein.
MRI showed a cutamesine-trend to reduce the infarct volume from 48 hours after reperfusion in animals with a 60-minutes occlusion.
Conclusions
MRI, biochemical and behavioral assays support a neuroprotective effect of cutamesine in a long-term (15 days) tCMAO model.

IMAGING INCREASED METABOLISM IN THE SPINAL CORD IN A MOUSE MODEL OF ISCHEMIC STROKE

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Ruiqing Ni[1], Nadja Straumann[1], Georgios Louloudis[2], Xose Luis Dean-Ben[2], Claudia Keller[3], Daniel Razansky[2], Simon Ametamey[3], Linjing Mu[3], Jan Klohs[2]

Emerging evidence indicates a crosstalk between the haematopoietic system and the brain following cerebral ischemia. Here, we investigated the metabolism and oxygenation in the spleen and spinal cord in the transient middle cerebral artery occlusion (tMCAO) mouse model that is widely used in focal cerebral ischemia research. Naïve, sham and tMCAO mice underwent positron emission tomography (PET) using [^{18}F]fluorodeoxyglucose (FDG) for assessing glucose metabolism and multispectral optoacoustic tomography (MSOT) for oxygenation in these tissues at 24 h after reperfusion in mice. We employed the non-negative model-based reconstruction and unmixing algorithm to map the MSOT oxygen saturation pattern. After *in vivo* imaging the ischemic lesion was confirmed by *ex vivo* 2,3,5-triphenyltetrazolium chloride staining. We found increased levels of [^{18}F]FDG uptake and reduced MSOT oxygen saturation indicating hypoxia in the thoracic spinal cord of tMCAO mice compared with sham-operated mice but not in the spleen. A positive correlation was observed between splenic and ipsilateral striatal [^{18}F]FDG uptake. No difference was observed in the spleen size between groups *ex vivo*. In conclusion, we demonstrated the utility of MSOT in measuring spinal cord oxygenation, and found hypoxia and increased metabolic activity in the spinal cord of tMCAO mice at 24 h after reperfusion compared to sham-operated mice.

H-FABP AS A BIOMARKER OF VASCULAR BRAIN DAMAGE IN TRANSIENT ISCHEMIC ATTACK

POSTER SESSION 04 - SECTION: BRAIN HYPOXIA-ISCHEMIA AND INFLAMMATION

Daisy Guamán[1,2], Elena Palà[1,2], Marcel Lamana[1,2], Ana Penalba[1,2], Elvira Chocano[1,2], Paula García-Rodríguez[1,2], Marta Rubiera[3], Alejandro Bustamante[2,4], Alex Rovira[5], Soledad Pérez-Sánchez[6], Jean-Charles Sánchez[7], Liere Azurmendi-Gil[7], Sandrine Reymond[7], Joan Montaner[1,2,6]
[1]Vall d'Hebron Research Institute, Neurovascular Research Lab, Barcelona, Spain, [2]Universitat Autónoma de Barcelona, Neurosciences Institute, Barcelona, Spain, [3]Hospital Universitari Vall d'Hebron, Department Of Neurology, Barcelona, Spain, [4]Hospital Germans Trias i Pujol, Department Of Neurology, Barcelona, Spain, [5]Hospital Universitari Vall d'Hebron, Department Of Radiology,, Barcelona, Spain, [6]Hospital Universitario Virgen Macarena, Department Of Neurology, Sevilla, Spain, [7]Translational Biomarker Group, Internal Medicine Department, University Of Genevaent, Genève, Switzerland

Background and purpose
The accurate diagnosis of transient ischemic attack (TIA) appears to be a challenge in clinical practice. Our objective is to evaluate the potential value of heart fatty-acid binding protein (H-FABP) as a possible biomarker for the differential diagnosis of TIA versus TIA-mimicking conditions (mimics).
Methods
A retrospective study with data from two prospectively recruited cohorts has been conducted. One hundred seventy-nine patients from the multicentric StrokeChip Study, and ninety-one patients from a biobank of TIA patients who underwent acute DWI were included. Blood was drawn within 6 and 24 hours of symptom onset respectively. H-FABP was measured using a rapid (15´) Point-of-care-test (POCT). Biomarker levels were compared between TIA and mimics, and between patients with or without brain injury in DWI. Accuracy was evaluated with ROC curves and cut-offs were obtained using PanelomiX algorithm.
Results
H-FABP level was significantly higher in TIA patients than in mimics [2.90 ng/mL (IQR 2.00 - 4.30) vs. 1.70 ng/mL (IQR 1.25-2.30)], p<0.001, respectively. The discriminatory power was 0.74 (95% CI, 0.66 - 0.83). A trend to higher concentrations was observed in those with DWI brain injury [3.20 ng/mL (IQR 2.40-4.10) vs. 2.40 ng/mL (IQR 1.90-3.77)] p=0.17.
Conclusion
High blood concentration of H-FABP measured in patients with transient neurological symptoms may point to vascular origin and to the presence of brain lesions following TIA. The availability of a rapid POCT will allow testing its clinical significance in real life in the emergency departments.

INFLAMMATION PATTERN AFTER RAT SPINAL CORD INJURY WITH A COMPARATIVE ANALYSIS OF CONTUSION VS TRANSECTION EXPERIMENTAL MODELS

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Chaimae Ahmanna, Kévin Boussion, Kadia Kanté, Hieu Tran, Sylvia Soares, Ysander Von Boxberg, Fatiha Nothias
Sorbonne Université- UMR8246, Neurosciences Paris Seine, paris, France

Spinal cord injury (SCI) in mammals leads to a series of cellular and molecular changes that will ultimately inhibit axon regeneration and autonomous nerve tissue repair. Regarding the immune response, the breakdown of the blood-spinal cord barrier (BSBC) favors infiltration of blood-derived monocytes/macrophages that, together with activated microglia, will spread inflammation, further exacerbated by formation of free radicals and glutamate excitotoxicity. This detrimental environment will cause secondary damage through neurodegenerative lesions that extend caudally and rostrally from the initial impact, aggravating the neurological deficits. The fundamental imbalance between pro- and anti-inflammatory cytokines during the second phase of injury leads to a persistent inflammatory state. Many studies have investigated the kinetics of inflammation-associated cytokines following SCI. However, the injured spinal segment, the time post-injury analyzed, and in particular, the lesion model differed among these studies, making a conclusive interpretation difficult. Accordingly, the present study compares the inflammation profiles at acute and chronic stages for the two commonly used lesion models, contusion vs. dorsal bilateral hemisection of rat thoracic spinal cord, revealing similarities and unexpected differences. In addition, we investigated possible correlations between serum- and intramedullary cytokine levels in rats after SCI. Multiple therapeutic strategies under pre-clinical development include an evaluation of the inflammatory response, whose modulation is considered crucial for a beneficial outcome. Our study should contribute to optimize the strategies to be adapted with respect to each trauma aspect; the type of injury and time post-lesion.

NEUROECTODERMAL STEM CELLS IMPROVE THE FUNCTIONAL AND MORPHOLOGICAL OUTCOME AFTER CHRONIC SPINAL CORD CONTUSION INJURY

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Tamás Bellák[1], Krisztián Pajer[1], Zoltán Fekécs[1], László Gál[1], Máté Ignácz[1], Annamária Marton[2], Dénes Török[1], Csaba Vizler[2], Antal Nógrádi[1]

Spinal cord contusion injury leads to severe tissue loss and subsequent deficit of motor, sensory and vegetative functions below the lesion. In this study we investigated whether transplantation of neuroectodermal stem cells into the injured rat spinal cord is able to induce morphological and functional improvement in a chronic spinal cord injury model. Mouse embryonic clonal neuroectodermal stem cells were grafted intraspinally five weeks after a thoracic spinal cord contusion injury performed in SD rats. Control animals underwent contusion injury without stem cell transplantation. Functional tests and detailed morphological analysis were performed to evaluate the effects of grafted cells. Grafted animals showed significantly better functional recovery compared with control animals. Morphologically, the contusion cavity was significantly smaller, and the amount of spared tissue was significantly higher in grafted animals than in controls. Retrograde tracing studies showed a statistically significant increase in the number of FB-labelled neurons rostral to the injury. The extent of functional improvement was related to the amount of inhibitory factors around the cavity and microglial reactions in the injured segment. Five days after transplantation the majority of grafted cells appeared to survive, formed clusters and a small proportion of the cells differentiated into neurons and astrocytes. Ten days after grafting the majority of the grafted cells appeared as nonviable fragments in microglia/macrophage cells. These data suggest that grafted neuroectodermal stem cells are able to induce morphological and functional recovery after chronic spinal cord contusion injury despite the limited survival of transplanted cells. This work was supported by grant NTP-NFTÖ-21-B-0039.

A SYNTHETIC SYNAPTIC ORGANIZER PROTEIN “CPTX” RESTORES DAMAGED NEURONAL CIRCUITS FROM SPINAL CORD INJURY : THE RECOVERY FROM THE CHRONIC-PHASE OF SPINAL CORD INJURY.

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Kosei Takeuchi[1], Hiroyuki Sasakura[1], Kunimichi Suzuki[2], Michisuke Yuzaki[3]
[1]Aichi Medical University, Dept.of Cell Biology, Aichi, Japan, [2]MRC Lab of Mol. Biol., Dept.of Neurobiology, Cambridge, United Kingdom, [3]Keio University, Dept. Of Neurophysiology, Tokyo, Japan

Spinal cord injury(SCI) causes permanent dysfunction in the body movement and sensation. It is well known that recovery becomes more difficult as time passes from injury. Even with the power of stem cell transplant, it is still hard to cure the late phase of SCI. Despite the difficulty, majority of patients suffering from SCI are clinically late phase. Thus, overcoming the late phase of SCI is an important mission. CPTX is the structurally guided synthetic peptide that joins the pre-synaptic neurexin and the post-synaptic AMPA receptors (Suzuki, Sasakura et al., *Science*, (2020)). We previously showed that CPTX recovered the early phase of SCI in mouse model. CPTX restored the behavioral deficiency of Ataxia and Alzheimer’s mouse model as well. Therefore, CPTX is expected to be a promising medical agent to cure degenerated or injured CNS with novel concept (Salines, Science, 2020). To test if CPTX is effective to the late phase of SCI, we applied CPTX to the mice 4 or 6 weeks after SCI, which correspond to subacute or chronic phase of SCI patients, respectively. CPTX restored the subacute- and chronic-phase of SCI. CPTX injection activated the hind leg movement within a few days, which otherwise showed the permanently poor movement. At 2 weeks after injection, the effect of CPTX became maximum to the extent that some animals smoothly stepped. These results suggest that CPTX boost the dormant neural pathway into the active circuit. We are attempting the more robust recovery combined with rehabilitation.

DYNAMIC ECM CONSTRUCTS FOR SPINAL CORD INJURY REPAIR

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Zaida Alvarez Pinto[1], Elisabeth Engel[1], Evangelos Kiskinis[2], Juan Alberto Ortega Cano[3]
[1]Institute for Bioengineering of Catalonia, Biomaterials For Regenerative Therapies, Barcelona, Spain, [2]Northwestern University, The Ken & Ruth Davee Department Of Neurology, Chicago, United States of America, [3]University of Barcelona, Patologia I Terapeutica Experimental, Hospitalet del Llobregat, Spain

Developing reliable therapeutic methods to treat spinal cord injuries (SCIs) has been a major challenge due to the complex and dynamic cellular microenvironment during the disease progression. While several current therapeutic approaches have aimed to restore neural signaling, and prevent subsequent damage to the injured area, to date, there is no single biological intervention that can address the physiological events that damage the spinal cord. Scaffold-based therapeutic strategies and particularly decellularized ECM (dECM) materials have shown great potential for regenerative medicine but only few studies have attempted to explore their potential in SCI repair. In this study, we test the effect of dECM constructs from different developmental stages (fetal versus adult dECM) on human iPSCs derived motor neurons maturation, which can be used to support mechanical, structural and functional aspect of damaged spinal cord tissues. Both dECM showed identical physical properties but different chemical composition in structural proteins such as laminins, collagens, Tenascins and glycoproteins. iPSCs derived motor neurons exhibited increased survival and became morphologically and electrophysiological more mature on adult dECM relative to fetal dECM and commercial laminin coatings. We also explored the effect of 3D dECM constructs into the spinal cord of rodents with a severe SCI. Overall, our technology highlights the importance of the ECM in recapitulating in vivo conditions and offers a translational platform to study the dysfunction of the CNS after injury.

NEW STRATEGY USING ALDYNOGLIA CELLS IN COMBINATION WITH FIBRIN AND SULPHOGLYCOLIPID INHIBITOR FOR SPINAL CORD INJURY REPAIR

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Alejandro Arriero-Cabañero
National Hospital of Paraplegics, Group Of Neuro-regenerative Chemistry, Toledo, Spain

A traumatic accident involving an injury to the spinal cord does not have effective treatment and implies of a deep social significance due to the effects it has on society. Traumatic spinal cord injury (TSCI) has a complex pathophysiologic events, that start after the trauma; one of them, formation of fibroglial scar performed by fibroblasts and reactive astrocytes. This provokes inhibition of axonal growth, by actived astroglial cells by secretion of inhibitory molecules, such as chondroitin sulphate proteoglycans. The objective of the study was to use the aldynoglia cells, a neuro-glial precursor, as a growth axon promoter, together with a biomaterial (fibrin gelated under alkaline conditions) to act as a cell support and directing neural cell growth. In addition, a synthetic sulphoglycolipid inhibitor of astrocytes and microglia was added to checking its effect in axonal growth promoting function of aldynoglia precursor cells. We observed an increase of differentiation to glial phenotype and cell outgrowth of aldynoglia in the modified fibrin. In dorsal root ganglia (DRG) and aldynoglia cocultures, a promotion in axonal growth was measured for DRG neurons. We concluded that modified fibrin combining it with synthetic sulphoglycolipid, increased adhesion capacity, promoting aldynoglia differentiation and growth. We observed that precursor cells were grouped first and then make niches from which they grew and connected to adjacent cell groups. There not negative effect on behavior of aldynoglia cells after the addition of sulphoglycolipid, suggesting that a combination of aldynoglia, plus the modified fibrin and inhibitor sulphoglycolipid compound could be useful as a new strategy for repair TSCI.

Single vs. Combined Therapeutic Approaches in Rats With Chronic Spinal Cord Injury.
The regenerative capability of the central nervous system is limited after traumatic spinal cord injury (SCI) due to intrinsic and extrinsic factors that inhibit spinal cord regeneration, resulting in deficient functional recovery. It has been shown that strategies, such as pre-degenerated peripheral nerve (PPN) grafts or the use of bone marrow stromal cells (BMSCs) or exogenous molecules, such as chondroitinase ABC (ChABC) promote axonal growth and remyelination, resulting in an improvement in locomotor function. These treatments have been primarily assessed in acute injury models. The aim of the present study is to evaluate the ability of several single and combined treatments in order to modify the course of chronic complete SCI in rats. A complete cord transection was performed at the T9 level. One month later, animals were divided into five groups: original injury only (control group), and original injury plus spinal cord re-transection to create a gap to accommodate BMSCs, PPN, PPN + BMSCs, and PPN + BMSCs + ChABC. In comparison with control and single-treatment groups (PPN and BMSCs), combined treatment groups (PPN + BMSCs and PPN + BMSCs + ChABC) showed significative axonal regrowth, as revealed by an increase in GAP-43 and MAP-1B expression in axonal fibers, which correlated with an improvement in locomotor function. In conclusion, the combined therapies tested here improve locomotor function by enhancing axonal regeneration in rats with chronic SCI. Further studies are warranted to refine this promising line of research for clinical purposes.

Role of Aldynoglia Cells in Neuroinflammatory and Neuroimmune Responses after Spinal Cord Injury.
Aldynoglia are growth-promoting cells with a morphology similar to radial glia and share properties and markers with astrocytes and Schwann cells. They are distributed in several locations throughout the adult central nervous system, where the cells of the aldynoglia interact and respond to the signals of the immune cells. After spinal cord injury (SCI), the functions of resident aldynoglia, identified as ependymocytes, tanycytes, and ependymal stem cells (EpSCs) of the spinal cord are crucial for the regeneration of spinal neural tissue. These glial cells facilitate axonal regrowth and remyelination of injured axons. Here, we review the influence of M1 or M2 macrophage/microglia subpopulations on the fate of EpSCs during

neuroinflammation and immune responses in the acute, subacute, and chronic phases after SCI.

32300328: Rodríguez-Barrera R, Flores-Romero A, Buzoianu-Anguiano V, Garcia E, Soria-Zavala K, Incontri-Abraham D, Garibay-López M, Juárez-Vignon Whaley JJ, Ibarra A
Use of a Combination Strategy to Improve Morphological and Functional Recovery in Rats With Chronic Spinal Cord Injury. Immunization with neural derived peptides (INDP), as well as scar removal (SR) and the use of matrices with bone marrow-mesenchymal stem cells (MSCs), have been studied separately and proven to induce a functional and morphological improvement after spinal cord injury (SCI). Herein, we evaluated the therapeutic effects of INDP combined with SR and a fibrin glue matrix (FGM) with MSCs (FGM-MSCs), on motor recovery, axonal regeneration-associated molecules and cytokine expression, axonal regeneration (catecholaminergic and serotonergic fibers), and the induction of neurogenesis after a chronic SCI. For this purpose, female adult rats were subjected to SCI, 60 days after lesion, rats were randomly distributed in four groups: (1) Rats immunized with complete Freund's adjuvant + PBS (vehicle; PBS-I); (2) Rats with SR+ FGM-MSCs; (3) Rats with SR+ INDP + FGM-MSCs; (4) Rats only with INDP. Afterwards, we evaluated motor recovery using the BBB locomotor test. Sixty days after the therapy, protein expression of TNFα, IL-4, IL-10, BDNF, and GAP-43 were evaluated using ELISA assay. The number of catecholaminergic and serotonergic fibers were also determined. Neurogenesis was evaluated through immunofluorescence. The results show that treatment with INDP alone significantly increased motor recovery, anti-inflammatory cytokines, regeneration-associated molecules, axonal regeneration, and neurogenesis when compared to the rest of the groups. Our findings suggest that the combination therapy (SR + INDP + FGM-MSCs) modifies the non-permissive microenvironment post SCI, but it is not capable of inducing an appropriate axonal regeneration or neurogenesis when compared to the treatment with INDP alone.
Front Neurol, 2020; 11
30762019: García E, Rodríguez-Barrera R, Buzoianu-Anguiano V, Flores-Romero A, Malagón-Axotla E, Guerrero-Godinez M, De la Cruz-Castillo E, Castillo-Carvajal L, Rivas-Gonzalez M, Santiago-Tovar P, Morales I, Borlongan C, Ibarra A
Use of a combination strategy to improve neuroprotection and neuroregeneration in a rat model of acute spinal cord injury. Spinal cord injury is a very common pathological event that has devastating functional consequences in patients. In recent years, several research groups are trying to find an effective therapy that could be applied in clinical practice. In this study, we analyzed the combination of different strategies as a potential therapy for spinal cord injury. Immunization with neural derived peptides (INDP), inhibition of glial scar formation (dipyridyl: DPY), as well as the use of biocompatible matrix (fibrin glue: FG) impregnated with bone marrow mesenchymal stem cells (MSCs) were combined and then its beneficial effects were evaluated in the induction of neuroprotection and neuroregeneration after acute SCI. Sprague-Dawley female rats were subjected to a moderate spinal cord injury and then randomly allocated into five groups: 1) phosphate buffered saline; 2) DPY; 3) INDP + DPY; 4) DPY+ FG; 5) INDP + DPY + FG + MSCs. In all rats, intervention was performed 72 hours after spinal cord injury. Locomotor and sensibility recovery was assessed in all rats. At 60 days after treatment, histological examinations of the spinal cord (hematoxylin-eosin and Bielschowsky staining) were performed. Our results showed that the combination therapy (DPY+ INDP + FG + MSCs) was the best strategy to promote motor and sensibility recovery. In addition, significant increases in tissue preservation and axonal density were observed in the combination therapy group. Findings from this study suggest that the combination theapy (DPY+ INDP + FG + MSCs) exhibits potential effects on the protection and regeneration of neural tissue after acute spinal cord injury. All procedures were approved by the Animal Bioethics and Welfare Committee (approval No. 178544; CSNBTBIBAJ 090812960) on August 15, 2016.

LSD1 INHIBITION IMPROVES FUNCTIONAL OUTCOME AFTER SPINAL CORD INJURY

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Raquel Del Río Astorga[1], Xavier Navarro[1,2], Clara Penas[1,2]
[1]Universistat Autònoma de Barcelona, Department Of Cell Biology, Physiology And Immunology, Institute Of Neurosciences, Bellaterra, Spain, [2]Centro de Investigación Biomédica en Red sobre Enfermedades Neurodegenerativas, Ciberned, Madrid, Spain

Spinal cord injury (SCI) is a major cause of sensorial, motor and autonomic dysfunction worldwide. The primary impact causes neuronal damage and blood-brain barrier disruption, leading to the activation of secondary neurodegenerative mechanisms such as inflammatory processes, excitotoxicity and oxidative stress. Lysine specific demethylase 1 (LSD1) is an epigenetic eraser that promotes and represses gene transcription by removing methyl groups from histone 3, being involved in a wide range of biological processes. LSD1 inhibition reduces neuronal death caused by glutamate neurotoxicity and oxidative stress and has also been related with neuroplasticity. However, studies of this demethylase after nervous system trauma are scarce. Therefore, we aimed to analyze the effects of LSD1 inhibition on neuroprotection, regeneration, and functional recovery after a SCI. Spinal cord injured mice were treated with the LSD1 inhibitor RN1. Locomotor function assessed using both the basso mouse scale and the walking track showed that the RN1-treated group had an enhancement of the functional outcome compared to vehicle-treated animals. Electrophysiological analysis suggested a better preservation of the spinal cord descending pathways after LSD1 inhibition. Injured mice treated with RN1 also presented a decrease in neuropathic pain compared to the vehicle group. However, histological analysis did not show significative changes in neuronal death nor glial reactivity. Finally, by analyzing protein levels in the spinal cord after LSD1 inhibition, we identify GLT-1 as a possible LSD1 target involved in neuroprotection after SCI. These findings suggest that LSD1 inhibition may be a therapeutic approach to enhance functional recovery after SCI.

Cannabinoid CB Receptor Modulation by the Transcription Factor NRF2 is Specific in Microglial Cells.
Nuclear factor erythroid 2-related factor 2 (NRF2) is a pleiotropic transcription factor that has neuroprotective and anti-inflammatory effects, regulating more than 250 genes. As NRF2, cannabinoid receptor type 2 (CB) is also implicated in the preservation of neurons against glia-driven inflammation. To this concern, little is known about the regulation pathways implicated in CB receptor expression. In this study, we analyze whether NRF2 could modulate the transcription of CB in neuronal and microglial cells. Bioinformatics analysis revealed an antioxidant response element in the promoter sequence of the CB receptor gene. Further analysis by chemical and genetic manipulations of this transcription factor demonstrated that NRF2 is not able to modulate the expression of CB in neurons. On the other hand, at the level of microglia, the expression of CB is NRF2-dependent. These results are related to the differential levels of expression of both genes regarding the brain cell type. Since modulation of CB receptor signaling may represent a promising therapeutic target with minimal psychotropic effects that can be used to modulate endocannabinoid-based therapeutic approaches and to reduce neurodegeneration, our findings will contribute to disclose the potential of CB as a novel target for treating different pathologies.

GUIDANCE LANDSCAPES UNVEILED BY QUANTITATIVE PROTEOMICS TO CONTROL REINNERVATION IN ADULT VISUAL SYSTEM

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Noémie Vilallongue[1], Julia Schaeffer[1], Anne-Marie Hesse[2], Céline Delpech[1], Béatrice Blot[1], Antoine Paccard[1], Elise Plissonnier[1], Blandine Excoffier[1], Yohann Couté[2], Stephane Belin[1], Homaira Nawabi[1]

Central nervous system (CNS) long distance regeneration has been achieved through the modulation of specific molecular pathways within neurons. However, regenerating axons display severe guidance defects: many axons are lost at choice points or avoid their initial targets compromising recovery of function. Therefore, depicting the mature neuronal environment, beyond the lesion site, is essential to understand adult axon guidance to build neuronal circuits in mature CNS. To this end, we used quantitative mass spectrometry to characterize the proteome of the adult visual system major nuclei: the suprachiasmatic nucleus, ventral and dorsal lateral geniculate nucleus, and the superior colliculus as well as the optic chiasm, where axons show the most impressive guidance defects. We uncovered the expression of guidance molecules and associated factors in the mature visual targets. Moreover, upon bilateral optic nerve crush, we showed that axon lesion modifies the proteome of all brain targets. In contrast, we found that the expression of guidance remains steady after injury. We hypothesized that guidance cues expression contributes to prevent axons to reconnect their appropriate brain targets and further recovery of functions. Indeed, we showed that mature regenerating axons are still sensitive to guidance molecules. Together our results provide an extensive characterization of the molecular environment of intact and injured brain. Moreover, as guidance factors could counteract brain reinnervation, our study opens new venues to build mature neuronal circuits upon injury.

FLEXIBLE NEUROTRANSMITTER PHENOTYPE OF SPINAL EXCITATORY INTERNEURONS REGULATES LOCOMOTOR ABILITY AFTER SPINAL CORD INJURY.

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Hannah Bertels[1], Guillem Vicente-Ortiz[1], Khadija El Kanbi[1], Aya Takeoka[1,2,3]
[1]KULeuven, Neuro-electronics Research Flanders (nerf), Leuven, Belgium, [2]KU Leuven, Department Of Neuroscience And Leuven Brain Institute, Leuven, Belgium, [3]VIB, Flanders Institute For Biotechnology, Leuven, Belgium

Severe spinal cord injury to the mature nervous system leads to irreversible paralysis below the lesion. However, adult rodents receiving a complete thoracic lesion just after birth demonstrate proficient hindlimb locomotion without input from the brain. How the spinal cord achieves such striking plasticity and functionality remains unknown. Here, we used a combinatorial approach of kinematic analyses, mouse genetics, and circuit manipulation to uncover age of injury-dependent circuit signatures with an aim to steer adult injured spinal cords to such autonomous circuits. We found divergent synaptic connectivity profiles from interneurons to motor neurons. Adult injury prompts neurotransmitter phenotype switching of spatially defined excitatory interneurons to inhibitory phenotype, promoting inhibition at synapses interfacing motor neurons. In contrast, neonatal injury causes synaptic sprouting of identical populations to facilitate excitation. Ablation of proprioceptive afferents leads to gain of inhibitory neurotransmitter phenotype after neonatal injury, whereas daily locomotor training to maximize proprioceptive afferent activity leads to partial maintenance of excitatory neurotransmitter phenotype after adult injury. These findings reveal activity-dependent, flexible neurotransmitter phenotype of defined excitatory spinal interneurons. Furthermore, genetic manipulation to mimic inhibitory phenotype observed after adult injury by excitatory interneurons abrogates autonomous locomotor functionality in neonatally injured mice. In comparison, attenuating inhibitory phenotype improves locomotor recovery after adult injury. Together, our study demonstrates that flexible NT phenotype of defined excitatory interneurons as a defining signature of age of injury-dependent locomotor circuit plasticity and an entry point to regulate locomotor capacity after injury.

BENEFICIAL EFFECTS OF ANGIOTENSIN II RECEPTOR TYPE 2 STIMULATION AFTER SEVERE SPINAL CORD COMPRESSION

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Jana Fedorova, Erika Kellerova, Maria Bacova, Jaroslav Pavel
Institute of Neurobiology of Biomedical Research Center SAS, Department Of Neurodegeneration, Plasticity And Repair, Kosice, Slovak Republic

In the present study we tested pharmacological AT_2 receptor stimulation as a therapeutic approach in an experimental model of severe spinal cord compression in adult female Wistar rats (n=15/group) using selective AT_2 receptor agonist CGP42112 (0.1 mg/kg per day) administrated systemically by osmotic minipumps (s.c.) from 14th to 28th post-injury day when the trauma-induced expression of AT_2 receptors occurs in the injured spinal cord parenchyma. During the 28-day posttraumatic period, the voiding, body weight changes, blood pressure and hind-limb locomotor function by using BBB scale and transcranial motor evoked potentials were evaluated. The motoric hind limbs function recovered rapidly and more profound after AT_2 receptor stimulation compare to spinal cord injury (BBB locomotor score: 10.4 points vs. 9 points) and strongly negatively correlates (Pearson r= -0,908) with evidently faster neural response latency (7.03 ms vs. 10.8 ms). Bladder function completely recovered on 20^{th} day of surviving period in all animals after AT_2 receptor stimulation while the dysfunction of urination persisted 26 days in animals that underwent spinal cord compression without any treatment. Obtained behavioural results clearly demonstrate that AT_2 receptor stimulation beneficially affects both the locomotor and sensory neurological functions of treated experimental animals. These beneficial effects were prevented by the AT_2 receptor blocking with specific antagonist PD123319 that confirms the neuroprotective features mediated through the stimulation. Our results suggested that the AT_2 receptor stimulation may be considered as promising therapeutic approach for the spinal cord injury that promotes the improvement of functional neurological outcomes. *Supported by grant APVV-18-0163, ERDF-IMTS:313011V344.*

The Histopathology of Severe Graded Compression in Lower Thoracic Spinal Cord Segment of Rat, Evaluated at Late Post-injury Phase.
Spontaneous recovery of lost motor functions is relative fast in rodent models after inducing a very mild/moderate spinal cord injury (SCI), and this may complicate a reliable evaluation of the effectiveness of potential therapy. Therefore, a severe graded (30 g, 40 g and 50 g) weight-compression SCI at the Th9 spinal segment, involving an acute mechanical impact followed by 15 min of persistent compression, was studied in adult female Wistar rats. Functional parameters, such as spontaneous recovery of motor hind limb and bladder emptying function, and the presence of hematuria were evaluated within 28 days of the post-traumatic period. The disruption of the blood-spinal cord barrier, measured by extravasated Evans Blue dye, was examined 24 h after the SCI, when maximum permeability occurs. At the end of the survival period, the degradation of gray and white matter associated with the formation of cystic cavities, and quantitative changes of glial structural proteins, such as GFAP, and integral components of axonal architecture, such as neurofilaments and myelin basic protein, were evaluated in the lesioned area of the spinal cord. Based on these functional and histological parameters, and taking the animal's welfare into account, the 40 g weight can be considered as an upper limit for severe traumatic injury in this compression model.

An Accurate Method for Histological Determination of Neural Tissue Loss/Sparing after Compression-Induced Spinal Cord Injury with Optimal Reproducibility.
In addition to behavioral testing, the efficacy of neuroprotective therapies applied after spinal cord injury (SCI) is commonly evaluated by means of histological quantification of spared neural tissue. The primary insult itself, but mainly the pathological processes of secondary injury are the underlying causes of spinal tissue degeneration, the extent of which depends on the injury severity and post-injury time. Under-estimation of tissue loss due to spinal cord shrinkage and subjective evaluation

(impeding reproducibility) are substantial factors that negatively affect the final results. Moreover, processing large numbers of stained spinal cord sections is very time-consuming. To overcome the problem, our new quantification approach combines a modified method for predicting the cross-sectional area at the lesion site with semi-automatic measurement of spared neural tissue and cystic cavities, using freely accessible National Institutes of Health (NIH) ImageJ software, with a Java-based image processing program. Based on the histological parameters measured after differing compression-induced SCI and correlated with behavioral outcomes, we can conclude that our new method is relatively fast, accurate, and optimally reproducible.

A Single Dose of Atorvastatin Applied Acutely after Spinal Cord Injury Suppresses Inflammation, Apoptosis, and Promotes Axon Outgrowth, Which Might Be Essential for Favorable Functional Outcome.
The aim of our study was to limit the inflammatory response after a spinal cord injury (SCI) using Atorvastatin (ATR), a potent inhibitor of cholesterol biosynthesis. Adult Wistar rats were divided into five experimental groups: one control group, two Th9 compression (40 g/15 min) groups, and two Th9 compression + ATR (5 mg/kg, i.p.) groups. The animals survived one day and six weeks. ATR applied in a single dose immediately post-SCI strongly reduced IL-1β release at 4 and 24 h and considerably reduced the activation of resident cells at one day post-injury. Acute ATR treatment effectively prevented the excessive infiltration of destructive M1 macrophages cranially, at the lesion site, and caudally (by 66%, 62%, and 52%, respectively) one day post-injury, whereas the infiltration of beneficial M2 macrophages was less affected (by 27%, 41%, and 16%). In addition, at the same time point, ATR visibly decreased caspase-3 cleavage in neurons, astrocytes, and oligodendrocytes. Six weeks post-SCI, ATR increased the expression of neurofilaments in the dorsolateral columns and Gap43-positive fibers in the lateral columns around the epicenter, and from day 30 to 42, significantly improved the motor activity of the hindlimbs. We suggest that early modulation of the inflammatory response via effects on the M1/M2 macrophages and the inhibition of caspase-3 expression could be crucial for the functional outcome.

Aims: Neurons of the central nervous system (CNS) display only a limited ability to survive and regenerate their axons after an injury. In mice, 85% of retinal ganglion cells (RGCs) in the retina die within 2 weeks of axotomy by optic nerve crush (ONC) and only few survivors regenerate axons. However, some treatments can enhance survival and promote regeneration. Here, to elucidate mechanisms underlying these protective effects, we investigated genes regulated by three well established survival and regeneration promoting interventions – activation of the MTOR pathway via deletion of its inhibitor PTEN, activation of the Jak/Stat-pathway by deletion of its endogenous inhibitor SOCS3, and overexpression of the neurotrophic cytokine CNTF. **Methods:** We collected >125,000 single RGCs at various time points after ONC (0,2,7 and 21dpc) and established a new method to separate regenerating RGCs from those that survived but did not regenerate, followed by scRNA-sequencing (10X and SS2). **Results:** Analysis of gene expression patterns, showed that our interventions improve the survival and regeneration of RGCs by mitigating injury responses and cell death associated genes while simultaneously upregulating survival and regeneration associated programs. These programs are differentially regulated among RGCs, with distinct signatures for dying, surviving and regenerating cells. **Conclusion:** Together, this study provides insights into why neuronal cell types respond differently to neuroprotective and pro-regenerative treatments. Moreover, overexpression of some the genes associated to the identified regeneration-program promote axonal regeneration *in vivo*.

Acute spinal cord injury (SCI) leads to severe damage to the microvascular network. The process of spontaneous repair is accompanied by formation of new blood vessels; their functionality, however, presumably very important for functional recovery, has never been clearly established, as most studies so far used fixed tissues. Here, combining ultrafast Doppler imaging and Ultrasound Localization Microscopy (ULM) on the same animals, we proceeded at a detailed analysis of structural and functional vascular alterations associated with the establishment of chronic SCI, both at macroscopic and microscopic scales. Using a standardized animal model of SCI, our results demonstrate striking hemodynamic alterations in several subparts of the spinal cord: a reduced blood velocity in the lesion site, and an asymmetrical hypoperfusion caudal but not rostral to the lesion. In addition, the worsening of many evaluated parameters at later time points suggests that the neoformed vascular network is not yet fully operational, and reveals ULM as an efficient *in vivo* readout for spinal cord vascular alterations. Finally, we show statistical correlations between the diverse biomarkers of vascular dysfunction and SCI severity. The imaging modality developed here will allow evaluating recovery of vascular function over time in pre-clinical models of SCI. Also, used on SCI patients in combination with other quantitative markers of neural tissue damage, it may help classifying lesion severity and predict possible treatment outcomes in patients.

Currently, there is no effective treatment for chronic spinal cord injury (SCI). Strong inhibitors of neural regeneration are chondroitin sulfate proteoglycans (CSPG). 4-methylumbelliferone (4MU) inhibits the synthesis of hyaluronan and CSPGs and regulates perineuronal net formation in the nervous system. Firstly, we investigated the pharmacological, biochemical, and biomechanical effects of long-term 4MU (2.5% w/w) treatment in non-injured rats. Results of haematological and serological parameters showed non-significant changes between groups. Tissue biochemistry showed significant downregulation of glycosaminoglycans (GAGs) in the 4MU-treated group suggesting attenuated PNNs, which was also confirmed by immunohistochemistry of WFA and HABP. Next, we tested 2.5% (w/w) 4MU to promote axonal plasticity and functional recovery in rat chronic contusion model of SCI. Animals were fed daily with 4MU for 8 weeks, starting 6 weeks after SCI, followed by daily treadmill training. Our results showed that oral administration of 2.5% (w/w) 4MU reduced glial scar and promoted anatomical plasticity, but not functional recovery in chronic stage of spinal cord injury. Our previous experiment has demonstrated efficacy of 4MU in enhancing recovery after acute SCI. We thus increased the dose of 4MU to 5% (w/w) to test in the chronic SCI paradigm. We observed the significant locomotor improvement of rats with SCI. Our results indicate that 5% (w/w) 4MU reopened a window of plasticity in chronic SCI, allowing rehabilitation to promote functional recovery.

New Model of Ventral Spinal Cord Lesion Induced by Balloon Compression in Rats.
Despite the variety of experimental models of spinal cord injury (SCI) currently used, the model of the ventral compression cord injury, which is commonly seen in humans, is very limited. Ventral balloon compression injury reflects the common anatomical mechanism of a human lesion and has the advantage of grading the injury severity by controlling the inflated volume of the balloon. In this study, ventral compression of the SCI was performed by the anterior epidural placement of the balloon of a 2F Fogarty's catheter, via laminectomy, at the level of T10. The balloon was rapidly inflated with 10 or 15 µL of saline and rested in situ for 5 min. The severity of the lesion was assessed by behavioral and immunohistochemical tests. Compression with the volume of 15 µL resulted in severe motor and sensory deficits represented by the complete inability to move across a horizontal ladder, a final Basso, Beattie and Bresnahan (BBB) score of 7.4 and a decreased withdrawal time in the plantar test (11.6 s). Histology and immunohistochemistry revealed a significant loss of white and gray matter with a loss of motoneuron, and an increased size of astrogliosis. An inflation volume of 10 µL resulted in a mild transient deficit. There are no other balloon compression models of ventral spinal cord injury. This study provided and validated a novel, easily replicable model of the ventral compression SCI, introduced by an inflated balloon of Fogarty´s catheter. For a severe incomplete deficit, an inflated volume should be maintained at 15 µL.

Planet of the AAVs: The Spinal Cord Injury Episode.
The spinal cord injury (SCI) is a medical and life-disrupting condition with devastating consequences for the physical, social, and professional welfare of patients, and there is no adequate treatment for it. At the same time, gene therapy has been

studied as a promising approach for the treatment of neurological and neurodegenerative disorders by delivering remedial genes to the central nervous system (CNS), of which the spinal cord is a part. For gene therapy, multiple vectors have been introduced, including integrating lentiviral vectors and non-integrating adeno-associated virus (AAV) vectors. AAV vectors are a promising system for transgene delivery into the CNS due to their safety profile as well as long-term gene expression. Gene therapy mediated by AAV vectors shows potential for treating SCI by delivering certain genetic information to specific cell types. This review has focused on a potential treatment of SCI by gene therapy using AAV vectors.

Clinical Neurosciences, Cambridge, United Kingdom

Spinal cord injury (SCI), a lifelong disability, remains an unsolved problem not only due to glial scar forming a physical barrier around the lesion site, but also due to the limited intrinsic capacity of axon regeneration. One of the main ECM inhibitory molecules upregulated after spinal cord injury is Tenascin-C. The migration-inducing tenascin-binding integrin is alpha9beta1, which is not upregulated after injury. Integrin α9, needs an activator kindlin 1 which prevents an integrin inactivation by inhibitory CSPGs and NogoA. The aim of this project was to achieve sensory axon regeneration in animals with dorsal column crush lesion using viral vector delivery of the relevant genes (integrin α9 and kindlin 1 in 3:1 ratio, kindlin 1 alone or GFP) to the DRG. We addressed two different levels of SCI, C4 lesion with DRG C6 and C7 injections for forelimb sensory restoration and T10 lesion with DRG L4 and L5 injections for hindlimb sensory restoration. The animals underwent dorsal column crush injury with concurrent DRG injections followed by 12 weeks of behavioural testing. Significant improvement was observed in Von Frey test for mechanical perception and Hargreaves test for thermal sensation in treated animals with both, cervical and thoracic lesions when compared to controls. Functional improvement was confirmed by cFos staining and counting GFP axons from integrin α9 and kindlin 1 group above the lesion. In conclusion, the AAV-mediated gene therapy leads to sensory regeneration after SCI at C4 and T10 level, proved by behavioural tests and immunohistochemical staining.

Involvement of mTOR Pathways in Recovery from Spinal Cord Injury by Modulation of Autophagy and Immune Response. Traumatic spinal cord injury (SCI) is untreatable and remains the leading cause of disability. Neuroprotection and recovery after SCI can be partially achieved by rapamycin (RAPA) treatment, an inhibitor of mTORC1, complex 1 of the mammalian target of rapamycin (mTOR) pathway. However, mechanisms regulated by the mTOR pathway are not only controlled by mTORC1, but also by a second mTOR complex (mTORC2). Second-generation inhibitor, pp242, inhibits both mTORC1 and mtORC2, which led us to explore its therapeutic potential after SCI and compare it to RAPA treatment. In a rat balloon-compression model of SCI, the effect of daily RAPA (5 mg/kg; IP) and pp242 (5 mg/kg; IP) treatment on inflammatory responses and autophagy was observed. We demonstrated inhibition of the mTOR pathway after SCI through analysis of p-S6, p-Akt, and p-4E-BP1 levels. Several proinflammatory cytokines were elevated in pp242-treated rats, while RAPA treatment led to a decrease in proinflammatory cytokines. Both RAPA and pp242 treatments caused an upregulation of LC3B and led to improved functional and structural recovery in acute SCI compared to the controls, however, a greater axonal sprouting was seen following RAPA treatment. These results suggest that dual mTOR inhibition by pp242 after SCI induces distinct mechanisms and leads to recovery somewhat inferior to that following RAPA treatment.

Traumatic spinal cord injury (SCI) is characterized by an acute mechanical insult followed by a series of secondary lesion events. In this study we investigated the effect of delayed intravenous neuroectodermal stem cell therapy which could reduce the severity of secondary injury and enhance tissue preservation and promote functional recovery. A thoracic contusion injury was induced at T5 spinal level in adult female Sprague-Dawley rats, followed by an intravenous tail vein infusion of NE-GFP-4C stem cells 30 min, 1, 2 or 3 weeks after the injury. Control animals underwent contusion injury without intravenous stem cell administration. Functional tests (BBB test, and kinematic analysis) and detailed morphological analysis (quantification of retrograde labelling and immunohistochemistry) were performed to evaluate the effect of grafted cells. One day after intravenous stem cell administration proteome profiler arrays were used to assess the cytokine expression in the spleen, blood serum and spinal cord. Significantly greater functional improvement was observed in transplanted animals treated intravenously with NE-GFP-4C cells immediately or one week after injury compared with controls. Significant neuroprotection was observed in the same treatment groups and significantly more retrogradely-labelled supra- and propriospinal neurons were counted compared with control animals. Immediate and one-week-delayed stem cell administration increased levels of the tissue inhibitor metalloproteinase-1 (TIMP-1, a potent beneficial candidate for vascular integrity) in the injured spinal cord and spleen one day after cell infusion. Our results suggest that immediate or one-week-delayed intravenous stem cell treatment is likely to induce nearly equal morphological and functional recovery through TIMP-1 modulation.

SELECTIVE MODULATION OF A1 ASTROCYTES BY DRUG-LOADED NANO-STRUCTURED GEL IN SPINAL CORD INJURY

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Valeria Veneruso
Istituto di Ricerche Farmacologiche 'Mario Negri' IRCCS, Neuroscience, Milan, Italy

Abstract: Spinal cord injury (SCI) is the most frequent disabling injury of the spine. The magnitude of SCI pathology and the related functional loss correlates with a robust astrocytes response. Astrocytes do not constitute a single uniform cell population, but comprise a family of cells with a spectrum of activation states with opposing phenotypes, some destructive (A1) and others beneficial (A2). This suggests that A1 astrocytes may be a good therapeutic target for SCI. **Aims:** In this project, we aimed to study a new therapeutic treatment to block the pro-inflammatory A1 response in SCI by acting on astrocytes with a selective drug-loaded nanovector system, in vitro and *in vivo*. **Methods:** A new functionalized nanogel-based nanovector (NG) was tested on activated primary cultures of mouse or human astrocytes. We measured: (i) uptake (ii) subcellular distribution (iii) biocompatibility and (iv) drug delivery (Rolipram). In vivo experiments were conducted to validate the NG system and therapeutic effect. **Results:** Rolipram administered by NG limits the inflammatory response of A1 astrocytes, reducing inflammatory factors (iNOS and Lcn2) and astrocytosis. Moreover, it improves motor performance in *in vivo* SCI mouse model. **Conclusion:** We demonstrated the capability of the NG system to selectively deliver drugs in astrocytes with a cell-specific therapeutic approach and demonstrated therapeutic effect in SCI. This delivery strategy could also be considered for other molecules which are able to enhance the neuroprotective A2 in SCI progression.

Functionalized nanogel for treating activated astrocytes in spinal cord injury.
Astrogliosis has a unique reaction during spinal cord damage, with helpful or adverse impacts on recovery. There is consequently a pressing need for treatment to target activated astrocytes and their unsafe response after injury to ensure some preservative effect during the progressive damage. We specifically developed and characterized a functionalized nanogel-based nanovector in vitro and in vivo, demonstrating its selectivity towards astrocytes, and limited uptake by macrophages when functionalized with both NH and Cy5 groups. In vitro experiments showed that the internalization was mediated by a clathrin-dependent endocytic pathway. After internalization into the cytoplasm of astrocytes, nanogels undergo lysosomal degradation and release compounds with potential therapeutic efficacy.
J Control Release, 2021; 330
31887011: Vismara I, Papa S, Veneruso V, Mauri E, Mariani A, De Paola M, Affatato R, Rossetti A, Sponchioni M, Moscatelli D, Sacchetti A, Rossi F, Forloni G, Veglianese P
Selective Modulation of A1 Astrocytes by Drug-Loaded Nano-Structured Gel in Spinal Cord Injury.
Astrogliosis has a very dynamic response during the progression of spinal cord injury, with beneficial or detrimental effects on recovery. It is therefore important to develop strategies to target activated astrocytes and their harmful molecular mechanisms so as to promote a protective environment to counteract the progression of the secondary injury. The challenge is to formulate an effective therapy with maximum protective effects, but reduced side effects. In this study, a functionalized nanogel-based nanovector was selectively internalized in activated mouse or human astrocytes. Rolipram, an anti-inflammatory drug, when administered by these nanovectors limited the inflammatory response in A1 astrocytes, reducing iNOS and Lcn2, which in turn reverses the toxic effect of proinflammatory astrocytes on motor neurons , showing advantages over conventionally administered anti-inflammatory therapy. When tested acutely in a spinal cord injury mouse model, it improved motor performance, but only in the early stage after injury, reducing the astrocytosis and preserving neuronal cells.

Stem cell paracrine effect and delivery strategies for spinal cord injury regeneration.
Spinal cord injury (SCI) is a complicated neuropathological condition that results in functional dysfunction and paralysis.

Various treatments have been proposed including drugs, biological factors and cells administered in several ways. Stem cell therapy offers a potentially revolutionary mode to repair the damaged spinal cord after injury. Initially, stem cells were considered promising for replacing cells and tissue lost after SCI. Many studies looked at their differentiation to replace neuronal and glial cells for a better functional outcome. However, it is becoming clear that different functional improvements recognized to stem cells are due to biomolecular activities by the transplanted stem cells rather than cell replacement. This review aimed to discuss the paracrine mechanisms for tissue repair and regeneration after stem cell transplantation in SCI. It focuses on stem cell factor production, effect in tissue restoration, and novel delivery strategies to use them for SCI therapy.

A lesion in the nervous system induces cellular and molecular mechanisms leading to irreversible dysfunctions. Post-injured environment is non permissive for axonal regeneration and CNS neurons also exhibit a reduced intrinsic growth capacity. Nevertheless, neuronal plasticity is still possible: injured axons can degenerate or regenerate, but mechanisms governing this response remains elusive. My aim is to understand the relation between microtubules and mitochondria on axon fate after a traumatic injury, in particular by focusing on the corticospinal tract connecting to the spinal cord neurons. Corticospinal neurons are known to show poor regeneration capacities after a spinal cord injury. Axonal degeneration is associated with a fast decrease of NAD+ leading to energy drop, cytoskeletal disorganization and finally axonal degradation. Mitochondria repositioning in the axon can stimulate regeneration and branching by rescuing energy deficits. In addition, microtubules (MT) to which converge extracellular cues for intracellular trafficking are also involved in mitochondrial transport. Thereby, mitochondria and MT are essential in determining the axon fate. I am developping an *in vitro* set-up with microfluidics oriented networks of cortico-spinal neurons on which a physical injruy can be apply. This system will allow to study the influence of post-translationnal MT modifications on mitochondria dynamic during axonal regeneration or degeneration.

MODULATION OF PRO-INFLAMMATORY M1 MICROGLIA AND A1 ASTROCYTES INTO THEIR ANTI-INFLAMMATORY M2 AND A2 PHENOTYPES IS CRUCIAL FOR SPONTANEOUS NEUROLOGICAL OUTCOME AFTER SCI

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

The goal of studies dealing with microglia/macrophages and astrocytes intracellular communication after spinal cord injury (SCI) is to improve our ability to contend this serious and incurable disorder. Both microglia and astrocytes are activated into two polarization states early after trauma: the pro-inflammatory (M1 and A1) and anti-inflammatory (M2 and A2) phenotypes, and this plays an important role in the regulation of immune responses under various pathological conditions and repair. The aim of our study was to examine the time depending behavior of reactive astrocytes and microglia/macrophages and their polarization states after Th9 compression (40g/15 min) at the lesion site and in adjacent spinal cord sections. Adult Wistar rats were divided into three experimental groups: 1) control, and 2-3) a group of animals that survived 7 and 14 days after SCI. While the gene expression of microglia/macrophages and pro-inflammatory M1 microglia was strongly upregulated one week after SCI at the lesion site and caudally from the injury epicenter and downregulated after two weeks, astrocyte gene markers and markers for A1 phenotype were significantly expressed predominantly 2 weeks after trauma at the site of injury and cranially. The positive correlation between neurological score and gene expression of anti-inflammatory M2a, M2c microglia and A2 astrocytes has been detected. The results show that the first post-injury week is critical for microglia/macrophages and astrocytes transformation into their neuroprotective states. We assume, this could be a very effective time window for treatment strategy after SCI. Supported by APVV-15-0766; APVV-19-0324; VEGA 2/0145/21; ERDF-IMTS 313011V344.

MICROGLIA-DRIVEN REGULATION OF GLIAL SCAR FORMATION AFTER SPINAL CORD INJURY: EFFECT OF Y-27632 IN REGENERATIVE PROCESSES

POSTER SESSION 04 - SECTION: SPINAL CORD, PERIPHERAL NERVE INJURY AND REGENERATION

Spinal cord injury (SCI) activates intracellular signaling molecule Rho, leading to a cascade of events culminating in the collapse of axonal growth cones, failure of injured axons to regenerate, as well as neuronal loss. We studied acute inflammatory response (1,3,7,14d) and its effect on neuropathological changes in the rat SCI model (Th9 compression; 40g/15 min) eight weeks post-SCI. Rho-kinase inhibitor, Y-27632 (40µg/d for 14d post-SCI) was delivered intrathecally via osmotic Alzet mini-pump. Two weeks post-SCI, the TGF-ß mRNA expression was ~five-fold higher (marker of neuroprotective M2c microglia) than in naïve control at lesion site and cranially, and ~two-fold higher caudally, suggesting its role in promoting the glial scar formation by enhanced secretion (~2- to 4- fold) of CSPGs (neurocan, phosphacan and NG2). Increased expression of these CSPGs at lesion site and cranially was consistent with strong expression of GFAP, S100B and reactive A1 astrocytes. Y-27632 modulated the inhibitory milieu by specifically targeting gray and white matter integrity (LFB staining) and GFAP-immunoreactivity, and significantly improved spinal cord repair eight weeks post-SCI. Increased outgrowth of neurofilaments (0.4-1µm -35%, 1-2µm -30%, 2-3µm -17%, 3-4µm-13%) and GAP-43 immunoreactive axons was observed across the lesion area, leading to significant functional outcome from the 3th to 8th week post-SCI. The results show that microglia-astrocytes modulation is key for glial scar formation in subacute phase after SCI. Y-27632 is able to support endogeneous regenerative processes leading to better axonal regeneration and locomotor recovery. Local inflammation is a deleterious process after spinal cord injury (SCI). Acute intravenous application of extracellular vesicles (EVs) secreted by human mesenchymal stromal cells were shown to dampen inflammation following SCI. Here, we compared the impact of intralesional vs intravenous application of EVs, on functional regeneration and structural integrity following SCI. Fischer-344 rats received a 200kdyn contusion (Th8) and were acutely treated with EVs. Expression of inflammatory cytokines in the spinal cord was determined at 24h post-injury. Locomotor recovery was assessed for 8 weeks and histological analysis was performed at 2 and 8 weeks post-SCI. In addition, DTI was performed *ex vivo* 8 weeks after injury. Locomotion recovery post-SCI was significantly improved by intralesional EV-application. Analyses 24h post-SCI revealed that acute application of EVs reduced IL-1beta and IL-6 gene expression. Two weeks post-injury, the density of microglia detected close to the lesion was significantly lower in rats treated with intralesional vs intravenous application of EVs. Furthermore, scar formation, based on astrogliosis, collagen-1 and CSPG deposition, was also more attenuated by intralesional EVs treatment. Finally, 8 weeks post-injury, DTI detected close to the lesion site more longitudinal fibre tracts after EVs-treatment compared to the vehicle, which correlated with higher degree of white matter sparing. Our observation demonstrates that acute intralesional EV-application is particularly potent to address the processes of inflammation and scarring and to promote locomotion recovery. Moreover, this improvement of the spinal microenvironment and the higher structural preservation obtained with EVs-treatment constitute valuable assets for follow-up pro-regenerative interventions.

Enhancing Functional Recovery Through Intralesional Application of Extracellular Vesicles in a Rat Model of Traumatic Spinal Cord Injury.
Local inflammation plays a pivotal role in the process of secondary damage after spinal cord injury. We recently reported that acute intravenous application of extracellular vesicles (EVs) secreted by human umbilical cord mesenchymal stromal cells dampens the induction of inflammatory processes following traumatic spinal cord injury. However, systemic application of EVs is associated with delayed delivery to the site of injury and the necessity for high doses to reach therapeutic levels locally. To resolve these two constraints, we injected EVs directly at the lesion site acutely after spinal cord injury. We report here that intralesional application of EVs resulted in a more robust improvement of motor recovery, assessed with the BBB score and sub-score, as compared to the intravenous delivery. Moreover, the intralesional application was more potent in reducing inflammation and scarring after spinal cord injury than intravenous administration. Hence, the development of EV-based therapy for spinal cord injury should aim at an early application of vesicles close to the lesion.

Neuroregenerative Potential of Prenyl- and Pyranochalcones: A Structure-Activity Study.
Loss of neuronal tissue is a hallmark of age-related neurodegenerative diseases. Since adult neurogenesis has been confirmed in the human brain, great interest has arisen in substances stimulating the endogenous neuronal regeneration mechanism based on adult neural stem cells. Medicinal plants are a valuable source of neuroactive small molecules. In the structure-activity study presented here, the activities of prenyl- and pyranochalcones were compared to each other, using a differentiation assay based on the doublecortin promoter sequences. The latter revealed that the pyrano ring is a crucial structural element for the induction of neuronal differentiation of adult neural stem cells, while compounds with a prenyl group show significantly lower activities. Furthermore, a decrease of pro-differentiation activity was observed following structural modifications, such as substitutions on the pyrano ring and on the B-ring of the chalcone. We also initiated the elucidation of the structural characteristics of the newly discovered lead substance xanthohumol C, which correlated with the activation of the doublecortin promoter during neuronal differentiation.

Involvement of Neuropeptide Galanin Receptors 2 and 3 in Learning, Memory and Anxiety in Aging Mice.
The neuropeptide galanin (GAL), which is expressed in limbic brain structures, has a strong impact on the regulation of mood and behavior. GAL exerts its effects via three G protein-coupled receptors (GAL-R). Little is known about the effects of aging and loss of GAL-Rs on hippocampal-mediated processes connected to neurogenesis, such as learning, memory recall and anxiety, and cell proliferation and survival in the dorsal dentate gyrus (dDG) in mice. Our results demonstrate that loss of -R, but not -R, slowed learning and induced anxiety in older (12-14-month-old) mice. Lack of -R increased cell survival (BrdU incorporation) in the dDG of young mice. However, normal neurogenesis was observed in vitro using neural stem and precursor cells obtained from -R and -R knockouts upon GAL treatment. Interestingly, we found sub-strain differences between C57BL/6J and C57BL/6N mice, the latter showing faster learning, less anxiety and lower cell survival in the dDG. We conclude that GAL-R signaling is involved in cognitive functions and can modulate the survival of cells in the neurogenic niche, which might lead to new therapeutic applications. Furthermore, we observed that the mouse sub-strain had a profound impact on the behavioral parameters analyzed and should therefore be carefully considered in future studies.

Combination of Defined CatWalk Gait Parameters for Predictive Locomotion Recovery in Experimental Spinal Cord Injury Rat Models.
In many preclinical spinal cord injury (SCI) studies, assessment of locomotion recovery is key to understanding the effectiveness of the experimental intervention. In such rat SCI studies, the most basic locomotor recovery scoring system is a subjective observation of animals freely roaming in an open field, the Basso Beattie Bresnahan (BBB) score. In comparison, CatWalk is an automated gait analysis system, providing further parameter specifications. Although together the CatWalk parameters encompass gait, studies consistently report single parameters, which differ in significance from other behavioral assessments. Therefore, we believe no single parameter produced by the CatWalk can represent the fully-coordinated motion of gait. Typically, other locomotor assessments, such as the BBB score, combine several locomotor characteristics into a representative score. For this reason, we ranked the most distinctive CatWalk parameters between uninjured and SC injured rats. Subsequently, we combined nine of the topmost parameters into an SCI gait index score based on linear discriminant analysis (LDA). The resulting combination was applied to assess gait recovery in SCI experiments comprising of three thoracic contusions, a thoracic dorsal hemisection, and a cervical dorsal column lesion model. For thoracic lesions, our unbiased machine learning model revealed gait differences in lesion type and severity. In some instances, our LDA was found to be more sensitive in differentiating recovery than the BBB score alone. We believe the newly developed gait parameter combination presented here should be used in CatWalk gait recovery work with preclinical thoracic rat SCI models.

Extracellular Vesicles Can Deliver Anti-inflammatory and Anti-scarring Activities of Mesenchymal Stromal Cells After Spinal Cord Injury.
Spinal cord injury is characterized by initial neural tissue disruption that triggers secondary damage and extensive non-resolving inflammation, which aggravates loss of function and hinders recovery. The early onset of inflammation following traumatic spinal cord injury underscores the importance of acute intervention after the initial trauma. Injections of mesenchymal stromal cells (MSCs) can reduce inflammation following spinal cord injury. We asked if extracellular vesicles (EVs) can substitute the anti-inflammatory and anti-scarring activities of their parental MSCs in a rat model of contusion spinal cord injury. We report that MSC-EVs were as potent as the parental intact cells in reducing the level of neuroinflammation for

up to 2 weeks post-injury. Acute application of EVs after spinal cord injury was shown to robustly decrease the expression of pro-inflammatory cytokines in the spinal cord parenchyma in the very early phase of secondary damage. Moreover, the anti-scarring impact of MSC-EVs was even more efficient than the parental cells. We therefore conclude that anti-inflammatory and anti-scarring activities of MSC application can be mediated by their secreted EVs. In light of their substantial safety and druggability advantages, EVs may have a high potential in early therapeutic treatment following traumatic spinal cord injury.
